7		Hospital Live		14/07/2019 *	14/07/2019
		PART 5 - POST COMPLETION WORKS			
8		MILESTONE 2- INTERNAL DRAINAGE SYSTEM - Complete		17/05/2019 *	17/05/2019
9		MILESTONE 4 - RADIANT PANELS IN ISOLATION ROOM - Complete		27/05/2019 *	27/05/2019
10		MILESTONE 3 - FIRE PROTECTION COMPLIANCE WITH SHTM82 - Complete		13/06/2019 *	13/06/2019
		PART 4 - OUTSTANDING WORKS			
11		Completion of Outsanding Base / Instructed Works by Multiplex		15/07/2019 *	15/07/2019
12		Tie-in Link to RIE Building Complete		04/07/2019 *	04/07/2019
13		Multiplex Demobilisation and Handback Car Park E		21/06/2019 *	21/06/2019
14	IT Ref. No.	INDEPENDENT TESTER'S SCHEDULE OF OUTSTANDING MATTERS	20w 3d	22/02/2019	15/07/2019
		Independent Tester Issues 'Schedule of Outstanding Matters'	20w 3d	22/02/2019 *	15/07/2019
16	1	Movement Joint through Critial Areas non-compliant with the requirements		22/02/2019 *	22/02/2019
17	2	Internal Drainage System - Milestone 2		17/05/2019 *	17/05/2019
18	3	Ventilation to Isolation Rooms (NHSL Turnkey Works dependant)		22/02/2019 *	22/02/2019
19	4	Lighting of Fire Fighting Stairs		22/02/2019 *	22/02/2019
20	5	Helipad not Compliant with HBN15-03 or CAP 1264 (CCP061)		22/02/2019 *	22/02/2019
21	6	Heater batteries in Isolation room lobbies - Milestone 4		27/05/2019 *	27/05/2019
22	7	Fire Protection System Compliance with SHTM 82 - Milestone 3		13/06/2019 *	13/06/2019
23	8	Interleave power supplies to Critical Areas		22/02/2019 *	22/02/2019
24	9	Opening windows as part of lobby smoke ventilation		08/04/2019 *	08/04/2019
25	10	Theatre / CT /Anaestetics Scrub Taps fitted at wrong Height		22/02/2019 *	22/02/2019
26	11	Threshold to Spiritual Care not Barrier Free		22/02/2019 *	22/02/2019
27	12	Goods Yard Access to Loading Bay - Constricted by Compactor		22/02/2019 *	22/02/2019
28	13	Key Suiting ready for Handover		22/02/2019 *	22/02/2019
29	14	Acoustic Testing - Atrium Reverbiration Post PC - TBC		22/02/2019 *	22/02/2019
30	15	Medical Gas Systems complete - Dependency on Turnkey Works		22/02/2019 *	22/02/2019
31	16	IT Documentation - Final Clause		26/06/2019 *	26/06/2019
32	17	Handover Clean - Last Clause		22/02/2019 *	21/06/2019
33	18	Removal of Site Establishment		22/02/2019 *	22/02/2019
34	19	Reinstatement of Car Park E		22/02/2019 *	22/02/2019
35	20	Operating Theatres complete - Post completion void detector works		03/05/2019 *	03/05/2019
36	21	Building Warrant Completion Certificate		31/03/2019 *	31/03/2019
37	22	Fire Alarm sounders - will require degree of recheck following alterations		06/06/2019 *	06/06/2019
38	23	Water systems (heating and domestic water) in accordance with CIBSE Commissioning Code W and SHTM 04-01 - Confirmation evidence being sought		22/02/2019 *	22/02/2019
39	24	Pneumatic Tube Transfer - Project Change to be Concluded [Works to complete Post Completion]		22/02/2019 *	22/02/2019
40	25	Ductwork physical cleaning certification in accordance with SHTM 03-01 and the HVCA (2005) 'TR/19 – Guide to good practice;		22/02/2019 *	22/02/2019
41	26	Proving of Isolation Rooms Differential Pressure - Works Complete		20/05/2019 *	20/05/2019
42	27	External Signage		05/07/2019 *	05/07/2019
43	28	Change of LTHW Pipework		22/02/2019 *	22/02/2019
44	29	Helipad Height Reduction		22/02/2019 *	22/02/2019
45	30	Change to Zone A Level 4 Plantrooms		22/02/2019 *	22/02/2019
46	31	Change to Link Building		22/02/2019 *	22/02/2019
47	32	Change to Gas Meter Housing		22/02/2019 *	22/02/2019
48	33	Change to Entrance Mat		22/02/2019 *	22/02/2019
49	34	BREEM Certification		22/02/2019 *	22/02/2019
50	35	Temprature Control Monitoring		22/02/2019 *	22/02/2019
51	36	Positioning of Node Rooms in Basement		22/02/2019 *	22/02/2019
52	37	Change to Curtain Tracks		22/02/2019 *	22/02/2019
53	38	Change to MRI Access		22/02/2019 *	22/02/2019
54	39	Changes to Ceiling Heights		22/02/2019 *	22/02/2019
55	40	Change to Service Yard Crib Wall		22/02/2019 *	22/02/2019
56	41	Radiology Room WC Omission		22/02/2019 *	22/02/2019
57	42	Change to Over Panels Over Doors		22/02/2019 *	22/02/2019
58	43	Change to Standing Seam Roof		22/02/2019 *	22/02/2019
59	44	Change to Warning Lights		22/02/2019 *	22/02/2019
60	45	Change to Skirting		22/02/2019 *	22/02/2019
61	46	Changes to Bed Lift Core 3		22/02/2019 *	22/02/2019
62	47	Provision of Gas Store Level 4		22/02/2019 *	22/02/2019
63	48	Provision of Shower Trays and Pumping		22/02/2019 *	22/02/2019
64	49	Fire Strategy Sprinkler Omission		22/02/2019 *	22/02/2019
65	50	Tactile Sensors to anti-lig sanitary spaces		22/02/2019 *	22/02/2019
66	51	OUT 904 Connections		22/02/2019 *	22/02/2019
67	52	Timing of the Audiolody Acoustic Tests		15/07/2019 *	15/07/2019
68	53	Change to SHPN 40 Intercon / Isolation Suite Functionality		22/02/2019 *	22/02/2019
69	54	Changes to As-Built Energy Model / Seasonal Commissioning		22/02/2019 *	22/02/2019
70	55	Neuropenic Ventilation Change		22/02/2019 *	22/02/2019
71	56	Single Bed Ventilation Changes		22/02/2019 *	22/02/2019
72	57	Change to FCU Traps		22/02/2019 *	22/02/2019
73	58	Change to High Level Drainage		22/02/2019 *	22/02/2019
74	59	Change to Node Room Cooling		22/02/2019 *	22/02/2019
75	60	Change to IPS Room Ceilings		22/02/2019 *	22/02/2019
76	61	4-CORR-007 Change to Ceiling Height		22/02/2019 *	22/02/2019
77	62	0-A1-062 Change to Ceiling Height		22/02/2019 *	22/02/2019
78	63	Group 2 Socket Change		22/02/2019 *	22/02/2019
79	64	Omission of RIE Adult Ambulant Canopy (Board Change 20)		22/02/2019 *	22/02/2019
80	65	Number Plate Recognition (Board Change 87)		22/02/2019 *	22/02/2019
81	66	Fire Evacuation Strategy (Board Change 106) - Works Complete		22/02/2019 *	22/02/2019
82	67	IOMRI Change Instruction (Board Change 109)		22/02/2019 *	22/02/2019
83	68	Vent Ductwork in MRI Equipment Rooms (Board Change 129) - Works Complete		22/02/2019 *	22/02/2019
84	69	ED Store Ventilation		22/02/2019 *	22/02/2019
85	70	Cycle Racks Change (does not form part of the Works)		22/02/2019 *	22/02/2019
86	71	Angiography Proceedures Machine Room (does not form part of the Works)		22/02/2019 *	22/02/2019
87	72	Testing and Commissioning Documentation to be completed following outstanding Works and current issues resolved		26/06/2019 *	26/06/2019
88	73	Issues with Water Proofing and Gas Proofing Specification - item closed		22/02/2019 *	22/02/2019

Line	User_Text_1	Name	Duration	Start	Finish
360		Install of new cladding around external pipework on wall	1d	08/05/2019 *	08/05/2019
361		Training on new installed pumps	1d	09/05/2019 *	10/05/2019
362		Install Double seals to Manhole covers	2d	11/05/2019 *	14/05/2019
363		Basement - Reinstatement and Making Good	1w	11/05/2019 *	17/05/2019
364		Full Demonstration of New Installation and Pump Replacement	3d	15/05/2019 *	17/05/2019
365		Independent Tester Certify		17/05/2019 *	17/05/2019
366		EXTERNAL SUMP PUMP	7w 2.86d	20/03/2019	10/05/2019
367		Excavate externally, core hole into chamber, Install cable ducting from chamber to External electrical junction box, leave in draw cords and Re-instate ground works.	2w	20/03/2019 *	02/04/2019
368		Increase height of external vent pipe to above roof level 3mtr from any opening	3d	01/04/2019 *	03/04/2019
369		Concrete around pump chamber lids	3d	03/04/2019 *	05/04/2019
370		Delivery of pumps, panels, Isolation box	1d	08/04/2019 *	08/04/2019
371		M+E Connections / Terminations	1w 2d	09/04/2019 *	17/04/2019
372		Isolations to Electrical supply for changeover and any connections testing required. Man in attendance from Mercury.	1d	18/04/2019 *	18/04/2019
373		Switchover from old system to new system	1d	23/04/2019 *	23/04/2019
374		Testing / Commision 2 x pumps, panels, controls, I-host	1d	24/04/2019 *	24/04/2019
375		Seal up ducts after cable install	1d	25/04/2019 *	25/04/2019
376		External Works - Reinstatement and Making Good	1w	26/04/2019 *	02/05/2019
377		Training on new installed pumps	1d	10/05/2019 *	10/05/2019
		MILESTONE 4 - RADIANT PANELS IN ISOLATION ROOM LOBBIES	13w 2d	18/02/2019	28/05/2019
379		Engineering + Procurement	7w	18/02/2019	06/04/2019
380		Order Radiant Panels - Material Lead In	7w	18/02/2019 *	06/04/2019
381		Order - Material Lead In	4w	18/02/2019 *	16/03/2019
382		Order New HEPA Filters - Material Lead In	4w	18/02/2019 *	16/03/2019
383		Construction Activity	13w 2d	18/02/2019	28/05/2019
384		Level 3 - 9 No. Locations	13w 3d	18/02/2019	23/05/2019

PART 5

PART A POST COMPLETION WORKS

Item	Post Completion Disputed Works	Description of Post Completion Works Agreed Resolution
1	**Fire detection** The Board believes that Project Co's design and installation of the fire detection and alarm system in relation to: 1. The void detection in voids with patient dependent services, detection in staff toilets and en-suites to bedrooms; and 2. In relation to provision of manual call point are non-compliant with SHTM 82. Project Co's position is that the design and installation of the fire detection and alarm system complies with SHTM 82 and they have demonstrated this through the Schedule Part 8 (Review Procedure) and implementation of developed risk assessments. Each party disagrees with the other party's position and therefore a dispute has arisen.	The agreed resolution of the Dispute is as follows; For the staff toilets which can be accessed by patients and visitors (i.e. staff toilets in public/clinical areas) - Digi-locks will be fitted on the doors, restricting access to staff members only. For the en-suites – the patient groups viewed as a potential risk are DCN & CAMHS. These en-suites will be treated with a high level grille and top cut reduced door respectively, along with increasing detector sensitivity within the bedroom. Where voids contain either natural gas, medical gas or IPS (Isolated Power Supply) circuitry, automatic smoke detection will be added within these voids. For the fire alarm manual call point, Project Co shall provide additional manual call points developed on the basis of the Risk Assessment. The Board and Project Co have reached agreement on this matter and Project Co shall carry out and complete works to the fire detection and alarm system in accordance with the information contained within aconex ref MPX-GC-029626 "void detection technical pack" and "manual call point technical pack" contained within aconex ref HCP UK-GC-001810 to meet the terms of the Project Agreement as supplemented and amended pursuant to this Agreement.
2	**Isolation room heating** The Board believes that Project Co has installed heater batteries within critical areas in contravention of SHTM 03-01. The Board is of the view that heater batteries should be located above corridors or other non-critical areas and never above patient occupied spaces. Project Co's position is that the design and installation meets the requirements of the Project Agreement and was based on the package approved through Schedule Part 8 (Review Procedure). Each party disagrees with the other party's position and therefore a dispute has arisen.	The agreed resolution of the Dispute is as follows; Following a collaborative review of the design between the Board and Project Co, Project Co will make changes to the location and support infrastructure on heater batteries in all location except Isolation rooms. These changes will include fitting of drip trays and leak detection at these locations. In Isolation rooms the heater battery will be replaced by radiant panels within these rooms and associated en-suites. Heater Battery in the ceiling void above the Isolation room lobby will be removed and replaced with a duct spool piece. The Board and Project Co have reached agreement on this matter and Project Co shall carry out and complete all works to the heater batteries, including to the isolation room heating accordance with the information contained within aconex ref MPX-GC-029622) "isolation room radiant panel technical pack" to meet the terms of the Project Agreement as supplemented and amended pursuant to this Agreement. The final location of panels and remote sensors should be discussed and agreed with the Board.

Item	Post Completion Disputed Works	Description of Post Completion Works Agreed Resolution
3	**Internal and external foul drainage** The Board believes that the number and location of sanitary appliances discharging into the basement and PARU sumps, as installed by Project Co, is in contravention with the BCR's (including the non-domestic technical handbook) and the PCPs. Project Co's position is that the design and installation meets the requirements of the non-domestic technical handbook and is unable to meet the PCPs due to topography of the site and proximity of the foul drainage network. Project Co's position is that the design and installation was based on the package approved through Schedule Part 8 (Review Procedure). Each party disagrees with the other party's position and therefore a dispute has arisen.	The agreed resolution of the Dispute is as follows; Both systems resilience in the case of an emergency to be enhanced. Internal Basement sump system, Project Co shall provide the following; Key to Pumps: Pump 1: Vortex – In use Pump 2: Vortex – In use Pump 3: Third Emergency Pump Pump 4: Vortex – Spare Pump Pump 5: Vortex – Spare Pump • Project Co changing the current installed duty and standby foul pumps (Pumps 1 & 2) to new Vortex Wilo submersible pumps; • Each pump shall be rail mounted; • A further full complete spare set of pumps shall be provided for rapid changeover by Project Co (Pumps 4 & 5) ; • The controls shall be upgraded to Ultrasonic measuring and I-host back up; • A third self-priming suction pump shall be provided by Project Co, located within the Heat Station 04 (B-PLANT-002) (Pump 3); • This third pump shall be fully automatic with its own control panel and dual fed power supplies; • The Third pump shall be located on a purpose made gantry, approximately 1 metre off the ground above the installed LTHW pipework; • Pipework within the sump chamber shall be ductile iron, pipework below ground shall be fusion welded HDPE and above ground section shall be ABS plastic solvent welded; • The third pump will utilize a 10m section below ground of the current pumped discharge and an additional 10m of newly installed pipework within the chamber and above ground with a series of control valves with the back-up of manual valves to open and close retrospectively in order to change the 10m section of pumped discharge pipework into a suction pipe, 20m in total; • The third pump shall be backed up by dual power supplies and separate controls; • The float switches shall be upgraded from float switches to ultrasonic measuring and with back-up float switch connected to the BMS as a critical alarm. I-Host monitoring and warning back up shall also be provided. Secondary local power isolation and disconnection for cabling shall be installed underneath the new control panel to facilitate quick change over; • The secondary discharge pipework from the third pump will run along the basement, up riser V10 and run within the ceiling void on the ground floor to exit the building externally into manhole FWMH20 located outside DCN outpatients; • Project Co shall provide and maintain on site a complete spare pump sets (pumps four and five); • Project Co shall provide one porta reid gantry system which is capable of all lifting requirements within the basement and PARU garden pumping stations; • Project Co shall provide and maintain on site a Zipwall plastic disposable and re-usable fire proof wall sheeting system, to allow the area in the basement to be cordoned off and contained; • Project Co shall provide and maintain on site a fan and carbon filter for the basement which will have the suction side

Item	Post Completion Disputed Works	Description of Post Completion Works Agreed Resolution
		connected to the screened off area in the basement; • The fan and filter shall be permanently connected to the electrical power supply and located within Heat Station 01 (B-PLANT-003) with flex ducting attached; • Maintenance and emergency procedures shall be submitted by Project Co through Schedule Part 8 (Review Procedure); • Project Co shall provide full demonstration of the pump replacement to the Independent Tester and Board's Representative. Demonstration shall include all tasks necessary to install and / or replace the pumps safely and satisfactorily in accordance with all manufacturers' requirements, including (without limitation) all relevant infrastructure required for the basement sump (for example the erection of zip wall, erection and use of lifting gantry, carbon filter fan, lifting pump out and swapping with spare); • Handover Clean shall be undertaken by Project Co following Post Completion Works. External sump system, Project Co shall provide the following; • Project Co changing the current installed duty and standby foul pumps to new Vortex Wilo submersible pumps; • Each Pump shall be rail mounted; • A further third full complete spare pump set shall be provided by Project Co (Bouygues); • The controls shall be upgraded to Ultrasonic measuring and I-host back up; • Secondary local power isolation and disconnection for cabling shall be installed on the main building wall in the PARU garden, adjacent to the pumping station to facilitate quick changeover within a lockable and suitable IP rated enclosure; • Hard standing with a minimum of 600mm around chamber lids shall be provided; • Chamber lids shall be sealed; • Maintenance and emergency procedures shall be submitted by Project Co through Schedule Part 8 (Review Procedure); • Project Co shall provide full demonstration of the pump replacement to the Independent Tester and Board's Representative. Demonstration shall include all tasks necessary to install and / or replace the pumps safely and satisfactorily in accordance with all manufacturers' requirements, including (without limitation) all relevant infrastructure required for the external sump (for example erection and use of lifting gantry, lifting pump out and swapping with spare); • Handover Clean shall be undertaken by Project Co following Post Completion Works. The Board and Project Co have reached agreement on this matter and Project Co shall carry out and complete works to the internal and external foul drainage system in accordance with the full details set out within the supporting documentation aconex ref MPX-GC-029655-"foul drainage technical pack" to meet the terms of the Project Agreement as supplemented and amended pursuant to this Agreement.

POST COMPLETION WORKS TECHNICAL WORKS

Schedule Part 5 Part B

in the

AGREED FORM

relative to the

Settlement Agreement and Supplemental Agreement

between

Lothian Health Board

and

IHS Lothian Limited

RHSC and DCN, Little France

This is the Post Completion Works Technical Packs as set out USB Memory Stick in the Agreed Form as referred to in the Settlement Agreement and Supplemental Agreement entered into by Lothian Health Board and IHS Lothian Limited 22 February 2019.

SCHEDULE PART 5 POST COMPLETION WORKS

PART B

POST COMPLETION WORKS TECHNICAL PACKS

Part B of Schedule Part 5 Post Completion Works Technical Packs are as set out on the USB memory stick is in the Agreed Form identified and executed as Part B of Schedule Part 5 Post Completion Works Technical Packs of this SA1, referred to in and forming part of this SA1

SCHEDULE PART 5 POST COMPLETION WORKS

PART C

POST COMPLETION WORKS COMPLETION CRITERIA

1. DRAINAGE COMPLETION CRITERIA

Project Co shall demonstrate that the following criteria (the "Drainage Completion Criteria") has been achieved:

1.1. The Drainage Works are installed as described at Parts A and B of this Part 5 of the Schedule (Post Completion Works).

1.2. The Drainage Works are tested, commissioned, and operating satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Project Agreement (as amended by this SA1).

1.3. The sump pumps are replaced in accordance with Parts A and B of this Part 5 of the Schedule (Post Completion Works), tested, commissioned and proven to operate satisfactorily in accordance with the manufacturers' operating requirements.

1.4. Spare sump pumps (2 for basement and 1 external) are available on site.

1.5. The third pump for emergency use is installed, tested and commissioned and proven to operate satisfactorily in accordance with the manufacturers' operating requirements.

1.6. The Building Management System alarms and iHost system are both installed, tested, commissioned and operating satisfactorily in accordance with the manufacturers' operating requirements.

1.7. Project Co has demonstrated to the IT and the Board's Representative single pump replacement of both the basement sump and external sump. Demonstration to include all tasks necessary to install and / or replace the pumps safely and satisfactorily in accordance with all manufacturers' requirements, including (without limitation) all relevant infrastructure required for the basement and external sumps (for example the erection of zip wall, erection and use of lifting gantry, carbon filter fan, lifting pump out and swapping with spare).

1.8. The areas within the Site where the Drainage Works were undertaken are free from all surplus materials, plant and equipment and any damage caused by the works undertaken to complete the Drainage Works reinstated.

1.9. A Handover Clean (as defined at paragraph 3 of Schedule Part 1 (Appendix B) Completion Criteria of the Project Agreement) has been undertaken to the areas within the Site where the Drainage Works were undertaken.

1.10. All mechanical and electrical plant and systems associated with the internal and external foul drainage shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements, and all other relevant terms of the Project Agreement (as amended by this Agreement).

2. VOID DETECTION COMPLETION CRITERIA

Project Co shall demonstrate that the following criteria (the "Void Detection Completion Criteria") has been achieved:

2.1. The Void Detection Works are installed as described in Parts A and B of Part 5 of the Schedule (Post Completion Works) .

2.2. The Void Detection Works are tested, commissioned and operating satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Project Agreement (as amended by this SA1).

2.3. The fire detector, manual call point and fire-alarm are re-tested and re-commissioned.

2.4. Cause and effect testing of the fire detector, manual call point and fire-alarm in each zone are complete and proven.

2.5. All ceilings and walls are reinstated.

2.6. The areas within the Site where the Void Detection Works were undertaken are free from all surplus materials, plant and equipment and any damage caused by the works undertaken to complete the Void Detection Works reinstated.

2.7. A Handover Clean (as defined at paragraph 3 of Schedule Part 1 (Appendix B) Completion Criteria of the Project Agreement) has been undertaken to the areas within the Site where the Void Detection Works were undertaken.

2.8. All mechanical and electrical plant and systems associated with the void detection shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Project Agreement (as amended by this SA1).

3. HEATER BATTERY COMPLETION CRITERIA

Project Co shall demonstrate that the following criteria (the "Heater Battery Completion Criteria") has been achieved:

3.1. The Heater Battery Works are installed as described in Parts A and B of this Part 5 of the Schedule (Post Completion Works).

3.2. The Heater Battery Works are tested, commissioned and operating satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Project Agreement (as amended by this SA1).

3.3. The radiant panels are tested, commissioned and operating satisfactorily in accordance with the specified design criteria and any manufacturers' operating requirements.

3.4. The room conditions are proven against the required testing regimes set out in Parts A and B of this Part 5 of the Schedule (Post Completion Works) in order to ensure the specified room conditions are achieved in all relevant isolation rooms.

3.5. Pressure testing of all relevant isolation room suites is completed satisfactorily.

3.6. All mechanical and electrical plant and systems associated with the heater batteries shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Project Agreement (as amended by this SA1).

3.7. The areas within the Site where the Heater Battery Works were undertaken are free from all surplus materials, plant and equipment and any damage caused by the works undertaken to complete the Heater Battery Works reinstated.

3.8. A Handover Clean (as defined at paragraph 3 of Schedule Part 1 (Appendix B) Completion Criteria of the Project Agreement) has been undertaken to the areas within the Site where the Heater Battery Works were undertaken.

4. GENERAL- COMPLETION CRITERIA APPLICABLE TO ALL POST COMPLETION WORKS

4.1. Project Co shall reinstate the work areas of the Site and/or rooms where the Post Completion Works are being undertaken to the standard set out in the Project Agreement (as amended and supplemented pursuant to this SA1). This will include reinstatement of fire protection, ceilings, floors and walls affected by the Post Completion Works and decoration of same.

PART 6

PART A: OUTSTANDING WORKS

BASE BUILD OUTSTANDING WORKS
Tail lift power supplies in service yard
Validation of air cascade between IOMRI and theatre
Provision of missing CCTV in imaging
Installation of low level grilles on en-suite doors (privacy and dignity)
Minor lead shielding remedials to room in imaging department
Imaging Department doors adjusted from double to single swing
Additional power and data sockets at each nurses station for the Nurse Call PC
Sealed hatches in all category 4 rooms and above
Plate testing and final commissioning of theatres
Opening widows size, smoke clearance
Heat station overheating
CT room (G-Q1-136)/control room (G-Q1-135) & MRI room (G-Q1-134) and MRI equipment rooms (G-Q1-133 and G-Q1-124) overheating
Replanting of soft landscaping areas, including grass, courtyards etc throughout the Facility
Re-routing of the oxygen pipe/s at VIE
Removal and reinstatement of pop out panels and main corridor doors to allow MRI delivery
Little France street lighting
RHCYP and DCN to be added to external signage
Fan upgrades to AHU 02, 04, 06
Project Co (Otto Boc) commissioning of orthotics grinder, router and dust extractor
RIE fire stopping
Isolation rooms – edging applied to doors
Internal RIE signage
Energy Centre Lighting Calcs - Project Co shall undertake any works necessary to make the Energy Centre Lighting Calcs compliant with LG2.
Base Build - Items awaiting Independent Tester confirmation they are complete
Connect lightning protection for Quench pipes
Protection to lift changeover gear in Energy Centre
Installation of removable bollards for fire tender egress at paediatric small car park
CCTV coverage of service yard
Video entry to Haematology and Oncology day care unit
Theatre sinks height amendments
Project Co updating (Static) guardian staff attack room naming
Theatre/Emergency Department and Radiology grilles changed
Installation of service yard ramp including handrail
Installation of nuclear medicine traps
Key suiting ready for handover

Fire suppression for substation 2A and 2B
Lights in service yard
Project Co Change Outstanding Works
Project Co Change 039 Helipad Certification
Project Co Change 065 PTS
Project Co Change 067 Building Warrant Completion Certificate
Project Co Change 068 Manual Call Points
Board Change Outstanding Works
Board Change Notice 087 Number plate recognition
Board Change Notice 109 IOMRI
Board Change Notice 118 O&M Manuals
Board Change Notice 119 Patient absconding system
Board Change Notice 122 ECHC shop (MPX works)
Board Change Notice 133 2 Security doors in OPD
Board Change Notice 137 Anti lig in CAMHS
Board Change Notice 139 Update to 3 signs
Board Change Notice 143 installation of additional cycle provision
Board Change Notice 144 Power Supply Alterations
Board Change Notice 145 Power / data for Massimo
Board Change Notice 146 Emergency Department Crash Box
Board Change Notice 147 Changes to Access Control
Board Change Notice 149 Infrastructure to support pager installation
Board Change Notice 151 Medirail Installation
Board Change Notice 154 Gas suppression in substation 1A and 1B
Board Change Notice 157 Patient entertainment equipment
Board Change Notice 160 updating of BIM model for quench pipes
Board Change Notice 164 Installation of water for bin washer
Board Change Notice 165 installation of temp protection
Board Change Notice 169 Internal Signage
Board Change Notice 170 Installation of dishwasher in cafe
Board Change Notice 172 Hospital Square works
Board Change Notice 176 Angio cooling
Board Change Notice 177 Fluoro cooling
Board Change Notice 178 MRI Access Control
Board Change Notice 179 MRI Access Control during fire alarm
Board Change Notice 180 for 9 additional power and data for TVs in 3-C1.4-084 and 3-C1.4-061
In addition to the above Board Changes, remaining ATD elements required to be undertaken post Actual Completion include - Board Change Notices No 067, 068, 075, 078A, 093, 094, 099, 100, 110, 111, 114, 156.

Outstanding Works Exclusions (post 20 May 19)	Completion Dates
Board Change Notice 167 Signage unveiled	As per Joint Completion Programme
Reopening of the bus stop	As per Joint Completion Programme

Removal of the site establishment	As per Joint Completion Programme
Project Co Change 030 Car park E	As per Joint Completion Programme
Link building opening including fitting motors to RIE ED and G1 access corridor	As per Joint Completion Programme
Open Link Ground Floor	As per Joint Completion Programme
Open link First Floor	As per Joint Completion Programme
Project Co Change 025 BREEAM Certification	01/03/20
Project Co Change 047 Audiology testing	As per Joint Completion Programme
As Built Energy Model / Seasonal Commissioning – former Project Co Change forming part of SA	01/05/20
Reverberation tests in POD	As per Joint Completion Programme

PART B: OUTSTANDING WORKS COMPLETION CRITERIA

1. Project Co shall demonstrate to the Independent Tester's satisfaction that the relevant Completion Criteria as set out in Appendix B of Schedule Part 10 (Outline Commissioning Programme) have been achieved for the Outstanding Works.

2. In relation to the Outstanding Works, Project Co shall also demonstrate the following to the Independent Tester's satisfaction;

2.1 The Outstanding Works are tested, commissioned and proven to operate satisfactorily in accordance with the manufacturers' operating requirements;

2.2 The areas within the Site where the Outstanding Works were undertaken are free from all surplus materials, plant and equipment and any damage caused by the works undertaken to complete the Outstanding Works Agreed are reinstated;

2.3 A Handover Clean (as defined at paragraph 3 of Schedule Part 1 (Appendix B) Completion Criteria of the Project Agreement) has been undertaken to the areas within the Site where the Outstanding Works were undertaken;

3. In relation to the Board Changes set out in the Outstanding Works, Project Co shall demonstrate to the Independent Tester the Completion Criteria have been achieved as set out in Appendix B of Schedule Part 10 (Outline Commissioning Programme), including any relevant information contained in the respective Board Change.

4. In relation to the Project Co Changes set out in the Outstanding Works, Project Co shall demonstrate to the Independent Tester the Completion Criteria have been achieved as set out in Appendix B of Schedule Part 10 (Outline Commissioning Programme), including any relevant information contained in the respective Project Co Change.

PART 7

PAYMENT AND MILESTONES

Project Co shall deliver invoices to the Board in accordance with the invoicing arrangements set out in column 3 of the table below. The relevant element of the Settlement Sum set out in column 2 of the table below shall be paid by the Board to Project Co in instalments by the payment dates set out in column 4 of the table below.

Event	Element of Settlement Sum (£)	Invoicing Arrangements	Payment Date
Milestone 1 Signature of this SA1	£6m (plus VAT)	Project Co to submit invoice to the Board on the date of final signature of this SA1	Board to pay invoice within five (5) Business Days of receipt of valid VAT invoice
Milestone 2 Completion of the Drainage Works in accordance with the Drainage Completion Criteria	£2m (plus VAT)	Project Co to submit an invoice to the Board when the Independent Tester has certified that Milestone 2 has been achieved	Board to pay invoice within five (5) Business Days of receipt of valid VAT invoice (which valid invoice can only be issued once the Independent Tester has certified that Milestone 2 has been achieved).
Milestone 3 Completion of the Void Detection Works in accordance with the Void Detection Completion Criteria	£2m (plus VAT)	Project Co to submit an invoice to the Board when the Independent Tester has certified that Milestone 3 has been achieved.	Board to pay invoice within five (5) Business Days of receipt of valid VAT invoice (which valid invoice can only be issued once the Independent Tester has certified that Milestone 3 has been achieved).
Milestone 4 Completion of the Heater Battery Works in accordance with the Heater Battery Completion Criteria	£1.6m (plus VAT)	Project Co to submit an invoice to the Board when the Independent Tester has certified that Milestone 4 has been achieved	Board to pay invoice within five (5) Business Days of receipt of valid VAT invoice (which valid invoice can only be issued once the Independent Tester has certified that Milestone 4 has been achieved).

PART 9

INDEPENDENT TESTER VARIED SERVICES LETTER

Dear Sirs

LOTHIAN HEALTH BOARD ("the **"Board"**");
IHS LOTHIAN LIMITED ("**Project Co**");
ARCADIS LLP (previously EC HARRIS LLP) (the "**Independent Tester**");

Royal Hospital for Sick Children, Child and Adolescent Mental Health Service and the Department of Clinical Neurosciences in a single building adjoining the Royal Infirmary of Edinburgh at Little France at the Site and Off-Site (the "Project")

The Board and Project Co entered into the Project Agreement in respect of the Project. The Board and Project Co have agreed to amend and supplement the Project Agreement (the "**PA Settlement Agreement**") on or around the date of this letter, and as a result of the PA Settlement Agreement the Board and Project Co have agreed to vary the Services of the Independent Tester.

Terms used in this letter have the meanings given to them in the PA Settlement Agreement. Any references to the Project Agreement shall be deemed to be references to the Project Agreement as amended and supplemented by the PA Settlement Agreement.

1. Pursuant to Clause 3 of the Independent Tester Contract amongst (amongst others) the Board, Project Co and the Independent Tester, we hereby instruct the Independent Tester to perform the following Varied Services:-

1.1 issue the Certificate of Practical Completion pursuant to Clause 17.12 (Completion Certificate) of the Project Agreement when he is satisfied that the Facilities and the Retained Estate Handback Infrastructure are complete in accordance with the Completion Criteria as amended by the Agreed Resolution and the other relevant provisions of the Project Agreement (as amended) notwithstanding:

1.1.1 any requirement to procure the completion of: (a) the Post Completion Works in accordance with Clause 6.11 of the PA Settlement Agreement; (b) the Outstanding Works; and/or (c) the RDD Status C Submitted Items;

1.1.2 the dispute between the Parties regarding the Concrete Specification, De-Watering, Geotechnical Reports, Submains Schedule and the Energy Centre Lighting Calcs;

1.1.3 that there are Snagging Matters;

1.2 certify the relevant works comprising Milestone 2, Milestone 3, and/ or Milestone 4 as the case may be as complete when the Independent Tester is satisfied that the works comprising Milestone 2, Milestone 3 and/ or Milestone 4 (as applicable) are complete in accordance with the relevant Post Completion Works Completion Criteria and all other relevant provisions of the Project Agreement (as amended by SA1) notwithstanding:

1.2.1 any requirement to procure the completion of: (a) the other Post Completion Works (to the extent not yet complete); (b) the Outstanding Works (to the extent not yet complete); and/or (c) the RDD Status C Submitted Items;

1.2.2 the dispute between the Parties regarding the Concrete Specification, De-Watering, Geotechnical Reports, Submains Schedule, the Energy Centre Lighting Calcs and any other disputes which arise after the SA1 Effective Date or any Future Claims;

1.2.3 that there are Snagging Matters;

1.2.4 that there are any defects in the Works not forming part of the applicable Post Completion Works;

1.3 issue certificates to the Board and Project Co confirming achievement of Milestone 2, Milestone 3 and Milestone 4 as the case may be; and

1.4 certify the relevant works comprising the Outstanding Works as complete when the Independent Tester is satisfied that the Outstanding Works are complete in accordance with the Outstanding Works Completion Criteria and all other relevant provisions of the Project Agreement (as amended by SA1) notwithstanding:

1.4.1 any requirement to procure the completion of: (a) the Post Completion Works (to the extent not yet complete); (b) the Outstanding Works Exclusions; and/or (c) the RDD Status C Submitted Items;

1.4.2 the dispute between the Parties regarding the Concrete Specification, De-Watering, Geotechnical Reports and Submains Schedule, any other disputes which arise after the SA1 Effective Date or any Future Claims;

1.4.3 that there are Snagging Matters;

1.4.4 that there are any defects in the Works not forming part of the applicable Outstanding Works;

1.5 familiarise himself with the PA Settlement Agreement in order to issue a Certificate of Practical Completion in accordance with Paragraph 1.1 above, certify completion of the Outstanding Works in accordance with Paragraph 1.4 above, and certify Milestone 2, Milestone 3 and Milestone 4 in accordance with Paragraph 1.2 above.

2. The Parties have enclosed a copy of Part 1 of the Schedule (Technical Schedule), a copy of Part 2 of the Schedule (Technical Schedule Documentation), a copy of Part 5 of the Schedule (Post Completion Works) and a copy of Part 6 of the Schedule (Outstanding Works) of the PA Settlement Agreement.

3. The Independent Tester acknowledges that no representations or comments concerning compliance of the Works forming part of Part 1 of the Schedule (Technical Schedule) of the PA Settlement Agreement and/ or the Post Completion Works forming part of Part 5 of the Schedule (Post Completion Works) of the PA Settlement Agreement shall be made to the Independent Tester by any party to the Independent Tester's Appointment provided that the Independent Tester is entitled to request or invite any such party to make representations or comments and/or to require information from any of such parties. In the event of such request or invitation and/or requirement for information to the Board or Project Co, the Board or Project Co (as the case may be) shall be obliged to respond to such request or invitation and provide the information required.

4. All oral representations and/or comments to the Independent Tester on compliance of the Works with the Project Agreement (under exclusion of the Works forming part of Part 1 of the Schedule (Technical Schedule) of the PA Settlement Agreement and/ or the Post Completion Works forming part of Part 5 of the Schedule (Post Completion Works) of the PA Settlement Agreement) shall be made at meetings with the Independent Tester, such meetings to take place twice weekly, or on such other date or such frequency as may be agreed at the said meetings, or as may be reasonably requested in writing by the Independent Tester or Project Co or the Board.

5. Any written submissions and/or comments to the Independent Tester concerning compliance of the Works with the Project Agreement (under exclusion of the Works forming part of Part 1 of the Schedule (Technical Schedule) of the PA Settlement Agreement and/ or Part 5 of the Schedule (Post Completion Works) of the PA Settlement Agreement) shall be discussed at the meeting immediately following issue of the written submission and or comment.

6. Project Co shall procure that the Contractor shall issue commissioning and testing methodology for the Post Completion Works to the Independent Tester and the Board's Representative not less

than five (5) Business Days prior to the date when Project Co (acting reasonably) considers that the Contractor shall commence the Post Completion Works commissioning.

7. By signature of this letter Project Co, the Board and the Independent Tester agree that the Services shall be varied as set out above.

Signed for and on behalf of Project Co's Representative

Signed for and on behalf of the Board's Representative

Receipt of Independent Tester Varied Services Letter acknowledged for and on behalf of the Independent Tester

PART 10

INDEPENDENT TESTER REPRESENTATIONS

1. No representations or comments concerning compliance of the Works forming part of Part 1 of the Schedule (Technical Schedule), Post Completion Works forming Part 5 of the Schedule (Post Completion Works) or Outstanding Works forming Part 6 of the Schedule (Outstanding Works) shall be made to the Independent Tester by either Party and Project Co shall ensure that no representations or comments shall be made by the Contractor, unless the Independent Tester requests and/or invites the Parties to make representations or comments and/or requires information from any of the Parties and/or the Contractor, and where any such request and/or invitation and/or requirement is made by the Independent Tester the Parties shall and Project Co shall ensure that the Contractor shall respond to such request or invitation and provide the information required.

2. All oral representations and/or comments to the Independent Tester on compliance of the Works with the Project Agreement (under exclusion of the Works forming part of Part 1 of the Schedule (Technical Schedule)) shall be made at meetings with the Independent Tester and such meetings to take place twice weekly, or on such other date or such frequency as may be agreed at the said meetings, or requested in writing by either of the Parties.

3. Any written submissions and/or comments to the Independent Tester concerning compliance of the Works with the Project Agreement (under exclusion of the Works forming part of Part 1 of the Schedule (Technical Schedule)) shall be discussed at the meeting immediately following issue of the written submission and or comment.

4. The Independent Tester's services in the Independent Tester's Appointment shall be varied to reflect the position outlined in Paragraphs 1 to 3 above.

Health Facilities Scotland

NHS National Services Scotland

Scottish Health Technical Memorandum 03-01 (Interim Version – Additional guidance related to COVID 19 to be added in an update in 2022)

Specialised ventilation for healthcare premises
Part A: The concept, design, specification, installation and acceptance testing of healthcare ventilation systems

February 2022
Interim Version 3.0

A46676816

Contents

Executive Summary

Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' is published in two parts:

Part A: The concept, design, specification, installation and acceptance testing of healthcare ventilation systems.

Part B: The management, operation, maintenance and routine testing of existing healthcare ventilation systems.

The documents give comprehensive advice and guidance on the legal requirements, design implications, maintenance and operation of specialised ventilation in healthcare premises providing acute care. The use of these premises is very intense, the occupancy level high and the patients may be particularly susceptible to airborne infection risks. Their condition may also require close control of the environment.

The ventilation of non-healthcare facilities within the hospital curtilage should be designed to suit the application and specific guidance relating to the activity should be followed, for example pharmacy, central decontamination unit, etc. However, as they are on the hospital site, the means of providing ventilation should not adversely impact upon the hospital (for example, evaporative cooling towers should not be installed, sound levels should be appropriate and if the facility is within or attached to an area accessed by patients, their needs and the risk of airborne contamination should be considered).

In other types of healthcare facility that are outside of the hospital curtilage, for example GP practices, health centres, minor injuries units, dental, ophthalmic and podiatry clinics, mental health facilities, respite and long stay care homes and hospices, a risk assessment of the nature of the treatment being delivered, condition of the patients and intensity of use needs to be undertaken by those responsible for the facility in order to determine the extent to which this guidance will be applicable.

The guidance contained in Part A of this Scottish Health Technical Memorandum applies to new installations and major refurbishments of existing installations and should be considered as the standard to be achieved.

The guidance contained in Part B of this Scottish Health Technical Memorandum applies to all ventilation systems installed in healthcare premises irrespective of the age of the installation and should be considered as the standard to be achieved.

Scottish Health Technical Memorandum 03-01 (2022) supersedes all previous versions of Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' (2014). It also supersedes SHTM 2025 (1994) and DV4 (1983).

Who should use this guidance?

This document is aimed at specifiers, designers, suppliers, installers, estates and facilities managers and operations. Elements of the document will also be relevant to

managers concerned with the day-to-day management of healthcare facilities and senior healthcare management.

Main changes since the 2014 edition

- design information for specific healthcare applications has been revised and information on the reason for ventilation given. For example, endoscopy rooms may now be either negative (to contain and remove odours and manage airborne risks to staff) or positive pressure (to maintain a higher level of cleanliness where it is intended to puncture body membranes with the endoscope). These endoscopy-specific risks (i.e. waste anaesthetic gases and pathogenic material (for example, multi-drug- resistant tuberculosis) discharged by the patient during the procedure being undertaken) were identified prior to the SARS-CoV-2 pandemic. As with other elements in Part A, the application of this change is not retrospective but applies to new installations and major refurbishments (see Preamble above);
- the client's needs and legal requirements are more clearly explained;
- this edition of Scottish Health Technical Memorandum 03-01 introduces the concept of the Ventilation Safety Group in healthcare organisations (similar to the Water Safety Group in Scottish Health Technical Memorandum 04-01 and the Electrical Safety Group in Scottish Health Technical Memorandum 06-01). This is a multidisciplinary group whose remit will be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises;
- the SHTM introduces a standard method of identifying and labelling ventilation systems and the creation of an inventory of installed systems;
- the issues of resilience and diversity are addressed;
- guidance is provided on refurbishments or when changing the use of an existing installation;
- guidance is given on lifecycle and the updating of mid-life plant;
- design information for specific healthcare application has been extensively revised;
- issues around rooms where anaesthetic agents are used are addressed;
- airflow rates are more tailored to the applications to take advantage of new fan and control technology and so reduce energy consumption;
- revised air quality and filter standards are given;
- new and emerging technologies are catered for;
- advice is given on installation standards and the appointment of an independent validator;
- more detailed information is given on the commissioning process;
- validation acceptance standards and methodology has been completely revised;
- routine inspection and maintenance guidance has been revised and updated.

Net Zero Carbon

Scottish Health Technical Memorandum 03-01 supports UK legislation to bring all greenhouse gas emissions to net zero by 2045, and promotes sustainable methods of ventilation in healthcare facilities.

SHTM's core principle is that the default method of ventilation should as far as possible be natural ventilation followed by mixed mode (natural with mechanical ventilation), with mechanical ventilation being the last option.

The energy consumption of ventilation systems should be further minimised by specifying solutions with the lowest lifecycle environmental cost. The basic objective of energy-saving strategies in this SHTM is to provide the required ventilation service using the minimum energy. To this end, Scottish Health Technical Memorandum 03-01 recommends switching a system "off" when not required to be the most energy-efficient policy. If the system is needed to maintain a minimum background condition, reducing its output by "setting back" to the minimum necessary to achieve and maintain the desired condition is the next best option.

Fans represent an enormous potential for energy savings to reduce carbon emissions, as they are among the largest single users of energy (they use approximately 40% of all electricity in ventilation systems). The European Regulation 1253/2014, implementing the Energy-related Products (ErP) Directive, has significantly reduced the power to drive fans. Accordingly, Scottish Health Technical Memorandum 03-01 recommends using electronically commutated fans, as these have been proven to be the most energy-efficient, while also advising that belt-driven fans should no longer be installed.

There have been many legislative changes aimed at reducing energy consumption and technical advances that have increased operational efficiency. This revised SHTM incorporates those changes and has amended many of the design parameters for healthcare ventilation. Designs that are simply repeated from previous installations designed to superseded standards and guidance will not meet the revised energy or operational standards and will not produce a compliant result.

NHSScotland would also like to thank all those who took the time to comment and send contributions during the scoping and technical engagement phases of this document.

1. Introduction

The needs of the building occupants

1.1 Ventilation is used extensively in all types of healthcare premises to provide a safe and comfortable environment for patients and staff and control odours. More specialised ventilation is provided to help reduce airborne infection risks in areas such as operating departments, critical care facilities, isolation rooms and primary patient treatment areas.

1.2 The Health and Social Care Act places a duty of care on healthcare providers. Increased health risks to patients will occur if ventilation systems do not achieve and maintain the required standards. The link between surgical site infection and theatre air quality has been well established. If the ventilation plant has been installed to dilute or contain harmful substances, its failure may expose people to unacceptable levels of risk. Proven breaches of the statutory requirements can result in prosecution and may also give rise to a civil suit against the operators.

The building environment

1.3. Healthcare buildings are visited and used by large numbers of people. Many will be unwell or anxious so a well-ventilated environment with a fresh feel and an absence of noxious odours is essential.

1.4 Ventilation may also be installed:

- to ensure compliance with highly regulated quality assurance requirements of items processed in pharmacies and central decontamination units;
- to protect staff from airborne microorganisms and toxic substances (for example, in laboratories and anaesthetic rooms);
- to contain the spread of smoke between fire compartments as part of the fire strategy.

1.5 Healthcare buildings are continuously occupied, intensively used and because of the specialised nature of the facilities it may be extremely difficult to provide the service elsewhere if the ventilation fails. In order to ensure continuity of service, ventilation systems should be designed and installed so that they can be quickly and easily maintained. The resilience of the proposed system in the event of service outage should also be considered.

1.6 The ventilation of healthcare facilities consumes a significant portion of their energy load, so wherever possible natural ventilation is the preferred option. Where mechanical ventilation is used, sustainable design concepts allied to good-quality installation and the provision of controls that maintain the desired environment when the facility is in use will result in the minimum energy input for the maximum benefit.

Airborne risks to staff

1.7 Most healthcare staff are no more at risk from airborne hazards when at their workplace than they are when not in a healthcare environment; however, certain groups as detailed below may be exposed to a variety of airborne contaminants.

- staff who administer anaesthetic agents or who work in areas where they are routinely used will be at risk of casual exposure to these agents;
- staff who routinely work in areas where they may come into close contact with patients who have respiratory symptoms will be at risk of exposure to the microorganisms causing the symptoms;
- staff who routinely work in areas where they may come into close contact with patients that have skin lesions, an infectious disease or a dermatological condition will be at risk of exposure to the microorganisms causing the condition;
- staff who routinely process pathology specimens;
- staff who decant, mix and/or process chemicals used as reagents for the setting or processing of pathology specimens;
- staff who harvest organs, tissues and specimens at a post-mortem;
- staff who handle drugs or the components of drugs;
- staff who pre-clean used scopes, surgical instruments and equipment prior to decontamination;
- staff who may be routinely exposed to airborne hazards listed in EH40 issued under the Control of Substances Hazardous to Health Regulations (COSHH) (for example, woodworking dust, welding fumes, chemical vapours).

1.8 A well-designed ventilation system can mitigate the airborne risks to staff. It should:

- supply sufficient unvitiated air to dilute the possible contaminants;
- have air terminals located to efficiently scour the ventilated space;
- move the air from the clean to the less clean space and/or out of the building;
- supply the air at high level and remove it at low level so that the breathing zone of staff is in a clean airflow path.

1.9 Adoption of these principles will be sufficient to control the general risk to the staff identified above in their particular working environment. More specific airborne hazards should be captured at source and removed by local exhaust ventilation (LEV) systems provided under the COSHH Regulations (see paragraphs 3.3–3.5).

Airborne risks to patients

1.10 In general terms an environment that is satisfactory for staff will be satisfactory for patients. There are, however, exceptions as below:

- intensive treatment units of any type;
- haematology/oncology units;

- transplant units and units treating patients that have had their immune system compromised;
- bone marrow transplant units (BMT);
- burns units;
- cystic fibrosis units;
- operating theatres.

Patients being treated in these areas will need an environment supplied with good-quality filtered air and that is maintained at a positive pressure with respect to surrounding areas

Note: Patients who are particularly at risk from airborne microorganisms will normally be placed in an isolation room or suite that is maintained at a positive pressure. Patients who have a condition that could be transmitted to others are normally placed in a negative pressure isolation suite. When the patient's exact condition is unknown they may be placed in a neutral pressure (PPVL) isolation suite (see Health Building Note 04-01 Supplement 1 – 'Isolation facilities for infectious patients in acute settings for detailed guidance).

1.11 A more general airborne risk will result from poorly designed and constructed air handling units (AHUs) that allow water to stagnate inside; they can then become a source of microorganisms such as Legionella. If their intake is badly sited or housekeeping in the area is poor, fungal spores such as aspergillus can be drawn in. The ventilation system will then become a means of spreading these microorganisms and fungal spores around the healthcare building.

1.12 All ventilation systems should conform to the principles set out in the Health and Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems' and Scottish Health Technical Memorandum 04-01 – 'Safe water in healthcare premises'.

Specialist equipment environment

1.13 Imaging and other non-invasive scanning equipment will require stable environmental conditions to stay within calibration and provide accurate repeatable results. Health Building Note 06-01 and Health Building Note 10 (2021) give detailed guidance and the equipment manufacturers should be consulted.

Note: Health Building Note 26 – 'Facilities for surgical procedures' (2004) and Health Building Note 10-02 – 'Facilities for day surgery units' (2007) are under revision at the time of writing and will become Health Building Note 10-01 once updated.

Health Building Note 06-01 (2001) on diagnostic imaging and interventional radiology is also under revision at the time of writing.

Medicinal products environment

1.14 Pharmacists are required to ensure that any manufacture or preparation activities involving medicinal products undertaken in their units conform with the requirements of the Medicine Act. Processes must be carried out in a suitable facility usually termed an aseptic preparation facility. The quality of air supply and design of the ventilation cascade are essential to ensure a suitable environment for the activities undertaken.

Fire and smoke control fundamentals

1.15 Scottish Health Technical Memorandums 81 to 87 (including sub-parts) are the base documents for fire aspects. When designing a ventilation system, a fire and smoke control strategy should be developed that is relevant to the site and its function. The fire and smoke strategy should take account of the planned activity within the area, the type of patient present, staff-to- patient ratio and treatment being delivered (see also Chapters 5 and 7).

1.16 When ventilation systems are originally designed, they will conform to an agreed fire strategy. This will determine the compartmentation, provision of fire-rated ductwork, fitting of sprinklers, the siting of fire and smoke dampers and an agreed control action for the ventilation in the event of a fire. The agreed fire and smoke control strategy must be clearly set out as part of the design specification.

1.17 The fire regulations require that, if ventilation ductwork penetrates the fabric of a building, it should be designed and installed to contain the spread of fire (see Health Technical Memorandum 05-02 – 'Guidance in support of functional provisions for healthcare premises' for further guidance).

1.18 If a ventilation system is upgraded or altered to suit a change of use, it will be necessary to reassess the fire strategy.

1.19 It is management's responsibility to ensure that the fire strategy applied during the design and installation of a system is not reduced during the subsequent operation and maintenance of the equipment.

1.20 The number and location of fire and smoke dampers can be problematic. Fire- rated ductwork within fire zones will reduce the need for fire and smoke dampers. It will eliminate the need to provide access for routine damper testing and the infection control problems associate with reversed airflow paths resulting from damper failures and nuisance tripping (see also Chapter 7 for ventilation control in the event of fire).

Note: In developing a fire and smoke containment strategy the design of ventilation for infection control cannot be ignored. Over-compartmentation and poorly chosen fire lines can prevent air moving from clean to less clean areas and thus increase the infection risk. This can be a particular problem in operating departments where the desire to create a protected escape route can be at odds with the need to cascade air through a suite of rooms and out into a corridor in order to control the airborne infection risk.

2. The User Requirements

2.1 Patient treatment falls into four basic categories:

- surgical procedures – physical interventions to diagnose, repair, remove or rebuild damaged or infected tissue;
- medical care – the administering of drugs or various forms of practical, non-invasive treatment to diagnose, cure or reduce the severity of an infection or condition;
- mental health – the use of counselling, often in conjunction with drugs, to control or alleviate abnormal behavioural or false perception issues in patients;
- palliative care – treatment to temporarily or partially relieve or mitigate long-term conditions;

In all cases a patient may require treatment in one or more of the categories as either an in-patient or an out-patient.

Surgical procedures

2.2 It is thought that up to 25% of infections that occur as a result of a surgical intervention are caused by the airborne route. The source of these infections are predominantly as a result of airborne microorganisms, typically skin scales, liberated during the surgical procedure becoming airborne and landing in the wound or on surgical instruments. These then become a means of inoculating the patient with the contaminant. There are five possible routes that may result in airborne infections:

- skin scales liberated by the surgical team during the procedure;
- organic material liberated from the patient as a result of the procedure;
- microorganisms remaining from a previous use of the space becoming airborne;
- airborne microorganisms liberated outside of the space entering during the procedure;
- microorganisms in the supply air from a ventilation system that has been contaminated with biological material.

2.3 The level of airborne organic material present or biological burden (bioburden) is typically defined in terms of the number of colony forming units (cfus) present at the wound site during the procedure. It will be dependent on:

- the number of persons present;
- the completeness and effectiveness of their gowning;
- the duration of the procedure;
- the type of procedure;
- the use of air-driven power tools;
- the extent to which a patient contributes to the bioburden in the space;

- the general cleanliness of the space;
- the discipline of the surgical team;
- the measures that have been taken to prevent or control contaminants from outside sources entering the space;
- the quality and volume of the incoming supply air;
- the efficiency of the incoming air to “scour” the space;
- the means of removing contaminated air from the space.

2.4 Good surgical discipline, effective patient preparation, the cleanliness of the space and control of the entry and exit of personnel during the procedure will all contribute to reducing the bioburden present.

2.5 A well-designed ventilation scheme that provides a suitable quality of air and efficiently scours the space will further reduce the bioburden. If the ventilation maintains the space at a positive pressure to adjoining areas, the risk of contaminants originating outside of the space entering will be reduced.

2.6 In addition to controlling the bioburden, the ventilation should provide comfortable conditions for the staff and patient.

2.7 The ventilation system should also control the risks to staff from anaesthetic agents and other hazardous fumes and emissions typically found in surgical facilities (see paragraphs 1.10–1.12).

2.8 Minor procedures may be carried out in a treatment room or at the bedside so surgical procedures are not exclusive to the operating department. (See Humphreys et al (2012) for further guidance on facilities for minor surgical procedures and minimal access interventions).

Medical care

2.9 In general the main requirement will be to ensure that staff and patients are kept in comfortable conditions.

2.10 There are specific instances where staff can be at risk of contracting an illness by the airborne route from a patient. This is the case in infectious disease units where the ventilation will be designed to maintain the unit and individual patient rooms at negative pressure relative to adjacent areas. This will protect persons outside of the unit from infection by the airborne route but not staff entering and working in the unit, who may need to take additional precautions to protect themselves.

2.11 The opposite problem occurs when patients are neutropenic, that is, they have a reduced or extremely low resistance to infection. They are then at risk of infection by the airborne route from other persons such as staff and visitors. This will be the case in cancer/oncology units, critical care areas, and bone marrow and general transplant units. The ventilation in these areas will need a higher air quality and be set to maintain a positive pressure to adjacent areas.

Mental health

2.12 Any specific patient needs should be assessed and addressed. The main requirement will be to ensure that staff and patients are kept in comfortable conditions (see comments on other types of healthcare facility in the Executive Summary).

2.13 The fire risk may be considered more likely and additional steps may need to be taken to control it.

Palliative care

2.14 The main requirement is to ensure that staff and patients are kept in comfortable conditions. Temperature control may be more stringent for patients with long-term and/or end of life conditions (see the Executive Summary for further information).

2.15 Difficulties with evacuating patients in the event of fire may need to be considered.

Diagnostic and support services

Imaging and Interventional imaging

2.16 There are major advances in diagnosis and minimally invasive treatment involving imaging. It may be necessary during these invasive or non-invasive procedures to provide sedation or general anaesthesia to help with anxiety or pain. This may involve the use of inhaled anaesthetic agents and/or nitrous oxide (N2O). Staff working in these areas may be exposed to these anaesthetic agents when they are administered or subsequently when they are exhaled as the patient is recovered.

2.17 A similar situation occurs in maternity units, where a mixture of nitrous oxide and oxygen (N2O/O2) (Entonox) is used as an inhaled analgesic.

2.18 In both of the above cases ventilation should be designed to provide a clean airflow path and dilute any casual spillages of the gas. This approach will help control the casual exposure of staff to the anaesthetic agent (see paragraphs 3.3–3.5).

Post-mortem and pathology

2.19 Staff who harvest organs and specimens at a post-mortem and place them into preservative solutions may be exposed to the microorganisms present and fumes from the preservative.

2.20 Staff who section organs and prepare specimens for analysis may be exposed to the microorganisms present and the chemicals used for staining and fixing the specimens.

2.21 In both of the above situations local exhaust ventilation (LEV) in the form of downflow benches, safety cabinets and fume cupboards need to be provided to control the risk.

Pharmacy

2.22 Exposure to the active ingredients of drugs represents a hazard to pharmacy staff who are involved in their production. These activities are carried out in an aseptic

preparation facility to ensure that the drugs themselves are not contaminated. The actual production typically takes place inside an isolator so that there is a physical barrier between the hazard and the operator.

2.23 Alcohol sprays are used and staff exposure may be controlled by the provision of downflow LEV systems to remove the hazard.

2.24 Comfortable conditions are essential for staff working in preparation facilities as they need to be fully gowned, and entry and exit is restrictive.

Decontamination facilities

2.25 Staff may be exposed to airborne biological material and chemicals when handling and processing used scopes, surgical instruments and equipment as part of the decontamination process. The ventilation should provide a clean airflow path to control staff exposure. The quality, quantity and flow pattern of the air are also critical to the protection of the decontaminated items.

Estates and facilities

2.26 Staff may be engaged in welding, soldering, machining wood or paint- spraying. They may also decant chemicals in quantity (for example, for boiler treatment or hydrotherapy-pool dosage). LEV systems are routinely used to control the hazards arising.

3. Legal Requirements – Applicable Legislation

Health and Safety at Work etc. Act

3.1 The Health and Safety at Work etc. Act 1974 is the core legislation that applies to ventilation installations. As these installations are intended to prevent contamination, closely control the environment, dilute contaminants or contain hazards, their very presence indicates that potential risks to health have been identified.

3.2 The Act places a duty of care on ALL to provide and maintain a safe workplace. This includes designers and suppliers of goods or services. Those trading as competent designers or suppliers are therefore liable to provide outcomes that meet the client's needs and are without hazard to staff, patients and others who may be affected by the work activity.

Control of Substances Hazardous to Health Regulations

3.3 The Control of Substances Hazardous to Health (COSHH) Regulations 2002 place upon management an obligation to ensure that control measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and microbiological safety cabinets.

3.4 Where specialised ventilation plant is provided as part of the control measures, there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of COSHH requires that the system be examined and tested at least every 14 months by a competent person (P601 certified) and that management maintain comprehensive records of its performance, repair and maintenance.

3.5 Certain substances have workplace exposure limits (WELs) as set out in the Health and Safety Executive's (2005) Guidance Note EH40 – 'Workplace exposure limits'. This contains the list of workplace exposure limits for use with the Control of Substances Hazardous to Health Regulations 2002 (as amended). If specialised ventilation systems are provided in order to achieve these standards, they will be subject to the COSHH Regulations.

Workplace (Health, Safety and Welfare) Regulations

3.6 These state that:

- all enclosed workplaces must be ventilated by natural or artificial means;
- any plant provided under this legislation must include an effective device to give an audible or visual warning of plant failure where necessary for health and safety;
- the Regulations require that ventilation systems are maintained in an efficient state, in efficient working order and in good repair.

The Building Regulations

3.7 Approved documents L and F:

- apply to domestic and non-domestic buildings;
- clarify satisfactory methods of providing ventilation and give ventilation rates;
- set minimum standards for:
  - the protection of the supply position;
  - precautions against *Legionella;*
  - the purity of recirculated air;
  - access for service and maintenance;
  - documentation and proof of performance;
  - energy performance.

Health and Social Care Act 2008 (Regulated Activities)

Regulations 2014

3.8 Regulation 12(2)(h) of the Act decrees that registered providers must assess the risk of, and prevent, detect and control the spread of, infections, including those that are healthcare associated.

3.9 Appropriate standards of cleanliness and hygiene should be maintained in premises used for the regulated activity. DH (2015) issued 'The Health and Social Care Act 2008 Code of Practice on the prevention and control of infections and related guidance' (the HCAI Code of Practice), which contains statutory guidance about compliance with regulation 12(2)(h).

3.10 Regulation 15 of the Act states that:

All premises and equipment used by the service provider must be:

- clean;
- secure;
- suitable for the purpose for which they are being used;
- properly used;
- properly maintained; and
- appropriately located for the purpose for which they are being used.

The registered person must, in relation to such premises and equipment, maintain standards of hygiene appropriate for the purposes for which they are being used.

Note: The "registered person" means, in respect of a regulated activity, the person who is the service provider or a registered manager in respect of that activity. A "service provider" means a person registered with the CQC under Chapter 2 of Part 1 of the Health and Social Care Act 2008 as a service provider in respect of that regulated activity.

The Medicines Act 1968 and Human Medicines Regulations 2012

3.11 Pharmacy aseptic preparation facilities should conform to the requirements of EudralLex – Volume 4 – Good Manufacturing Practice (GMP) guidelines or equivalent UK legislation, and the requirements of the UK Medicines Inspectorate (MHRA) if a licensed manufacturing unit.

3.12 There are specific requirements under the Medicines Act 1968 to maintain accurate records of plant performance, room conditions and maintenance events. Such records would need to be preserved for up to 25 years as part of a quality assurance audit trail.

3.13 Specialised ventilation plant installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified microorganisms, may be subject to legislation regarding their operation in addition to that mentioned above.

Indoor air quality (IAQ)

3.14 There is increasing awareness that IAQ has an important impact on health and well-being. The World Health Organization and the Royal College of Paediatrics and Child Health (2020) have produced papers on the importance of IAQ, and the National Institute for Health and Care Excellence (NICE) (2020) has issued guidelines for domestic environments. Indoor and outdoor sources of contaminants are important contributors to IAQ, and designers of ventilation systems should consider both. The Department for Environment, Food and Rural Affairs (Defra) gives data for outdoor air quality by postcode for the UK. This enables designers to choose suitable filter grades by location and application (see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02 – 'Change in air filter test and classification standards' for further information).

Other relevant standards and sources of guidance

3.15 The Chartered Institution of Building Services Engineers (CIBSE) Guides and associated published documents (TMs) are the principal source of general ventilation specification and design guidance.

3.16 ISO 14644 and ISO 17141 provide basic information on cleanrooms used in pharmacy preparation facilities and inspection, assembly and packing (IAP) rooms for the processing of medical devices in central decontamination units.

3.17 BS EN 15780 applies to both new and existing ventilation and air-conditioning systems and specifies the assessment criteria of cleanliness and cleaning procedures of these systems.

3.18 HSG 258 issued by the Health & Safety Executive provides guidance on the design of local exhaust ventilation (LEV) systems.

3.19 Other relevant guidance is listed in the References.

3.20 The Board and their supply chain must ensure that the competence of all parties is considered at the point of their introduction and on an ongoing basis. The philosophies that are included in the HSE leaflet INDG368 (current revision), "Using Contractors" should be adopted. In addition, the outputs from the "Setting the Bar" report should be adopted as they are introduced through legislation. Evidence that the recommendations of "Setting the Bar" are being implemented in advance of the legislation would be considered to be good practice, particularly for high risk buildings. BSI Flex 8670 “Built environment. Core criteria for building safety in competence frameworks. Code of practice” should also form part of the project planning.

Note: In all cases the most recent version of any legislation, regulation, standard or guidance document should be consulted.

4. The Design and Specification Process

Project brief

4.1 The ventilation aspects of a contract will normally form part of a wider project to provide, upgrade or replace a healthcare facility. It is important that the ventilation designer closely liaises with the architect, as the layout of the facility and the adjacency of spaces within it will have a major impact on the ability of the ventilation system to achieve the client's requirements. All new major projects are required to use building information modelling (BIM) in order to ensure a coordinated design and provide information for the subsequent operation and possible future development of the facility.

4.2 The Building Services Research and Information Association (BSRIA) has produced an approach to project delivery known as "Soft landings" (BSRIA, 2018). It aims to ensure that the client's success criterion is kept in focus during the inception and briefing, design, construction, pre-handover, initial aftercare and extended aftercare phases of a project. It is strongly recommended that the client and project contractor adopt this approach.

Basis of design

4.3 This SHTM assumes that designers will be familiar with current CIBSE guidance and will use it as the basis for specifying and designing ventilation systems. However, the actual guidance contained in this SHTM may differ from the CIBSE guidance due to healthcare-specific issues and will take precedence over the CIBSE guidance where there are conflicts.

Note: Scottish Health Technical Memorandum 03- 01 Parts A and B need to be read and considered in their entirety when specifying and designing ventilation systems to ensure that the end result will comply with the client's needs.

Ventilation Safety Group (VSG)

4.4 The management of the ventilation systems of a healthcare provider should be overseen by a Ventilation Safety Group (VSG). The VSG should have clearly defined roles and responsibilities, be part of a healthcare organisation's governance structure and report to the "Designated Person" at Board level. It should be led and chaired by a person who has appropriate management responsibility, knowledge, competence and experience (for example, the Designated Person). (See Chapter 2 in Part B of Health Technical Memorandum 03-01 for further information.)

4.5 The VSG should be a multidisciplinary group and should typically comprise:

- an Authorising Engineer/independent adviser for ventilation (AE(V));
- an Infection Prevention and Control person;
- the Authorised Person(s) for ventilation services (AP(V));
- estates (operations and projects) staff;

- clinicians and specialist departments (for example, theatres, critical care areas, pharmacy, medical microbiology, nursing, decontamination);
- personnel from the finance department with accountability for capital and revenue evaluation;
- other stakeholders as appropriate;
- coopted expertise (for example, ventilation designers, consultants and suppliers).

4.6 The VSG remit should be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises. It should inform the following areas:

- the design process for new healthcare premises;
- the design process for modifications to existing premises;
- the commissioning and validation process;
- operational management and maintenance;
- annual verification and performance testing;
- prioritising the plant replacement programme;
- decommissioning and removal of redundant equipment.

Note: Where estates and facilities provider services are part of a contract (including PFI), it is essential that these providers participate fully in all those aspects of estate and facilities management that can affect patients. This includes responding to specific requests from the VSG, which may be in addition to relevant guidance and documentation.

4.7 It is important that decisions affecting the resilience, safety and integrity of the ventilation systems and associated equipment are not taken without the agreement of the VSG. The VSG should ensure that appropriate expertise and competence is available when making such decisions.

4.8 Whenever significant building work is undertaken; the VSG should consider its effects on the existing ventilation system air intakes. These may need to be protected from airborne dust during construction by the fitting of temporary additional filtration. There will also be a need to identify any risks to construction personnel who may be working in the vicinity of extract air discharges.

4.9 When construction or alteration work is undertaken inside an occupied building, its effects on the occupiers should be considered. The VSG should be consulted, and they may require that the area be sealed off from the occupied parts of the building and that a temporary extract be provided to maintain the worksite at a negative pressure to prevent the spread of dust into the rest of the building.

Derogations and alternative design strategies

4.10 Any derogations or alternative design strategies from this guidance should be subject to the scrutiny and agreement in writing by the VSG. The reason for the derogation or alternative design strategy and limits to its application should be recorded.

4.11 Designers proposing a derogation or alternative design strategy should be able to supply a body of evidence that their proposal will provide a degree of safety no less than if the guidance in this document had been followed.

Definition of clinical areas and critical systems

4.12 Healthcare ventilation may serve clinical or non-clinical areas of the estate:

- clinical areas are defined as spaces within the building where surgical or medical treatment is administered to patients. This includes patient bedrooms;
- non-clinical areas are defined as spaces where patients may be present but are not under direct treatment. It also includes staff and healthcare services areas.

4.13 Certain clinical and non-clinical areas within a healthcare establishment are considered critical to its ability to provide healthcare. Typically, ventilation systems serving the following are considered critical:

- operating suites of any type including rooms used for image-guided surgical procedures and their recovery areas;
- airborne isolation facilities, both source and protective;
- critical care areas and neonatal units;
- invasive treatment, endoscopy and bronchoscopy rooms;
- containment level 3 laboratory;
- pharmacy aseptic preparation facility;
- inspection, assembly and packing (IAP) room in a central decontamination unit;
- MRI, CAT and other types of emerging imaging technologies that require particularly stable environmental conditions to remain within calibration;
- any system classified as an LEV system under the COSHH Regulations;
- any other system that clearly meets the definition that “a loss of service from such a system would seriously degrade the ability of the premises to deliver optimal healthcare”.

Note: If any doubt exists about whether a system falls within this definition, the VSG should be consulted regarding the risk to patient safety and business continuity.

Resilience and diversity

4.14 When planning the ventilation of healthcare facilities, it is important at the outset to consider how the service will be delivered if the installed ventilation system fails or the area served has to close due to the effects of fire, flood or an outbreak of

infection. The loss of power, primary heating or cooling medium, or an integrated control system can cause the loss of ventilation to an area, so subsystem resilience is an important consideration.

4.15 Resilience in critical healthcare areas can be provided by splitting the ventilation load between two or more AHUs and/or employing a design that allows two or more AHUs to feed a common plenum with isolation dampers on individual branches to each critical zone. (Note that it is not proposed that duplicate back-up units be provided.) As an example, a large critical care area (CCA) level 2 or 3 could be split into two sections with an AHU for each. A small CCA cannot easily be split, so a decant area with a suitable level of ventilation should be pre-designated.

4.16 Diversity can be achieved by having several facilities each served by its own AHU. As an example, in an operating department, if each theatre suite is fed from its own dedicated AHU, the loss of one suite, while inconvenient, will not shut the department. The same scenario applies to isolation rooms if several of them are each independently ventilated (see Health Building Note 04-01 for further information).

Note: Providing twin ventilation fans in an AHU delays the time at which the system needs to be completely shut down in the event of a fan failure. It does not in itself provide resilience in terms of delivering healthcare (see Chapter 9 for further guidance).

New build facilities

4.17 New build healthcare facilities must be fully compliant with the requirements of all legislation in force at a date agreed when signing the contract. They should comply with the guidance contained in the current SHTM unless a derogation has been agreed with the VSG (see paragraphs 4.10 and 4.11).

Assessment of service requirements: selection of design criteria

External design conditions

4.18 The most accurate data that is available for the summer and winter conditions at the site should be used. The Meteorological Office supplies data for the United Kingdom; data is also available from CIBSE and other sources. It is essential that the designer agrees with the client as to which source of data is used and the design risk associated with the chosen external design conditions.

Note: It is essential to design to future climate projection to ensure design temperatures are maintained even in the event of prolonged heatwave conditions. CIBSE (2014) publishes design summer year weather files morphed to reflect future climate change.

4.19 Local adjustments for height above sea level, exposure factor, or other local climate peculiarities should be made as appropriate.

Internal design conditions

4.20 The design conditions selected within patient areas should strike a balance between the comfort requirements of staff and patients, who often have very different levels of clothing and activity.

4.21 Recommendations for the operative temperature and humidity of individual spaces are given in Activity Data A-Sheets (see Chapter 8 for specific requirements). Particular departmental requirements are given in the respective SHPN/HBN and room data sheets. However, the determination of the room environment must be driven by the patient cohort plus the range of procedures envisaged for that room.

Minimum fresh air requirements

4.22 In general areas and wards within healthcare premises, odour control is the main reason for providing ventilation. In the absence of other guidance, 10 L/s/person should be taken as the minimum ventilation requirement. Healthcare ventilation systems will normally be “full fresh air” either by natural, mixed mode or mechanical means, with energy recovery from the extracted air.

4.23 In non-clinical areas recirculated air systems may be considered. At least 20% of the recirculated air should be fresh. Additional filtration will be required to remove airborne particulate contamination and, if necessary, odours. This will affect running and maintenance costs and, given the high ErP rating of heat recovery devices, it will be necessary to prove that recirculating the air will be more energy- efficient overall.

Note: Ultra clean ventilated (UCV) operating theatres use air recirculation. The fresh air requirements of this specific application are given in Chapters 8 and 9.

4.24 Smoking is generally not permitted in healthcare premises, so no allowance need be made. Reference should be made to local national policy guidance.

4.25 In treatment and support areas the overriding requirement may be due to airborne infection control, hazard containment, the stability of specialist equipment or relate to a specific department’s function. Each case should be considered independently in order to determine the overriding minimum requirement for ventilation (see Chapter 8 for specific guidance).

Limiting supply air conditions

4.26 For most applications in healthcare buildings, it is the temperature differential between the supply and room air, rather than the actual temperature of the supply air, which is the critical factor. The maximum recommended supply-to-room air temperature differential is:

- summer cooling: 7 K
- winter heating: 10 K

4.27 Room air humidity should be kept below 70% in order to minimise risks associated with condensation and mould growth. There is no lower limit in unoccupied spaces.

4.28 Some types of diagnostic imaging technologies require close control of both temperature and humidity as well as the rate of change of conditions to ensure clarity of the image and accuracy of the data generated. The manufacturer’s guidance should be followed.

Air purity

4.29 In healthcare premises, the standard of filtration will depend on the activities within the occupied spaces. Except for special areas (for example, manufacturing pharmacies), the requirement for aerobiological needs is not stringent and filtration is only required to:

- maintain hygienic conditions for the health and welfare of occupants, or for processes such as centralised food preparation facilities;
- protect finishes, fabrics and furnishings – to reduce redecoration costs;
- protect equipment either within the supply air system – to prevent blocking of coils – or in the space itself to prevent dust accumulation

4.30 Given that almost all viable particles will originate from the occupants of a space and not from the incoming air, dilution is the more important factor aerobiologically. Therefore, for general areas an ISO ePM 2.5 ≥55% filter may be suitable. More critical areas would require an ISO ePM1 ≥50% filter. Efficiency or high-efficiency (EPA or HEPA) filters will only normally be required in ultra-clean systems, designated “cleanrooms” (see Chapter 9 for specific information) or for some immune-suppressed patient areas

4.31 In some inner-city areas the local airborne particulate level may be particularly high. In those special cases filters to ISO ePM1 ≥50% may be required to achieve the required indoor air quality. (See Defra’s website and the Specialised Ventilation for Healthcare Society’s (2018) SVHSoc.02 – ‘Change in air filter test and classification standards’.)

Humidity control requirements

4.32 Close control of humidification was originally required for some healthcare applications (for example, operating theatres) in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased.

4.33 Providing humidification is expensive in terms of plant, running costs and maintenance, and therefore its use should be restricted to where it is necessary for physiological or operational reasons (see Chapter 8 and associated SHPNs/HBNs).

4.34 In general terms the humidity within an occupied building or space will naturally float between 30% and 70% RH (relative humidity). Humidity should not be allowed to rise above 70% at any time but there is no need to maintain a background minimum level when the building or space is unoccupied.

Maximum noise levels

4.35 Noise will be generated in an air distribution system by the fan, ductwork fittings, dampers and grilles. The specified maximum noise level will depend on the activities within the occupied spaces.

4.36 Attenuation should be incorporated into the ductwork system or plant arrangement as necessary to reduce noise from fans and plant items in order to achieve the acceptable limits within the rooms at the design airflows.

4.37 Plant room noise level from fans when starting up or running should not be greater than 80 dB(A), and should be reduced where the plant is near to departments sensitive to noise.

4.38 Attention should be given to the reduction of tonal components. High tonal components from air diffusers etc. can seriously disturb concentration over longer periods even when the overall noise level is low. Broadband noise causes less annoyance.

4.39 The values recommended in Table 1 are for the total noise environment of space. In general, there will be noise transmitted into the space and noise generated within the space. The designer requires knowledge of the total hospital layout and operational policies, to assign acceptance magnitudes to all the possible noise sources, in order to arrive at the correct rating.

4.40 In Table 1 the overall noise level takes account of all internal and external noise sources. The noise level is the level measured with a sound-level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise which will have to be considered in the overall design, that is, in specifying the attenuation of walls, partitions, ceilings, etc.

Table 1: Interior Noise Level

Area	Room: overall noise level – dB(A)	Ventilation design value – dB(A)
Operating department all rooms including preparation, anaesthetic, scrub and utility, interventional and diagnostic imaging departments – all rooms	48	Operating department all rooms including preparation, anaesthetic, scrub and utility, interventional and diagnostic imaging departments – all rooms
UCV operating theatre and adjacent open- plan scrub only	53	–
Treatment rooms Consulting rooms Sleeping areas/rooms Recovery rooms	35	Treatment rooms Consulting rooms Sleeping areas/rooms Recovery rooms
Sanitary facilities	45	40
Aseptic preparation facility	45	40
Industrial areas	50	45
Circulation waiting areas	50	45
Plantrooms	85	80

4.41 The recommended criterion is measured as the “A” weighted sound pressure level expressed in decibels, which should not be exceeded for more than 10% of the time. See Scottish Health Technical Memorandum 08-01 – ‘Acoustics’ for further information.

4.42 The designer should also consider noise escaping to the external environment and this should not be unacceptable to occupants of adjacent buildings.

Calculation of building loads

Air infiltration

4.43 Air infiltration occurs due to a complex combination of wind pressure, thermal effects, location relative to other features and the construction standard of the building. The infiltration rate is governed by the size and number of doors and other openings in the building envelope and the complexity of internal air paths.

4.44 CIBSE guide TM52 provides information and formulae for the calculation of air infiltration in buildings. In all cases the requirements of the appropriate section of the current Building Regulations Part L (airtightness minimum requirements) must be met.

Summertime temperatures

4.45 To prevent overheating and avoid the future need for portable room air- conditioners, thermal modelling should be undertaken to ensure that internal temperatures in all areas do not exceed CIBSE Guide A guidance. Thermal modelling should be carried out whether the space is ventilated by natural, mixed mode or mechanical means. The modelling should be undertaken by a competent software user and take into account not only absolute values but also the time component.

4.46 Where thermal modelling indicates internal temperatures will exceed the recommended levels defined in CIBSE Guide A, additional measures should be explored to achieve compliance such as reducing solar and casual gains, improving building fabric performance, etc.

Peak heating load

4.47 Peak heating local calculations are necessary on all mechanical supply systems to establish the size of heater-batteries and subsequently the central plant. Note that with the introduction of the requirement to fit energy recovery set out in EU 1253, the heater-battery size will be reduced. If the energy-recovery value is ignored, the heater-battery and its control valve will be oversized and the system when put to use will be unstable and liable to hunt.

4.48 Where ventilation systems provide tempered air to spaces which have supplementary low pressure hot water (LPHW) to offset the building fabric losses, the AHU heating load should be calculated based on the external winter design temperature, the design internal air temperature, and the calculated total air volume (including a suitable allowance for leakage).

4.49 Where the ventilation system is the only means of heating a space, an increase in load equivalent to the calculated fabric heat losses from the space should be added to the ventilation load. A check of supply temperature difference should be made. If it exceeds that recommended in paragraph 4.26 the ventilation supply volume should be increased to suit.

Peak cooling load

4.50 In addition to the base data of airflow rates and temperatures, when calculating cooling loads, the designer should take into account:

- solar cooling loads;

- surface conduction cooling loads;
- internal gain cooling loads;
- air infiltration cooling loads;
- cooling loads due to high limit humidity control;
- method of control of internal conditions;
- fluctuations in internal temperatures.

Allowances must be made for all medical equipment in every space. Where the final item has not yet been selected, a unit that is reflective of the needs must be agreed with the stakeholders. A record must be included in the design documentation as to the unit which has been included in the design and the impact on all MEP systems of this unit. The stakeholders must have access to this data to ensure the compatibility of equipment and MEP systems can be checked against final medical equipment selections.

4.51 When the peak internal loads have been assessed and a suitable allowance made for non-coincidence, the supply temperature can be calculated.

4.52 Once the lowest required supply temperature of the air handling unit has been established, and an allowance made for temperature rise through the fan and ductwork (usually 1 K for low pressure systems), the off-plant enthalpy can be established from a psychrometric chart or table.

4.53 The cooling loads for all plant on the chilled water system should be calculated at each of the individual peak times in order to accurately establish the required (diversified) capacity of the chiller.

Note: Note that as with heating, the introduction of the requirement to fit energy recovery set out in EU 1253 means that the cooling-coil size will be reduced. If the energy-recovery value is ignored, the cooling coil and its control valve will be oversized and the system when put to use will be unstable and liable to hunt.

Annual energy consumption

4.54 The annual energy consumption of simple heating-only ventilation systems is simple to calculate, based on supply to external air temperature rise, and frequency of occurrence of external temperature data (see CIBSE Guide A).

4.55 Minimum air volumes are usually fixed by the room loads or fresh air requirements; however, the designer may increase airflow to some rooms or zones in order to balance loads, as detailed in paragraphs 4.63–4.68

4.56 The method of zoning and control can significantly influence energy consumption.

4.57 The nature of air-conditioning operation, that is, cooling and reheating for humidity or zonal temperature control, makes prediction of energy consumption very complex. It is imperative that these calculations are performed to ensure optimum energy efficiency.

4.58 The concept of load and plant operation charts is outlined in the CIBSE Guide TM52. The method requires the designer to establish the minimum and maximum loads on

all zones across the range of external temperatures between winter and summer design conditions. The total coil loads can be calculated taking account of the external air temperature and humidity plus the supply air conditions.

4.59 When all temperatures/enthalpies for all zones are plotted on the plant operation chart, set points and resetting schedules can be established. From this information, the outputs of individual heaters, coolers and humidifiers can be established at any given external condition. When those loads are computed against annual frequency of occurrence of external conditions as given in CIBSE Guide TM52, the annual energy consumption of individual elements, and thus the air-conditioning system, can be established.

4.60 In order to prevent surface condensation occurring, it is necessary to provide enough ventilation to maintain the maximum and ambient dew-point temperature below the lowest surface temperature, the coldest usually being the glazing.

4.61 Where this would require excessive ventilation levels, the designer should consider removal of the moisture at the source of the evaporation via an exhaust hood or similar device.

4.62 In intermittently heated buildings, it is necessary to consider the condensation risk at night set-back conditions as well as during normal operation. Calculation methods for this assessment are given in CIBSE Guide A.

Calculation of plant requirements

Air supply volumes

4.63 The minimum air supply volume for a room is determined by the greatest of:

- the minimum fresh air requirement;
- the air required to achieve the room differential pressure and provide open door protection at the key door;
- the minimum supply volume for the room load as determined by the maximum heating or cooling supply temperature differential;
- the desired air-change rate;
- the make-up air for a local extract (for example, cooker hood or LEV system).

Plant sizing

4.64 Once the design airflow has been established, the cross-sectional area of the air-handling unit can be calculated based on values given in Commission Regulation EU 1253/2014.

4.65 The fan duty should be calculated by adding the resistances of all elements that contribute to the pressure drop of the index circuit.

4.66 In order to establish the length of the AHU, it will be necessary to refer to manufacturers' literature, ensuring all necessary access panels and components are included as detailed in Chapter 9.

4.67 The designer should ensure that an allowance has been made for “dirty filter” conditions and confirm whether the fan pressure quoted is the total or static pressure.

4.68 Upon completion of the resistance calculation exercise, the designer should make allowances for calculation and construction tolerances as indicated below:

Total pressure loss margin:

- for leakage and balancing requirement =+5%
- for uncertainties in calculation = +5%

Combined total pressure loss margin =+10%.

Note: All installed ductwork whether new or reused should be subject to a leakage test on site prior to the application of any insulation. The leakage test should be to BESA DW144 but with a permissible leakage rate of not greater than 3%.

Refurbishment of existing facilities and fitting out shell schemes

4.69 When refurbishing existing facilities or fitting out “shell” schemes, every effort should be made to achieve full compliance with this SHTM and current Scottish Health Planning Notes (SHPNs). It is important that use of the space is revisited at this stage. Patient cohort, forms of treatment and all other stakeholder requirements must be compared to the capabilities of any existing system/plant and adjustments made to suit.

4.70 The physical constraints of the building may mean that some derogation in terms of layout and room dimensions are unavoidable, but it is vital that the infection control aspects, clean airflow paths, cascade of air from clean to less clean areas and fire and smoke requirements are not compromised and that the complete facility will be fit for purpose. The VSG should be consulted and agree in writing to any derogations.

4.71 A new AHU fully compliant with current standards will normally be required. The existing AHU should only be retained if it is not more than 10 years old and is (or can be made) fully compliant with current standards.

Note: The application of the ErP regulations may mean that new plant could be physically larger than that previously installed. If the replacement plant cannot be accommodated in the existing plant space, the plantroom may need to be expanded or a new plant space created. It may be that reconsidering how the ventilation load is determined, whether it can be shared, which type of AHU configuration will fulfill the design need, etc., will provide a satisfactory solution rather than just specifying like-for-like replacement plant.

4.72 The most commonly used original standard operating theatre design solutions from previous versions of this HTM have been revised and updated (see Appendix 7). They have been retained in this guidance as they will remain applicable to older theatre suites that are being refurbished within their original footprint. They may also be applicable where a pre-built “shell” is being fitted out.

Change of use of existing facilities

4.73 When a change of use of existing facilities is contemplated, the ventilation requirement should be completely revised to suit the new use (see paragraphs 4.63 and 4.69). All requirements must be agreed with the Ventilation Safety Group.

4.74 A new AHU fully compliant with current standards will normally be required. The existing AHU should only be retained if it is not more than 10 years old and is (or can be made) fully compliant with current standards.

4.75 If the ventilation load is to be increased or reduced and the existing system is retained, its output should be adjusted to suit. This will necessitate a recalculation of the heater and cooler loads and resizing of the control valves to match the new loads. It may also necessitate a change in fan size. Failure to carry out this exercise will carry an energy penalty and loss of control function.

4.76 The area/zone fire strategy should be reassessed to suit the new layout and purpose.

Computer-aided design (CAD) and building information modelling (BIM)

4.77 The design of new ventilation systems should be created using a CAD package, and the information generated should be incorporated into the BIM for the project. The client should have access to the BIM model as the project progresses; it will be transferred over to the client on completion (see paragraph 13.28 onwards)

5. Ventilation Strategies

5.1 In order to reduce energy costs and provide a more sustainable healthcare estate and support the declared zero- carbon target, ventilation selection should be as follows:

- first choice – natural ventilation;
- second choice – mixed mode ventilation;
- final option – mechanical ventilation.

Natural ventilation

5.2 Natural ventilation is usually created by the effects of wind pressure. It will also occur if there is a temperature difference between the inside and the outside of a building. The “thermo-convective” effect frequently predominates when the wind speed is low, and will be enhanced if there is a difference in height between inlet and outlet openings.

5.3 Ventilation induced by wind pressures can induce high air-change rates through a building, provided air is allowed to move freely within the space from the windward to the leeward side. However, in most healthcare applications, internal subdivisions will restrict or prevent this effect.

5.4 Current guidance restricts the opening of windows for safety reasons; also, as many designs are top-hung, their ability to permit natural ventilation is limited. Some types of window (for example, vertical sliding) can enhance single-sided air change by temperature difference, and these will improve the overall rate of natural ventilation in protected or sheltered areas where the effect of wind pressure is likely to be minimal.

5.5 Current healthcare building design philosophy suggests that windows are provided to allow light into and a view out of a healthcare building. Ventilation should be provided by purpose-made openings with appropriate consideration for thermal comfort and air quality. The airflow may need to be controlled by motorised dampers linked to temperature and/or occupancy sensors in the ventilated space.

Note: Natural cross-flow ventilation can provide reasonable air distribution for a distance of up to 6 m inwards from the external facade, provided that reasonably clear air paths are maintained. Beyond this distance – in areas where clear air paths cannot be maintained and in areas where high minimum air-change rates are specified – mechanical ventilation should be provided.

If natural ventilation is single-sided, it will usually only be effective for a 3 m depth within the space. Beyond that it should be supplemented by mixed- mode or mechanical ventilation.

5.6 With natural ventilation, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. However, this variability is normally acceptable in non-clinical spaces such as office accommodation, staff areas, library/seminar rooms and dining rooms, and some

clinical areas such as level 0 and 1 care spaces and waiting and consulting rooms where risk of airborne infections is likely to be low. The design must still aim to achieve agreed limits for room temperatures and, for clinical areas, achieve the desired room air change rate with “thermo-convective” effect (at peak room temperature coincident with summer external design temperature). Where it is essential to achieve a minimum ventilation rate at all times, mixed mode or mechanical methods will be needed.

5.7 Constraints caused by a building’s shape and/or the functional relationships of specific areas will inevitably result in some measure of deep planning, thus reducing the opportunity for natural ventilation.

5.8 In all cases, for natural ventilation to be effective it will be necessary to take steps to reduce any solar gain to a minimum. Outdoor air-quality, excessive heat gain, indoor air-quality requirements or external noise are all factors that may limit or preclude the use of natural ventilation.

5.9 Further information can be found in Health Building Note 00-10 Part D – ‘Windows’, BS 5925 and CIBSE’s Applications Manual AM10 – ‘Natural ventilation in non-domestic buildings’.

Mixed mode ventilation

5.10 Mixed mode ventilation is an assisted form of natural ventilation. Fans are fitted in purpose-made damper-controlled ventilation openings. Alternatively, a separate draw- or blow-through ventilation unit may be installed. In both cases the dampers and fans are controlled by temperature and occupancy sensors to ensure a minimum airflow rate while taking advantage of natural ventilation effects when present.

5.11 Where natural or mixed mode ventilation is adopted with complex air paths, the designer should produce an airflow diagram in order to ensure correct provision of air-transfer devices. CIBSE’s Applications Manual AM13 – ‘Mixed mode ventilation’ gives guidance. Modelling of the airflows under a range of conditions should be undertaken to establish the airflow paths.

Mechanical ventilation

Central versus local plant

5.12 Mechanical ventilation is expensive so it should only be provided when the space being served requires close control of its environmental conditions.

5.13 If the ventilation loads throughout a department or building are in phase, or are not significant, a central plant with single zone control may be adopted. However, this is rarely the case, so the condition or quantity of supply air to different areas or zones of the building will be varied accordingly. This may be achieved by either providing individual plant to each zone or providing separate controls for each zone such as provided by a variable air volume (VAV) system. Where there is a high density of rooms with similar ventilation requirements in an area of a building or department, it is usually economical to combine them into a central system; however, the operational resilience should be considered.

5.14 In large buildings, a choice between a small number of large ventilation systems located in centralised plant areas, or a larger number of smaller locally distributed systems, may arise

5.15 Large distribution systems and their plant can have the advantage of lower capital costs, but because they operate to a fixed supply condition, reheating or cooling may be locally required which will reduce energy efficiency. The distribution system will require more space for vertical shafts. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage and difficulties in balancing during commissioning. As the pressure losses in the long runs will be greater and a higher initial static pressure will be required, this may lead to a more expensive class of ductwork.

5.16 Decentralised AHUs feeding multiple smaller distribution systems may be more expensive in capital costs but as they avoid long runs, large ducts and vertical shafts, this may reduce overall costs. They can provide a more robust service, as the failure of an individual system does not prevent the use of the rest of the building. Future refurbishment or replacement of AHUs is also simpler. See also Chapters 4 and 9.

Horizontal and vertical AHUs

5.17 AHUs may be configured as horizontal or linear units that are single or double-stacked in the case of combined supply and extract units. They may also be configured more compactly as vertical or cabinet-style units. Selection will be dependent on the plant space available and where the unit is to be located. Whichever style is selected, good access for service and maintenance is essential. See legal requirements in paragraphs 3.6 and 3.10.

Chilled beams

5.18 Active chilled beams can provide an energy-efficient means of controlling environmental conditions. They are, however, subject to increased maintenance requirements due to the need for regular cleaning if they are to remain working efficiently. Access for this will not pose problems in non-clinical and office areas, but in clinical areas and patient bedrooms, routine access will be a major problem in an operational hospital.

5.19 Chilled beams should not be installed in clinical areas without the agreement in writing of the VSG.

Note: Patient bedrooms are classed as clinical areas as treatment is often delivered at the bedside rather than in a designated treatment room.

5.20 Where chilled beams are installed in non-clinical areas, they should be positioned to ensure that cold draughts are avoided.

5.21 In order to avoid condensation on the beam coils and the potential for mould growth, the temperature of the secondary chilled water circuit needs to be kept above dew-point (usually 15ºC). With active beams the supply air may, under some outside air conditions, need to be dehumidified. Manufacturers of these devices can provide specific advice on the design limits and siting of their equipment.

5.22 Where chilled beams are installed in rooms with opening windows, the window should be fitted with a switch to automatically turn off the beam when the window is open. To avoid condensation, chilled beams should not be installed in entry lobbies that directly connect to the outdoors.

5.23 Active and passive chilled beams require regular cleaning if they are to remain efficient. They should be of a design that allows full access to the beam coils for cleaning and be positioned where they will be accessible for maintenance and not installed above fixed items of equipment.

5.24 There is no benefit in installing chilled beams if the resources to keep them in efficient working order over their entire life cycle will not be available. The maintenance aspects of using chilled beams should be discussed and the decision to use them agreed in writing with the client.

Note: Maintenance access to chilled beams will require the use of pulpit steps or wheel-around access equipment. The use of such equipment in a working hospital is very restricted.

Stand-alone air-conditioners

5.25 Stand-alone air conditioners include fan coil units, split-comfort air-conditioners, room conditioners and cassette units. All of these devices recirculate air which affects indoor air quality and may increase the risk of healthcare-associated infections (HAIs). Therefore, they should not be installed in clinical areas.

Note: Patient bedrooms are classed as clinical areas as treatment is often delivered at the bedside rather than in a designated treatment room.

5.26 Stand-alone air conditioners may be installed in suitable non-clinical areas, but they should be positioned to ensure that cold draughts are avoided. The control settings should ensure that the external elements of the units are always above dew-point. Manufacturers of these devices can provide specific advice on the siting and design limits of their equipment.

5.27 Stand-alone air-conditioners recirculate air, therefore, a primary fresh air supply of at least 20% of the room air-change rate, or that required by the Building Regulations, or 10 L/s/person − whichever is the greatest − should be provided.

5.28 Whether single or multiple systems are used, it is essential that the designer give due consideration to the source of electrical supply, location of the heat rejection unit, environmental effects and flammability of the refrigerant used, and drainage provision for the cooling-coil condensate.

5.29 Stand-alone air conditioners require regular cleaning if they are to remain efficient and not become a source of airborne bio-hazards. If they incorporate an open water drainage system, they must be risk assessed under L8/HSG274 as part of the Legionella assessment (see the Health & Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems'). They should be easily accessible for maintenance and should not be installed above fixed items of equipment which would make access difficult.

Notes: Maintenance access to stand-alone air-conditioners will require the use of pulpit steps or wheel-around access equipment. The use of such equipment in a working hospital is very restricted.

Traditional refrigerants are being phased down because of their effects on the environment and are becoming ever more expensive. Their replacements at the time of writing have a degree of flammability. Both these factors pose serious consideration as to whether stand-alone air-conditioners are suitable devices to choose. In scanning and control equipment rooms, the use of chilled racks, shelves and embedded panels supplied with water above dew- point would be a more suitable option.

Where the refrigerant pipework is located must be checked against the need to restrict risk. This may necessitate the need for refrigerant gas monitoring. The requirement must be checked during the design (refer to BS EN 378, using the relevant current edition for the application).

System selection

5.30 Natural ventilation is always the preferred solution for a space, provided that the quantity and quality of air required, and consistency of control to suit the requirements of the space, are achievable. This should also take account of the guidance from the WHO (Natural Ventilation for Infection Control in Health-Care Settings). If this is not the case, mixed mode or a mechanical ventilation system will be required.

5.31 Ventilation costs can be minimised by ensuring that, where practicable, core areas are reserved for those rooms that need to have mechanical ventilation. Examples are:

- sanitary facilities, dirty utilities and those rooms where clinical or
- functional requirements have specific environmental needs; and
- those rooms where – for reasons of privacy, absence of solar gain, etc. – windowless accommodation is acceptable.
- Other spaces appropriate to core areas are those which have only transient occupation and therefore require little or no mechanical ventilation (for example, circulation and storage areas).

Zoning of the building

5.32 The efficiency and effectiveness of any ventilation or air-conditioning installation depends largely on the zoning and control of the installation. The factors to consider when determining the zoning of a ventilation system for a building or department are:

- periods of occupancy;
- the service delivery resilience;
- fresh-air/ventilation requirements;
- the fire and smoke control strategy for the area.

5.33 Where the ventilation system is not merely tempering the air, but also providing the heating and/or cooling requirements (air-conditioning) the following additional factors should be considered:

- internal or peripheral location;
- orientation of windows;
- variation of internal loads;
- level of control required.

5.34 For single-zone plant in staff areas, local control (with a run-on-timer if required) is recommended, as the system can be turned off when the space is not in use, thus saving both thermal and electrical energy. Most clinical-zone supply and extract systems, conversely, are required to operate continuously while the department is occupied; thus some form of time or use control is necessary.

5.35 The control of individual plant items is covered in Chapter 9, with examples of typical control strategies in Chapters 6 and 7. For control parameters of particular critical ventilation and air-conditioning systems, see Chapter 8.

5.36 On rare occasions a duplicate standby air-handling plant may be justified. If installed, it should be provided with a gas-tight damper (see BS EN 1751) at its junction with the supply distribution duct so that no back-flow can occur. Standby plant can become sources of contamination if warm, moist air is allowed to dwell within them. Their design and control system should ensure that this cannot happen.

Note: The presence of duplicate plant should be reflected in the fire strategy.

Fire and smoke control

5.37 Within a designated departmental fire zone, the total mechanical supply and extract ventilation volumes should be approximately equal so that in the event of a fire, smoke is neither drawn into nor blown out of the zone. Note that individual sub-zones within the departmental zone may be positively or negatively pressured to suit the clinical need (for example, isolation rooms, operating theatres).

Note: In atria, stairwells and designated escape routes, dedicated smoke clearance fans may be installed to keep evacuation routes clear in the event of a fire. These together with their associated smoke dampers do not form part of the building's general ventilation system and their operation will be automatically initiated by the building's fire detection system and/or manually controlled by fire service personnel (see Health Technical Memorandum 05 Firecode).

Air-conditioning

5.38 Air-conditioning is the facility to filter, heat, cool, dehumidify and if required humidify the supply air to maintain an internal condition regardless of changes in the external conditions or internal load. It is expensive in plant and energy.

5.39 Due to capital and running costs, air-conditioning should only be used in essential areas. These include operating departments, critical care areas, manufacturing pharmacies and areas with particularly sensitive equipment. Information on system performance requirements for individual departments is given in Chapter 8.

Local exhaust ventilation

5.40 There is a statutory requirement under the COSHH regulations to prevent or control the escape of chemicals, toxic fumes, biological materials or quantities of dust into the general environment. For airborne hazards to people, control may be by the provision of an LEV system designed to the standard set out in HSG 258.

Ventilation for general areas

5.41 Chapter 8 and Appendix 2 provide recommended air-change rates, temperatures and pressures for general areas requiring mechanical ventilation in healthcare buildings.

Mechanical extract ventilation

5.42 General extract systems can vary in complexity from a single wall-mounted fan to a central ducted air system with dual extract fans.

5.43 Replacement air is provided by either a central supply system or enters the building through gaps in the structure or purpose- made openings. The design should ensure that the latter does not result in an unacceptable level of draughts occurring in winter.

5.44 If individual systems are used, the ventilation can be operated intermittently, provided it continues to run for at least 15 minutes after the room is vacated (as with light-switch-operated fans in individual toilets).

5.45 If general exhaust systems are used, filtered and tempered replacement air should be provided to adjoining lobbies or corridors, to prevent the risk of discomfort caused by the ingress of cold air. Fire compartmentation requirements should be maintained.

5.46 Information on specialised extract systems is given in Chapters 8 and 9.

Mechanical tempered-air-supply systems

5.47 Where mechanical supply systems are required, the fresh air should be tempered and filtered before being delivered to the space in order to avoid discomfort.

5.48 The majority of space air temperature heating load will be provided by the energy-recovery device with the balance from a constant or variable temperature battery. In most instances, the low pressure hot water (LPHW) heating system should offset any fabric loss so that set-back room temperatures can be maintained during unoccupied periods without the need for the ventilation system to operate.

Balanced ventilation

5.49 A balanced ventilation system is a combination of both a supply and an extract system of equal volume; either a single space or a whole building may be considered to be balanced.

5.50 A balanced system is necessary in instances where it is essential to maintain consistent air movement within an area (for example, recovery rooms).

Cascade ventilation

5.51 In operating departments, it is normal practice to supply air to the operating theatre and allow it to flow through less clean areas – corridors, utility rooms, etc (from where

it is eventually extracted). Pharmacy aseptic preparation facilities, maternity delivery rooms and treatment rooms are similar.

5.52 In negative pressure facilities it will be necessary to provide make-up air in order to promote the correct pressure cascade from the clean to the less clean (for example, supply in an outer area – to lobby to patient's room – to toilet extract). Infectious diseases units and bronchoscopy rooms are similar.

Recirculation systems

5.53 Air recirculation systems are normally used in HEPA-filtered cleanrooms where the return air is significantly cleaner than the outside supply and where odour levels are not significant.

5.54 Recirculation is also routinely used in the canopy section of ultra-clean operating theatre ventilation systems (UCV). The recirculated air is EPA filtered to ensure that biological contaminants released by the surgical team are not discharged back into the clean zone.

5.55 Recirculation may also be used for swimming and hydrotherapy pool ventilation.

5.56 Where the designer is considering the installation of an air recirculation system, due account should be taken of:

- a 20% minimum fresh air supply volume or that required by the Building Regulations or 10 L/s/person, whichever is the greatest;
- prevention of supply air contamination from vitiated return air;
- prevention of stratification occurring within plenum chambers and mixing boxes, which may result in freezing of downstream coils;
- ensuring sufficient velocities through automatic control dampers (ideally 5–6 m/s) where fitted, to provide suitable authority and good shut-off;
- modulating control of mixing to provide optimum on-plant conditions;
- the use of "free cooling" by cycling the dampers to minimum fresh air when the enthalpy of the outside air is greater than that of the extract air under conditions when cooling is required.

Note: Recirculating air can create particular problems when its ductwork breaches fire compartmentation. Designers should ensure that the system complies with the fire strategy in all modes of operation.

Dilution ventilation and clean airflow paths

5.57 In the past dilution ventilation has been used as the sole means of controlling levels of airborne hazardous substances in a space. This approach in itself is no longer considered acceptable. COSHH requires that airborne hazardous substances should be controlled at source by using a closed system (such as an anaesthetic gas scavenging unit) or a protective enclosure (such as a fume cupboard). A good level of background ventilation will assist in diluting any casual release of the substance.

5.58 In anaesthetic rooms, the casual exposure of staff to leakage or spillage when administering anaesthetic agents should be dealt with by establishing a clean airflow

path. Air should be supplied at high level above or behind the area where the staff will typically stand and extracted at low level directly behind the anaesthetic equipment position (see Figure A25 and photographs in Appendix 9).

5.59 The philosophy of establishing a clean airflow path – from the air-supply point, past the breathing zone of the staff, on to the patient or other source of airborne hazard, and out via a low-level extract – would also apply in recovery rooms, birthing rooms, bronchoscopy rooms, laboratories and post-mortem rooms. A suitable air-change rate (see Chapter 8) will provide background dilution ventilation as an additional safeguard. This approach ensures that regarding the ventilation aspects, “all reasonable steps are taken to prevent or control exposure (of staff) to the hazardous substance” as required by COSHH.

Note: In these areas the supply air should be 100% fresh and not recirculated.

5.60 In operating theatres, patients will be on a closed breathing circuit in a room with a high air-change rate. Under these circumstances, the dilution effect would be considered sufficient to control any casual exposure of staff to anaesthetic gases.

Displacement ventilation

5.61 Displacement ventilation introduces air at low level and removes it at high level. It uses the natural thermal buoyancy resulting from heat gain to achieve air movement throughout a space with minimal or no energy input. Displacement ventilation can be natural, mixed mode or mechanical with the supply untreated, tempered or fully conditioned depending on the application.

5.62 Displacement ventilation can be very energy-efficient and works well in applications that have significant casual heat gains from solar effects, people or equipment. Typical applications in a healthcare setting would be the ventilation of atria, central dining rooms, main kitchens, hydrotherapy pools, computer server rooms, lecture theatres and open- plan waiting or office areas. It is also applicable to non-interventional imaging and scanning suites where there are significant equipment-generated casual gains but no aerobiological infection risks.

5.63 Supply terminals will be located at low level, usually in the form of large perforated plate style diffusers mounted vertically. The supply air terminal face velocity is low so that it does not create draughts. It is essential that they are located in several positions so that they can ventilate the entire space. Care should be taken to ensure that fixed or movable equipment and devices cannot obstruct them. Extract will be at high level through vents or by a ducted extract system. The ventilation rate may be controlled by temperature or CO2 sensor-initiated motorised dampers with or without fan assistance at the extract points. The supply air volume is then slaved to match.

6. Energy Control Strategies

6.1 The operation of ventilation systems should be monitored through a building management system (BMS). The basic objective should be to provide the necessary service utilising the minimum energy. To this end, switching a system “Off” when not required is the most energy-efficient policy.

6.2 If the system is needed to maintain a minimum background condition, reducing its output by “Setting back”, to the minimum necessary to achieve and maintain the desired condition, is the next best option.

Note on “Set back”:

In previous times when fan motors only had two speeds, turning the system

to “Set back” meant switching to the lower fan speed. With modern fans the speed is widely variable so “Set back” is not a fixed fan speed but rather a

control strategy that reduces the system output in order to maintain a desired minimum condition. This may be related to the air velocity at a fixed point,

air-change rate, pressure differential, temperature, humidity or a combination of these parameters. Providing a dew- point sensor in an internal space that brings the system on to “Set back” is a simple way of maintaining a minimum condition.

6.3 The system should only run at full output when needed to achieve and maintain the defined “in-use” operating condition

6.4 Care should be taken when specifying plant to discover the true “in-use operating condition”. Overstating the condition will lead to oversized plant, unstable control and excessive energy consumption.

6.5 The design and selection of set points for an AHU and associated extract system will have a significant impact on the overall energy consumption and efficiency of the system as a whole (see Chapter 9 for detailed information).

Timed control

6.6 Switch the AHU “On” and “Off” at fixed times using a time clock or BMS programme. The AHU needs to come on early enough in the morning to bring the space up to temperature by the normal start time.

6.7 As above but with an “Optimum start” control that uses the outside temperature to determine the start time. In the winter, the lower the outside temperature, the earlier the AHU starts. In summer, the higher the outside temperature above that desired, the earlier the AHU starts.

6.8 As above but link the AHU to a temperature sensor in the space. If out of hours the temperature inside drops to the dew-point, typically 16ºC in winter, or rises above 25ºC in summer, the AHU will start and run at “Set back” (see definition in the Note after paragraph 6.2).

6.9 Any combination of the above or any other appropriate and applicable method that uses the least energy to maintain the specified condition is valid. Various options for the control of single- and multi-zone air-conditioning systems are given in CIBSE Guides F and H.

Occupancy control – user triggered

6.10 The ventilation system output should be linked to occupancy detectors. These may take the form of movement, CO2, passive infrared (PIR) or other sensing technologies that can detect that the area served is in use and switch the system “On” or “Off” and/or adjust the ventilation output to suit the actual load.

6.11 In intermittently used spaces such as operating suites, movement sensors (for example, PIR or similar) should be installed in the space with a “double knock” program so that if movement is detected twice within 10 minutes the AHU will switch “On” to full speed. If no movement is detected for 30 minutes, the AHU switches “Off”. Double-knock detection prevents the system from switching on in situations where a person has briefly entered a space when it is not in use.

6.12 The above may be combined so that if there is no movement for 15 minutes, the AHU switches to “Set back” (see definition in the Note after paragraph 6.2) during the working day and “Off” outside of normal hours.

Note: In Ultra Clean Ventilated (UCV) operating theatres the UCV terminal should be linked to the AHU control so that when the AHU goes to “Set back” the UCV also goes to “Set back”, and if the AHU goes “Off”, the UCV terminal fans also switch “Off”. There is no aerobiological benefit in keeping the UCV terminal fans running when the theatre is not in use, it results in wasted energy.

6.13 An alternative strategy in operating suites is to link the AHU control to the lighting. If the theatre general lights are switched “On” the AHU switches “On” in “Set back” mode. If the main operating lamp is then switched “On” the AHU goes to “Full speed”. If all the lights are out the AHU goes “Off”.

Note: There are occasions when this approach may need to be used with caution; for example, if a type of surgical procedure requires the operating or general lights to be “Off” during a part of the operation, an override timer or plant extension switch will be needed. The operating department manager and VSG should be consulted for approval before adopting this strategy.

User control

6.14 Some applications require intermittent mechanical ventilation, frequently at a high air-change rate (for example, in certain types of treatment room for odour control). Local controls to facilitate this mode of operation if required should be placed in a prominent position to encourage economical use. Specifying timers that shut the system down after a suitable operating period and need to be reset manually will reduce energy waste.

6.15 Local controls that enable the user to select more than one mode of operation should be clearly labelled to identify the particular mode selected.

6.16 Where the system allows different room pressures to be selected, a direct- reading pressure gauge should be fitted within the eye line of the users, 1.5 m above floor level, adjacent to the selector control unit to provide an independent confirmation of the resultant mode of operation. A permanent notice giving a clear description of the selectable modes of operation should be mounted adjacent to the control unit.

7. Environmental Control

7.1 The primary objective of a ventilation control system is to keep the space served within the required environmental control limits, at the appropriate times – regardless of external conditions or internal loads – and with the minimum energy consumption.

7.2 The building heating load will normally be met by a wet heating system with ventilation provided to suit the activities within it. The control of the heating system will normally be compensated to the outside air temperature. Control of the ventilation will usually be via a building management system (BMS) with “outstations” in individual plantrooms and/ or for individual AHUs.

7.3 A BMS incorporating self-adaptive control algorithms that automatically adjust the set-point to suit the usage and load is preferred. This will enable the operating conditions and control tolerances to be set and monitored. It is often not possible to accurately predict building load variation at the design stage. Information provided by monitoring the operation of the plant via a BMS will enable optimum set-points to be established and energy consumption reduced.

7.4 The BMS may also be set to log the actual energy consumed by the system together with that recovered by the energy- recovery device. This will provide a useful check on overall operating efficiency and provide evidence that energy targets are being achieved. The provision of movement sensors within the controlled space in order to determine the actual occupancy will facilitate this process.

7.5 The failure of ventilation systems serving critical areas can have grave consequences for the delivery of healthcare. Control systems should therefore be simple, robust and reliable.

7.6 Computer-software-driven control systems are now the norm in building services. However, healthcare ventilation systems need to be available for operation outside of normal working periods when software support is not available. Should the software fail, it will be left to site staff, who may have little knowledge of the control algorithms, to restart the ventilation system. It is therefore essential to ensure that a simple means of restarting critical systems in the event of a software failure is provided (see also Chapter 9).

7.7 Where BMS use “outstations” to control plant, the “outstation” should be independently able to control the plant if the BMS link is lost.

Location of controls

7.8 Whether within the plant, duct or room, sensors should be located to provide accurate measurement of the condition of the air being monitored.

7.9 Sensors and control items such as control valves should be located close to the element being sensed or plant item being controlled in order to minimise time lags within the system. These may create over- shoot of conditions beyond the design envelope and result in additional energy consumption.

7.10 Where there is a requirement for close control of air-conditioning parameters in a number of zones (for example, an operating department), separate plant should be

provided for each zone in order to avoid the need for expensive over-cooling and reheating of individual zones. The control of most multi-zone systems within healthcare premises is based on off-coil control within the central plant, with trimmer heater-batteries on individual zones.

Note: In modern buildings the cooling load is often significantly greater than the heating load and may exist all year round. Whenever possible, the design should take advantage of free cooling when available.

7.11 Facilities to start, set back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location (for example at the reception or staff base).

7.12 Many ventilation systems may be completely shut down when the area served is not in active use (for example, operating suites). Alternatively, where there is a need to maintain a background condition, the ventilation output may be reduced by "setting back" the system (see paragraph 6.2 and associated Note). This will significantly reduce energy consumption and extend the life of filters and other system components

Multi-zone control methods and application

7.13 Close control of all air-conditioning parameters may be difficult to achieve with multi-zone systems, since each zone will in theory require a reheater and humidifier to give total control of humidity, if that is what is required. In reality, such close control is rarely required. It is therefore usual with multi-zone systems to provide control of zonal temperature only, with humidity control, where fitted, being based on average conditions within all zones, or a minimum condition within one zone.

7.14 Designers should consider whether it is necessary for the supply and extract fans to be interlocked – either so that the supply fan will not operate unless airflow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served (see also Chapter 8).

7.15 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratories and pharmacies that contain fume cupboards, safety cabinets and other LEV systems.

Fire aspects

7.16 The control strategy for ventilation systems in the event of a fire should be set out in an agreed fire and smoke control strategy for the site (see Chapter 1).

7.17 All supply AHUs should have a smoke sensor linked to the fire control panel and mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the AHU to shut down and the main supply-air damper and system fire damper(s) to close.

7.18 In critical areas a ventilation control panel should be mounted at the main entrance of the area that the ventilation serves (see Health Technical Memorandum 05-02 for more detailed guidance). Access to the panel should be restricted to the fire officer and appointed site AP(V). It should include independent on/off controls and an

indication of the status of the supply and extract systems. A notice should be affixed to the control panel stressing the need to liaise with departmental staff before switching off fan units

Note: In certain critical care areas, it is preferable to maintain the supply ventilation in case of a fire within the area. For example, in an operating department, while undergoing surgery, the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department, or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. This will allow time for the patient to be stabilised so that they can be safely evacuated if necessary.

User requirements

Room temperature control

7.19 The limits for room temperature set- point are generally between 18ºC and 22ºC depending on the particular application. In some specialised applications (for example, operating departments), the user may require a wider range of adjustment (see Chapter 8).

7.20 The selection of temperature set-point for each room or zone may be by a control facility in the room/zone or be carried out remotely at the control panel or BMS. Where the control device is mounted within the room/zone and is adjustable by the user, it should be marked either “raise” and “lower” or “+” and “–”. It should control within a specified temperature range to suit the user requirement with a control tolerance of ±1 K. All other control set- points should be selectable either on the control panel or at the BMS interface.

7.21 Where local control is provided, an indication of temperature will be required locally or at a staff base (if appropriate) using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example at the operating table in a theatre). This may be mounted in a supervisory control panel, with the signal repeated on the main system control panel or BMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

Alarms and indication

7.22 Supply and extract systems should include indicator lamps on the control panels to confirm the operational status of each system. Where the usage is on a regular daily pattern, time control with a user-operated, timed manual override should be provided.

7.23 Where a system is provided for a particular space, the indicator should be in, or immediately adjacent to, that space, and local controls should be provided with permanent labels clearly defining their function (for example isolation suites).

7.24 If room differential pressure gauges are required, they should be mounted directly adjacent to the entry door of the room to which they apply at a height of 1.5 m above floor level so that they are in the eye line of staff entering the room. If a mechanical gauge is fitted, it should have a green sector to indicate the acceptable normal

pressure range. If electronic, it should have a permanent label affixed underneath it giving the normal acceptable pressure range.

Note: For specific departmental control parameters, see Chapter 8. For plant controls see Chapter 9.

Maintaining balanced air flow rates

Consideration must be given to the method of maintaining the correct proportional balance throughout a system when in use. This becomes particularly important where duct or terminal mounted filters are to be used. As the filters soil, the pressure and flow balance of the system would change unless control measures are included to enable automatic compensation/adjustment (e.g. constant volume boxes, variable speed drives).

8. Specific Healthcare Department Requirements

General considerations

8.1 The foregoing chapters of this document contain general information on healthcare aspects of ventilation system design and specification. This chapter gives information relating to the specific design requirements for a range of healthcare applications.

8.2 The following departments will require a degree of ventilation appropriate to their function.

- the operating department;
- treatment rooms, endoscopy and minimally invasive suites;
- critical care area – levels 2 and 3;
- diagnostic and interventional imaging and cardiology suites;
- obstetrics/maternity;
- infectious diseases unit and isolation facilities;
- bone marrow and other transplant units;
- chemotherapy and oncology units;
- the pharmacy department;
- the pathology department, mortuary and post-mortem suite;
- central decontamination units;
- burns unit;
- cystic fibrosis unit;
- tissue bank, gene therapy and emerging treatment specialties;
- physiotherapy and hydrotherapy;
- estates infrastructure.

Design information for many of these applications is given below, in Appendix 2 or the relevant SHPN/HBN.

8.3 It is not possible to give definitive guidance for every healthcare ventilation application; however, the section on operating theatres contains much information that is common to other applications. Where no specific guidance is given, the principles set out below should be followed:

- the CIBSE guides and technical manuals contain basic information on ventilation design that can be applied to most applications;
- where a British or European standard exists that is specific to the application (for example, a cleanroom), it should be used as the basis of the design requirement;

- air should always move from clean to less clean areas. A hierarchy of room cleanliness is given in Appendix 3;
- differential pressure will prevent contamination between areas when doors are closed. Information on air leakage through gaps around closed doors and hatches for a range of differential pressures is given in Appendix 4;
- the flow of air will prevent contamination between areas of different cleanliness when doors are open. Information on airflow through open doors and hatches is given in Appendix 5;
- a methodology for calculating a design solution for a non-standard operating suite in terms of its room sizes, layout or number of people present is given in Appendix 8. This may be adapted as necessary to suit other less complex applications where air is required to cascade through rooms from clean to less clean areas.

Note: In all cases it is essential that the design solution adopted will ensure adequate scouring of the space being ventilated. The selected airflow rates, relative position of supply terminals, extract terminals, air transfer devices and pressure stabilisers will all have a bearing on the effectiveness of the room ventilation.

8.4 There are four routes by which airborne contaminants may appear in a room:

- shed directly by the room occupants;
- arising as a result of the work activities;
- transferred from adjacent spaces;
- through the supply air.

Particles shed directly by the room occupants can be controlled by:

- restricting access to essential persons only;
- the choice of the occupants' clothing;
- the room air-change rate.

Particles arising as a result of the work activity can be controlled by:

- enclosing, semi-enclosing or otherwise controlling the work-based source;
- the room air-change rate.

The transfer of particles from adjacent spaces can be controlled by:

- a differential pressure between spaces when doors are shut;
- airflow paths flowing from clean to less clean spaces when doors are open.

Particles entering with the supply air can be controlled by the selection of a suitable filter.

When designing ventilation for a healthcare application, the sources of airborne contamination, their degree of hazard to patients and/or staff and the ability of ventilation to control them should be taken into account. For any particular healthcare

application, the ventilation safety group (VSG) should be able to give advice on any specific risks to patients and staff.

8.5 The supply of air to a room has the following main functions:

- to dilute airborne contamination;
- to control air movement within such that the ingress or discharge of airborne contaminants from or to adjacent areas is minimised;
- to control the temperature and, if necessary, the humidity of the space;
- to aid the removal of and dilute fumes, odours and waste gases.

8.6 The supply air volume flow rate for any particular application will be that required to:

- achieve the application's recommended air-change rate;
- provide closed and/or open-door protection;
- achieve comfort or application-specific room conditions;
- replace (make up) that removed by an installed extract system;
- meet the fresh air requirement relating to the number of people anticipated to be present;
- achieve the minimum fresh air requirement if air is recirculated.

Whichever is the greatest amount.

Note: Air-change rates are given in Appendix 2. These figures have been found to give enough dilution of airborne contaminants, provided the mixing of room air is reasonably uniform. Closed and open door protection volumes are given in Appendices 4 and 5. Fresh air requirement is at least 10 L/s/person. Minimum fresh air volume if recirculated is 20%, whichever is the greater.

8.7 Natural and/or mixed mode ventilation should be used wherever possible. Where mechanical ventilation is chosen, a downward displacement turbulent air distribution is generally preferred, though displacement ventilation may be used if appropriate.

8.8 The supply and extract terminals should be positioned to ensure that all parts of the room are actively ventilated and that where necessary the staff will be in a clean airflow path. Extract and air-out paths via door gaps, transfer grilles, pressure stabilisers and low-level active extract should be evenly distributed to encourage efficient scouring of the room. (See paragraphs 8.37–8.40 and 9.161–9.172 for additional guidance on location and types of terminal.)

8.9 Horizontal flow room air distribution with or without a coanda effect (see paragraph 9.162) can be a source of draughts and difficult to set up correctly. Its use should be confined to non-critical areas or situations where ceiling-mounted diffusers could be obstructed by movable equipment support tracks (for example, in imaging rooms). Alternatively, a displacement ventilation scheme may be considered.

Temperature and humidity control

8.10 Supply flow rates to achieve the required room conditions are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the base heating load will be provided by a heating system. In critical systems the room or suite being considered will be within the heated building envelope so the ventilation will be sized to suit the casual gains or losses.

8.11 Temperature differences between supply and room air of up to 10 K for winter heating and 7 K for summer cooling should not be exceeded.

8.12 Room air humidity should be kept below 70% in order to minimise risks associated with condensation and mould growth. There is generally no lower limit in unoccupied spaces; however, see application-specific guidance.

Ventilation where anaesthetic agents are present

8.13 During treatment, anaesthetic gas or anaesthetic agents may be delivered to the respiratory tract of a patient either directly or using a carrier gas. Anaesthetic gases and agents are subject to workplace exposure limits and while beneficial to the patient are harmful to staff. Waste anaesthetic gas should be contained and removed by a suitable anaesthetic gas scavenging system (AGSS). Some leakage from the anaesthetic equipment and the patient's breathing circuit will occur with all systems, particularly during connection and disconnection and from the interface with the patient. In recovery areas the patient will exhale the anaesthetic agent directly into the room air. The room ventilation scheme should ensure that any leakage or exhaled anaesthetic agents are diluted and removed.

Note: Staff tend to be standing and patients lying down when anaesthetic agents are delivered; also anaesthetic agents are slightly heavier than air, so locating the supply terminal at high level behind where staff normally stand, with an extract at low level adjacent to the source (for example, the anaesthetic gas terminal units), will ensure that staff are in a clean airflow path.

8.14 The design primary air supply to an operating suite anaesthetic room that is equipped with a N2O terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas, or an operating department recovery room, should be 15 ac/h.

8.15 In delivery rooms the intake of anaesthetic gas is controlled on demand by the patient, who will then exhale directly into the room air. Locating the supply air at high level at the foot end of the bed with extract at low level at the head end will establish a clean airflow path and reduce the casual exposure of staff to the waste gas.

8.16 The primary air supply to any other room that is equipped with a N2O or N2O/O2 (Entonox) terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas or in which the patient is subsequently recovered, where the anaesthetic is employed for the purpose of pain relief or sedation but not full anaesthesia, should be 15 ac/h. However, subject to risk assessment, consideration may be given to reducing this to no less than 10 ac/h, only where use of the anaesthetic gas release into the space will be both very infrequent and in very small quantities.

Note: Staff employed in operating suite anaesthetic rooms and an operating department recovery room will potentially be exposed to anaesthetic agents for the duration of their working day. In other areas (for example, maternity, imaging, treatment rooms), anaesthetic agents are only used for pain control and/or sedation. The strength, quantity and frequency of use may be significantly less, hence the the option to carry out a risk assessment.

Door protection

8.17 Air should flow from the cleaner to the less clean areas as shown in Appendix 3 and Figure A23 in Appendix 8. There are several factors that affect the likelihood of a reverse airflow through doorways:

- when a person passes through a doorway, both the passage of the person and the movement of the door flap cause a transfer of air between the areas separated by the door;
- when a door is left open, there is a transfer of air between the two areas separated by the doorway. This is caused by air turbulence, but is greatly increased by any temperature differential between the areas (a 1.4 m wide doorway may allow the transfer of 0.19 m3/s of air in each direction when there is no temperature difference, but when the temperature differential increases to say 2 K, the volume transferred may increase to 0.24 m3/s). This may be a problem if for example the heat gain from a fluid warming cabinet is not allowed for.

8.18 In order to reduce the likelihood of contamination of a clean area by a reverse airflow from a less clean area two methods of door protection are used:

- closed door protection – a pressure differential is created across a closed door so that any air leakage is from the clean to the less clean area. Appendix 4 gives details of closed door leakage rates for a range of differential pressures;
- open door protection – the pressure differential drops when a door is opened (see Appendix 6) and is effectively replaced by a flow of air through the doorway from the clean to the less clean area. The flow of air needs to be sufficiently large to ensure that significant reverse airflow cannot occur and will be related to the relative cleanliness of the areas being considered. Appendix 5 gives airflow rates for open-door protection related to door/opening size and the classification of the adjoining area.

8.19 Pressure stabilisers enable the room differential pressure to be set when the doors are shut, thus providing closed-door protection. When a door is opened, the stabilisers will close, forcing air to be directed through the doorway, thus providing open-door protection. Provided that the dilution criteria in Appendix 3 are met, the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.

8.20 In applications where it is critical to maintain a specific airflow and/or pressure regime, for example isolation rooms, all windows in the zone should be locked shut or sealed. Trickle vents, if fitted, should also be sealed.

8.21 The design of the ventilation system for an area depends on the overall configuration of the department. Where the department is served by more than one AHU the

control of the units may need to be interlocked so that reverse airflow patterns do not occur.

8.22 Extract grilles should be sited and balanced to promote air movement in the desired direction.

8.23 Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room pressure differentials.

8.24 The relative locations of supply and extract terminals and their design air volume rates will determine the basic airflow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces, ensuring a flow from the clean to less clean areas of the suite. Failure to provide such devices will lead to uncontrolled airflows when personnel move between rooms and doors being held partially open by air pressure.

Air handling unit

8.25 AHUs should be to the standard set out in Chapter 9. The extent of the system served by an individual AHU should reflect the operational need and required resilience of the application.

Fire aspects

8.26 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system to limit smoke spread in the event of a fire.

Operating department

General

8.27 An operating department will consist of one or more operating suites, a recovery area, sterile pack and equipment stores, entry/exit/service corridors, office, staff changing and support facilities. Each operating suite will typically comprise a preparation room, operating theatre, anaesthetic room, scrub area and a utility room. In order to ensure satisfactory conditions and the correct movement of air, the entire department will usually be mechanically ventilated.

8.28 The information given in this section relates to conventional operating suites used for general surgery. It will be applicable to other types of operating suite such as maternity whose layout and dimensions conform to the principles of Health Building Note 26 (see Note below). Additional information for UCV theatres is given in paragraphs 8.75 onwards.

Note: Health Building Note 26 − ‘Facilities for surgical procedures’ (2004) and Health Building Note 10-02 − ‘Facilities for day surgery units’ (2007) are under revision and will be replaced by a single document: Health Building Note 10-01. It will provide guidance on the planning and design of infrastructure for in- patient and day-patient surgical services in the UK.

8.29 For other types of operating suite, the standard values may need to be adjusted to reflect non-standard room sizes, pressure regimes and air-change rates. A method of obtaining a design solution for non- standard theatres from first principles is given in Appendix 8 (see also paragraph 8.3 and accompanying Note).

Standard air movement control schemes

8.30 In all previous versions of this guidance, standard air-movement control schemes were given that provided a range of design solutions for typical operating- suite layouts. Improvements in the technology of ventilation control systems coupled with the ability to accurately sense and control real-time fan output has enabled operating-suite ventilation parameters to be tightened. These now more accurately meet the airborne- infection-control requirement (see the Lidwell Report). The previous standard design solutions have therefore been fully revised to take advantage of the technological advances and benefit from the reduced energy consumption and plant size they allow.

8.31 A new set of standard operating suite design solutions extensively amended to conform to the guidance contained in this edition of Scottish Health Technical Memorandum 03-01 are given in Appendix 7. They contain diagrams that show the relationship of rooms and the various doors and transfer devices between them but should not be regarded as architectural layouts. The schemes have been developed using the methodology described in Appendix 8.

These design solutions should be used for new projects and when refurbishing or upgrading existing operating suites.

8.32 Any other scheme may be used, and the standard solutions applied, if the following conditions are met:

- room relationships in air network terms are as shown in the plans;
- room sizes and shapes approximate to those given in Health Building Note 26 (under revision at the time of writing and to become Health Building Note 10-01);
- door gaps approximate to those given in the designer's notes in Appendix 4;
- casual heat gains are accounted for;
- a trimmer battery is installed in the air supply to the anaesthetic room and lay-up prep room;
- leakage through the structure is kept to a minimum. Note that theatre suites will be subject to an air permeability test at first-fix and final validation (see Chapters 10 and 12).

It is recommended that every effort should be made to adopt one of the schemes described above.

Ventilation design requirement

8.33 The need for ventilation of the individual rooms and areas within the operating department will be as follows:

- Preparation room – to protect sterile packs and instruments from pre-contamination;

- operating theatre – to control the airborne infection risk, remove airborne contaminants and prevent the ingress of airborne contaminants from adjacent areas;
- anaesthetic room – to protect staff from casual exposure to anaesthetic agents and maintain a suitable environment for patients;
- scrub – to remove aerosolised microbiological contamination and moisture released when staff scrub- up;
- utility (also known as sluice or disposal) – to contain any airborne hazards arising from the initial processing of biological material, contaminated instruments and general waste and prevent it entering the operating theatre or adjacent spaces;
- entry/exit/service corridors – to remove vitiated air cascading from the operating suite(s);
- sterile pack/ Layup Prep and equipment stores – to prevent airborne contamination of the packs and equipment;
- staff changing, shower and toilet facilities – odour control and moisture removal;
- staff rest room – moisture and odour control;
- office and general areas – comfort conditions;
- recovery – to protect staff from casual exposure to exhaled anaesthetic agents and maintain a suitable environment for patients.

The ventilation requirement for each space will be met by the desired air-change rate, room pressure differential, relative position of the room supply and extract, comfort requirement or a combination of all elements.

8.34 **Preparation room – sterile pack store (SPS)** - The preparation room is used simply as a store; sterile packs are set out on trolleys but not opened. They are then transferred to the operating theatre and opened as required. The nominal room pressure can therefore be the same as that of the operating theatre and the air allowed flow between the rooms in either direction. Air supplied to the preparation room should be directed into the operating theatre either through a door-mounted transfer grille or if no door is fitted, through the opening. It should not flow via a pressure stabiliser or transfer grille into the corridor.

8.35 **Preparation room "lay up"** – When the preparation room is used as an instrument "lay up" room (that is, sterile packs are opened and their contents exposed ready for transfer to the operating theatre), it should be regarded as being of greater cleanliness than the operating theatre. The preparation room should be at 10 Pa above the operating theatre to minimise the transfer of air and prevent pre-contamination of the instruments. The design air supply volume should relate to the door protection factors (for example, open door to theatre and closed door or hatch to corridor, where provided) and result in not less than 22 ac/h. Air should discharge into the operating theatre through a pressure stabiliser fitted with a stand-off baffle plate on the theatre side (see photograph). It should not flow via a pressure stabiliser or transfer grille into the corridor. The volume of supply air being discharged through the pressure stabiliser may be used to offset the volume of supply air to the operating theatre.

Where the unpacking of the instruments involves not only the removal of the protective packing but also the opening of the sterile barrier, the supply air to the room must be delivered via a terminal HEPA filter (H12 grade). The system must include constant volume and variable speed controls to ensure that the air flow rates remain constant as the HEPA filter soils. In this case it is also necessary to design a specific air flow regime to enhance the cleanliness of the environment. The supply air must be delivered from the ceiling in a manner which directs that air down into the zone where the sterile barriers are to be removed. Air will then be relieved from the room at low level with an air pressure stabiliser into the theatre.

8.36 **Operating theatre** – The supply of air to an operating theatre has four main functions:

- to dilute airborne microbial contamination – this will arise from the surgical activity and microbiological material shed by staff;
- to aid the removal of and dilute fumes, odours and waste anaesthetic agents;
- to control air movement so that the airborne contaminants from other less clean areas do not enter;
- to control the temperature and if necessary, the humidity of the room.

Design notes

- an air-change rate of 22 ac/h will control (a) and (b) above. When calculating the air volume required to achieve the air-change rate, the physical volume of the operating theatre will be based on whether the scrub does or does not form part of it. See Note to paragraph 8.46 for further information;
- the room to corridor differential pressure and amount of air required to give door protection will control (c). Door protection is calculated on the basis that during use, only one door or a single leaf of a double door will be open transiently, and all the rest will be closed. The designated “open” door will be the worst case (for example, typically that between the operating theatre and utility). The volume of supply air can be calculated from the flow rates for open and closed door protection given in Appendices 4 and 5. The smaller the number of rooms (and therefore doorways) leading from the operating theatre the better, as traffic is reduced, and a less complicated air movement control scheme is required;
- the supply air volume to control (d) temperature and humidity conditions can be calculated conventionally, taking account of all heat and moisture gains and losses resulting from equipment, lighting and number of occupants. Supply to room air temperature differences of up to 10 K for winter heating and 7 K for summer cooling should not be exceeded. Room humidity should not exceed 70% saturation.

The design supply air volume for an operating theatre will be whichever of the above calculations yields the greater figure.

In the case of an operating suite with a “lay up” preparation room, the actual air volume supplied by the operating theatre terminals will be the design air volume determined above minus that entering via the preparation room pressure stabiliser.

Note: In the majority of operating theatres the air-change rate will be the dominant factor; however, for small operating theatres the door protection factor may dominate.

8.37 The supply and extract terminals should be positioned to ensure that all parts of the operating theatre are actively ventilated. The ceiling should be divided into four quadrants and a supply terminal positioned at the centre of each quadrant and along the lines that join them as necessary to ensure that all parts of the room are equally supplied. In a large theatre, additional terminals around the centre point may be necessary to promote efficient scouring and achieve satisfactory air movement at the operating table level. This will help create in ventilation terms a well-mixed space and ensure good dilution of any airborne contaminants. Extract and air-out paths via door gaps, transfer grilles, pressure stabilisers and low-level active extract should be evenly distributed to encourage efficient scouring of the room. A minimum of three and preferably fourair-out paths, approximately equally spaced, should be provided.

Note: In order to ensure correct air distribution, it is essential that the supply terminal locations are not displaced by light fittings or ceiling-mounted pendants and articulated booms. Ideally the supply terminals should alternate with light fittings along the quadrant lines described above.

8.38 Supply terminals should be ceiling- mounted circular “air master” style, square “four-way blow” or perforated plate style that produce a downward displacement, turbulent airflow (see paragraph 9.170 onwards). Multi-section plenum-style perforated-flow diffusers with a footprint that encompasses the operating site are acceptable but may be prone to buoyancy effects as a result of temperature difference. Manufacturers’ type test data should be consulted to ensure that the terminal will achieve the required performance envelope. Note that these are not true laminar flow systems in the strict sense of the word but produce a downward displacement parallel flow style of air distribution.

Note: Where an operating theatre requires a higher than normal air-change rate (for example, cranial surgery, which may specify 35 ac/h), the volume of supply air means that four-way blow diffusers would be noisy and probably cause unacceptable draughts. A UCV terminal would deliver too much air, which could result in exposed tissue drying out during the procedure. A multi-section, plenum-style perforated flow diffuser with a footprint that encompasses the operating site would be the most suitable option.

8.39 The diffuser equipment chosen should not cause “dumping” and provide an air velocity 1 m above floor level at the operating position of between 0.2 m/s and 0.3 m/s.

8.40 Horizontal flow distribution should not be used in new installations; however, space constraints may force its retention when refurbishing existing installations. Where fitted, the supply grilles will require a means of directional adjustment that is lockable in position to prevent casual alteration in future when being cleaned.

8.41 Anaesthetic room – Anaesthetic gas or anaesthetic agents will be delivered to the respiratory tract of a patient either directly or using a carrier gas. Anaesthetic gases and agents are subject to workplace exposure limits and while beneficial to the patient are harmful to staff. Some leakage from the anaesthetic equipment and the

patient's breathing circuit will occur with all systems, particularly during connection and disconnection, and from the interface with the patient. The room ventilation scheme should ensure that any leakage is diluted and removed, and that staff are in a clean airflow path. Locating the supply terminal on the ceiling in a position behind where the anaesthetist will normally stand, and the extract terminal at low level adjacent to the medical gas pipeline terminals, will encourage a clean airflow path past the breathing zone of the anaesthetist, thus reducing their casual exposure to airborne anaesthetic agents (see information in Appendix 9).

8.42 An operating theatre suite anaesthetic room that is equipped with a N2O terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas should have a design primary supply and extract flow rate to achieve 15 ac/h.

8.43 In order to maintain the core temperature of patients being anaesthetised, a trimmer heater-battery should be provided in the anaesthetic room supply. It is also important that the location of pressure stabilisers and transfer grilles does not cause draughts across the patient.

8.44 The anaesthetic room will be at an intermediate pressure between the operating theatre and corridor.

8.45 **Scrub** – This may be a separate room or a bay within the operating theatre. If the scrub is a separate room, a door between the scrub and operating theatre is an inconvenience to scrubbed staff and may be replaced by an opening that is larger than a normal single doorway. If a door is fitted between the scrub and operating theatre is should have a transfer grille in its lower half. In either case there should be an active extract at low level under the end of the scrub trough most remote from the operating theatre, or a low-level pressure stabiliser that discharges onto a corridor at the end of the scrub room most remote from the operating theatre (see figure 1). If the scrub has an outside wall and/or is particularly large, additional extract terminals may be required to ensure air movement throughout the entire space and prevent surface condensation and mould growth.

Figure 1 Scrub room with extract under trough

8.46 Where the scrub is a trough on the wall or in an open bay within the operating theatre, it should have low-level extract under it.

Note: If the Scrub is in effect a separate room that is open (no door) to the operating theatre and it has a low-level pressure stabiliser discharging onto a corridor or an active low-level extract at its far end, so that air has to travel through the scrub to leave the operating theatre, the volume of the scrub will not be counted as being a part of the operating theatre room volume.

If the scrub is a trough on the wall or in an open bay within the operating theatre, the volume of space it occupies will be considered part of the operating theatre room volume for the purpose of calculating the operating theatre air supply.

8.47 **Utility (sluice or disposal)** – The room is kept at negative pressure with respect to the operating theatre so that contaminants contained in the surgical waste do not re-enter the operating theatre. A utility opening onto a clean corridor is considered to pose a greater risk than one opening onto a service corridor and so has a greater differential pressure. A utility may be shared between two operating theatres or be centralised to serve a group of operating suites.

8.48 **Entry/exit corridor** – Air cascading from the operating suite should be removed in the adjacent corridors. Note that though design flows may be calculated, the actual extract airflows may need to be adjusted at commissioning in order to achieve the design room differential pressures.

8.49 **Service corridor** – If materials to be disposed of are placed in impervious material for transportation, it is not necessary to have a separate corridor for this purpose. However, a service corridor has many operational advantages in terms of the flow of materials through the operating suite. It provides a heated envelope around the operating suite, thus obviating the need to run the theatre ventilation out of hours to maintain its temperature above dew-point, so significantly reducing energy consumption. Lastly it permits access for routine service and maintenance, and the eventual refurbishment of an operating suite without compromising the use of adjacent suites.

8.50 **Sterile pack store** – The central operating department sterile pack and prosthesis store should be supplied with 6 ac/h and be at a positive pressure to their corridor. It is important to coordinate the position of the supply air terminals with any racking so that the terminals are accessible for annual airflow measurement with a balometer.

8.51 **Equipment store(s)** – Supply air ventilation only to keep them at positive pressure to the corridor.

8.52 **Staff changing, shower and toilet facilities** – ventilation as per building regulations and for moisture control.

8.53 **Staff rest room** – Ventilation for kitchen area and general comfort.

8.54 **Office and general areas** – Ventilation as per building regulations and comfort.

8.55 **Recovery room** – Anaesthetic agents will be exhaled by patients while recovering; they are subject to workplace exposure limits and are harmful to staff. Anaesthetic gas scavenging systems (AGSS) will be provided but the room ventilation scheme should ensure that any leakage is diluted and removed.

8.56 The supply air terminals should be ceiling-mounted above the foot end of the recovery bed positions. Extract should be at low (bed height or below) level behind the bedhead positions or in the corners of the bed bay. This will establish a clean airflow path so that staff do not inhale anaesthetic agents exhaled by recovering patients (see the COSHH Regulations).

8.57 In an operating department recovery room, the design primary air supply will be 15 ac/h with a balanced airflow.

General notes

8.58 Supply flow rates for the main rooms of the operating suite are given in Appendix 7. For the other areas where room sizes and activities vary from site to site, air-change rates are given in Appendix 2 and Tables 2–7 in this chapter. These figures have been found to give enough dilution of airborne microbial contaminants, provided the mixing of room air is reasonably uniform.

8.59 For conventionally ventilated operating theatres, the primary air supply would be filtered in the AHU. Terminal filters, EPA or HEPA, are not required.

8.60 Air extracted from operating suites should not be recirculated as it may contain malodorous contaminants.

Note: Where thermal wheels are used for energy recovery, the small leakage across them from extract to supply should not cause odour problems and is not considered aerobiologically significant. In any event, all the air supplied will pass through the final filter.

Operating suite pressure regime

8.61 When designing the ventilation scheme the room pressure differentials given in Appendix 7 should be used. However, when the suite is balanced and commissioned these values are not to be taken as immutable but rather as desired orders of magnitude. What is important is the direction of airflow between rooms when doors are closed. Specifying doors of a laboratory standard that close and sit against a seal or have drop seals on their bottom edge is not necessary and will be counterproductive of the aim to allow air to flow from clean to less clean areas.

Note: Fire officers often require that doors are fitted with cold smoke seals as standard. These will significantly reduce the door- leakage rate and increase the differential pressure when new and undamaged. It is therefore recommended that provision for the design door leakage be factored into the sizing of the appropriate transfer grille or pressure stabiliser.

Temperature and humidity control and indication

8.62 In an operating theatre the temperature should be adjustable within the range 18ºC to 25ºC by the staff at the theatre control panel. The ventilation system should be capable of maintaining an internal temperature of 20ºC at summer outside design and 22ºC at winter outside design in all but the most extreme outside conditions. There may be instances where these temperatures may not be appropriate (for example, children and patients with a low body mass). The internal design temperatures should then be discussed with the VSG and agreed in writing.

8.63 Theatre temperature and humidity control sensors should be actively ventilated. They would typically be located in a sampling extract duct mounted in or adjacent to the theatre control panel, positioned at normal working height (1.5 m above finished floor level). Alternatively, they may be mounted in one of the operating theatre's low-level extract ducts. Whichever location is chosen they should be accessible for cleaning, and removable for periodic calibration and replacement.

8.64 Passive wall-mounted temperature and humidity sensors are not recommended.

8.65 Controls should be provided to enable operating department ventilation plant to be closed down when the operating suites are unoccupied (see also Chapter 9).

8.66 When in the "off" mode, to provide dewpoint protection the control system should switch the ventilation "on" to "Set back" if the space temperature falls below 16ºC.

8.67 All operating theatres and rooms where surgical interventions are carried out should have a control panel mounted on a wall with its screen centre at 1.5 m high and in the direct line of sight of staff standing at the normal operating position. The theatre control panel should include plant status indication, clearly readable temperature and humidity indicating gauges, and a means of adjusting the set point for temperature. Theatre ventilation plant status indication should also belocated at the operating department staff control base (see the Specialised Ventilation for Healthcare Society's (2017) SVHSoc.01 – 'Operating theatres: energy control strategies and the surgeon's panel' for further details).

8.68 The following indicators should be incorporated in the theatre control panel and their functions clearly labelled.

- a readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the temperature of the air in the theatre;
- a readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the relative humidity of the air in the theatre;
- a red indicator light that will illuminate when either the supply AHU fails or is switched off or is in "Set back" (legend: "Theatre not to be used in this condition");
- a green indicator light that will illuminate when the supply AHU is operating at full speed (legend: "Conventional theatre mode").

Note: In touch-screen panels, the red indicator should be a band across the screen with the statement "Theatre ventilation not operational. Do not use". The green indicator may be moving arrows representing airflow with the legend "Ventilation operational".

8.69 The humidity within the operating department when in use should fall within the range 35% to 60%. Where it is considered necessary to fit a humidifier, it should be selected to humidify to 40% saturation at 22ºC during the design winter outside conditions. The cooling coil should be able to remove sufficient moisture so that 60% saturation at 20ºC is not exceeded during the design summer outside conditions.

Note: When not in use the humidity may be allowed to fall below 35% but should not be allowed to rise above 70%.

8.70 The automatic control of ventilation in operating suites needs to be simple and robust. Over-reliance on complex room pressure and flow relationships linked to automatic fan speed control are unnecessary and in the long term have been shown to be unreliable. Complex software algorithms that can only be accessed and interpreted by off-site specialists should not be used. Whichever control strategy is chosen, it is important that on-site staff have the facility to override the control system and keep the ventilation operating at least until the surgical procedure is complete (see also Chapter 9).

Operating suite air handling unit

8.71 Each conventional operating theatre suite should have its own dedicated AHU to the standard set out in Chapter 9. To ensure operational flexibility and permit routine maintenance, an air handling unit should not be shared between suites.

8.72 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances, subject to VSG approval, an AHU may be shared between not more than two operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre suite so that the primary air volume to each can be determined. In addition, the branch supply and extract should be capable of being physically isolated and the main airflow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

Note: An AHU provided under paragraph 8.72 may be shared between two conventional operating suites, but not between a conventional and a UCV suite

8.73 The AHU supply and extract fans should be interlocked so that the supply starts up first and shuts down last, thus preventing reverse airflows. If the extract plant fails when the theatre is in use, it may continue to be used but a warning should show on the BMS and theatre control panel. If the supply fails when the theatre is in use the extract should shut down to prevent reverse airflows and an alarm should sound and show on the theatre control panel.

Fire aspects

8.74 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system to limit smoke spread in the event of a fire. However, this is a highly staffed department with a low fire risk/load status and these factors need to be recognised when developing the fire strategy. Operating departments typically comprise a series of linked rooms with multiple exits. Over-compartmentation can lead to difficulties in establishing clean airflow paths and room air dilution rates. This will lead to an increased risk of healthcare- acquired infections. Staff areas within the department should be treated as a subcompartment.

Ultra-clean ventilation system

General requirements

8.75 The design philosophy of a conventionally ventilated operating suite is based on the need to dilute contaminants and control both the condition and movement of air in an operating suite. Ultra-clean ventilation (UCV) is a means of significantly increasing

the dilution effect by providing a large volume of clean filtered air to the zone in which an operation is performed, and sterile items are exposed. Air is discharged above the operating zone and while not truly laminar, its downward displacement purges the clean zone of contaminants and particles generated by the activities within it. The airflow in and around the clean zone also serves to prevent particles originating outside the zone from entering it. The resulting reduction in contaminants has been shown to significantly reduce post- operative sepsis following certain orthopaedic procedures.

Note: The number of microorganisms that are present in the air at the wound site and exposed surgical items is dependent on the operating team, their procedural discipline, choice of clothing and the type of UCV system. Ultra-clean air is defined as that containing not more than 10 colony forming units per cubic metre of air (10 cfu/m3) present at the wound site during a surgical procedure. In practice levels of only 1 cfu/m3 are often attained.

8.76 UCV systems are very successful in reducing contaminants at the wound site so it is often considered that there is no need for complex air movement control schemes in the rest of the suite. However, when designing the ventilation scheme, it should be noted that the users may switch the UCV terminal to “low speed” when non-orthopaedic surgery is taking place. This is because the high airflow rates can cause increased moisture evaporation of exposed tissue which may be detrimental to the surgical outcome. In recognition of this, the ventilation scheme should be capable of providing operating conditions to at least a “conventional” theatre standard throughout the suite with the UCV in “low speed” mode. It should also be remembered that suitable levels of ventilation will always be required in the peripheral rooms.

8.77 UCV systems can be designed and built from first principles or a range of bespoke modular units of varying shapes and sizes are available, with each manufacturer having a slightly different approach to UCV design. Notwithstanding any variation in their design philosophy, all UCV systems will be required to completely achieve the performance standard set out in Chapter 12.

8.78 As with conventional theatres, each UCV operating suite should have its own dedicated AHU to the standard set out in Chapter 9. To ensure operational flexibility and permit routine maintenance, an AHU should not be shared between suites.

8.79 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances, subject to VSG approval, an AHU may be shared between not more than two UCV operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre so that the primary air volume to each UCV canopy can be determined. In addition, the branch supply and extract should be capable of being physically isolated and the main airflow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

Note: An AHU provided under paragraph 8.79 may be shared between two UCV operating suites, but not between a conventional and a UCV suite.

8.80 An inherent feature of a UCV system is its large airflow so it is essential to recirculate the air supplied to the operating theatre and/or to recover its energy in order to optimise operating costs.

8.81 The primary fresh air volume supplied to a UCV operating suite will be the same as for a conventional suite and it should be dispersed to the rooms in the suite in the same manner. The UCV canopy will typically incorporate recirculation fans. In order to prevent these fans “robbing” the air supply to the rooms, the primary air supply to the UCV theatre suite should be split into two ducts each with a volume control damper, one duct to feed the UCV canopy and the other for the anaesthetic and preparation rooms (which will be subdivided to accommodate heater batteries before they serve their respective room).

8.82 “Laying up” instruments in the clean zone is preferable microbiologically and considered best practice by the Royal College of Orthopaedic Surgeons, so an SPS preparation room should be provided. A transfer grille will be needed in the door between the theatre and preparation room.

8.83 If the client requires a “lay up” preparation room, a pressure stabiliser will be required between the preparation room and theatre. It should be fitted with a baffle on the theatre side to prevent air transfer interfering with the airflow distribution under the UCV canopy (see figure 2). Where space planning permits, consideration may be given to a location of the lay up preparation room in which the air pressure stabiliser discharges from it into the theatre at a point beyond the end of the canopy.

Figure 2 Pressure stabiliser fitted in preparation “lay up” room with stand-off baffle in theatre

8.84 Separate scrub-up or disposal facilities are not necessary for air cleanliness, although operational policy may prefer such a provision. A separate anaesthetic room should however be provided.

Types of UCV system

Remote plant systems

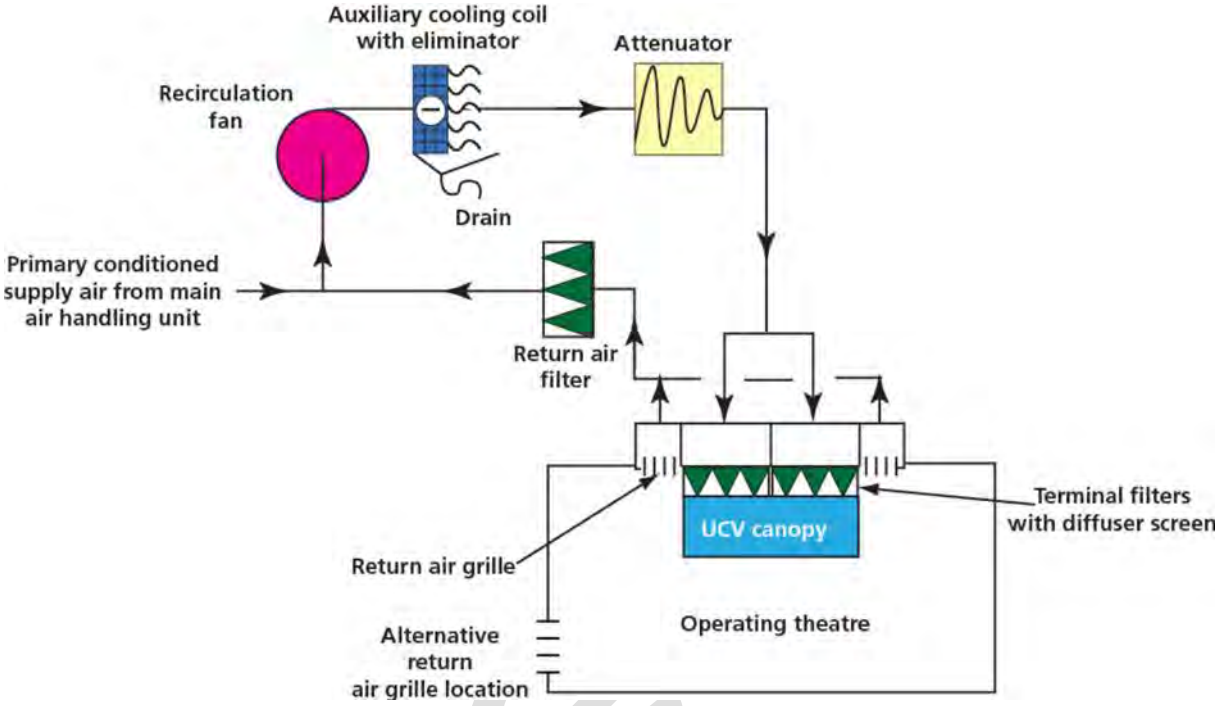
8.85 In a remote plant system, all the air- conditioning equipment is located outside of the operating theatre, except for the unidirectional airflow terminal, terminal filter, air diffuser and the return air grilles (see Figure 3).

8.86 This arrangement has the following advantages:

- the recirculation fans are out of the theatre, thus reducing noise. Multiple recirculation fans may be replaced by a single fan unit.
- casual heat gains from recirculation fan(s), canopy lights, equipment and people within the theatre can be removed by a cooling coil in the return air stream. This will prevent heat build-up in the theatre.

- the return air filters can be changed without needing access to the theatre, making routine maintenance more feasible.
- the opportunity exists to locate the EPA filter in the primary supply duct rather than the theatre terminal. This will reduce the number of filters required and allow them to be changed without entering the theatre.

Figure 3 Remote plant UCV systems



Modular systems

8.87 Vertical-flow modular units comprise a ceiling-mounted canopy containing return air filters, final filter and air diffuser. Primary air is supplied by a remote air- conditioning unit at the volume and to the standard required for a conventional operating suite. The UCV-canopy return-air fans may be within the unit or mounted independently of it in the ceiling void or wall space (see Figure 4).

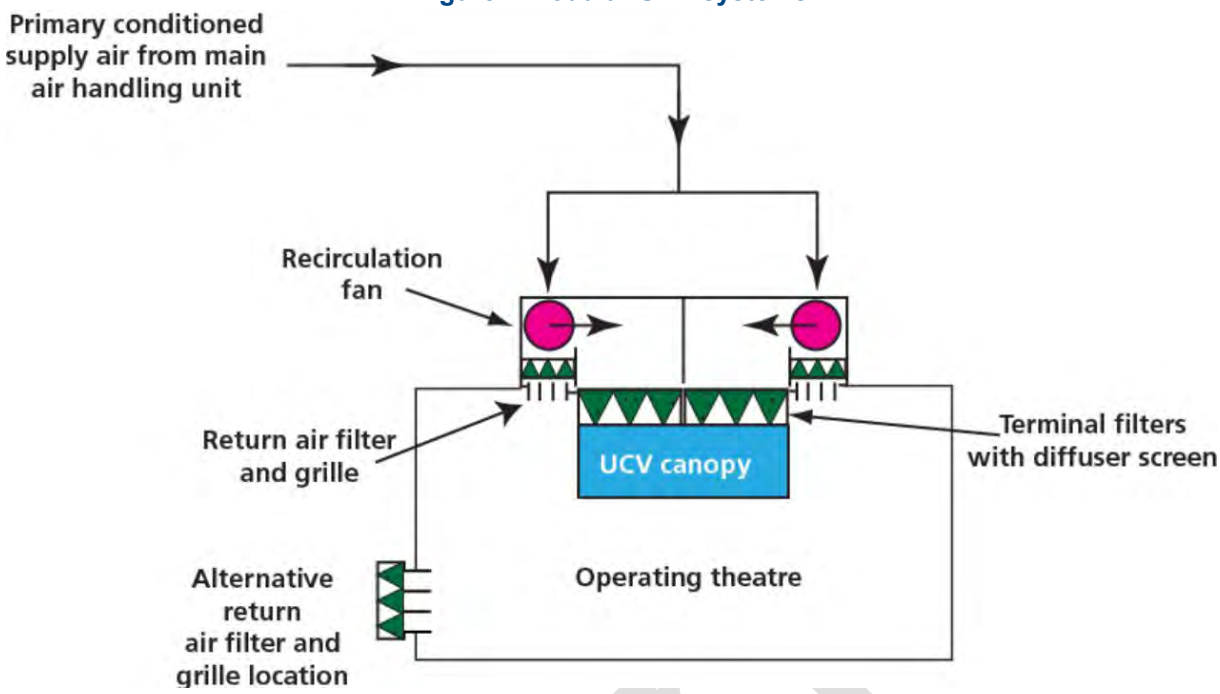
8.88 Modular units have the following advantages:

- as they are produced in a modular form, installation is generally more straightforward;
- they can be used to upgrade an existing conventional operating suite to a UCV suite without the need to change the AHU;
- all the UCV elements are in one place, making maintenance simpler.

8.89 UCV systems can be designed and built from first principles, or a range of bespoke modular units of varying shapes and sizes are available, with each manufacturer having a slightly different approach to UCV design. Whichever system is used, in order for the UCV terminal to produce the desired airflow within its footprint without entraining non-filtered air, the physical outside edge of the UCV canopy unit should not be less than 1 m from the operating theatre wall.

Notwithstanding any variation in their design philosophy, all UCV systems will be required to completely achieve the performance standard set out in Chapter 12.

Figure 4 Modular UCV systems



Vertical flow UCV systems

8.90 Vertical flow systems are effective at reducing infection risks (Lidwell et al., 1982). Some systems have no walls and use auxiliary fans to create an air curtain around the clean zone. Partial wall systems have side screens that terminate 2 m above floor level and full wall UCV have side screens that terminate 1 m above floor level.

8.91 Full wall systems provide a physical barrier between the operating team and other theatre occupants and guide the air down to the operating table level. They can therefore work at a lower air velocity.

8.92 Siting the return air grilles around the periphery of the theatre at low level will help control short-circuiting and give an improved airflow path. In any event there should be an “air out” path on each face or in each corner of the theatre. These may be provided by combination of pressure stabilisers and passive or active low-level extract grilles. Failure to provide “air out” paths on all faces of the theatre may result in the surplus air causing entrainment into the clean zone.

8.93 Vertical systems should have a clean zone large enough to encompass the operating site and all instrument trays likely to be needed for the procedures to be undertaken. Where the surgical site is small, a 1.4 m circular or rectangular terminal may be provided. For major orthopaedic procedures, a minimum size of 2.8 m × 2.8 m will be required. This is the area projected on the floor under the supply air terminal within the full walls, partial walls or air curtain. Any air outside this zone cannot be guaranteed to be ultra-clean although given the dilution factor, the level of microbiological contamination will be much lower than the general level in a conventional operating theatre. Having a contrasting coloured area on the floor delineating the extent of the “clean zone” will assist staff and is therefore essential.

Note: The entire “clean zone” footprint of the UCV canopy will be designated by a contrasting coloured inlay in the floor covering. A line marked on, or cut into, the floor covering is not sufficient and will not be accepted at validation.

8.94 When upgrading an existing conventional theatre to an ultra-clean standard the only solution may be the installation of a modular system. In these units, the heat gains from the return air fans may warrant the inclusion of supplementary cooling within the module. However, issues of cooling-coil drainage, condensate removal and maintenance access within the space constraints of the module may make this option impracticable. The additional cooling load should then be catered for by conditioning the primary air to compensate.

8.95 If an existing AHU is to be retained, it may require modification to ensure that it achieves the standards set out in Chapter 9 of this document (see also paragraph 4.73). The fan may need re-rating to accommodate the change in system resistance. The cooling coil may also need to be upgraded to cater for the increased load resulting from the return air fans and terminal lights. Failure to make adequate provision for this may make the theatre unusable during prolonged warm spells.

8.96 A factor affecting the airflow pattern is the supply/room air temperature difference. When the supply air temperature is significantly above room temperature, buoyancy effects will reduce the volume of air reaching the operating zone. This can occur at start-up in a large theatre where the temperature when not in use has dropped below 18ºC. If it is anticipated at design stage that this will be a regular occurrence, a system incorporating full walls should be used. Demountable extensions that convert a partial wall to a full wall unit are available.

8.97 Convection up-currents from the surgical team and operating lamp tend to counter the movement of clean air towards the operating site, hence the air velocity reaching the operating level is critical. The minimum velocity given below has been selected to take account of these factors and is greater than the theoretical minimum value. For all vertical UCV systems the design discharge velocities will be as follows:

- air velocity 2 m above floor level:
  - no side wall system = 0.38 m/s average;
  - partial wall system = 0.38 m/s average;
  - full wall system = 0.30 m/s average.
- air velocity 1 m above floor level:
  - all systems = 0.2 m/s minimum within the inner operating zone.

Chapter 12 gives details of the method of measurement.

8.98 Variable speed recirculation fans with differential pressure control may be the most suitable solution for maintaining consistent performance and energy saving. The recirculation fans should be accessible for replacement without the need to disturb the fabric of the operating suite.

UCV filters

8.99 The AHU primary and secondary filters should be to the standards and in the location set out in Chapter 9.

8.100 Terminal filters should be provided within the UCV canopy or in the air supply to it. Efficiency particulate air (EPA) filters grade E10 as specified in BS EN 1822 will be required as a minimum. There is no aerobiological benefit in fitting filters of a higher grade than this.

8.101 In some modular UCV units their manufacturers state that the terminal filter is used as a pressure equaliser to balance airflow so a grade higher than E10 is fitted. The increased resistance may affect the velocity of air reaching the operating level and there will be penalties in terms of installed fan power, energy consumption and higher noise levels.

8.102 The final filters should be installed in a leak-proof housing in a manner which allows the terminal unit, filters and their seals to be validated. The UCV canopy and its terminal filters will be scanned with a light scattering airborne particle counter (LSAPC) during validation to prove the effectiveness of the complete installation.

8.103 Where UCV units are constructed in sections, a means of measuring the pressure drop across the terminal filters in each section should be provided. The pressure test points should be located outside of the partial wall, capped to prevent air leakage and accessible within the theatre without the need to open the unit inspection panels. Alternatively, direct-reading non- electronic pressure gauges (of the minihelic type) may be fitted.

8.104 The UCV system will require a return air filter to capture the relatively coarse particles which would otherwise significantly reduce the life of the final filter. This should be at least an ISO 16890 Coarse 60%. In remote recirculation systems there may be advantages in fitting a higher- grade return air filter as it will reduce the load on the terminal EPA filters and extend their life.

Noise level

8.105 If sound-attenuating material is used to line any portion of the inside of the UCV unit it should be non-particle shedding and non-combustible.

8.106 The maximum noise level in an operating theatre fitted with a UCV terminal of any type should not exceed 53 dB(A). Chapter 12 gives details of the method of measurement.

Lighting and operating lights

8.107 The position of the UCV light fittings and style of partial walls, where fitted, should neither adversely disturb the airflow nor result in significant spatial variations in illuminance levels.

8.108 In vertical units, specialised task lighting should be provided by toroidal, cruciform or small multiple dome-shaped luminaires as they have good aerodynamic properties. The ideal luminaire will have a minimal effect on the airflow regardless of where it is positioned. Large diameter saucer-shaped luminaires should not be used in vertical

flow systems as they will occlude the airflow in the critical central zone. It is important to consider the suitability of existing luminaires when retrofitting UCV systems.

8.109 In vertical UCV installations the distance between the UCV canopy diffuser screen and the floor should be between 2.75 m and 3 m. This will allow space for the operating lamps and their articulation arms, and ensure that air at the correct velocity arrives at the operating level. When parked the lowest point of the central light stem, luminaire, monitor, camera, their associated articulation arms and any other ceiling-hung equipment should never be less than 2 m above floor level.

Note: The traditional means of light support is a central column that passes through the UCV canopy and is rigidly fixed to the building structure. The position of the support therefore prevents air being supplied at the centre of the canopy. Separate supports displaced from the centre of the clean zone would lead to improved airflow. This approach was advocated in the 1994 version of this guidance but at the time of writing no UK manufacturer has chosen to adopt this solution. Alternatively, equipping the operating team with battery- powered headset lamps may remove the need for traditional operating lamps and their supports.

Controls and instrumentation

8.110 The functions of the supply AHU and extract ventilation should be continuously monitored by a BMS control unit and interlocked with the UCV terminal control and monitoring functions. The room temperature sensor should be located in the re-circulated air return path. The controls and instrumentation for the main plant are set out in Chapter 9.

8.111 UCV systems will additionally require a low speed facility that can reduce the air supplied through the UCV canopy to a volume that equates to not less than 22 ac/h of the operating theatre gross volume or that required for door protection, whichever is greater, whilst still leaving the supply AHU operating at full speed. In this operational mode the theatre may be used as a conventional operating suite. A means of switching between conventional and UCV mode will be provided on the theatre control panel and its function clearly labelled (see the Specialised Ventilation for Healthcare Society's (2017) SVHSoc.01 – 'Operating theatres: energy control strategies and the surgeon's panel' for further details).

Note: UCV theatre ventilation may be completely switched off when the theatre is not in use, but the room temperature should not be allowed to drop below 18ºC (see paragraph 8.96). The AHU and UCV control should be interlocked so that when the AHU goes to "Set back" the UCV also goes to "Set back", and if the AHU goes "Off", the UCV terminal fans also switch "Off".

There is no aerobiological benefit in keeping the UCV terminal fans running when the theatre is not in use, it results in wasted energy.

8.112 The following indicators should be incorporated in the theatre control panel and their functions clearly labelled. In retrofit installations, an auxiliary panel for the UCV may be the most practical option. If fitted it should be mounted adjacent to the theatre panel and their control functions interlocked.

- A readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the temperature of the air at the UCV canopy.
- A readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the relative humidity of the air at the UCV canopy.
- A red indicator light that will illuminate when either the supply AHU or the UCV canopy fails, or either or both are switched off or the AHU is in “Set back” (legend: “Theatre not to be used in this condition”).
- An amber indicator light that will illuminate when the UCV canopy is at low speed and the supply AHU is running at full speed (legend: “Conventional theatre mode”).
- A green indicator light that will illuminate when both the supply AHU and UCV canopy are operating at full speed (legend: “UCV theatre mode”).
- A blue indicator light that will illuminate when the UCV canopy airflow, as detected by a differential pressure sensor, falls below 80% of the design flow rate (legend: “UCV requires service”).

Note: In touch screen panels the red indicator should be a band across the screen with the statement “Theatre ventilation not operational. Do not use” The amber indicator may be moving arrows representing airflow with the legend “Conventional Theatre mode”. The green indicator may be moving arrows representing airflow with the legend “UCV Theatre mode”. The blue indicator may be a band across the UCV terminal mimic stating “UCV requires servicing”.

8.113 When a system is designed to have partial walls with full wall extensions, a volume control facility may be incorporated to allow the system to be run with reduced velocity when the demountable full walls are in place. It would be the responsibility of the user to ensure correct operation of the system. To assist the user, an explanatory notice should be included on the theatre control panel.

8.114 The UCV unit manufacturer’s control box should be located in an accessible position preferably in the operating department adjacent to the operating theatre that it serves. A service corridor, if provided, is an ideal location. The control box should be clearly labelled with the identity of the operating theatre that it serves.

Barn and semi-barn theatres

8.115 There is no aerobiological reason why two or more UCV systems should not be installed in a common area if adequate spacing is provided. These are known as barn theatres and require special design considerations and operational discipline. The relative positions of the UCV units, temperature control range and location of doors and openings to other areas will all significantly affect the airflow at the operating positions.

8.116 A barn theatre has two or more operating positions each ventilated by a UCV canopy all in one open operating theatre. There may be a common scrub trough, SPS preparation room and shared utility, all of which reduce the facility’s footprint. For reasons of privacy and dignity, there is usually a separate anaesthetic room for each operating position. The operating positions may be separated by glass screens to

prevent bone fragments being propelled from one position to another when high-pressure air-driven surgical tools are being used.

8.117 A semi-barn theatre is very similar but would have a full-height dividing wall between the operating positions. The wall will not extend across the full width of the room, only its middle section. This creates a degree of physical separation between the operating positions but allows staff to walk from one to another around the ends of the dividing wall.

8.118 It is important that the physical layout and ventilation strategy of the barn or semi-barn are in harmony if the installation is to work successfully. The following points should be resolved with the architect and VSG when considering the design:

- in order to reduce the risk of pre- contamination, surgical instruments should not have to pass one operating position in order to get to the one that they are destined for;
- staff having scrubbed should not have to pass one operating position in order to get to the one that they are destined for;
- waste material being cleared from an operating position should not pass another when being removed from the operating theatre;
- the operating positions and their UCV canopies should be placed in line and not staggered or offset, otherwise their airflow patterns will interfere with each other;
- while barns and semi-barns have, from the staffing and space utilisation point of view, many advantages, they can create problems with temperature control and energy efficiency. It is not advisable to shut their ventilation off at night or weekends as if the operating theatre temperature drops it can take a considerable time for the ventilation to achieve the required air velocity at the operating position (paragraph 8.96). Because the barn is a large open space, when it becomes cold the warm air supplied by the UCV canopies tends to rise and stratification occurs. As a result, although from the user's point of view the ventilation appears to be running, the air being delivered does not actually have enough velocity to reach the operating table;
- access for service, maintenance and future upgrades or refurbishment will be restricted as this can only be carried out when none of the operating positions is in use.

8.119 Ventilation of each UCV canopy and associated anaesthetic room will be by a dedicated AHU; ventilation of the shared spaces and perhaps recovery area would either be shared between the operating position AHUs or provided by a separate AHU.

Hybrid theatres

8.120 A designation given to operating theatres that contain scanning equipment on a robotic arm. Major surgical procedures are carried out and the patient is scanned as necessary during the procedure. The scanning equipment may be floor-mounted or ceiling-hung and there will be one or more large monitors, a variety of screens and the medical gas terminal units all ceiling-hung on articulated pendants. The number of pendants and their supporting steelwork can reduce the space available to install

ventilation ductwork and compromise the location of the supply air terminals. Liaison with the architects at an early stage in the project design is essential to ensure a satisfactory ventilation solution.

8.121 Hybrid theatres tend to be significantly larger than conventional theatres and may have a radiation protected control room and an equipment room to house the servers for the scanning equipment and its robotic arm in addition to the standard operating suite of rooms. The ventilation load will therefore be larger and standard solutions should be adapted to suit or the designer will need to return to first principles (see Appendix 8).

8.122 Because of the increased airflow requirement, the AHU will be larger than for a standard conventional operating suite.

8.123 In all other respects the ventilation design and theatre control panel will be as for a conventional operating suite as above.

Neutral pressure theatres for infectious patients

8.124 The client may have a requirement for an operating suite for surgery on infectious patients. This may be a dedicated neutral-pressure operating suite or a standard operating suite that is designed to be easily convertible to a neutral-pressure suite. If airborne microorganisms liberated from a patient during a surgical procedure are allowed to cascade out into the adjacent corridors, they could infect other patients or the staff in the operating department.

8.125 The room provision and layout will be as for a conventional operating suite with the following variation to the ventilation scheme:

- the operating theatre will have a balanced supply and extract so that it is at the same pressure as the corridor;
- air should not cascade from the theatre to the surrounding rooms, so pressure stabilisers and/or transfer grilles should not be fitted. In the case of a convertible operating suite, permanently fitted hinge-down blanking plates with clamps should;
- be provided to close the pressure stabiliser/transfer grille openings when required;
- the preparation room may be dispensed with to avoid having stock that could become pre-contaminated. Sterile packs, instruments and consumables would be delivered to the theatre on a case by case basis. If a preparation room is required, it should be maintained at 10 Pa to both the theatre and corridor;
- the anaesthetic room should have a supply in excess of extract so that is maintained at 10 Pa above both the corridor and the theatre. There should be a pressure stabiliser between the anaesthetic room and the corridor but no transfer device between the anaesthetic room and the theatre;
- the scrub should have an active extract as for a conventional operating suite but no pressure stabiliser between it and the corridor;
- the utility should be at negative pressure of not less than –5 Pa to the theatre and its corridor;

- the corridor extract will be sized to cater for the air leakage from the preparation and anaesthetic rooms.

Overall, the ventilation scheme should ensure that all air supplied to the operating theatre is removed in the theatre. The theatre should be neutral (at the same pressure) to the corridor so that when the theatre exit door is open there is effectively no interchange of air between them. When the preparation or anaesthetic doors are opened, air flows from them into the theatre and not the other way.

8.126 The theatre control panel, automatic control strategy and air handling unit will be as for a conventional operating suite.

Interventional imaging suites

8.127 Interventional imaging refers to rooms in which surgical interventions are carried out guided by imaging equipment. The risk of infection by the airborne route is low as the surgical site is small, and sterile instruments tend to be unwrapped immediately before use. Anaesthetic gas or agents are used for pain relief or sedation Patients requiring full anaesthesia will normally be treated in a hybrid or conventional operating suite. The VSG should advise on the likely scope of use.

8.128 An interventional image suite may simply be a room containing the imaging equipment, an adjoining radiation protected control room or bay for staff and an equipment room for the imaging server. Support rooms for patient changing, sit recovery, toilets and a utility may also be needed.

8.129 Ventilation of the imaging room would be 10 ac/h with the room at a positive pressure to the corridor. Ceiling- mounted steelwork to support the imaging equipment may reduce the space available to install ventilation ductwork and compromise the supply terminal locations. This may mean that sidewall linear terminals are the only viable option. If fitted, their discharge velocity should not cause draughts and the direction vanes should be fixed or capable of being locked to prevent alteration during routine cleaning. Alternatively, a displacement ventilation scheme may be considered.

8.130 A full “theatre style” control panel is not required, but a green light to show the ventilation is operational and a red one to show it is not should be provided.

8.131 Radiation shielding and warning notices may be required to ductwork where it penetrates ceilings, walls or floors to plantrooms or adjacent spaces to which staff may need access.

Other application-specific design guidance

Application: Bronchoscopy, Endoscopy, Dental and General treatment facilities

Table 2: Treatment and procedure facilities

Area/zone	Reason for ventilation	Typical design factors
Bronchoscopy procedure room	Control of exposure of staff to airborne pathogenic material discharged by the patient e.g. multi-drug-resistant tuberculosis (MDR-TB) during the procedure being undertaken. (COSHH Regs) Control of exposure of staff to waste anaesthetic agents when used. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level at foot end of patient's chair/couch and extract terminal at patient's head level behind the chair/couch. Design parameters Air change: 15 per hour Pressure regime: Where patient membranes are breached and the procedure would present an infection risk to the patient, the pressure should be +10 Pa to the corridor. In Bronchoscopy and all other Endoscopy procedure rooms –5 Pa to corridor shall be established. (NOTE The decision as to the preferred pressure regime for each room must be made at design stage. They must not be designed and set up as switchable pressure rooms) Noise level: 40 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via BMS Humidity: Floating; max 70%RH Air quality: BS EN 16798 - SUP2 Extract discharge – Discharge in safe position away from people or open windows. If no suitable position available treat the discharge in the same way as a LEV with a discharge stack at a minimum of 3 m above the roof line.
Endoscopic procedure room	As above and odour control	
Dental treatment room	Control of exposure of staff to airborne pathogenic material discharged by the patient during the procedure being undertaken. (COSHH Regs) Control of exposure of staff to waste anaesthetic agents when used. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level and extract terminal at low level near patient's chair/ couch. Design parameters Air change: 10 per hour Pressure regime: Neutral to corridor Noise level: 40 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via BMS Humidity: Floating; max 70%RH Air quality: BS EN 16798 - SUP2
Emergency department resuscitation room	As above	
General treatment room	Comfort conditions only	

All of the above rooms are suitable for aerosol-generating procedures (AGPs)

Applications: Level 2 and 3 critical care areas, bone marrow transplant (BMT), oncology, organ and tissue transplant units

Table 3: Airborne protective facilities

Area/zone	Reason for ventilation	Typical design factors
Note: Level 2 & 3 Critical care areas should be treated identically in terms of service provision as their only difference is the staff- to-patient ratio.		
Level 2 or 3 critical care individual room	Protection of patients from airborne organisms and fungal spores	Supply only in patient's room and cascade air out via door undercut, transfer grille or pressure stabiliser through rooms of a lower classification. Design parameters Air change: ≥10 per hour Pressure regime: +10 Pa to general area Noise level: 35 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via BMS Humidity; Floating; max 60%RH Final filter; BS EN 1822 – EPA10
Level 2 or 3 critical care open bays	As above	
Bone Marrow Transplant (BMT) unit	Protection of patients from airborne organisms and fungal spores Note: Patient(s) will have a very poor immune system (neutropenia) so will be particularly vulnerable to infection by the airborne route.	Supply only in room and cascade air out via door undercut, transfer grilles or pressure stabilisers through rooms of a lower classification. Design parameters Air change: ≥10 per hour Pressure regime: +15 Pa to corridor Noise level: 35 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via BMS Humidity: Floating; max 60%RH Final filter: BS EN 1822 – EPA12
Haematology/Oncology ward	As for BMT	
Organ and Tissue Transplant unit	As for BMT	

Applications: Isolation rooms category 2 & 3, Infectious disease units, Containment level 3 rooms

Table 4: Airborne isolation facilities

Area/zone	Reason for ventilation	Typical design factors
Category 2 isolation room	Protection of staff and all other building occupants from airborne organisms dispersed by a patient with an infectious disease. See Scottish Health Planning Note 4 Supplement 1	Extract only in patient's room and en-suite. Supply air from corridor passing into room via door undercut, transfer grille or pressure stabiliser. Alternatively the patient's room may have a supply and extract provided they are interlocked to ensure that the room is always at –ve pressure with regard to the corridor. Design parameters: Air change: ≥10 per hour Pressure regime: –5 Pa to general area Noise level: 35 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via BMS Humidity: Floating; max 60%RH Air quality: BS EN 16798 – SUP2
Category 3 isolation room		

Area/zone	Reason for ventilation	Typical design factors
Positive pressure ventilated lobby (PPVL) isolation room Universal isolation facility	Protection of building occupants from patients who may be infected and protection of patients who may be immunocompromised and protection for patients with both conditions. See Scottish Health Planning Note 4 Supplement 1	Supply in lobby flowing through a pressure stabiliser to patient's room and on via a door undercut or transfer grille to an extract in the en-suite. Design parameters: Bedroom air change: ≥10 per hour Lobby pressure: +10 Pa to corridor Bedroom pressure: Neutral En-suite pressure: –ve Comfort parameters as above Air quality: BS EN 16798 – SUP2 With facility to fit BS EN 1822 – EPA12
Containment level 3 laboratory	Protection of occupants in adjoining spaces from airborne bio-hazards	For design details see the Medical Research Council's "Standards for containment level 3 facilities"
Category 4 facility	Design advice will be provided by the client	

Application: Obstetrics theatre, delivery rooms, nursery, neonatal intensive care and special care baby units

Table 5: Maternity facilities

Area/zone	Reason for ventilation	Typical design factors
Obstetrics theatre	Protection of patients from airborne organisms and fungal spores. Control of exposure of staff to waste anaesthetic agents (COSHH Regs)	Ventilation design parameters as for a conventional operating suite. System should normally be at "set back" with a minimum temperature of 18ºC and be able to attain full operating conditions within 5 minutes of triggering the system
Delivery room	Control of exposure of staff to waste anaesthetic agents. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level at foot end of bed and extract terminal at low level at head end of bed. Design parameters: Air change: 15 per hour Pressure regime: Neutral to corridor Noise level: 35 d(B)A Temp range: 20 to 25ºC must maintain any selected set point in the range via local control Humidity: Floating – max 70%RH Air quality: BS EN 16798 – SUP2
Delivery room with birthing pool	As for standard delivery room above	
Specials delivery room	As for standard delivery room above	
Nursery	Comfort conditions only	
Neonatal intensive care unit or special baby care unit (SCBU)	Protection of neonates from airborne organisms and fungal spores. Neonates are kept in incubators but may be removed for feeding, changing etc. so local temperature control and ensuring a draught-free environment is essential.	Standard supply and extract Design parameters: Air change: 10 per hour Pressure regime: +5 Pa to corridor Noise level: 45 d(B)A Temp range: 20 to 28ºC must maintain any selected set point in the range via local control Humidity: Floating – max 70%RH Air quality: BS EN 16798 – SUP1 (Filter grade depends on ODA category – see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02)
N.B. This is a critical healthcare facility and consideration should be given to system resilience and/or how suitable alternative accommodation may be provided in the event of a ventilation system failure.		

Applications: pharmacy aseptic suite, gene therapy, radiopharmacy, support rooms

Table 6: Pharmacy facilities

Area/zone	Reason for ventilation	Typical design factors
Aseptic suite Cleanroom	Protection of product during and after processing. Protection of the wider environment from cytotoxic agents and antibiotics. EUGGMP standards (European Commission, 2011) apply and the Medicine Act if the facility is licensed. Control of exposure by the airborne route to staff of substances during and after processing products. (COSHH Regs). Note: While this application is a critical facility, it is usual to have a plan in place to decant to another site in the event of a ventilation system failure	Supply only in cleanroom and cascade air out via pressure stabilisers through rooms of a lower classification or where there are multiple cleanrooms, a balanced supply and stable cascade out. Thimble extract may be provided for class 3 safety cabinets depending on the location of room within the building. Note: Advice from the client's lead pharmacist should be sought prior to engaging in detailed design. Design parameters: Air change: ≥20 per hour Pressure regime: +15 Pa between unclassified rooms and +10 Pa between classified rooms Noise level: 45 d(B)A Temp range: 20–24ºC must maintain any selected set point in the range via BMS Humidity: Floating – max 60%RH Final filter: BS EN 1822 – HEPA14
Gene therapy cleanroom	As above, plus protection of the wider environment from product	As per cleanroom above plus negative-pressure access lobby and controlled exhaust
Radiopharmacy cleanroom	As for standard cleanroom with additional requirements of the Ionising Radiation (Medical Exposure) Regulations	As per cleanroom above
Non-sterile stores and support rooms	Comfort conditions only	

Application: decontamination facilities

Hydrotherapy: general requirements

8.132 In a hydrotherapy suite, heat recovery should be via a heat pump.

8.133 In general, the quantity of supply air should be calculated as 25 L/s/m2 wetted surface, with the wetted surface taken as 110% of the pool water surface area. (See the Swimming Pool and Allied Trades Association (SPATA) for detailed guidance.)

8.134 A recirculation plant is recommended, with fresh air make-up to the standard required by the Building Regulations Part F – Non-domestic Buildings. In practice this may need to be increased to control condensation.

8.135 As far as practicable, recirculated pool air should be provided to the ancillary changing and recovery accommodation, with the only extract from the toilets, laundry/utility room and pool hall.

8.136 Supply air to the pool hall should be introduced at high level and directed towards the perimeter to mitigate condensation, with extract air taken from directly over the pool.

8.137 The ceiling void above the pool may need to be ventilated to prevent condensation.

Control of hydrotherapy pool installations

8.138 The supply and extract fans should be interlocked so that the supply fan does not operate until flow is established within the extract system.

8.139 Time-clock control should be provided, with a local override switch to extend the normal operating period as required.

8.140 Night set-back temperature (in the range of 21–25ºC) and high humidity control (in the range of 60–75% sat) should be provided to override the time clock in order to prevent condensation. The exact set points should be ascertained post- installation.

8.141 A remote indication panel should be provided in the pool hall, giving a visual display of the pool water and pool air temperature.

Extract systems

LEV systems

8.142 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as local exhaust ventilation (LEV) systems under the COSHH

Regulations. Note that the supply or make- up air to a room containing an LEV system may itself be considered to be a part of the LEV system.

8.143 An LEV system may comprise a self- contained unit incorporating its own carbon filter such as a simple bench-top fume cupboard. Alternatively, it may be a complete “ventilation system” comprising a make-up air supply, multiple exhaust protected workstations, branch and central extract ductwork, duplex extract fans and a high-level discharge terminal. It may also incorporate a special filtration system appropriate to the hazardous substance being controlled. Such systems could be required for workshops containing woodworking machinery or large centralised pathology laboratories housing multiple safety cabinets, cut-up benches, fume cupboards and specimen stores.

8.144 It is important to recognise at the design stage whether an extract is being provided for comfort, to remove odours or as an LEV system. Typical LEV systems in healthcare include:

- microbiological safety cabinets and containment level 3 rooms;
- fume cupboards;
- welding fume extracts;
- woodworking-machinery duct collectors;
- lead-acid battery charging-bay extracts;
- powered plaster and bone saws;
- pharmaceutical preparation cabinets and tablet machines;
- dissection benches, cut-up tables and some specimen stores;
- medium- and high-risk infectious diseases isolation facilities;
- dental furnaces, grinders and polishers.

Note: Post-mortem tables may incorporate downflow peripheral ventilation but unless otherwise specified by the equipment supplier, their ventilation is only provided to control odours.

8.145 Information on the design of ductwork, fan and discharge stack arrangements will be applicable to all types of LEV system and is given in Chapter 9.

8.146 LEV systems are statutory items that will be subject to an independent examination and test at least every 14 months by a competent person holding an in-date P601 certificate.

Note: For AGSS, see Scottish Health Technical Memorandum 02-01.

Bench extract systems

8.147 Bench extract ventilation is required in departments such as pathology and mortuary, where activities involve the release of malodorous or toxic fumes which should not be inhaled. They may also be required in central decontamination units and wash-rooms within endoscope reprocessing units to remove airborne biological material liberated when the used items are given a preliminary clean.

8.148 In all cases bench extract systems that create an airflow from the front to the rear are preferred over those that rely on a downflow of air through a perforated surface, as the airflow is easily obstructed when in use.

Typical arrangements

8.149 Each ventilated position will usually be accommodated in a continuous run of benching, which should not be more than 650 mm from front to rear and which should be provided with a continuous upstand at the rear. Each position should have a 1200 mm × 150 mm linear extract grille mounted on a purpose-designed plenum box (incorporating guide vanes as necessary), with its face flush with the upstand. The bottom of the grille should be as close as practicable to the level of the working surface (usually 75 mm above, to allow for cleaning). The minimum velocity across any part of the grille should be 1 m/s. The grille should be readily demountable to allow for cleaning.

Control of bench extract systems

8.150 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the bench extract and any associated supply may be shut down. However, a run-on timer with a minimum setting of 30 minutes should be provided. To this end, local control should be provided.

8.151 Processes that produce hazardous vapours, fumes, dusts or noxious vapours should be enclosed or semi-enclosed in a suitable cabinet or exhaust-protected workstation (LEV).

Microbiological safety cabinets and fume cupboards

8.152 Safety cabinets and fume cupboards are devices that have an inflow of air to control exposure of staff to hazardous substances. The units and their exhaust systems, filters, fans and discharge terminals are all classified as LEV systems under the COSHH Regulations. The make-up air system to a room that contains an LEV system may also be considered as an essential part of the system and be included in the LEV classification.

Special requirements

8.153 The supply air system should not distort the unidirectional and stable air pattern required for fume cupboards and microbiological safety cabinets. In general, supply air ceiling diffusers should not discharge directly towards fume cupboards or safety cabinets, unless the terminal velocity is such that the airflow pattern at the front of the cabinet is unaffected. The design should ensure that high air-change rates, and/or the opening and closing of doors, do not have any adverse effect on the performance of safety cabinets or fume cupboards. A damped door closure mechanism may help.

Arrangements for safety cabinet installations

8.154 The manufacture and installation of microbiological safety cabinets will be in accordance with the relevant national standards and guidance issued by the Advisory Committee on Dangerous Pathogens (ACDP).

8.155 A Class 1 microbiological safety cabinet will be specified for routine work involving Group 3 pathogens. It should be housed in a containment level 3 room. Specific

design information on containment rooms is issued by ACDP in conjunction with the Health and Safety Commission.

8.156 Siting and installation of microbiological safety cabinets are of particular importance because:

- the protection afforded to the operator by the cabinet depends on a specific and stable unidirectional airflow through the open front;
- the protection to the environment by the cabinet depends on the high-efficiency particulate air (HEPA) filters. The exhaust air should never be considered as totally free from microbiological hazard.

8.157 Microbiological safety cabinet extract is HEPA filtered prior to being discharged to outside. Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2 m); such an installation, however, is likely to be noisy and is not recommended for use in new buildings.

8.158 Ductwork and discharge arrangements should be as set out in Chapter 9.

8.159 Discharge should be to outside but where this is impracticable, discharge into the room via a double HEPA filter will be accepted if approved in writing by the VSG.

Arrangements for fume cupboard installations

8.160 The manufacture and installation of fume cupboards will be in accordance with the relevant national standards and associated guidance.

8.161 The primary factors which contribute to the effective performance of fume cupboards include:

- an adequate volume of supply air and its means of introduction;
- an effective exhaust system to promote the safe dispersal of waste products to atmosphere.

8.162 The air velocities through sash openings should be enough to prevent hazardous materials from entering the laboratory while avoiding excess flow rates that interfere with the investigation process. Average face velocities should be between 0.5 and 1 m/s, with a minimum at any point within 20% of the average, the upper end of the range being applicable to the containment of materials of high toxicity. The design velocity should be maintained irrespective of whether the sash opening is varied, or whether doors or windows are open or closed (see BS EN 14175).

8.163 The possibility of a fire or explosion which may not be contained by a fume cupboard should always be considered. A fume cupboard should not, therefore, be sited in a position where exit to an escape route will necessitate passing directly in front of it.

Control of extract systems

8.164 It is desirable to provide local control of safety cabinets in order to maximise the life of the HEPA filter, and to permit the sealing of the cabinet and room for fumigation if spillage occurs.

8.165 To cope with the risk of an accident or spillage outside safety cabinets, a panic button should be provided to switch off the supply to that area and to discharge all extracted air to atmosphere.

8.166 In pathology departments, it will always be necessary to have one or more microbiological safety cabinets and one or more fume cupboards available for use, including weekends; therefore, local overriding controls for all these items and any associated ventilation plant will be necessary.

Hood extract systems

Special requirements

8.167 Extract canopies will be required over steam-and-heat-emitting appliances, for example sterilisers, catering and washing equipment and for the extraction and removal of unpleasant odours. These installations are for the control of non-hazardous airborne contaminants, they are not LEV systems.

8.168 Perimeter drain gulleys and corrosion-proof grease eliminators should be provided on kitchen hoods (see BESA DW 172 – 'Specification for kitchen ventilation').

Typical arrangements

8.169 The airflow rate should be enough to ensure an adequate capture velocity in the vicinity of the process. Advice from equipment suppliers should be sought, as excessive velocities will be wasteful of power and generate noise.

8.170 The lowest edge of the canopy should be 2 m above finished floor level, with a minimum of 300 mm overhang beyond the edge of the equipment on all sides.

8.171 A compact arrangement of equipment (but with access for maintenance) will minimise the canopy area, and hence reduce the air volume necessary to achieve the optimum capture velocity.

8.172 Hoods required for the control of heat gain and vapours may be connected to the general extract system when it is convenient to do so, but where non- corrosive ductwork materials are necessary, a separate extract system is preferred.

8.173 Lighting and internal divider plates are often required to be built into the perimeter of large canopies; however, built-in shelving systems are not recommended, as they interfere with the airflow, and constitute a maintenance problem.

Control of hood extracts

8.174 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the hood extract and any associated supply may be shut down. To this end, local control should be provided.

Plantroom ventilation

General requirements

8.175 Plantrooms are required to be ventilated in order to maintain acceptable temperatures for satisfactory operation of the plant and controls, and for maintenance activities. Natural ventilation through louvred openings protected from infestation by a

mesh with openings of no less than 6 mm and no more than 12 mm are required. Powered plantroom ventilation should only be needed if natural ventilation is not adequate.

8.176 Ventilation requirements should consider all heat sources within a plantroom, and where there are large glazing areas, solar gains. The ventilation rate should limit the maximum temperature within the plantroom to 32ºC.

8.177 Air handling equipment cannot be located in a fire compartment that houses combustion equipment.

8.178 AHUs and other ventilation equipment that serve occupied areas cannot draw their intake air from a plantroom. Neither should extract ventilation plant or medical vacuum pumps discharge air into a plantroom.

8.179 Statutory regulations for plantroom ventilation are contained in the Building Regulations, and further guidance in the CIBSE Guide B2. Note the need to assess the risk of services to AHUs freezing in unheated plantrooms.

9. Equipment Selection Factors

General requirements

9.1 The following gives detailed guidance on the design and selection of ventilation equipment, the distribution system, terminals and control aspects. Designers should take note of the supporting information given in Chapters 10 and 12. Failure at the design stage to make due allowance for the standards to be achieved may mean that the installed ventilation system will not be acceptable to the client's validator at handover.

Location and access

9.2 The plant should be located so that it is remote from possible sources of contamination, heat gains and adverse weather conditions. The design should ensure that wind speed and direction have a minimal effect on plant throughput.

9.3 Safe access to and around plant is essential to facilitate inspection, routine maintenance, repair and plant replacement.

9.4 Air-handling units (AHUs) should be located in an accessible area secured from unauthorised entry. They may be grouped together in dedicated plantrooms or distributed around the building with AHUs located adjacent to or within the area that they serve. In the healthcare setting, because of the difficulty in gaining access for routine service and maintenance, mounting ventilation units of any type in ceiling voids above clinical spaces is not permitted.

Note: If it is proposed to install ventilation units of any type in a ceiling void above a non-clinical area, it should be subject to a formal risk assessment and its use being agreed by the ventilation safety group (VSG) prior to design approval. Their assessment will consider how the unit may be safely accessed and maintained.

9.5 AHUs should be located in purpose- built plantrooms or designated service spaces within a building. This will allow for routine service and maintenance (which is a statutory requirement) to be carried out at any time of day and regardless of weather conditions. It will also protect the plant from contamination by bird droppings, so reducing the risk of fungal spore contamination of the air supplied by the AHU. Control of pests and vermin will be simpler and while not in themselves a source of airborne contamination, their corpses can become a reservoir of biological material that may lead to insect infestations within the AHU.

Note: In a new building it is not envisaged that there will be any need to locate AHUs outside. The design of the building should incorporate central or distributed plant spaces of sufficient size to accommodate the plant required to service the building.

9.6 When refurbishing or changing the use of an existing building, plant space should be created to house the ventilation plant and other services. If located on a roof they should be enclosed in a plantroom with a safe means of access. If located at ground level they should be secured within a plantroom to prevent unauthorised access. Measures should be taken to exclude vehicles from the vicinity to ensure that exhaust fumes will not be drawn into intakes. Intakes for ground level AHUs should

be extended to a height and distance from contamination sources that allows them to draw in unvitiated air.

9.7 In the unlikely event that an internal or external plant room cannot be provided, and ventilation units have to be located outside, they should be fully weatherproof to IP65 and secured from unauthorised access. Protection against the elements should also be provided for personnel carrying out routine inspection and maintenance activities. As an example, when two units are outside, and they are installed with their access doors facing each other, if the gap between them is roofed over and the open ends capped, the AHUs themselves create what is in effect a plant room (see photographs).

9.8 Water will be used during routine cleaning or spilt when maintenance is being undertaken. The area around plant should be tanked to prevent water penetration to adjacent areas and adequately drained

Figure 5 AHU formed plant room (external)

Figure 6 AHU plant room (internal)

Note: Plant rooms should be provided with a sink so that glass drainage traps may be cleaned out and staff can wash their hands after handling contaminated/dirty filters. A source of domestic hot water (DHW) with a valved hose connection point will also be required so that AHUs can be washed out internally as part of their routine maintenance. Plant rooms at roof level should be served by a lift.

9.9 Fire precautions should be incorporated in accordance with the Health Technical Memorandum 05 Firecode series. Guidance is available in Chapter 1 of this document.

9.10 Combustion equipment cannot be located in a fire compartment that houses air handling equipment

Standard requirements

Identification and labelling

9.11 All ventilation systems should be clearly identified with a permanent (traffolyte type preferred) label in accordance with the requirements of Chapter 13. The label should identify both the AHU and the area that it serves. The lettering should be at least 100 mm high and be screwed or riveted onto the AHU in an easily visible place near the fan of the unit, adjacent to the local electrical isolator. Any subsystems and the principal branch ducts should be similarly labelled.

Note: The AHU identification code should conform to the plant identification system in use at the premises (see Chapter 13).

9.12 The nature of air and direction of flow should be clearly marked on all ducts using the symbols given in BS 1710.

9.13 All airflow test-points should be clearly identified with a permanent label and the design information given (for example, TPS 1 – Anaesthetic supply; 400 × 300; Design 185 L/s).

Plant minimum standards

9.14 Plant should comply with the minimum standards set out in Table 8.

9.15 External finish to be corrosion resistant and may be available in a variety of colours at no additional cost. This can aid identification by colour-coding of units in a plantroom (for example, green for general ventilation; blue for theatres; red for laboratories and isolation facilities; grey for extract).

9.16 Organic materials or substances that can support the growth of microorganisms cannot be used in the construction of the plant or its distribution system. The water fittings and materials directory list suitable materials for sealants and gaskets (see also BS 6920).

9.17 AHU internal wiring should comply with BS 7671 and be installed in a cable containment system providing suitable mechanical protection. The wiring and its containment system should not allow air bypass at the filters. The wiring, its containment system, connection boxes and fixings should permit the effective internal cleaning and inspection of the AHU.

9.18 Plastic-bladed dampers and plastic plate heat exchangers should not be fitted. This accords with the national policy to reduce the use of plastics.

9.19 Motorised spring-return low-leakage (BS EN 1751 class 3) isolation dampers should be located at the intake, supply, return air and discharge duct connections of an AHU and associated extract unit. They should be of the opposed-blade type and be fitted with end switches. They should close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow. They will also function to isolate the plant from the distribution system when undertaking cleaning or maintenance.

Note: Internal plant dampers or provision for the fitting of shut-off plates, also known as dagger plates, between elements within an AHU are not required.

9.20 Access to elements that require routine service such as filters, fans and all types of heat-transfer device should be via hinged doors. In horizontal units the doors should be wide enough: 500 mm minimum at a unit height >1 m. For smaller units the doors need to be at least 600 mm wide, to allow easy access. Items requiring infrequent access such as attenuators may be via removable panels fitted with lifting handles, or access hatches. All doors and panels should be secured from casual access, close-fitting and without leaks.

Table 8: Plant minimum standards

AHU Element	Minimum Standard	Notes
Construction	Double metal or composite skin with sandwiched insulation to "Euroclass A" fire rating Smooth internal surface without channels or ridges No projecting spire or tech screws inside the unit.	Note: Capping projecting spire screws is not acceptable.
Internal surface finish	Non-corrodible, washable and smooth and of a colour that allows accumulations of dirt to be easily seen	Stainless steel or white powder coated mild steel or with an equivalent protective treatment; but NOT surface galvanised
Thermal transmittance	BS EN 1886 Class T2	Manufacturer's declaration
Thermal bridge	BS EN 1886 Class TB2	Manufacturer's declaration
Deflection	BS EN 1886 Class D2	Manufacturer's factory test
Factory airtightness test – pre-delivery	BS EN 1886 Class L2	Test at +700 Pa and –400 Pa
Site airtightness test	BS EN 1886 Class L2	+700/–400 Pa
Filter frame bypass leakage	BS EN 1886 Section 7	
Supply and extract intake and discharge isolation dampers	BS EN 1751 C3 (low loss)	Motorised opening and fitted with an end switch and spring return
Access doors	Secured from casual access. Fan chamber doors to be fitted with a two-stage latch	Key or similar device required to open access doors Door hinges should be adjustable to so that leakage can be eliminated on site
Specific fan power -Internal (SFPint)	Current Eco design requirement for energy-related products (ErP)	EU 1253 – 2014
Specific fan power - System (SFPsyst)	UK Building Regs	Part L2
Energy recovery	Current ErP EU 1253	Run-around coil – 68% Heat pipes – 73% Plate heat exchanger – 73% Thermal wheel – 73% Heat pump – EU 2281/201 Any other device – see standard

9.21 All access doors should be fitted with seals and have adjustable hinges so that leakage can be eliminated once the unit is installed on site. Access doors to fan chambers should have a two-stage opening sequence to prevent the door blowing violently open if it is unlatched while there is still residual pressure in the unit.

Note: Providing the AHU is located in a plantroom or area secured from unauthorised entry, its access doors can only be opened with a key or similar device, the fan door is fitted with a viewing port and a two-stage opening latch and there is a fan electrical isolation switch adjacent to the fan-chamber access door, there is no requirement to fit an internal fan chamber mesh guard.

9.22 In the healthcare setting it can be difficult to turn off AHUs in order to inspect filters and drainage trays. Viewing ports and internal illumination will therefore facilitate routine inspection of such items. Viewing ports should be at a convenient height so that temporary ladders are not required. In double-stacked units the viewing ports in the upper section will be located in the lower portion of their access doors. Internal illumination should be provided by fittings to at least IP55 rating. Light fittings should be positioned inside the unit (not on the access doors) so that they provide illumination for both inspection and task lighting. All lights in a unit should be operated by a single switch and be powered independently of the AHU main switch. LED lights are preferred.

9.23 Access to air intakes and discharges, AHUs and items in the distribution system such as filters or auxiliary trimmer batteries located in a plantroom or plant area above 1.5m should be via platforms, fixed ladders, hook ladders, pulpit style movable steps or access platforms. The method of access chosen should reflect the frequency and nature of the maintenance requirement. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow access equipment to be moved into position.

Chiller units: heat rejection devices

9.24 The design conditions given in Chapter 8 make no allowance for the elevated temperatures that can occur on the roof of buildings. Refrigeration condensers and chiller units should, if practicable, be shaded from direct solar radiation, or the design adjusted to take account of the gain. Care should be taken to ensure that there is sufficient clearance around the plant to allow effective air movement. Allowance may also be needed for the effect of walls, obstruction or other equipment in the area and for the prevailing wind direction.

9.25 Air-cooled condensers and/or dry coolers will always be the first choice for heat rejection from any refrigeration plant. The use of heat pump systems is also an option. Wet evaporative cooling systems cannot be used in healthcare premises unless limitations of space mean that they are the only way that the cooling load can be met. If they are used, national guidance on preventing and controlling Legionella should be closely followed (see the Health and Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems').

9.26 Traditional refrigerants are being phased down and some of their replacements at the time of writing have a degree of flammability. The level of risk this poses should be formally addressed at the design stage and agreed with the client or their fire safety representative. The selection of a refrigerant should be made with reference to the F-Gas Regulations and should take account of the life expectancy of the plant versus the future availability and increasing cost of the refrigerant. Ultimately, choosing refrigerants with the lowest global warming potential is the ideal and will ensure that

greenhouse gas emissions are minimised. Refrigerant gas monitoring must be included where required under BS EN 378.

Chiller selection: size and resilience

9.27 There is a tendency to meet the calculated maximum chiller load by specifying multiples of a standard size of chiller (for example, the calculated load to be met by three chillers each capable of 33% and an extra chiller of the same size to achieve the N+1 resilience requirement). This approach does not lend itself to efficient operation. It is preferable to split the load with, for example, two chillers capable of 40% each and two capable of 25% each. This will give an overall minimum capacity of 90% resilience at maximum summer design conditions and allow for the actual part load demand to be met in the most energy-efficient way.

Supply AHUs and associated extract units

Typical sequence of components

9.28 The AHU should be arranged so that most of the items are under positive pressure. Cooling coils and humidifiers will require a drain and should be on the positive pressure side of the fan. The following arrangement of components is typical, although in many instances not all elements will be required:

- fresh air intake;
- motorised isolation damper;
- fog coil if energy recovery fitted or frost coil if no energy recovery fitted;
- pre-filter;
- energy-recovery device (possible location);
- attenuator1;
- supply fan;
- attenuator1;
- energy-recovery device (possible location);
- cooling coil;
- eliminator (for face velocities above 2 m/s);
- heater-battery;
- humidifier (if required);
- final filter;
- motorised isolation damper.

9.29 AHUs may be configured as horizontal, linear single or double-stacked; or as cabinet type units. For double-stacked supply/extract units, the fans should be located on the bottom deck where possible as it will make them simpler and safer to change (see Figures A1–A3 in Appendix 1 for possible arrangement.).

Intakes and discharges

9.30 Air intakes and discharge points should preferably be located at high level, to minimise the risks of noise nuisance to surrounding buildings, contamination and vandalism.

9.31 Intakes and discharges should be designed and located so that wind speed and direction have a minimal effect on the plant throughput.

9.32 Helicopter landing pads in the vicinity of ventilation intakes and discharges can result in large short-term pressure changes. This can cause pressure surges in supply systems and reverse airflows in extracts. Exhaust fumes from the helicopter may also be drawn into intakes.

Note: It is not appropriate to "plan to turn the ventilation off when a helicopter lands" as a means of permitting the location of a helipad adjacent to ventilation intakes and discharges.

9.33 Intake points should be situated away from cooling towers, heat sources, boiler flues, vents from oil storage tanks, fume cupboards and other sources of contaminated air, vapours and gases and places where vehicle exhaust gases may be drawn in.

Note: Attenuators may be located in the intake and discharge duct if they are of a suitable type and provided with cleaning access both sides (see paragraph 9.116).

Note: Steps should be taken to prevent birds landing or roosting in the vicinity by removing ledges or fitting anti-pigeon spikes.

9.34 On the rare occasions where intakes have necessarily to be sited at or near ground level, the surrounding area should be paved or concreted to prevent soil or vegetation being drawn in. In addition, intakes should not be situated near established gardens/trees so as to avoid intake of environmental microorganisms. They should be caged or located within a compound to restrict unauthorised access and prevent rubbish being left in the vicinity. The likely proximity of vehicle exhausts should also be taken into account when determining the protected area around the intake and additional filtration may be required. The VSG should be consulted about the standard of air quality required. There should be a minimum 4 m clear zone around the intake (see paragraph 9.50 and paragraphs 9.63–9.64).

9.35 The discharge from an extract system will be located so that vitiated air cannot be drawn back into the supply air intake or any other fresh air inlet. Ideally, the extract discharge will be located on a different face of the building from the supply intake(s). At all times, there has to be a minimum separation of 4 m between them, with the discharge mounted at a higher level than the intake.

Note: Ventilation intakes and discharges cannot face each other across a passageway or courtyard even if they are 4 m or more apart.

9.36 Each intake and discharge point should be fitted with a corrosion-resistant weatherproof (BS EN 13030 class B) louvre or cowl to protect the system from

driving rain. Louvres should be sized based on a maximum face velocity of 1.5 m/s in order to prevent excessive noise generation and pressure loss.

Note: If there is a bend in the ductwork directly behind a louvre, it will affect the air velocity through the louvre. This may result in moisture carry-over or increased noise.

9.37 The inside of the louvres should be fitted with a mesh of not less than 6 mm and not more than 12 mm to prevent infestation by vermin.

9.38 The duct behind a louvre should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system.

9.39 Cleaning access should be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a floor-level common plenum is provided, cleaning access should be via a walk-in door. High-level plenums should be able to be safely accessed by temporary or permanent means

Note: Builders' work plenums or intake ducts will need to have a smooth finish and be surface-sealed to prevent dust shedding (see paragraph 10.5).

Fans

9.40 Direct-drive electronically commutated (EC) fans are the preferred choice for ventilation systems. If necessary, resilience and an increased capacity can be achieved by installing two or more EC fans with gravity or motorised dampers to prevent backflow.

Note: At the time of writing the concept of a "fan wall" made up of multiple small variable speed fans all controlled as a single unit was under development. This concept has several advantages as the failure of one fan can be accommodated by speeding up the rest. Because the fans cover the full area of the duct, it will result in a more uniform air velocity downstream at the battery face. This will increase the heat transfer efficiency and may allow a reduction in battery size. Nothing in this document will preclude the use of such innovation that improves resilience and reduces energy usage.

9.41 For an application outside of the capacity range of EC fans, direct-drive plug fans controlled by an inverter mounted externally to the air stream may be selected.

9.42 In either case, the fan motor will be protected with a high-temperature safety cut-out.

9.43 Whichever type of fan is selected, if it serves a critical area it will be fitted in a way that allows it to be changed within 20 minutes. Mounting the fan unit on slide rails with plug and socket connections for power and control cables will facilitate this. Whenever possible, both supply and extract fans should be located on the bottom deck of a double-stacked AHU.

9.44 Selecting fans from a preferred size range will reduce the number of spares held.

9.45 Belt- and pulley-driven fans should not be installed in healthcare ventilation systems.

9.46 Supply fans should be positioned to blow through the central plant so that the cooling coil and humidifier drains (when fitted) will be under positive pressure. The energy-

recovery device may be either side of the fan and should have a drainage system on the extracted air discharge side.

9.47 In extract systems where the air is potentially contaminated, explosive, aggressive or has a high moisture content, the extract fan motor will be located outside the air stream and be capable of being changed without the need to access or change the fan impeller.

Control

9.48 Where two or more fans are fitted in a fan wall, the preferred normal operation is all fans running in parallel. In case of a single fan failure the remaining fan(s) should provide at least 80% of the design output.

9.49 For most healthcare applications, the fan output should be set to give a constant volume of air. This should be controlled by measuring the pressure drop across the fan suction nozzle using a sensing ring and associated volume controller that will automatically integrate the fan K factor to determine and control the preset output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.

Note: Measuring the air pressure in the main supply duct and using that to set the supply fan speed as a percentage of its rated output and using that to set the extract fan speed as a percentage of the supply fan speed is not a satisfactory, accurate or an acceptable way of controlling the desired supply and extract air volumes.

Filters

9.50 The purpose of filtration is to reduce the level of airborne contamination in an air stream. It is generally carried out in stages

9.51 Filters should be securely mounted in well-fitting frames designed so that the airflow pushes the filter into its housing to minimise air bypass. Vertical supports with seals should be provided to master the joints between filters and eliminate bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred.

9.52 Filters need to be readily accessible, so a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.

9.53 For AHUs, provided that each filter's pressure drop is monitored by a sensor linked to the BMS, direct reading gauges or manometers will not be required. Capped pressure tappings should be provided so that a portable manometer can be connected for diagnostic purposes when necessary.

9.54 General air filters (see Table 9) are divided into four categories, related to the size of particle (in microns (μm)) that they can remove as a percentage of the load.

- coarse filters – remove less than 50% of 10 μm particles;
- PM10 medium filters – remove 50 to 95% of 10 μm particles;

Table 9: General filters: typical healthcare selections

ISO 16890 Class	Notes and typical healthcare
ISO Coarse 60%	May be used as temporary addition filtration at an air intake when building or demolition works are being undertaken in the vicinity
ISO ePM10 ≥50%	Panel pre-filter or return air filter to protect the energy-recovery device
ISO ePM2.5 ≥50%	Supply air filter for areas with temporary occupancy
ISO ePM1 ≥50%	Supply air filter for areas with permanent occupancy

- PM2.5 medium filters – remove 50 to 95% of 2.5 µm particles;
- PM1 fine filters – remove 50 to 95% of 1 µm particles.

Note: Ventilation filters can only remove particles from the incoming air. Most particles that could cause an infection originate from the occupants and activities within the building. In AHUs the pre-filter and return air filter will keep the energy-recovery device, cooling coil and heater-batteries clean and working efficiently. The secondary filter will keep the distribution ductwork and supply air terminals clean.

Note: For additional information on filter selection and indoor air quality, see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02 – 'Change in air filter test and classification standards'.

9.55 In areas of high atmospheric pollution, a higher standard of filtration may be required in order to meet the indoor air quality standard (IAQ).

9.56 Compact filters are preferred, because bag filters are often incorrectly oriented and prone to damage when changed.

Efficiency and high efficiency particulate air (EPA and HEPA) filters

9.57 These filters are designed to provide filtration of particles in the sub-micron size range. EPA and HEPA filters self-select the particle that they are least able to trap and are graded against that "most penetrating particle size" (MPPS) (see Table 10):

- efficiency particulate filters (EPA): three grades E10 to E12;
- high efficiency particulate filters (HEPA): two grades H13 to H14;
- ultra-low particulate air filters (ULPA): three grades U15 to U17.

Table 10: EPA and HEPA filters: typical healthcare selections

Typical healthcare application	Minimum filter grade to BS EN 1822 - 2019	% Efficiency @ MPPS
UCV theatre terminal	EPA – E10 – (EU10)	85
No standard healthcare application	EPA – E11 – (EU11)	95
Immunosuppressed and neutropenic patient rooms or wards	EPA – E12 – (EU12)	99.5

Typical healthcare application	Minimum filter grade to BS EN 1822 - 2019	% Efficiency @ MPPS
No standard healthcare application	HEPA – H13 – (EU13)	99.95
Pharmacy aseptic preparation facility supply Containment level 3 room extract	HEPA – H14 – (EU14)	99.995
*Incorporates ISO 29463 tests methods.		

Note: ULPA filters are designed to remove particles below a size that is either surgically or aerobiologically significant. There would have to be exceptional circumstances in order to justify their use in a healthcare ventilation system.

9.58 EPA and HEPA filters are expensive, so their use should be kept to a minimum. When used they should be of the replaceable panel type with leakproof seals and installed in a manner that permits the validation of the filter and its housing (see Chapter 12).

9.59 In supply systems an EPA or HEPA filter will have a non-shedding metal case.

Return air and extract air filters

9.60 Return air filtration will always be required where heat recovery devices are installed. Return air filters are also used to reduce the load on EPA filters in recirculating applications such as ultra clean operating suite ventilation canopies and pharmacy aseptic preparation facilities. They should be the same grade as their AHU pre-filter.

9.61 EPA or HEPA filters are sometimes fitted in extract systems to capture hazardous substances or organisms. Design provision should be made for the subsequent safe handling of contaminated filters by maintenance staff. This may be achieved by:

- sealing the hazardous substance into the filter before it is removed;
- providing a system to fumigate the filter to kill any organisms;
- housing it in a “safe change” unit that permits the filter to be ejected into a bag and sealed without personnel having to come into direct contact with it.

Notes:

1 In view of the costs and problems associated with placing EPA or HEPA filters in extracts, it is essential that a full risk assessment be carried out at the design stage. This should include defining the true need for a filtered extract, the validation of its performance at installation, the method of safely changing a contaminated filter, and its subsequent disposal.

2 General extracts from mortuaries and post-mortem rooms may contain odours, but these are not in themselves hazardous to health and do not require filtration prior to discharge. In high-risk post-mortems (for example, known or suspected tuberculosis cases), the infected organs will be removed and then dissected in a class 1 microbiological safety cabinet provided under the COSHH Regulations.

Extracts from infectious disease Isolation rooms or wards do not normally require filtration prior to discharge. However, if the discharge cannot be made in a safe location and it is likely that the vitiated air could be drawn back into the building or there are people in its vicinity (for example, a discharge into a courtyard), filtration would be required

9.62 Extract EPA or HEPA filters should have a particleboard or plywood case so that they can be incinerated.

Activated carbon filters

9.63 Activated carbon filters can remove gases and vapours from an air stream and are graded according to the range of substances they can remove. They are not normally fitted in air-conditioning supply systems. They are occasionally fitted retrospectively because an air intake has been poorly sited and is drawing in noxious fumes or the outdoor air quality is exceeding WHO levels for NOX/O3 or SOX. Where used they should be protected by or incorporated into a particulate air filter.

9.64 Activated carbon filters are more commonly used in specialised fume extraction systems when the location of the discharge means that dilution cannot be relied upon to disperse noxious fumes.

Energy-recovery devices

General requirements

9.65 Energy recovery will be fitted to all supply and extract healthcare ventilation systems. It may be omitted only where permitted by the current ErP Directive EU 1253/2014.

9.66 For most systems in healthcare premises, a plate heat exchanger, “run- around coil” system or thermal wheel would be appropriate. Selection should be based on the relative locations of the supply and extract units, ease of maintenance and practicality. Cleaning access will be required to both sides of any energy-recovery device.

Note: Plate heat exchangers are the preferred option as they require the least maintenance to retain their energy transfer efficiency. Thermal wheels may be used, as the degree of air transfer from extract to supply is not sufficient to cause aerobiological problems and in any event the air will be filtered before being supplied to the user. Run-around coils are used when the supply and extract units are separate or in case of space problems.

9.67 At the time of writing, the following are the minimum energy transfer efficiencies required under EU 1253 for devices handling equal air volumes:

- run-around coil – 68%;
- plate heat exchanger – 73%;
- thermal wheel – 73%;
- heat pipe – 73%;
- heat pump or any other device – see specific regulations.

Note: These efficiencies are regularly reviewed and are likely to be increased periodically.

9.68 If a plate heat exchanger is chosen, the plates should be constructed of metal; in coastal areas stainless steel is preferred. Plastic should not be used for the plates, internal bypass dampers or gears. (This is in keeping with the reduction in the use of single use plastics.)

9.69 If a thermal wheel is selected, only a sensible heat wheel should be used that incorporates a purge sector. In order to reduce bypass leakage, brush seals should not be used; enhanced airtightness seals should be fitted.

9.70 Whichever energy-recovery device is chosen, the extract side should be protected by at least an ISO ePM10 ≥50% filter and provided with a drainage system as described in paragraphs 9.105−9.112, to remove condensate. Note that most condensate will occur at intermediate rather than at extreme outside air conditions.

9.71 The energy-recovery device should be located downstream of the fog coil and pre-filter, before the cooling coil and main heater-battery. It may be on either side of the supply fan.

9.72 It is essential to consider the set points and control of the fog coil, energy- recovery device, cooling coil and heater- battery in order to achieve the most efficient operation for the maximum time. The primary energy provided by the fog coil will directly reduce the heat exchange of the energy-recovery device. To this end, the off-coil setting of the fog coil should be the minimum possible to keep the pre-filter dry (2 to 3 K above intake air temperature) (see paragraph 9.75 onwards for further guidance).

9.73 The energy-recovery device should be controlled in sequence with the main heater-battery and should incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the required plant set-point.

9.74 In instances where the plant is cooling the air, it may be possible to remove heat from the supply air at high ambient conditions, under the dictates of enthalpy sensors in the intake and extract ducts.

Heater-batteries

General requirements

9.75 Fog coils are installed to protect the downstream filters from low temperature, high humidity intake air conditions. They should raise the incoming air temperature by 2 K so that it is above its dew-point when it arrives at the filter. As they handle unfiltered air they should be constructed of plain tubing without fins and be as near to the outside as possible to minimise condensation during cold weather. Access for cleaning should be provided to both sides of the coil. In order to prevent them freezing they should be controlled as constant flow variable temperature devices.

9.76 Traditionally frost coils were set to raise the incoming air temperature to between +2ºC and +5ºC to protect the batteries downstream. All new AHUs should be equipped with an energy-recovery device (see paragraph 9.65); the greater the temperature difference across this device, the more heat will be recovered. Also, the

device will now provide the frost protection. Where an energy-recovery device is fitted, the frost coil will be replaced by a fog coil.

9.77 Where steam coils are used for a fog or frost coil, they may be constructed using spiral finned copper tube. As they will be prone to fouling, the tube layout and spacing should permit easy access for regular cleaning.

9.78 Main and branch heater-batteries should be constructed of solid drawn copper tube coils with copper fins, generally connected in parallel. In coastal and particularly exposed areas the client may require an anti-corrosion treatment.

9.79 Where there is a wet heating system in the areas served, the main heater-battery should be sized, in conjunction with the energy-recovery device, for the ventilation requirements only and not for the building fabric loss. Ventilation should only be used for heating the building fabric if the room specification precludes the use of heat emitters and it is not within the heated volume of the building (for example, a cleanroom or operating theatre with external walls).

9.80 Access for cleaning will be provided to both sides of all fog coils and heater-batteries.

9.81 Main heater-batteries may be water or steam. Electric heaters are expensive to operate, and their efficiency is particularly dependent on the air velocity through them. Their use should be restricted to branch trimming control.

9.82 Where steam supplied heater- batteries are used, their control, venting and trapping systems should be designed so that a vacuum cannot occur within the coil. The condensate drainage arrangements should not allow pressure to build in the condensate main as this will result in a back-up of condensate in the battery.

9.83 Where possible, wet trimmer heater- batteries should be located in plant areas.

9.84 Where it is necessary to locate heater- batteries in false ceilings etc, consideration should be given to the use of electric heaters (note that additional fire detection may be required). If this is not practicable and a LPHW system is used, a drip-tray should be installed under the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-clinical areas and never above patient-occupied spaces

9.85 Auxiliary fan coil units are not to be installed in the ceiling above a patient- occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the area that they serve.

Cooling coils and drift eliminators

9.86 Cooling coils supplied with chilled water are the preferred option. For small loads, or where chilled water cannot be made available, direct expansion (DX) coils may be used.

Note: For DX coils, it may be necessary to divide the chiller circuits unevenly in order to achieve efficient operation under part-load conditions. The turn- down ratio should allow stable control down to 10% of the peak load.

9.87 Cooling coils should be periodically decontaminated so the fin spacing needs to be ≥2.5 mm and the fins rigid enough to withstand cleaning (for example, ≥0.25 mm thick). Hinged access doors with viewing ports and illumination inside the AHU or duct should be provided both sides of the coil.

9.88 In an AHU when the cooling-coil face velocity is greater than 2 m/s a drift eliminator will be required downstream of the coil. The eliminator will be an entirely separate device mounted on slide rails so that it can be easily removed without the need for tools. If the size of the AHUs precludes the use of slide rails, and the eliminator is constructed in sections which maintenance personnel will have to enter the unit to remove, each section should have lifting handles. In order to reduce the use of plastics, alternative materials should be considered for the eliminator elements.

Note: For small DX coils and in fan coil units, the eliminator may take the form of a joggled extension of the fins.

9.89 All cooling coils are to be fitted with their own independent drainage system as specified in paragraph 9.105 onwards. A baffle or similar device should be provided in the drip-tray to prevent air bypassing the coil. The tray should be large enough to capture the moisture from the coil headers and drift eliminator.

9.90 Where coils are greater than 1.8 m high and the air velocity is >2 m/s, either intermediate drip-trays will be required or the fin spacing should be increased to ≥3 mm.

9.91 In order to minimise electrolytic action resulting from condensation on the air side, cooling coils constructed from copper tubes with copper fins and electro- tinned after manufacture are preferred. Aluminium fins should only be used if vinyl- coated.

9.92 All parts of the coil and its associated ductwork in contact with moisture will be manufactured from corrosion-resistant materials. Pressed steel coil headers, even if treated, have been shown to be prone to corrosion over time and should not be used. Steel mounting frames and casings present similar problems so stainless steel is preferred.

9.93 Where a cooling coil has to be located above a ceiling, a drip-tray should be installed under the battery and control valve assembly to protect the ceiling from leaks and condensation drips. A moisture sensor and alarm should be fitted in the tray. To facilitate maintenance access, they should be located above corridors or other non-clinical areas and never above patient- occupied spaces. The air velocity should be below 2 m/s to avoid the need for a drift eliminator. All drainage piping should be rigid type not flexible hose.

9.94 Auxiliary fan coil units should not be installed in the ceiling above an occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the department that they serve. The drainage of such items is often problematic. If a suitable fall in the drain line cannot be achieved, a pump out system should be provided. Drainage piping should be rigid type (not flexible hose).

Humidifiers

9.95 Humidification was originally required for some healthcare applications in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement (see Chapter 8 and associated SHPNs/HBNs).

Note: In an operating theatre, if high humidity is required to help prevent tissue drying during surgery, it should be provided when required using sterile water in a disposable nebuliser driven by medical air, and not from a humidifier installed in the ventilation system. In that way the quality of the moisture delivered will be assured.

9.96 If it is unclear at design stage whether humidification is required, provision for retrofitting in terms of space provision and a capped drainage system may be provided either in the AHU or in a zone branch duct. The need for such provision and the amount of space allowed for it should be agreed in writing with the client.

9.97 If a humidifier is required, the manufacturer's instructions regarding selection, capacity, installation and control need to be followed. Incorrectly sized, installed or operated humidifiers can become a source of fungal and microbiological contamination within a ventilation system. This may result in a significant airborne infection risk to patients and staff.

9.98 Only steam injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. The injected steam will be generated locally either by mains steam or electricity, within or adjacent to the humidifier. Water-curtain, water mist or spray humidifiers of any type cannot be used.

Note: Jacketed lance mains steam humidifiers will always be a source of heat within the system during the cooling season unless completely isolated when not required.

9.99 All parts of the humidifier and its associated ductwork in contact with moisture should be manufactured from corrosion-resistant materials. Stainless steel is preferred.

9.100 For self- and locally-generated steam humidifiers, the cleanliness of the water supply is essential for their safe operation. The water supply should be derived from a wholesome source or demineralised supply. Chemical treatments cannot be added to the water supply to humidifier units. The electrodes of self-generating electrode boiler-type humidifiers should be stainless steel.

9.101 If the quality of the water supply to a self-generating humidifier unit cannot be assured, an ultraviolet (UV) system to control microbiological growth may be installed. However, given the limitations of UV systems, this will require high-quality water filtration to ensure the effectiveness of exposure of organisms to the UV irradiation. As with all water treatment systems the unit should be of proven efficacy and incorporate UV monitors so that any loss of transmission can be detected.

9.102 Provision should be made for draining down supply pipework and break tanks for periodic disinfection and cleaning during the seasons when they are not required in service. The humidifier branch water supply isolation valve will be located at the junction with the "running" main to prevent the creation of a dead leg. All parts of the system should be capable of being cleaned or disinfected as necessary. Hinged

access doors with viewing ports and internal illumination should be provided. A label warning that the device emits live steam and should be isolated prior to opening should be affixed to the access door.

9.103 A zone humidifier, if required, may be installed in a supply branch. The ductwork in which the humidifier is mounted and for at least 1 m downstream should be stainless steel.

9.104 All humidifiers wherever installed will be fitted with their own independent drainage systems as detailed in paragraph 9.105 onwards and be completely accessible for cleaning.

Drainage

9.105 All items of plant wherever located that could produce moisture should be provided with a drainage system. The system will comprise a drip-tray, glass trap, air break and associated drainage pipework.

9.106 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent “pooling”, it is essential that the drain connection should not have an up-stand; and that a slope of approximately 1 in 20 in all directions should be incorporated into the drain outlet position.

9.107 In AHUs that have access doors large enough for a person to enter, the drip-tray should be easily accessible for inspection and cleaning.

9.108 In AHUs with access doors too small for a person to enter, the complete drip- tray should be capable of being withdrawn. It should be clamped into the AHU with thumb screws so that it can be removed without the need for tools (see photograph).

Figure 7 Removable AHU drainage tray

9.109 Each drip-tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed, thus giving an early indication of corrosion, biological activity or contamination within the duct. The trap should have a means for filling and incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting the drainage tray to the trap should have a continuous fall of not less than 1 in 20.

9.110 Traps fitted to plant located outside or in unheated plant rooms need to be trace heated in winter. The trace heating should not raise the temperature of water in the trap above 5ºC.

9.111 Water from each trap will discharge directly via a clear air gap of at least 15 mm above the unrestricted spill-over level of either an open tundish connected to a foul drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish providing each has its own air-break.

9.112 Drainage pipework from the tundish may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22 mm and have a fall of at least 1 in 60 in the direction of flow. It should be well- supported and located so as not to inhibit access to the AHU.

Note: In the case of fan coil units, the glass trap and air-break may be omitted and a pump out system fitted. The unit drainage should connect to the main drainage system via a waterless trap that does not allow discharged water to return. The drainage tray itself will be easily removable for routine inspection and cleaning.

Attenuators

9.113 Provided care is taken in the design and construction of low pressure systems to avoid significant noise generation in the ductwork, attenuation should only be needed to absorb fan noise

9.114 Fans radiate noise through both the inlet and outlet connections, and it may be necessary to provide attenuation to limit the noise from both of these connections. It is always preferable and more economic to control noise and vibration at source, or as close to source as possible. It should be noted that attenuators offer a resistance to airflow and by causing turbulence can be the cause of regenerated noise in a system.

9.115 A thorough assessment of the design should be made to assess the potential noise problems. It should consider the following factors:

- fan and plant noise generation;
- airflow-generated noise in ductwork fittings and dampers;
- noise generated at grilles, diffusers and other terminals;
- noise break-in and break-out of ductwork;
- cross-talk and similar interference;
- the noise limitations for the building and surrounding areas;
- external noise generation.

A method of assessment of these factors and the sound attenuation requirements of ductwork systems is given in CIBSE Guide B

Note: Attenuators fitted in distribution ducts can themselves become a source of regenerative noise if the air velocity through them exceeds their tested performance value.

9.116 Attenuator units with a sound- absorbing in-fill suitable for the quality of air being handled and protected by a perforated sheet metal casing are the preferred option. Absorption of moisture, dirt and corrosive substances into the “in- fill” and the release of fibrous particles into the airstream should be prevented using a membrane with a declared service life of at least 25 years. If these conditions can be met, the attenuator may be located in the supply ductwork downstream of the final filter. Cleaning access should be provided at both ends of the unit.

9.117 Sound-absorbing material should not be applied to the inside surface of a duct.

9.118 End of line mixing and VAV boxes may be supplied lined internally with sound-absorbing material. The material will be non-particle-shedding, protected from casual damage during maintenance and be fire-resistant.

9.119 See paragraph 9.149 onwards for guidance on distribution and point of use noise control.

Note: Developments in “dynamic attenuation” may replace the more traditional physical attenuators and overcome noise “break in” and point of use noise regeneration issues.

Recirculation – minimum fresh air requirement

9.120 Where return air is recirculated, fresh air should be introduced equivalent to at least 20% of the supply air volume, or that required by the Building Regulations, or at least 10L/s/person, whichever is greater.

Distribution system

9.121 The CIBSE guide B2 provides the standard design Information for ventilation systems, their ductwork and terminal devices. The guidance in this SHTM highlights the specific factors that are required for or excluded from healthcare ventilation installations.

9.122 For normal applications in healthcare buildings, low velocity systems are recommended; velocities below 2 m/s are unlikely to be justified.

9.123 The site will often dictate the main routing of ductwork systems, as will the location of the AHU relative to the load. Grouping AHUs in centralised plantrooms results in large vertical service shafts and long main duct runs. Decentralising AHUs into service spaces adjacent to the load results in a more compact duct layout.

9.124 Whichever option is chosen, the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid balancing and may reduce the number and variety of duct fittings that are needed.

9.125 Main distribution ductwork should not be routed above sleeping areas. Where there is no alternative route, additional external acoustic insulation may be required.

9.126 Where auxiliary air-conditioning units, fans, filters or trimming devices are installed in the distribution system, they will be independently supported and fitted with a suitable drainage system where appropriate. If they are a source of vibration, they should be linked to the distribution ductwork via flexible connections.

Ductwork materials and construction

9.127 The choice of duct material should take account of the nature of the air or gas being conveyed and the environment in which the duct will be placed.

9.128 Galvanised sheet steel is suitable for normal ventilating and air-conditioning applications. Its inherent mechanical strength renders it resistant to casual damage both during the construction phase and throughout its service life when mechanical and electrical services around it are accessed. It may also readily withstand the impacts sustained when rotary equipment is used to clean it internally.

9.129 In instances where moisture levels and/or corrosive elements in the air being conveyed are very high, aluminium, stainless steel, PVC or GRP ducts should be used. Stainless or black steel are the only suitable materials for high temperature ductwork.

9.130 Where other ductwork materials are considered, care should be taken to ensure that the material is satisfactory for the application having regard to the likely service life, possibility of mechanical damage and performance in the event of a fire. Where used it will be installed strictly in accordance with its manufacturer's instructions.

9.131` Rectangular ducting with an aspect ratio of 1:1 is preferred but ratios of up to 3:1 are acceptable where there are space constraints. Circular spiral-wound or flat- oval are also acceptable providing they meet the leakage standard when tested (see Note after paragraph 9.136). Flexible ductwork is not suitable for air distribution in healthcare applications. In situations where solid ductwork cannot be used, flexible ductwork may be used to make the final connection to a terminal providing it does not exceed 0.5 m in length, is extended as far as possible and is never used in lieu of a bend (see paragraph 9.160).

9.132 The inside of the ductwork should be free from structural projections and as smooth as possible. Flanged gasketed joints between sections are preferred for rectangular ductwork, blind-riveted mastic- sealed slip-joints for circular and flat-oval.

9.133 In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in paragraph 9.105 onwards.

9.134 Where builders' work plenum chambers or ducts are employed, all internal surfaces should have a smooth finish and be sealed to prevent dust shedding.

9.135 All types of ductwork should be manufactured and installed to the appropriate current BESA specification.

9.136 Ductwork should be supported with threaded rod and channel. Note that sheet metal ductwork cannot use bolt-through supports. Gripple wire may only be used for circular galvanised spiral-wound or flat-oval ductwork.

Note: All installed ductwork whether new or reused should be subject to a leakage test on site prior to the application of any insulation. The leakage test will be to BESA DW144 but with a permissible leakage rate of not greater than 3%.

Fire aspects: damper types and locations

9.137 It is essential that all relevant fire aspects of ducting systems are agreed with the fire officer before the design is finalised (see paragraph 1.15 onwards).

9.138 Ductwork will be fire-stopped where it penetrates fire compartment walls, floors and enclosures, cavity barriers and subcompartment walls or enclosures, and provided with weatherproof collars where roofs or external walls are penetrated.

9.139 Fire and smoke dampers should be provided at the locations required by the Health Technical Memorandum 05 series of documents. The damper mounting frame should be securely attached to the building fabric strictly in accordance with the manufacturer's tested details. Where a fire and smoke damper is not mounted directly in a fire compartment wall, it must be correctly supported and the ductwork between it and the fire wall must possess the same fire rating as the fire wall that it penetrates. The fire-rated portion of ductwork must not be penetrated by test holes or inspection hatches (see also BESA DW145).

9.140 Any non-standard fire duct or damper arrangement should be agreed in writing by the client's fire advisor and subsequently tested and signed off by the installer.

9.141 An access hatch should be provided adjacent to each fire and smoke damper so that its correct operation can be directly observed. The hatch will be as large as necessary to permit inspection, testing and maintenance. The damper test switch should be mounted adjacent to the inspection hatch so that the routine test and visual confirmation of the damper operation can be carried out by a single person. For circular ductwork, rectangular saddle mounted hatches should be fitted (see BESA DW144).

9.142 Smoke-diverting dampers will be provided on recirculation air systems to automatically divert any smoke-contaminated return air to the outside of the building in the event of a fire. It should be arranged so that the normally open diverting damper in the return air branch to the input unit closes and all the return air is exhausted to outside (see paragraph 5.53 onwards).

Duct sections

9.143 When sizing ductwork, the designer should consult the CIBSE B2 guide.

9.144 All fittings should conform to the current BESA specification. Wherever possible, long radius bends, large radius main branches, not more than 45º angle sub-branches and long taper transformations should be used.

9.145 Bad design in relation to airflow can lead to vibration of flat duct surfaces, an increase in duct-generated noise, pressure loss in ductwork, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of installed plant items, such as trimmer batteries.

Thermal insulation

9.146 In order to reduce energy consumption, achieve efficient energy recovery and prevent condensation in service voids, all supply and return air ductwork should be thermally insulated. Insulated ductwork runs outdoors should be weatherproofed.

9.147 The thermal insulation of intake and discharge ductwork will be dependent on its location in heated or unheated plant spaces and risk of surface condensation.

9.148 In normal circumstances, the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the insulation thickness for vapour resistance may be greater than that for heat resistance. When cold ducts pass through areas of high dew- point, carefully selected vapour barriers should be applied externally to the insulation.

Noise generation within the ductwork

9.149 Noise is generated in ductwork at sharp edges, by tie rods, damper blades, duct obstructions, sharp bends, etc. This airflow-generated noise becomes an important factor if it is about the same or greater level than the upstream noise level. Airflow-generated noise is often referred to as regenerated noise.

9.150 The noise level generated by airflow in ductwork is very sensitive to the velocity. The sound power of this noise is approximately proportional to the sixth power of the velocity; that is, a doubling of the duct velocity will increase the sound power by a factor of 64 (or about 18 dB). The duct velocities should therefore be kept as low as possible. In general, duct fittings which have lower pressure loss factors in similar flow conditions will generate less noise.

9.151 Ductwork serving quiet areas should not be routed through noisy areas, where noise break-in can occur and increase the noise level in the ductwork.

9.152 Grille register and louvre noise should be kept to the minimum by selecting types having low noise-producing characteristics, without high tonal noise; and should be fitted with acoustically treated external inlet and outlet louvres.

9.153 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. They will normally be of the “through-the- ceiling, up-and-over” type and may include a fire and smoke damper.

Volume control damper locations

9.154 In order to be able to carry out a full proportional balance, manually operated dampers are typically needed:

- in branches of zone ducts;
- in sub-branch ducts serving four or more terminals;
- in dedicated sub-branch ducts serving a room;
- at terminals not covered by any of the above.

9.155 Dampers integral with terminals are to be avoided for final trimming of air volumes, as they often create noise and air distribution problems.

9.156 Dampers in rectangular ducts should be opposed-blade multi-leaf type. In circular ducts, iris-type dampers are recommended. Dampers should be accessible, incorporate a position indicator and means of locking in the commissioned position. They should be installed with the adjusting handle or knob at the lower vertical edge

so that they are accessible for the commissioning team once the ceilings are in place. Dampers should be located as far away as possible from adjacent branches or plant items.

Duct cleaning and access door locations

9.157 Cleaning and access doors are required to facilitate access to plant items and ductwork components for inspection, maintenance, cleaning and replacement, and should be of sufficient size to permit safe access for the required functions.

9.158 Recommended locations for access doors are given in the current BESA TR/19 specification and are generally provided to give access to:

- every regulating damper;
- every fire-and-smoke, and motorised damper;
- filters (to facilitate filter withdrawal);
- both sides of trimmer cooling/heating coils;
- zone humidifiers;
- auxiliary fans;
- ducts, where required for cleaning.

9.159 Care should be taken when siting access doors to ensure that no other services to be installed will prevent reasonable access.

Flexible ducting

9.160 Flexible ductwork can only be used to make the final connection between rigid ductwork and a terminal in exceptional circumstances where a solid connection is not possible. Where used it will cause a significant frictional loss and may be difficult to clean, so it should take the most direct route and be as short as possible, never exceeding 0.5 m in length. It can never be used in lieu of a bend and will possess the same fire rating as the ductwork it is connected to.

Terminal fittings selection and sizing

9.161 The effectiveness of all ventilation and air-conditioning systems depends on the methods by which air is introduced to, and vitiated air is removed from, the space. The usual results of poor air-terminal selection and/or positioning are:

- draughts;
- stagnation;
- poor air quality;
- large temperature gradients;
- excessive noise.

9.162 Air can be supplied to a space in a number of ways, although any device can be broadly placed into one of two categories:

- that producing a diffused supply;

- that producing a perpendicular jet.

Diffusers may be radial or linear, and normally utilise the coanda effect (that is, adhesion of the air stream to an adjacent surface) to reduce the risk of excessive room air movement. A perpendicular jet is formed by discharging air through grilles, louvres or nozzles, which are generally adjustable.

9.163 Supply air terminals can be incorporated into any room surface, for example, floors, walls (high or low level), desktop.

9.164 As they operate on the jet principle, the use of sidewall and linear grilles is restricted to areas where air-change rates are low, that is, less than 10 per hour.

Perforated rectangular diffusers can provide acceptable conditions within the occupied zone at up to 15 ac/h. In areas where a higher air-change rate is required, square or circular ceiling-mounted diffusers should be used.

9.165 The performance of supply air terminal devices is based on three criteria – throw, spread and drop:

- throw is defined as perpendicular or parallel distance from the terminal to the point at which the air velocity is;
- 0.5 m/s isovel;
- Spread is defined as the width of the;
- 0.5 m/s isovel;
- Drop is defined as the vertical distance from the centre line of the terminal to the bottom edge of the 0.25 m/s isovel.

9.166 It is necessary to consider each of these parameters in both summer and winter conditions to ensure satisfactory operation of the air terminal device, as warm jets behave very differently from cold jets.

9.167 A warm jet tends to rise until it attaches itself to a horizontal surface, while a cold jet falls. Care should be taken to ensure that this does not lead to unacceptable temperature gradients in winter, or excessive air velocities in the occupied zone in summer.

9.168 In order to ensure satisfactory air movement within a space, it is necessary to consider interaction between air movement from adjacent terminals, and ceiling-mounted fixtures (light fittings, etc), as well as interaction between air movement and room surfaces.

9.169 If the supply and extract terminals are too close, short-circuiting may occur, while if they are too far apart, stagnant zones may be formed. Where two opposing air streams meet, the individual velocities should not be greater than 0.25 m/s. Further guidance on the selection of grilles and diffusers is given in the CIBSE Guide B

9.170 In operating theatres, the supply terminals should be able to produce a movement of air in the operating zone 1 m above floor level of between 0.2 and 0.3m/s:

- ceiling-mounted diffusers with fixed directional vanes that provide a downward turbulent airflow are the preferred option: 600 × 600 four-way blow or circular “air-master” style;
- plenum boxes fitted with perforated screens to produce a laminar downflow are also acceptable;
- linear ceiling-mounted diffusers that provide a downward-flowing air curtain around the operating theatre may also be used (additional supply terminals may be located within the area bounded by the linear diffusers to provide ventilation within the;
- air-curtained zone).

9.171 The following terminal types are not suitable for use in operating theatres because they do not produce an appropriate pattern of air distribution:

- swirl diffusers;
- single- or multi-outlet adjustable directional nozzles or jets of any type;
- sidewall-mounted linear diffusers that utilise the coanda effect to send air across the ceiling and “droop” it into the operating zone.

9.172 Extract terminals should be of an easy-to-clean design and, in order to assist identification when commissioning and subsequently measuring, be of a different design style to the supply terminals. Extract terminals mounted at low level should be of the spring clip retained, pull off face type to enable ease of cleaning. The terminal should be mounted on an angled face to prevent it becoming occluded by movable equipment or stores (see Appendix 9 for examples). Perforated plates are not to be fitted in extract terminals or extract plenums as they quickly become blocked with lint. Extract terminals do not need any directional adjustment so fixed-vane or “egg-crate” styles are preferred.

UCV terminal canopy

9.173 UCV canopies should be fitted with one or more non-electronic, mechanical, direct reading pressure gauge(s) to indicate the pressure drop across either a representative terminal EPA filter or the pressure in each zone of the canopy.

9.174 If a UCV canopy incorporates a method of adjusting the air discharge direction so that the canopy can be “tuned” to the room in which it is installed, the directional adjustment device(s) are to be capable of being locked in position once commissioning is complete to prevent future casual alteration.

9.175 Ceiling-mounted canopy diffusion screen(s) can become contaminated with blood spatter when in use. If the UCV canopy is fitted with perforated diffusion screens the blood spatter can penetrate, so the screens should be capable of being hinged down for cleaning between theatre cases. The screen retaining mechanism will have a double action to release the screen. Mono-filament diffusion screens should be retained by clip-in profiles or an alternative system that allows them to be easily removed when necessary.

9.176 For the validation of UCV terminal canopies, see Chapter 12.

Transfer grille: size and location

9.177 Air transfer grilles in walls, partitions or doors form an integral part of the building's air distribution system. Modern door sets have very low leakage rates so cannot be relied upon to permit even quite small airflows. Failure to make adequate provision for air to move from room to room will result in excessive pressure differentials and "door whistle".

9.178 Transfer grilles are required in locations where there is a significant imbalance between the supply and extract rates in a room. They will relieve any pressure differentials which may affect the operation of the spaces and/or the ventilation system and permit airflow in a known direction.

9.179 Care needs to be taken to ensure that the positioning of transfer grilles does not interfere with the fire or smoke integrity of the building. In general, the air transfer grilles should not be installed within fire- resisting boundaries, although if this is unavoidable, they should be fitted with fire or smoke dampers.

9.180 Where installed, transfer grilles should be of the non-vision type, sized for a maximum face velocity of 1.5 m/s.

Note: Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required.

Pressure stabilisers: size and location

9.181 Pressure stabilisers are required in areas where it is necessary to maintain a pressure differential between adjacent rooms and to prevent reversal of airflows for example, in operating suites, isolation facilities and cleanrooms (see paragraph 8.24).

9.182 Fire precautions for pressure stabilisers are the same as for transfer grilles. If the pressure stabiliser is fitted with a fire and smoke damper, the damper test switch should be easily accessible from, in airflow terms, the least clean side of the damper.

9.183 Pressure stabilisers should be of the balanced blade type, with the facility to make fine adjustment of the pressure setting. They should be silent in operation and give a seal as tight as practicable when closed. The materials of construction and method of assembly should allow for cleaning and disinfection.

9.184 Pressure stabilisers should be wall- mounted in a visible location so that their operation can be readily observed. For sizing criteria, refer to the manufacturer's information. When fitted at low level, they may require a stand-off cage to prevent occlusion (see photograph).

Figure 8 Pressure stabiliser with stand-off cage

9.185 Pressure stabilisers may need to be fitted with a stand-off baffle on their discharge side to prevent a sight line in situations where a laser will be used, and may be lead-lined for radiological protection if required (see photograph after paragraph 9.184). Baffles may also be needed to preserve privacy or prevent discharge air causing draughts within an anaesthetic room or bedroom. A stand-off baffle will always be needed on the theatre side of the pressure stabiliser between a “Lay-up” preparation room and a UCV theatre to prevent perturbation of the UCV canopy air pattern

Note: Baffles should be easy to clean and where radiological or laser protection is not required can be made of a rigid transparent material so that the action of the pressure stabiliser can be easily observed.

Distributed air-conditioning elements

Active and passive chilled beams

9.186 See paragraph 5.18 onwards for information on the use of these devices in healthcare premises and CIBSE Guide B for technical guidance.

Constant volume boxes

9.187 These are units fitted in or at the termination of ductwork that contain a mechanism to maintain a constant output air volume regardless of variation in the air pressure to the supply side of the unit. Where fitted they should be accessible for maintenance as the internal mechanism that controls the constant output will need periodic cleaning.

Variable Air Volume (VAV) boxes

9.188 Variable air volume systems are all-air systems which achieve local control by varying (throttling) the amount of air being supplied to each space, room or zone.

Standard type VAV systems deliver air that has been cooled to a set temperature (usually 13ºC) and then control the temperature in a space by varying the quantity of air supplied rather than the supply air temperature – which is kept constant.

VAV boxes are used as terminal devices at the supply end of ductwork to modulate the quantity of supply air to the space.

There are variations to standard VAV systems which allow air supply temperatures to modulate upwards with the aim of:

- reducing energy usage by allowing higher air supply temperatures at part-load conditions;
- improving ventilation effectiveness at part-load by having higher airflows
- – VAV can be as low as 10% of peak at low-load conditions depending on the equipment used;
- allowing the system to operate using warm air in winter for pre-heating warm-up in well-insulated buildings where heating is only used in very cold weather and for building pre- heat.

9.189 In most critical areas of a hospital a fixed air-change rate is required when they are in use. VAV is therefore generally limited to non-clinical applications.

Stand-alone air-conditioners

9.190 See paragraph 5.25 onwards for information on these units. The ceiling void should never be used as a plenum either for the primary air supply or fan coil supply or return air paths. (See CIBSE Guide B for installation notes.)

Powered air terminal filter units

9.191 This is an air-distribution-supply terminal box fitted with a fan and EPA or HEPA filter. Their use in the healthcare setting would be confined to spaces where a high air quality is required for a single room in an area supplied by a general AHU (for example, a local cleanroom).

9.192 They are not suitable for use in patient bedrooms due to the fan noise and maintenance access issues.

AHUs: automatic control

9.193 Chapter 6 of this document gives guidance on energy control strategies and Chapter 7 gives guidance on the point of use factors. Chapter 8 contains guidance to specific healthcare departments and their environmental and functional requirements. This section gives guidance on the control of the AHU and its subsystems. When developing a “controls specification”, the designer should consider the guidance given in all of these chapters.

9.194 Various options for control of single- and multi-zone air-conditioning systems are given in CIBSE Guide B.

General requirements

9.195 The basic requirements for an automatic control system are as follows:

- plant start, run, set-back and stop sequence;
- control of the volumetric airflow;

- control of the system or room pressure;
- temperature control and indication;
- humidity control and indication;
- devices to monitor and indicate the plant's operating state;
- alarms to indicate plant failure, low airflow, and filter state;
- the facility to collect data of actual usage and energy consumption.

The control functions actually provided will depend on the purpose of the ventilation system.

9.196 The designer should consider whether it is necessary for the supply and extract fans to be interlocked, either so that the supply fan will not operate unless airflow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served.

9.197 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratory and pharmacy areas that also contain fume cupboards, safety cabinets and other LEV systems.

9.198 There will also be a need to determine the control strategy in the event of a fire either within the zone being served or within an adjoining zone and as detailed in the fire alarm cause and effect statement (see paragraph 7.16 onwards).

9.199 All supply AHUs should have a smoke sensor linked to the fire control panel and mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the supply air fire damper to close and shut down the AHU.

Note: In certain critical departments, it is preferable to maintain the ventilation in the case of a fire within the area. For example, in an operating department while undergoing surgery the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke.

This will allow time for the patient to be stabilised so that they can be safely.

Location of controls

9.200 Facilities to start, set-back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location, for example, at the reception or staff base.

9.201 Many ventilation systems may be completely shut down when the area served is not in active use. Alternatively, where there is a need to maintain a background condition, the ventilation output may be reduced by "setting back" the system. This will significantly reduce energy consumption and extend the life of filters and other system components. Controls to facilitate this should be triggered by the actual occupancy of the area rather than by a fixed time program (see paragraph 6.2 and associated Note).

Start up and shut down control sequence

9.202 The AHU should start and shut down in a pre-determined sequence. It should ensure that the fan does not start until the main dampers are open and the energy- recovery device is operational. On shut down there may be a need for a “run on” time to purge the area served before stopping the fan and closing the main dampers. Whether the supply or extract fan should start first and stop last will be determined by the pressure regime for the area served.

Set-back control

9.203 In previous times when fan motors only had two speeds, turning the system to “Set back” meant switching to the lower fan speed. With modern fans the speed is widely variable so “Set back” is not a fixed fan speed but rather a control strategy that reduces the system output in order to maintain a desired minimum condition. This may be related to the air velocity at a fixed point, air-change rate, pressure differential, temperature, humidity or a combination of these parameters. Providing a dew-point sensor in an internal space that brings the system onto “Set back” is a simple way of maintaining a minimum condition.

AHU running controls

Fog/frost coil control

9.204 Fog coils supplied by low pressure hot water (LPHW) should be controlled using the Proportional mode. Their sensor should be located downstream of the coil to give “closed loop” control. The coil should raise the incoming air temperature by 2 K in order to ensure that air entering the pre- filter is above its dew-point, thus keeping it dry. The greater the energy put into the incoming air by the fog coil, the lower will be the efficiency of the energy-recovery device.

9.205 If the temperature downstream of the fog coil, as sensed by a serpentine thermostat, falls below the required set point over any part of the coil, the plant should automatically shut down in order to prevent damage to the other batteries. The serpentine thermostat cannot be in direct contact with the coil and should cover the entire coil face.

9.206 Steam-supplied fog or frost coils should be operated as an on/off device to ensure that there is no standing condensate at the base of the coil. They should be fitted with a serpentine sensor mounted upstream of the coil but not in contact with it. This will give “open loop” control; a set point of +1ºC is recommended.

Energy-recovery device

9.207 The energy-recovery device is normally controlled by sensors in the air intake downstream of the supply fan, before the cooling coil and the extract duct from the ventilated space.

Supply & extract fans

9.208 The ErP Directive 1253/2014 requires a means of adjusting the fan speed. For plug fans this is provided by a separate inverter unit; for EC fans the control is integral to the fan motor. It should be remembered that most healthcare applications require known amounts of air to be delivered while the system is in use. Constant volume systems that deliver specified air-change rates are therefore the norm. Duct- or room-

pressure-controlled variable-volume systems have a limited application in healthcare. However, fan-speed control is beneficial when “setting back” the system.

9.209 Inverters should not be mounted inside the air stream within the AHU. Ideally, they will be mounted on a frame with the control valves. Where inverters are mounted inside a control box with a safety master switch to cut the power supply when the box is opened, the inverter control and indicator pad will be located on the outside of the box. This will allow on- site staff to view the operating parameters and switch the system to manual control if a fault occurs with the automatic control system.

9.210 It is necessary to ensure that should the computer control system or its software develop a fault, the fan can be switched to manual operation. This is particularly important for critical systems serving operating suites, high dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites.

Note: In the healthcare setting it is important to recognise that “off-site” software support is no substitute for the ability of “on-site” staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff.

Heater-batteries

9.211 The main heater-battery should be controlled in the same manner under the dictates of an off-coil temperature sensor, or a room temperature sensor, or the return air temperature depending on the plant configuration and method of control. Trimmer heater-batteries are generally controlled by a temperature sensor within the room, or by averaging temperature sensors within a zone.

9.212 Heater-battery control valves should drive closed on system shutdown or fan failure. The control system should then automatically set to provide frost protection.

Cooling coils

9.213 There are two basic methods of control for cooling coils:

- off-coil control – used in multi-zone systems or single-zone systems where close humidity control is required, to provide a constant maximum off- plant condition which satisfies the temperature and humidity requirements of the zone with the highest load;
- sequential control – used in single- zone systems, or multi-zone systems with averaging sensors where close control is not required. A room or duct temperature sensor controls the cooling coil and heater-battery in sequence to maintain constant room conditions.

9.214 The advantage of off-coil control is that accurate humidity control can be provided without relying on humidity sensors, which are prone to inaccuracy and drift. Off-coil control is expensive to operate in terms of energy consumption because of the lack of feedback of room loads. As a result, at low loads and in systems where there are large zonal variations, significant over-cooling and reheating will occur.

9.215 The control logic should prevent the cooling coil and heat recovery and/or heater-battery being on at the same time.

Humidifier control

9.216` Accurate humidity control can only be provided on single-zone systems, or multi-zone systems with zonal humidifiers. In the above systems, humidity sensors control the humidifier for low-level humidity control, and override the temperature controls to open the cooling-coil valve for high-level humidity control.

9.217 Multi-zone systems are more usually controlled by a minimum humidity sensor located in the supply duct(s) following the last heater-battery.

9.218 Overriding controls separate from the normal plant humidistat should be installed. Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay should be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/ plant start-up. In addition, a high limit humidistat should be installed to limitthe output of the humidifier so that the saturation in the duct does not exceed 70%. This humidistat is to control the added moisture; it is not necessary to install a dehumidifier to reduce the humidity of the incoming air if it already exceeds 70% (part load control).

9.219 The humidifier control valve should close when the ventilation system is in “set back”. In addition, on system shutdown, low airflow or fan failure, the humidifier should be isolated.

9.220 In a self-generating humidifier, if the humidifier is unused for a period exceeding 48 hours, it should automatically drain its water content, including that contained in the supply pipework, right back to the running main and leave itself empty.

9.221 With certain types of steam humidifier, it may be necessary to install a thermostat in the condensate line from the humidifier’s steam supply, to ensure that the steam at the control valve is as dry as possible before it is injected into the air supply.

9.222 The humidifier control system should ensure that it is switched off with the fan. It is preferable to design the control system so that the humidifier is isolated for an adequate time before the fan is turned off to purge humid air from the system.

Control valves: general

9.223 The fog/frost battery control valve should fail-safe, that is open in the event of power or airflow failure. All other valves will stop in their current position in the event of power failure and should drive closed in the event of airflow failure.

9.224 Control valves should be located in an accessible position. Isolation valves should be provided to enable the control valve to be removed for service or replacement without the need to drain down the system

9.225 Care should be taken to ensure that the installation of control valves and their associated pipework do not obstruct access to the AHU inspection doors, removable drainage trays, eliminator units and access hatches.

Note: There are practical advantages in locating all control valves for an AHU in a bank (at a convenient height) at one end of the unit. (This should not result in an

additional control lag.) The bank will hold the control valves and actuators, and fan inverters/controllers as necessary, and can be constructed “off site” (see also paragraph 9.209).

Monitoring and alarms

9.226 Monitoring of the plant performance should be via a BMS to the estates and maintenance department.

9.227 The “plant failure” and “low airflow” alarm should be initiated by a sensor located in the main air supply duct. This should operate when the air quantity fails to reach or falls to around 80% of the design value and will give indication of fan failure, damper closed, access door left open, or any other eventuality that could cause a reduction of air quantity. Monitoring the current drawn by the fan motor is not a substitute for a sensing device that is directly affected by the airflow. The sensing ring fitted to plug and EC fans will fulfil this function.

9.228 The “filter fault alarm” should be initiated by a predetermined increase of pressure differential across the filters, thereby indicating a dirty filter. The filter fault indication and alarm is information for the maintenance department; it should not appear on any point of use indicator or control panel.

9.229 Visual indication that the AHU is operating within its prescribed parameters should be provided in critical areas at a manned staff location, for example, the reception or staff base. These need only take the form of a green light to show the system is operational and a red light to show that it is not.

Room temperature control

9.230 The limits for room temperature set point are generally between 18ºC and 25ºC depending on the particular application, and in some specialised instances (for example, operating departments) are adjustable within a predetermined range by the user.

9.231 The selection of temperature set point for each room or zone may be by a control facility in the room/zone, or remotely at the control panel or BMS. Where the control device is mounted within the room/zone and adjustable by the user, it should be marked either “raise” and “lower” or “+” and “–“. It should control within a specified temperature range to suit the user requirement with a control tolerance of +1 K. All other control set points should be selectable either on the control panel or at the BMS interface.

9.232 Where local control is provided, an indication of temperature will be required locally, or at a staff base (if appropriate), using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example, at the operating table in a theatre). This may be mounted in a supervisory control panel, with the signal repeated on the main system control panel or BMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

Local exhaust ventilation (LEV)

9.233 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as LEV systems under the COSHH Regulations.

9.234 An LEV system will typically comprise a unit where the airborne hazard is captured, ductwork to convey the extract air to the fan and a discharge stack. The extract air may be filtered or centrifugally separated to remove any particulate material prior to discharge. HSG 258 produced by the Health & Safety Executive gives detailed guidance.

9.235 It is important to recognise at the design stage whether an extract is being provided for comfort, to remove odours or to remove hazards, in which case it will be an LEV system. Chapter 8 lists typical devices used in healthcare applications.

9.236 The quantity and location of the terminals supplying the make-up air is an important factor in the design of LEV systems.

9.237 LEV systems are statutory items that will be subject to an independent examination and test at least every 14 months by a competent person.

Extract ductwork and fan

9.238 Extract ductwork for an LEV system should, where possible, be installed outside of a building. Where it has to be inside, it should take the most direct route through, with as few bends or changes of direction as possible.

9.239 All ductwork joints should be sealed and ideally there should be no access hatches. Where access hatches have to be provided, they should be of a type that has a hermetic seal.

9.240 Some substances are particularly corrosive, so the choice of material for the ductwork, and type of extract fan fitted, should reflect the nature of the substance being conveyed.

9.241 The ductwork should either be fire rated or fitted with intumescent collars where it passes through fire compartments within the building. This will ensure that the extract system is unobstructed and always open to atmosphere up to the discharge point.

9.242 Some LEV systems (for example, microbiological safety cabinets) HEPA-filter the extract air within the cabinet unit, but it should not be assumed that the exhaust air will be totally free from microbiological or other hazardous material.

9.243 The extract ductwork should as far as practicable be kept under negative pressure while inside the building. The extract fan should be located outside of the building or if this is not practicable, as close as possible to the outside so that any ductwork on the discharge side inside the building is kept to an absolute minimum.

9.244 The extract fan drive motor should be out of the airstream and it should be possible to change the motor without disturbing the fan or its casing.

9.245 Duplex fans are only required when several LEV systems share a common extract system (for example, multiple fume cupboards in a large pathology department where it can be anticipated that at least one cupboard will always be in use or need to be

available for use). In such a situation each cupboard should be fitted with a non-return damper at the point that it joins the common system and be capable of being isolated from the common extract system. The common extract duct should be large enough to handle the combined extract volume from all the systems that feed into it.

9.246 If extract filters are fitted in the ductwork the system design should allow them to be changed safely.

9.247 Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2 m); such an installation, however, is likely to be noisy and is not recommended for use in new buildings.

LEV discharge stack arrangements

9.248 Roof-level discharge, wherever practicable, is preferred since it removes much of the uncertainty over air re- entering the building through ventilation inlets or windows. In such an installation, the extract fan should be situated separate from the LEV captor unit and close to the discharge stack to maintain the duct within the building under negative pressure.

9.249 The discharge point on a flat roof should be through a terminal at least 3 m above roof level but as high as necessary to limit re-entry into supply air inlets or other plant openings. This will protect those who may need to access the roof. Terminals at other roof types need to be high enough to prevent the wind blowing across the roof from causing downdrafts.

9.250 Where there are adjacent buildings with opening windows, or where downdraughts are likely to occur, it may be necessary to increase the height of the discharge stack in order to achieve adequate dispersal. In complex locations, airflow modelling or wind tunnel tests may be required to determine the optimum height.

9.251 The discharge stack should have an open end. It may be fitted with a collar to reduce its area and so increase the air efflux velocity at the point of discharge (known as the venturi effect). To ensure that air leaving the terminal is not deflected down but allowed to disperse freely, the terminal cannot be fitted with any sort of cover or hat. A drain may be required at the base of the discharge stack to remove any rain that enters (see photograph).

Figure 9 Typical LEV discharge stacks

LEV system information and identification

9.252 Once installed, all elements of each LEV system should be uniquely identified with a permanent label as described in Chapter 13. There is a statutory requirement to have information on the design and required operational performance of an LEV system available to those who are responsible for its operation and

9.256 maintenance. The designer should ensure that this information is available at handover.

10. Installation Standards

General

10.1 AHUs, ductwork sections and associated elements of the ventilation system will be delivered to site suitably packaged to protect them from damage and casual contamination. They should remain protected when stored on site awaiting installation.

10.2 Ductwork should be installed to the “Advanced Level” as defined in BESA’s (2019) ‘TR/19: Guide to good practice – internal cleanliness of ventilation systems’. Should any doubt exist as to whether the guidance has been observed, the ducts should be cleaned internally to restore them to this standard and be visibly clean before being taken into use.

10.3 When the ventilation elements are installed, all open ends have to be sealed to prevent the ingress of construction dust as installation progresses. The access doors and panels of AHUs should be kept closed. All AHU dampers and fire dampers should be covered to prevent casual contamination during the construction phase. This is particularly important for fire dampers mounted in the plantroom floor. The damper blades should be wiped clean before final connection to the distribution ductwork.

10.4 The area around the supply air intake should be kept free of vegetation, waste, rubbish, builders’ debris or any other possible source of contamination.

10.5 “Builders’ work” ducts of brick or concrete should have a smooth internal finish and be surface sealed to prevent the release of dust before being taken into use. They should be fitted with a drainage system if not self-draining.

10.6 Every effort should be made to prevent the internal contamination of the ventilation system during the construction phase as once contaminated, it is extremely difficult to completely remove dust and debris. In particular, extract and recirculation fans should not be run up until the area is at least “builders clean” – that is, the floors swept and wet-mopped – otherwise the energy-recovery device in the AHU could become contaminated and its efficiency significantly reduced.

AHUs

10.7 Units should have a working life of up to 20 years; it can be anticipated that over this period there will be a need to access every element within the unit for deep cleaning. It is also quite possible that during the life of the unit, the main fan and all control valves will need replacement. Heater and cooling coils may also need to be repaired or replaced. Suitably positioned service connection joints and adequate spacing should permit these items to be isolated and withdrawn without the need to drain down entire systems or dismantle other installed plant.

10.8 Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access. Mounting all control valves and fan controllers on a frame positioned adjacent to the unit is the

preferred option. This approach has the advantage that the frame and its components can be built and tested “off-site”.

10.9 In order to reduce the effects of galvanic corrosion, black iron fittings should not be used in the pipework installation. Rolled jointed stainless-steel pipework is preferred.

10.10 Vibration from a remote plantroom can be transmitted by the structure of the building, and may be regenerated and sometimes magnified many times. Pipe and ductwork should incorporate anti-vibration couplings, pipe hangers and supports, preferably in two planes at right angles, as close to the vibration source as possible.

10.11 The service connection points for pipework and electrical conduits will have been made during construction of the unit. The unit will then have been leak-tested in the factory prior to delivery to site. If there is a need to drill through the AHU casing or panels (for example, to mount a sensor), the hole should be as small as practicable and sealed to prevent air leakage.

10.12 It is essential that the AHU/ductwork is mounted far enough from the floor to permit the correct installation of drainage systems for cooling coils, humidifiers and heat recovery systems. If the AHU is located on a roof, it will require a clearance of 600 mm to provide access to maintain the building structure below. Sufficient height for the installation of drainage pipework and traps should always be allowed. Easy access for maintenance of drainage systems and their associated pipework should be provided. It should be possible to fully withdraw the drainage tray if it is of the removable type.

10.13 AHUs should be positioned so that all parts are easily and safely accessible for routine inspection and service. If a unit is located against a wall or backs onto another unit, access to all parts should be available from the front. Units greater than 1 m wide should preferably have access from both sides or access doors large enough to permit the full and safe entry of maintenance personnel.

10.14 Air filters, cooling-coil drainage trays and drift eliminators are all items that should be changed, inspected or withdrawn on a regular basis. The installation of the AHU should permit this without the need for tools or to dismantle other plant or systems.

10.15 Access to air intakes and discharges, AHUs and items in the distribution system such as filters or auxiliary trimmer batteries located in a plantroom or plant area should be via fixed ladders, hook ladders, pulpit style steps or other moveable access platforms. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow access equipment to be moved into position.

Distribution systems

10.16 Where ductwork penetrates a roof, it should be protected by an upstand to prevent water penetration. Where it penetrates an outside wall, the method of installation should prevent water tracking along the ductwork into the building or its wall cavity.

10.17 The installation of all services in service ducts and above ceilings should be coordinated so that cable trays, medical gas and other pipework do not obstruct or

prevent access to the ductwork cleaning doors, dampers and any auxiliary plant elements. The use of BIM should highlight clashes at the design stage.

10.18 Plant elements such as VAV boxes, trimmer heaters or cooling coils, humidifier lances or branch filters that are located outside of plant spaces should be accessible for routine inspection and have a cleaning access door on both sides. They cannot be installed above any of the following areas:

- operating theatres;
- preparation rooms or sterile pack stores;
- anaesthetic rooms or recovery areas;
- rooms containing imaging equipment;
- pharmacy cleanrooms;
- containment laboratories;
- patient bedrooms and isolation rooms.

10.19 Rectangular ductwork sections should be joined by bolted or clipped gasketed flanges. Circular and flat-oval slip-joints should be mastic-sealed and held with blind rivets, not screws. The mastic used should not support biological growth. The ductwork installation will be leak-tested prior to acceptance.

10.20 Volume control dampers (VCD) should be oriented so that their adjusting handles or knobs are located at the lower vertical edge or bottom of the damper when mounted above ceilings. The means of adjusting the damper will be within sight and reach from a designated ceiling void access hatch once the ceiling is complete. Volume control dampers mounted in any location should have the control adjuster mounted to allow easy access for the commissioning team and for future access when a post-cleaning rebalance is undertaken.

10.21 Access to VCDs or local auxiliary fans mounted above ceilings should be via low-leakage access hatches mounted in the ceiling or hatches integral to a light fitting.

Note: Obtaining access by removing a light fitting is not acceptable.

10.22 Where ducts are drilled to provide test holes or to mount sensors, the swarf should be removed, and the hole deburred before the fan is started.

Note: Care should be taken to prevent the inadvertent drilling of attenuators.

10.23 Flexible ductwork may only be used if there is no other way of connecting an air terminal to a duct. The flexible duct should be not more than 0.5 m in length, be as fully extended as possible and never used in lieu of a bend. The fire rating of the flexible duct should be no less than that of the fixed duct that it is connected to (see also paragraphs 9.131 and 9.160).

10.24 Fire and smoke dampers must be installed strictly in accordance with their manufacturer's instructions. There will be a rectangular access hatch (saddle mounted for circular ducts) and test switch adjacent to the damper so that a single person can trigger the damper and directly observe its operation during the annual

test (see photograph). When pressure stabilisers incorporate a fire damper, the test switch is to be located in an easily accessible position on the less clean side of the pressure stabiliser.

Figure 10 Fire damper with test switch and inspection hatch

Point of use

10.25 Items of equipment that require access for inspection and cleaning should not be accepted if they are installed in locations that prevent easy access.

10.26 Items of equipment that require access for inspection and cleaning such as fan coil units will not be accepted if they are installed directly above medical or diagnostic equipment.

Note: A common problem occurs because installation layout drawings show fan coil or similar units on the room plan. These are often only “indicative” of the fact that there will be a unit in the room but are taken as the desired position by those carrying out the installation. As an example, the installation drawing for an interventional imaging room shows a fan coil unit in the centre of the ceiling. If it is installed in this position it will be directly above the scanner once that is installed. The fan coil unit will then not be accessible for routine inspection and maintenance, and should it leak water, it will put the scanner out of action.

10.27 The installed position of ceiling terminals in storerooms (for example, a theatre's bulk sterile pack store) should coordinate with the siting of the storage racking. The airflow at the terminals should be routinely measured, so the racking and its contents should not obstruct access to the terminal when using a calibrated hood. The same problem can occur in recovery rooms and ward areas where bed curtain rails and bed hoist tracks can prevent the measurement of airflow from ceiling terminals.

10.28 Low-level extract grilles should be of the pull off face type for ease of cleaning.

10.29 See pictures of low level extract installations in Appendix 9.

Service penetrations

10.30 Where services penetrate the fabric of the building, they should be sealed to prevent any uncontrolled air leakage between rooms and service spaces or voids. Situations where this occurs will be:

- service spaces behind IPS panels at wash basins and scrub troughs;
- cased in wall-mounted medical gas pipeline units and ceiling-mounted pendants;
- electrical trunking and bedhead rail systems;
- boxed-in main and local drainage pipework;
- ceiling-mounted operating lights, examination lights and other pendant-supported items.

10.31 The sealing should be at the point that the service penetrates the wall, ceiling or floor and not at the access panels or covering shrouds as these will need to be removed from time to time. Sealing of the penetrations should be done at first-fix stage as access will become progressively more difficult once final covers and finishes are applied. In certain applications, permeability testing will be carried out at first-fix stage to ensure that this has been done.

Note: The "clean zone" is not the same as the overall size of the canopy, and it is vital to consult the UCV canopy supplier in order to get the position and size of the zone correct, as mistakes are expensive to rectify.

11. Commissioning Systems

General

11.1 Commissioning is the process of advancing a system from physical completion to an operating condition. It will normally be carried out by specialist commissioning contractors working in conjunction with equipment installers. Commissioning of the ventilation system will normally be the responsibility of the main or mechanical contractor who should coordinate the process.

11.2 Commissioning is often subdivided into sections (for example, air handling unit, automatic controls, air side balance, building fabric and fittings). Each section may be commissioned by its specialist installer, and they are often accepted in isolation.

11.3 Commissioning is an essential process for ventilation systems. It is therefore important that adequate provision for the process be made at the design stage of the project. Procedures for commissioning air-handling systems are given in CIBSE Commissioning Codes and BSRIA BG 49 – Commissioning Air Systems.

11.4 The duct design process should take into account the requirements of system balancing. The position and number of regulating dampers included in the design should be sufficient for this purpose.

Location of dampers and test holes

11.5 Balancing/commissioning dampers will be required in each branch of the distribution ductwork. In a critical system such as an operating suite, the branch to each room and each location where it is required to carry out a proportional balance should have a balancing damper.

11.6 Test holes for the measurement of airflow will be required at carefully selected points in main and all branch ducts. The number and spacing of holes are given in the BSRIA BG 49/2015 Commissioning Air Systems. Their positions should be identified at the design stage.

11.7 The test positions need to be accessible for commissioning to take place. They may also be required for subsequent annual verification of the system performance, so they should not be covered by permanent lagging.

11.8 The measurement point should be in a straight length of duct as far away as possible from any upstream bends, dampers or other elements that could cause disturbance to the airflow. The actual location should be:

- at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends;
- if this is not possible, ten diameters downstream of dampers, bends or tees, and five diameters downstream of eccentric reducers;
- where there is enough space round the duct to insert the pitot tube and take readings;
- where the duct has a constant cross- sectional area.

Test holes for measuring total airflow from a fan should be located either four diameters upstream or ten diameters downstream of the fan. Provision should also be made for measuring the fan's speed of rotation.

Note: Plug and EC fans are supplied with a measuring ring so their output can be read directly. This needs to be connected to an external pressure tapping or electronic fan control unit.

Information to be provided

11.9 It is essential that the designer should pass on the system-design intent fully to the commissioning engineer by providing:

- relevant parts of the specification;
- schematic drawings indicating data listed in Table 11;
- equipment schedules;
- controller and regulator schedule;
- fan performance curves;
- wiring diagrams for electrical equipment, including interlock details

Table 11: Information to be provided on schematic drawings

Items in system	Information to be provided
Fans	Fan total pressure Volume flow rate at normal and set back speed Maximum motor current
Plant items	Type and identification numbers from equipment schedules Fluid and air volume flow rates Fluid and air side pressure losses Dry bulb temperatures Wet bulb temperatures Humidity
Dampers, including motorised and fire dampers	Identification numbers from equipment schedules Location Identification number Volume flow rate
Main and branch ducts	Dimensions Volume flow rates and velocities Identification numbers from equipment schedules
Test holes and access panels	Location and size of duct Identification number Design airflow rate
Room supply and extract terminals	Location Identification number Grille or diffuser factor Volume flow rate and neck velocity Operating static pressure
Pressure cascade	Room differential pressures Airflow direction between rooms Pressure stabiliser and transfer grille locations
Internal environment conditions	Design room conditions and adjustable range Specific room air velocity if specified Noise level
Controllers	Set points

Notes: Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet. Where volume flow rates are variable, maximum and minimum values should be provided.

Commissioning personnel

11.10 It is unlikely that all the required commissioning skills will be possessed by one individual; a commissioning team is therefore usually needed. The objective of commissioning is to ensure that the necessary performance and safety requirements are met.

11.11 During the commissioning process a great deal of information will be generated which will form an invaluable future source of reference about the plant. It is essential to ensure that it is collected together in the form of a commissioning manual and handed over to the client on completion of the contract together with the “as fitted” drawings.

11.12 In order to be successful the commissioning process will need to start before practical completion, as many parts of the system will become progressively less accessible. The correct installation of those parts should be witnessed and leak rate tests carried out as construction proceeds. Failure to establish responsibility for commissioning early enough will delay the completion of the project or lead to unsatisfactory plant performance (see CIBSE Commissioning Code M).

Commissioning brief

11.13 The commissioning team will require a detailed brief from the system designer. This should include:

- a “user” brief comprising a description of the installation and its intended mode of operation;
- the precise design requirements with regard to the scheme of air movement, room static pressures, supply and extract airflow rates and acceptable tolerances;
- full details of the design conditions both inside and out, for winter and summer, together with the control strategy;
- equipment manufacturers’ type test data, commissioning, operation and maintenance recommendations;
- drawings showing the layout of the system, positions of airflow measurement test points, dampers, regulating devices and filters within the duct runs, together with sizes of ducts and terminal fittings. It will save time if these drawings are annotated with the design volumes and static pressures required at each branch and outlet point;
- wiring diagrams for all electrical equipment associated with the air- handling systems, including motor control circuit details and any interlocking and safety devices.

11.14 CIBSE Commissioning Code A – ‘Air distribution’ or BSRIA BG 49 – ‘Commissioning air systems’ provide full guidance on the information that will be required by the commissioning team.

11.15 Designers should specify the type of measuring instruments and test procedures. They should include in the contract documents instructions on verifying the accuracy of test instruments, which should be supported by reference to relevant calibration certificates.

11.16 The system, on completion, should be operated by the contractor as a whole and subject to performance tests in accordance with the contract requirements. These will include independent validation of the system performance on behalf of the client.

11.17 The commissioning process should be carried out in the order in which it appears in this guidance document. That is to say, the static checks and visual inspections itemised in paragraphs 11.20–11.26 should be followed by the dynamic tests described in paragraphs 11.27–11.46, the performance tests listed in paragraphs 11.47–11.64 and finally the handover procedures set out in paragraphs 11.63–11.65.

11.18 Once the system is shown to meet the design intent, the handover documentation should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract arrangements.

Pre-commissioning checks

11.19 The pre-commissioning checks consist of visual inspection, manual operation of equipment, static measurements and functional tests of individual components. They should be carried out prior to setting the system to work and undertaking the dynamic commissioning process set out in paragraph 11.27 onwards.

Note: Before commencing commissioning, it is essential that builders' work in the area served by the system is complete. The doors and windows should be fitted, floor finishes applied, walls and ceilings completed and their final finish applied. Fans should not be run until the area is clean (see paragraph 10.6).

Standard of installation

11.20 During the installation of the system the following will be witnessed:

- that the plant and installations have been provided and installed in accordance with the design specification and drawings;
- that only approved sealants have been used in the installation;
- that all components function correctly;
- that the satisfactory sealing of access doors and viewing ports has been carried out;
- that the AHU airtightness test as per BS EN 1886 has been carried out;
- that air-pressure tests and air-leakage tests on ventilation ducting have been carried out in accordance with the methods set out in the BESA DW143 – 'Ductwork leakage testing' but the leakage rate to be not greater than 3% (it is usual to carry out these tests a section at a time as the ductwork is installed and before its insulation is applied. The results will be recorded in the commissioning manual);
- that gaps around doors and hatches are as specified in the design;

- that the permeability tests are carried out as per paragraph 12.17;
- that the correct operation of pressure stabilisers, control dampers, isolating and non-return dampers have been checked;
- that test holes have been provided in their specified locations and are sealed with suitable grommets;
- that control dampers are secured and their quadrants fitted correctly;
- that any interlocks are operative and in accordance with specification;
- that the electric circuits are completed, tested and energised;
- that electric motors have been checked for correct direction of rotation both at full speed and set back;
- that cooling and heating media are available at correct temperatures and pressures and in specified quantities
- that the air-conditioning plant components and controls function correctly;
- that the air-conditioning plant interlocks and safety controls function correctly;
- that the plant is physically complete, insulation is applied and all ducts and pipework are identified as specified;
- that all service penetrations of the fabric of the area are sealed at the point of penetration (see also paragraph 10.30);
- that the building housing the ventilation plant is generally in a fit condition for commissioning and performance tests to commence, that is, windows, doors, partitions, ceilings, etc. are completed, surfaces sealed and their final finish applied;
- that the areas containing the ventilation plant and those being served by it are clean;
- that access to all parts of the system is safe and satisfactory.

Certification of equipment

11.21 The following test certificates should be assembled by the commissioning team and be available for inspection at any time during the contract period. They will form part of the handover information and should be placed in the commissioning manual:

- type test performance certificates for fans;
- pressure test certificates for:
  - heater-batteries;
  - cooling coils;
  - humidifier (if appropriate);
- type-test certificates for attenuators;
- type-test certificates for primary and secondary filters;
- individual test certificates for EPA or HEPA air filters.

Equipment tests

11.22 Prior to setting the system to work the following will be witnessed and proving tests should be carried out as detailed:

Filters

11.23 The quality of filter housing and in particular, the seals, is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter elements. Therefore, the following checks should be made:

- filter seals should be fitted and in good condition;
- filters should be installed correctly with respect to airflow;
- bag filters should be installed so that the bags are vertical and their pockets free;
- all filters should be checked to ensure they are free of visible damage;
- EPA or HEPA filters should be scanned with an LSAPC to prove that they and their housings achieve the specified filter efficiency;
- the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.

Drainage arrangements

11.24 The drain should conform in all respects to the standard set out in paragraph 9.105 onwards. In addition, the following should be proved:

- that the drain tray is easily removable or completely accessible;
- that the drift eliminator (if fitted) is removable without the use of tools;
- that a borosilicate glass trap is fitted and is easily removable;
- that the trap discharge point to drain has a clear air-gap of at least 15 mm;
- that the pipework is supported so that the air-break cannot be reduced;
- that the drain system from each drain tray is independent up to the air- break.

11.25 The operation of the drainage system is then proved by introducing water into the duct at the drain tray and observing that it completely drains out. This check is to be repeated both at normal speed and set back once the fans have been commissioned. At this time the clear trap can be marked to indicate the normal water level with the fan running.

Fire dampers

11.26 The following will be witnessed and proving tests should be carried out as detailed:

- the operation of all fire and smoke dampers (fire dampers fitted with a thermally actuated “memory metal” mechanism should be proved using a hot air heat source);
- the access provided to enable the dampers to be visually inspected and/ or reset should be sufficient for the purpose;
- indication should be provided of the dampers’ position (open/tripped);

- indication of the fire dampers' location should be provided both on the ductwork and at a visible point on the building fabric if the ductwork is concealed.

Dynamic commissioning

Air-handling and distribution system

11.27 Before commencing the dynamic commissioning all rubbish should have been removed and the floors swept and wet- mopped (see paragraph 10.6). Any IPS panels should be in position, access hatches closed, light fittings in place and ceiling tiles clipped down as necessary.

11.28 The fan drive, direction of rotation, speed and current drawn should be set in accordance with their manufacturer's instructions. In the vast majority of healthcare applications, the fan output should be set to give a constant volume of air. This to be controlled by measuring the pressure drop across the fan using a sensing ring and associated volume controller that will automatically integrate the fan 'K' factor to determine and control the pre-set output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.

11.29 After the installation has been checked to ensure that it is in a satisfactory and safe condition for start-up, it should be set to work and regulated to enable the plant to meet its design specification. The proportional balancing method described in the CIBSE Commissioning Code A should be followed. The airflow rates will be set within the tolerances laid down in the design brief. This will normally be the design airflow rate +10%; –0%.

Note: Plug fans are fitted with a measuring ring so that the design volume flow can be set when first started. It can then be reset as the airflow balance progresses. This method will result in the correct airflow with the least total system resistance once balancing is completed.

Air commissioning measuring equipment standards

11.30 All test and measuring equipment used will have a certificate to prove that its calibration has been checked within the previous 12 months at a facility using traceable national standards.

11.31 System performance should be measured at the main and branch duct supply and extract test points using a pitot and manometer or a thermal anemometer.

11.32 Supply and extract air volumes at the room terminals should be measured using a calibrated hood with back pressure compensation. If a hood correction factor is applied, it should be determined by a direct comparison with a duct measurement immediately adjacent to a terminal and not a general comparison between air at the main supply duct and the total as measured at the terminals. For multi-directional terminals a correction cross will be fitted in the measuring hood.

Note: Measurements taken with a "home- made" hood or cone will not be accepted.

11.33 Measurements at extract grille faces should, where possible, be taken using a calibrated hood. Alternatively, they may be measured with a rotating vane anemometer fitted with a hood, or as a last resort, scanned using a rotating vane anemometer and a free area factor applied. The grille face free area and factor used should be stated in the commissioning report.

Order of commissioning

11.34 When combined supply and extract systems are to be balanced and the area that they serve is to be at or above atmospheric pressure, the supply should be balanced first with the extract fan switched off, and then the extract balanced with the supply fan(s) on. The supply balance should then be rechecked.

11.35 For combined systems where the area that they serve is to be below atmospheric pressure, the extract should be balanced first with the supply fan switched off and then the supply balanced with the extract fan on. The extract should then be rechecked.

11.36 On completion of the balance, all volume airflows in supply and extract ducts and from grilles and diffusers will be measured and recorded. The true air- change rate can then be calculated from the data obtained.

Note: For accuracy the room dimensions should be actually measured on site rather than deriving them from design drawings.

11.37 All supply and extract duct volume control dampers should be locked and their position marked and the fan motor settings noted and recorded.

11.38 All grille and diffuser volume control registers should be locked to prevent alteration and their final position marked.

Room air distribution

11.39 The pressure relief dampers and pressure stabilisers will be set to achieve the specified room differential pressures and locked. The grille direction control vanes and diffuser cones will be set to give the specified air movement pattern. Visualisation techniques may need to be employed to prove the required airflow pattern is being achieved and detect any adverse coanda effects (see paragraph 9.162).

Note: When balancing combined supply/ extract cascade ventilation systems (for example, operating suites, cleanroom suites), the airflow through the extract terminals in the adjacent corridors may need to be adjusted outside of their original design values in order to achieve the desired room pressure differentials.

Air-conditioning plant

11.40 The specified flow rate and/or pressure drops will be set for all heater- batteries, cooling coils and humidifiers. The methods described in the CIBSE Commissioning Codes W and R should be followed. On completion their regulating devices will be locked to prevent alteration.

Control system

11.41 The control system should not be commissioned until both the air distribution system and air-conditioning equipment have been commissioned.

11.42 Because of the specialised nature of control systems and the fact that each manufacturer's system will contain its own algorithms and settings, commissioning should be completed by the supplier, and witnessed and documented by a representative of the client (for example, the healthcare organisation's appointed validator).

11.43 In the vast majority of healthcare applications, the fan output should be set to give a constant volume of air. This to be controlled by measuring the pressure drop across the fan using a sensing ring and associated volume controller that will automatically integrate the fan factor to determine and control the pre-set output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.

Note: Measuring the air pressure in the main supply duct and using that to set the supply fan speed as a percentage of its rated output and using that to set the extract fan speed as a percentage of the supply fan speed is not a satisfactory, accurate or acceptable way of controlling the desired supply and extract air volumes.

11.44 The location of all control and monitoring sensors should be checked and their accuracy proved.

11.45 The control system's ability to carry out its specified functions will need to be proved. The correct operation of any alarm systems should also be proved.

11.46 If the plant is provided with a "users" control panel in addition to the one located in the plantroom, the operation of both should be proved. This will typically apply to operating departments and laboratory systems.

Specific performance standards

11.47 The performance of the system should be measured and compared with information provided by the designer.

Plant capacity and control

11.48 When setting to work and proving the design, both the manufacturer of the air handling plant and the control specialist should attend site together and jointly commission the system.

11.49 If any doubt exists as to the capacity of the installed system, its ability to achieve the specified inside design conditions with the plant operating at winter and summer outside design conditions should be proved. Artificial loads will be required in order to simulate the internal gains/losses and the outside design conditions.

11.50 On completion of the plant performance test, recording thermo- hygrographs should be placed in each room/ area served by the plant and also the supply air duct upstream of the fog coil. The plant should be run for 24 hours with all doors closed.

During this period the inside conditions should stay within the tolerances specified. Alternatively, the BMS may be used to obtain the information required.

Noise levels (general)

11.51 The commissioning noise level is that measured with a sound level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. Chapter 8 and Table 1 in Chapter 4 give information for many applications.

11.52 The noise levels apply at the maximum velocity for which the system is designed to operate. Acoustic commissioning tests should be carried out with all plant and machinery running normally and achieving the design conditions of airflow, temperature and humidity.

11.53 An industrial-grade Type 2 sound level meter will normally be sufficient to check the noise level. Its accuracy should be checked using a calibrated sound source before use.

11.54 The noise level readings are to be taken at typical normal listening position 1.5 m above floor level and at least 1 m from any surface and not on any line of symmetry. In critical rooms the noise should be measured at the centre of the room and at the centre of each quarter. The mean of the five readings should then be calculated

11.55 In the event of a contractual deficiency a Type 1 precision-grade sound level meter should be used and the noise level determined by the procedure given in Scottish Health Technical Memorandum 08-01.

Filter challenge

General ventilation filters

11.56 In-situ performance tests will not normally be required for primary and secondary filters and their housings. However, the filters should be visually inspected for grade, tears, orientation and fit within their housing. Filters should be clean and a replacement set available. Bag filters should be installed so that their bags are vertical and spaced so that air can move through them freely.

11.57 Air leakage around a filter housing significantly reduces the filter efficiency. The as-fitted filter housing and access door arrangement should not permit air to bypass.

EPA or HEPA filters (for exhaust protective enclosures and laboratories)

11.58 Pathogenic material may be discharged through damaged or badly installed EPA or HEPA terminal filters. The complete installation should be tested using the method set out in BS EN ISO 14644 and ISO 17141.

The challenge tests may be carried out using either of the following techniques:

- a light scanning airborne particle counter (LSAPC) and a natural challenge to detect leaks;
- dispersed oil particle (DOP) to provide the challenge and a photometer to detect leaks.

11.59 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the EPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.

11.60 With an LSAPC the filter face is sampled at several points to establish the smallest non-penetrating particle size. This will directly relate to the grade of filter under test. The filter face, its seal and housing are then scanned, and if a significant number of particles at or above this size are detected, there is deemed to be a leak at or near the test position.

11.61 With DOP a challenge aerosol of inert particles of the type produced by a dispersed oil particle generator is introduced into the air, upstream of the EPA or HEPA filter. The downstream face of the filter, its mounting seal and housing are then scanned for leakage using a photometer. A leak should be deemed to have occurred if a steady and repeatable reading on the photometer at any point exceeds 0.01% of the upstream reading.

11.62 Should the EPA or HEPA filter fail this test, it will be replaced. Should the filter mounting seal or housing fail this test, it may be repaired and the test repeated.

Ventilation system commissioning records

11.63 Following commissioning, the main contractor will collate the individual commissioning reports together with the plant user manuals ready for handover.

11.64 The fire dampers will have been tested by a specialist, and a written statement detailing which fire dampers were tested, when and by whom should be provided. If any fire dampers in the system were not tested, they should be listed and appended to the statement.

11.65 The airflow balancing report compiled by the commissioning engineers should be available to the validator. The report should include copies of the equipment calibration certificates.

12. Acceptance Testing: Validation

12.1 All new and refurbished ventilation systems should be independently validated prior to acceptance by the client.

12.2 Validation differs from commissioning in that its purpose is to look at the complete installation from air intake to extract discharge and assess its "fitness for purpose as a whole". This involves examining the fabric of the building being served by the system and inspecting the ventilation equipment fitted as well as measuring the actual ventilation performance. Validation is not a snagging exercise; see the Note after paragraph 12.30.

12.3 Validation is a process of proving that the system in its entirety is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that "*The system will be acceptable to the client if at the time of validation, it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life*."

Appointment of validator

12.4 In order to ensure that the complete system operates correctly it will be necessary to validate it as a whole from the air intake through to the extract discharge. It is unlikely that the client's in-house staff will possess the knowledge or equipment necessary to undertake this process. Validation should therefore be carried out by a suitably qualified competent engineer appointed by the client. The validator would be the client's AE(V) (see Chapter 2 in Part B of Scottish Health Technical Memorandum 03-01) or someone of similar standing who is familiar with the ventilation requirements for healthcare facilities. They will be completely independent of the system designers, contractors, suppliers, installers, commissioners and those who will subsequently operate and maintain the system.

12.5 To retain independence, the validator should be appointed and paid directly by the client. The validator will act as the client's representative to inspect the system, check its performance and recommend acceptance, or not, to the client.

Note: "Client" means the healthcare provider, not a contractor or service provider.

Design proposal review

12.6 It is essential that whoever has been appointed to carry out the final validation acceptance of the system should be involved in the initial client's brief and design specification, preferably prior to the project being put out to tender. They will then be fully aware of the client's requirements and any limiting factors.

Note: While it is beneficial to involve the client's validator in the design process, it should be remembered that the appointed designer carries the "design risk" and advice from the validator will not obviate this.

12.7 It is important that the validator understands the complete project and not just the obvious ventilation aspects. Decisions about the type of ceilings, doors, access

hatches, fire compartmentation, floor markings, room functions, their adjacency and the proposed workflow patterns all have a direct effect on the likelihood of being able to achieve the desired ventilation performance. It is not sufficient to consider the ventilation in isolation.

12.8 During this process any derogations proposed by the contractor/supplier should be clearly defined, agreed and documented with the client (for example, through the VSG). All parties will then be clear as to what will be the acceptable standard of installation and performance when finally validated.

12.9 The ventilation designer(s) should provide the validator with system information listed in Table 11. The information should be in the form of an annotated drawing for each ventilation system to be validated. They should also provide any other design or specification information that will assist the validation process.

12.10 The contract arrangement should give the validator the right to visit the site as often as they deem necessary during the contract period.

First fix inspection

12.11 The validator should carry out a physical walk-around inspection of the installation at a point in the project when the AHU is “on site” and the main and branch ductwork is for the main part installed, but prior to the ductwork being concealed behind wall panelling or ceilings.

12.12 If possible, the following airtightness tests should be witnessed during the inspection:

- AHU installation leakage (BS EN 1886);
- supply and extract duct leakage (BESA DW/143);
- initial permeability test (see paragraph 12.17).

12.13 The quality of the installation, compliance of the AHU, suitability of the basic installation, location and future accessibility of commissioning dampers, location and compliance for testing of fire dampers, etc., can all be assessed during the visit.

12.14 When validating large projects that have many AHUs, it is worthwhile to visit the AHU manufacturer to inspect a specimen unit and agree its compliance before all remaining units are built and transported to site. At that time the leakage and deflection tests can be demonstrated by the AHU supplier in their factory.

12.15 Once units are delivered to site, it is useful to get all mechanical and electrical services connected to a specimen AHU. The location of pipework joints, drain points, anti-vibration couplings, isolating and control valves can all be agreed, as can the route of cable ways and control wiring. The object will be to create an agreed “exemplar unit”. If all other AHUs are installed in an identical fashion, they will normally be considered compliant at the time of final validation.

12.16 On completion of the first fix visit the validator should provide the client with a short report identifying items that are not compliant with the specification.

Permeability testing

12.17 The following areas will require permeability testing:

- isolation suites of any type;
- operating suites of any type;
- pharmacy aseptic preparation facilities;
- IAP cleanrooms in central decontamination units (containment leak test in accordance with BS EN ISO 14644-3:2019);
- category 3 and 4 containment facilities;
- any other area specified within the contract.

The methodology for permeability testing is set out in BSRIA document BTS 3 – 'Air permeability testing of isolation facilities'.

12.18 An initial permeability test should be witnessed at first-fix stage when the envelope of the suite is physically complete but before wall, ceiling and floor finishes are applied. The objective will be to find and eliminate any construction leaks (for example, between a floor slab and curtain wall) before they become covered up during the fit-out stage (see paragraph 10.30).

12.19 A full permeability test in accordance with the methodology given in BSRIA BTS 3 will be carried out at practical completion to ensure that all service penetrations have been adequately sealed.

Note: Any leaks discovered during the test are to be sealed at the point of penetration of the building fabric envelope and NOT at the gaps around IPS panels, ceiling hatches or bedhead trunking covers, etc. (see also paragraph 10.30).

Follow-on inspections

12.20 Dependent on the size and complexity of the installation, a second and further inspection visits may be required. The validator should attend site as frequently as necessary in order to try to eliminate any installation issues as the project develops and while trades are still in attendance, rather than having to resolve them at the time of final acceptance.

Final acceptance inspection: validation

12.21 The commissioning of a ventilation system will normally be carried out by the suppliers of the various elements. The final acceptance validation will check that all of the elements work as a whole to achieve the project aim.

12.22 The following regime of inspection and testing should be applied to the validation of all new and refurbished ventilation systems. It may also be applied to systems that have undergone significant changes such as the replacement of a fan or other major component.

Basic requirements

12.23 The area served by the ventilation system to be validated should be physically complete with final finishes applied. The doors should fully close against the design pressure differential with IPS panels fitted and any access hatches closed. All ventilation plant serving it should be operating correctly and have been commissioned in accordance with the project contract.

> **Note**: In projects on existing sites, the area of the building being built/refurbished is often sealed off from the “in use” part to prevent dust penetration. At final validation the seals need to be at least temporarily breached in order to be able to determine the ventilation performance in “normal” conditions.
>
> If this is not possible, validation will be conditional on a final “actual” performance check when the seal is removed at the time of handover.

12.24 The area served should be free of any rubbish, debris, obvious dust and have been wet-mopped before the validation is undertaken.

> **Note**: There is no need to clean the area to the point that the validator needs to gown up in order to enter it. A certain amount of disturbance to hatch seals, ceilings, panels, etc. will be inevitable during
>
> the validation process, so the area will require a final “clinical” clean prior to being taken into use.

12.25 The validation process should be a continuation of the earlier site inspections and will in many cases be carried out in parallel with the commissioning process.

12.26 Unless stated elsewhere in the design specification, the conditions in the principal space served by the ventilation system being validated should be stable and within the given ranges.

Temperature: 18–22ºC dry bulb.

Humidity: 30–70% Relative humidity.

12.27 Any test or measuring equipment used should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards.

12.28 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

12.29 The validator has the right to either witness readings taken by the commissioning team or to independently take such readings and measurements as they deem fit in order to satisfy themselves as to the actual performance of the system.

Validation process

12.30 The validation process should follow the sequence given below. Any failures discovered during the process should be rectified before continuing. The validator should check the following:

- the location of the air intake and discharge and their position relative to each other and other intakes and discharges;
- inspection and cleaning access to the vermin mesh and as necessary throughout the installation;
- the security, suitability of and access to the AHU location;
- sufficient space and access arrangements for service and maintenance;
- that the AHU is uniquely identified (see paragraph 13.17) and complies with the minimum standards set out in Chapter 9;
- that the AHU and distribution system have been leak-tested and comply with the design;
- that the AHU and supply ductwork system are clean and free of visible dust;
- that all fire and smoke dampers have been inspected and tested for correct installation and operation. A certificate to that effect, signed and dated by the inspector and tester, will be available for inspection;
- that the area served by the ventilation system is complete and free from significant defects that could invalidate the validation process;
- that the supply and extract airflow rates are in accordance with the design +10%; –0% and the system terminals are in balance. Note that the total supply and extract air volumes measured at the AHU should equate to those measured at the terminals. A discrepancy in the totals would indicate a leak in the system which should be resolved before proceeding further;
- that the air-change rate calculated from the measured airflow and room dimensions accords with the design specification;
- that the room differential pressure regime is in accordance with the design and that if pressure stabilisers are fitted, they operate correctly and silently;
- the air velocity at a specific location(s) if required in the application specification;
- that the noise level does not exceed the design value;
- that the system indicators correctly and clearly show whether or not the ventilation system is in an operational state;
- that any user controls fitted operate correctly (for examples of “cause and effect testing”, see Appendix 10);
- that the temperature and humidity in the space being ventilated are accurately indicated on the user panel and that they can be adjusted within the specified limits, if applicable;
- that the estates control functions operate correctly and the plant condition is clearly shown both on the plant control panel and at the BMS/ BEMS interface;
- that the fire cause and effect strategy has been demonstrated and operates correctly. This may be carried out by others, in which case a statement signed

and dated by the person carrying out the test will form part of the handover information;

- that any additional tests called for in the project specification have been carried out and witnessed by the validator or the client's appointed expert.

Note: Validation is not a "snagging" inspection. The main contractor has presented the installation as being complete, fully commissioned, achieving the specified level of performance and ready for handover. The validator's role is to check on behalf of the client that the contractor is correct in that assertion.

If the validator discovers that there are a significant number of snags and non-compliances, the validation should be terminated. It is the contractor's responsibility to snag the project, carry out remedial works and re-present the installation for acceptance. The validator will then need to repeat the validation process. The client is entitled to deduct any resulting additional validation fees incurred from the contractor.

12.31 It is vitally important to complete the validation process before the system is accepted by the client. Due to the nature of the ventilation installation and the intensity of use in the healthcare setting, it will not be possible to correct any faults or non- compliances once the system has been accepted and taken into use. There are also medico-legal aspects around taking a non- compliant system into use. Pre-announced handover or occupancy dates are not a reason for the validator or client to accept a non-compliant installation.

Validation report

12.32 Following validation, a full report detailing the findings will be produced and sent to the client's lead project manager. The report should conclude with a clear statement on whether the system achieved or did not achieve the standard set out in the agreed design specification.

12.33 The client's lead project manager should lodge a copy of the validation report with:

- head of the user department;
- infection prevention and control;
- estates and facilities.

Additional specialist tests

12.34 Certain critical areas will require additional testing and validation in addition to the process given above.

UCV theatres

12.35 The following regime of inspection and testing should be applied to the validation of new installations designed to provide ultra-clean conditions in an operating suite. The test regime has been devised to ensure that the system as installed fully achieves the operational requirement for these systems as set out in Chapter 8.

UCV canopy validation procedure

12.36 The validation procedure set out in paragraph 12.30 onwards should have been satisfactorily completed prior to attempting to validate the UCV canopy. The

operating suite to be validated should be physically complete with final finishes applied. All ventilation systems serving it should be operating correctly and delivering their design airflow rates.

12.37 Tests to validate the suitability and performance of a UCV canopy should be undertaken in the order that they appear below. If an item fails to meet the required standard it should be rectified and successfully retested before passing on to the next test.

Summary of test regime

12.38 Leakage tests should ensure that:

- the UCV canopy is correctly assembled and sealed so that no air will bypass the filters;
- the canopy terminal filters are correctly sealed in their housings;
- the canopy terminal filters are of a uniform quality and undamaged.

12.39 Air velocity measurements should ensure that:

- a sufficient quantity of air is being delivered by the canopy;
- the airflow has sufficient velocity to reach the operating site plane.

12.40 An entrainment test should ensure that contaminants arising outside of the UCV canopy footprint are not drawn into it.

12.41 Visualisation techniques should gain an understanding of the overall system performance.

12.42 Noise measurement should ensure that working conditions are satisfactory.

12.43 Control system “cause and effect” checks should ensure that the system operates and indicates as specified (for example, see Appendix 10).

12.44 The successful completion of the test regime will ensure that the system will be effective if used correctly.

Test and measuring background conditions

12.45 The entire theatre suite should be clean and free from debris and visible dust. It should be in a condition that if the validation is successful the suite will only require a final clinical clean before being taken into use (see paragraph 12.24).

12.46 All doors should remain closed when readings and scans are being taken.

12.47 The conditions in the operating theatre should be stable and within the given ranges.

Temperature: 18–22ºC dry bulb.

Humidity: 30–70% Relative humidity.

Test and measuring equipment

12.48 Any test or measuring equipment used should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards.

12.49 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

Test grid – vertical flow canopies

12.50 A test grid should be constructed on the floor within the UCV canopy footprint as projected by the inside dimensions of the side walls or boundary air curtain. A suitably marked test sheet will provide a consistent standard of test grid.

Note: The entire clean zone footprint of the UCV canopy will be designated by a contrasting coloured inlay in the floor covering. A line marked on or cut into the floor covering is not sufficient and will not be accepted.

12.51 The test grid should comprise test squares of 280 mm × 280 mm dimension.

12.52 The test grid should be aligned along the centre lines of the canopy footprint with its centre under the centre point of the canopy.

12.53 Any test square with 80% of its area within the UCV footprint should be used as a test position.

12.54 An inner zone will be designated that is not less than 36% of the total footprint. It will be made up of a number of test squares distributed symmetrically about the canopy footprint centre line. Regardless of the size or shape of the canopy footprint, the inner zone will comprise a minimum grid of 6 × 6 test squares.

12.55 Unless specified otherwise, a test position should be in the geometric centre of a test square.

12.56 Test position 1 will be the left-most test square in the row nearest to the operating theatre wall that houses the theatre control panel. (For an example of a grid for a 2.8 m × 2.8 m canopy, see Figure 11.)

UCV canopy leakage tests

12.57 The diffuser screen fitted below the face of the canopy terminal filters should be lowered or removed while the leakage tests are being carried out.

12.58 The installed terminal EPA filters are to be checked to ensure that their grade accords with the design specification and that their performance has been certified by their manufacturer.

Test equipment

12.59 An LSAPC connected to an isokinetic fishtail scanning probe will be used to detect the size and number of particles present.

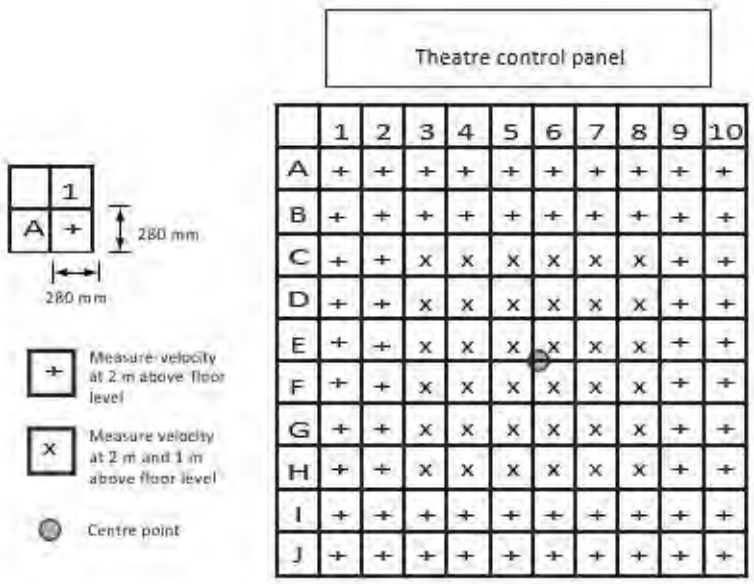
12.60 Spot readings are taken at several filter faces to establish the smallest non-penetrating particle size. If particles at or above this size are detected when subsequent scans are made, there is deemed to be a significant leak at, or near, the test position.

UCV canopy clean zone leak test

12.61 The test will confirm that there is no unfiltered air leakage in the canopy.

12.62 The construction joints and service penetration points under the UCV canopy within its side walls or boundary air curtain should be scanned to prove that there are no leaks.

Figure 11: Example of a test grid for a 2.8 m × 2.8 m UCV terminal



Note: For larger UCV terminals, add extra (280 mm x 280 mm) test squares symmetrically around the periphery of the grid and increase the inner zone in accordance with the guidance in paragraphs 12.50–12.56 of Scottish Health Technical Memorandum 03-01 Part A.

12.63 A leak is defined as a significant and repeatable rise above the background level.

Terminal EPA filter seal leak test

12.64 The test will confirm that there is no unfiltered air bypassing the EPA filter seal.

12.65 Each EPA filter seal should be scanned to prove that there are no leaks.

12.66 A leak is defined as a significant and repeatable rise above the background level.

EPA filter media leak test

12.67 The test will confirm that the EPA filters have not sustained damage while being installed.

12.68 The face of each EPA filter should be scanned to prove that there are no leaks.

12.69 A leak is defined as a significant and repeatable rise above the background level.

Vertical flow UCV canopy air velocity tests

Test setup

12.70 The canopy face diffuser screen should be in place for these tests.

12,71 Take spot readings to establish that the room is within the specified temperature and humidity test conditions.

12.72 Set out the test grid as described previously.

12.73 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to airflow, are perpendicular to the front edge of the test sheet and face the back edge. Any lamp and equipment heads should as far as practicable be outside of the UCV canopy footprint (see photographs).

Test instrument

12.74 The measuring instrument should be a thermal anemometer with a digital readout. The instrument resolution should be at least 0.01 m/s, have a tolerance of ±0.015 m/s or 3% and be calibrated down to 0.15 m/s or lower. An alternative instrument may be used providing it is of no lesser specification.

Test method

12.75 The instrument should be mounted on a test stand and set to take a mean reading over a 10-second sample interval.

12.76 The test instrument should record readings automatically for later download or be connected to a printer.

12.77 The test stand should be positioned on each test point in turn and the reading taken when the instrument has stabilised.

12.78 When taking a reading, the test person should not stand within the same quadrant as the test instrument.

12.79 Readings are to be taken at the test positions with the instrument probe facing the wall housing the theatre control panel commencing at the first test position. Readings are taken either working along the rows from left to right or for all test positions in one quadrant at a time.

12.80 When all test positions under one half of the canopy have been covered, readings of temperature and humidity are taken at the specified height in the centre of the canopy. The readouts from the theatre control panel should be recorded at this time.

12.81 Having completed one half of the test grid, the operating lamp arms and any other stem arms should be swung round through 180º and the test stand reversed so that the wall housing the theatre control panel is behind the test person. Readings are recommenced starting at the right of the test row and working from right to left or a quadrant at a time, as above.

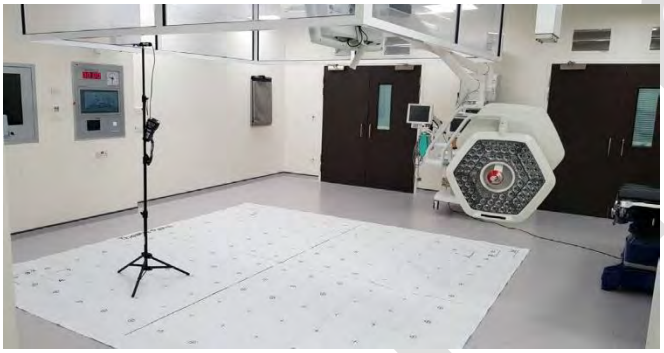
UCV canopy high level discharge velocity test

12.82 Measurements of air velocity are to be taken at every test position 2 m above floor level and the results averaged. The average of the total readings taken is to be not less than:

- 0.38 m/s for a canopy with no side walls or side walls that terminate at 2 m above floor level.
- 0.30 m/s for a canopy with side walls that terminate 1 m above floor level.

12.83 For UCV canopies that are an assembly of two or four units, each fed by a recirculation fan, the average air velocity for each unit should not exceed ±6% of the measured average velocity for the canopy.

Figure 12: UCV 2m air velocity test set-up



UCV canopy low level air velocity test

12.84 Measurements of air velocity are to be taken at each of the inner zone test positions 1 m above floor level.

12.85 The measured velocity at every test position in the inner clean zone should be not less than 0.20 m/s.

Figure 13: UCV 1m air velocity test set-up

UCV canopy entrainment test

Rationale for the entrainment test

12.86 The performance of a UCV canopy may be compromised by room air being drawn into the ultra clean airflow, a phenomenon known as entrainment. Significant levels of entrainment could lead to microbial contamination of items left exposed on instrument trolleys laid out beneath the canopy.

12.87 UCV canopies having permanently fitted side walls that terminate 1 m above floor level do not need to be tested, as the walls physically prevent entrainment.

Principle of the test

12.88 A source of particles is produced outside of the UCV canopy footprint and is used to challenge the system. A sample probe and detector are placed within the ultra clean airflow and used to determine the percentage penetration of the test particles at predefined locations under the UCV canopy footprint. The source and sample probe are moved in tandem around the UCV canopy and pairs of readings taken at the detector, from which the percentage penetration at specified locations is calculated. The degree of penetration should be below specified maximum limits if entrainment is to be declared not significant.

Test setup

12.89 The challenge will be provided by using non-EPA-filtered air emerging from the preparation room via the pressure stabiliser or transfer grille and ducted to the specified release position.

12.90 The canopy face diffuser screen should be in place for these tests.

12.91 The test is performed without any theatre equipment in place beneath or closely adjacent to the UCV canopy. All doors in the theatre suite should be closed and remain so for the duration of the test.

12.92 The operating lights and support booms should be moved to a central position beneath the canopy and raised to 2 m above floor level, so as not to interfere with the peripheral airflows (see photograph).

12.93 Spot readings are taken at the centre of the canopy, 1 m from floor level, to establish that the room is within the specified temperature and humidity limits (see paragraph 12.47).

12.94 The test grid is set out as described previously (see paragraph 12.50).

Test equipment

12.95 The source unit will be a fan/blower or other method that ducts non-EPA- filtered air (see paragraph 12.89) and expels it via a delivery head mounted on a test stand or clamped to the UCV canopy sidewall at the specified release position to provide the particle challenge. The challenge air will be delivered vertically downwards from a position 2 m above floor level alongside the outside edge of the side wall or in line with the downward air curtain if the canopy does not have side walls. The challenge airflow velocity should be the same as the measured average velocity at the 2 m level for the canopy under test.

Figure 14 UCV entrainment test setup

12.96 The detector will be an LSAPC capable of sampling a minimum of 28.3 L of air (1 ft3) per minute and providing readings for particle sizes from to 5 µm to 0.3 µm. Measuring instruments should be compliant with the requirements of BS EN ISO 14644 or ISO 17141 to reflect the type of test. An alternative instrument may be used providing it is of no lesser specification

12.97 The sampling head will be an isokinetic fishtail scanning probe mounted horizontally on a test stand 1 m above floor level and connected to the LSAPC by a hose no longer than 2 m

Test positions and orientation of source and detector sampling probe

12.98 The test positions will be at the centre of each test square, as defined for the velocity test (see paragraph 12.50).

12.99 For rectangular UCV canopies, measurements of penetration are to be taken at the four corner test squares of the test grid and at intermediate positions along the line of test squares between the corners. The number of intermediate test positions will be

as equally spaced as possible around the periphery, with not fewer than three and not more than five complete test squares between test positions.

12.100 A further series of measurements are to be obtained around the periphery of the inner zone (defined in paragraph 12.54). Measurements of penetration are to be taken at the four corner test squares of the inner zone of the test grid and if necessary at intermediate positions along the line of test squares between the corners as equally spaced as possible, with not fewer than three and not more than five complete test squares between test positions.

12.101 The centre of the challenge particle source delivery head is aligned with the centre of the designated test square, with its longer edge against the outer edge of the side wall or air curtain and delivering the challenge 2 m above floor level. The air containing challenge particles is directed vertically downward. Where there is physical interference due to obstructions such as gas pendants, the source will be moved to the next available non-obstructed test square location nearest to the stipulated test position. The sampling probe will then also be moved to remain opposite the source.

12.102 In the case of non-rectangular canopies, an interpretation of the above strategy should be adopted that will yield a no less searching examination of the unit's ability to control entrainment.

Test method

12.103 A measurement of particle penetration through a representative section of the EPA filter media is to be taken. The smallest non-penetrating particle size will be used as the reference background level and set in the detector instrument. The detector instrument should be set to take a reading over a 15-second sample interval and record the number of particles at the non-penetrating particle size determined above.

12.104 An initial sample of air at the source delivery head should be taken to check that there are sufficient particles of the considered size present. The challenge will be considered suitable if:

- the particles are within the size range 5 to 0.3 µm and thus capable of remaining airborne for a substantial time;
- the particles should not be able to penetrate the canopy EPA filters in sufficient numbers to cause a background count that is more than 0.1% of the challenge count;
- the number of particles present will enable a minimum of three logarithm (1000-fold) range of counts to be recorded between the source and background readings. A concentration of approximately 105 particles per cubic metre of source air has been shown to be adequate.

Note: The same equipment should be used to measure both the challenge source and penetration so as not to bias results through particle losses within the test equipment.

12.105 The sampling probe of the detector instrument is mounted on a test stand with its orifice facing outwards horizontally from the centre of the UCV canopy, 1 m above floor level. The sampling probe will be orientated at right angles to the partial wall

when sampling along the sides of the test grid but will be set to bisect the angle when measuring at the corner test positions. (See Figure 15 for test locations and see photograph of entrainment test equipment in Figure 13.)

12.106 The test will commence at the first test position; this being designated the left-most corner of the test grid when facing the wall housing the theatre control panel. The penetration will also be measured at the corresponding test point on the inner zone commencing at the corner nearest to the first test position.

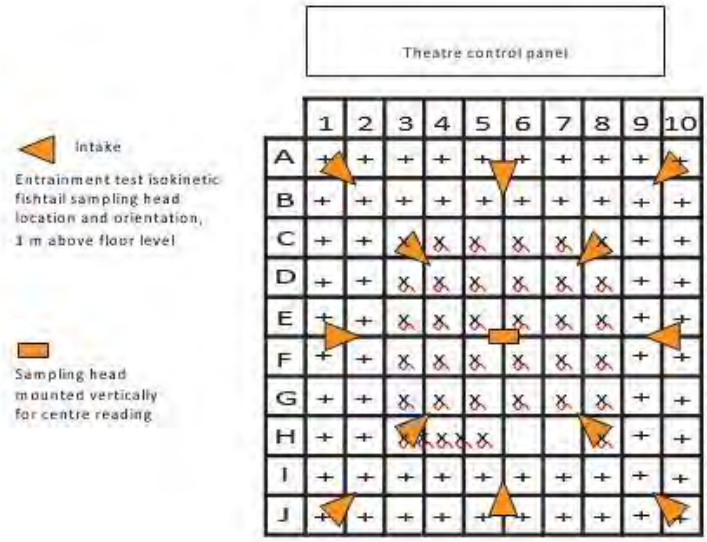
When these tests have been completed, the source distribution head and sampling probe will be moved to the next test positions, working around the test grid in a clockwise direction.

12.107 The test stands will be positioned on each test point in turn and a pair of readings (challenge, then penetration) taken when the instrument has stabilised.

12.108 When taking a reading, the test person should stay within the UCV canopy footprint but on the side opposite the sampling probe.

12.109 A single measurement will be taken at the geometrical centre of the UCV canopy footprint. The centre measurement will be taken with the sampling probe mounted vertically 1 m above floor level

Figure 15: Entrainment test locations for a 2.8 m ×2.8 m UCV terminal



Note: Test grid layout is as for Figure 11. Entrainment test set-up and guidance is given in paragraphs12.86 onwards.

For this test the challenge source distribution head will be placed at the test position that yielded the greatest penetration at the periphery of the canopy footprint.

Analysis and interpretation

12.110 The following standard is to be achieved:

- penetration to be no greater than 10% of the challenge at each test position in the outer zone;

- penetration to be no greater than 1% of the challenge at each test position in the inner zone;
- penetration to be no greater than 0.1% of the challenge at the centre of the test grid.

12.111 If a result is close to or above the given limits, a further reading should be obtained using a longer time base (1 minute) and the penetration should not exceed the given limit.

UCV canopy flow visualisation

12.112 The use of smoke to gain an understanding of the overall performance of the canopy may prove useful at this stage in the validation process but cannot be relied on to produce a contractually definitive measure of performance.

UCV canopy noise level

12.113 An industrial-grade sound level meter to BS EN 61672 Type 2 fitted with a muff will be used to check the noise level. The instrument should be calibrated using a matched sound source prior to each set of readings.

12.114 The noise level readings are to be taken at a typical normal listening position 1.5 m above floor level and at least 1 m from any surface and not on any line of symmetry. Measurements should be taken under the centre of each quadrant and in the centre of the canopy, and the five readings averaged.

12.115 The readings should be taken with the UCV canopy at operational speed and repeated with it at set back.

12.116 For UCV operating suites, the noise level should not exceed:

- operating theatre and spaces without doors that are open to it (for example, the scrub): 53 dB(A);
- all other peripheral rooms of the suite: 48 dB(A).

UCV terminal control system checks

Temperature

12.117 The readings of temperature taken under the UCV canopy should be within ±1ºC of the readout on the theatre control panel.

Humidity

12.118 The readings of humidity taken under the UCV canopy should be within±5%RH of the readout on the theatre control panel.

Direct reading differential pressure gauges

12.119 The differential pressure across the terminal filter should be measured to confirm the accuracy of the indicated reading of any gauge.

Control functions

12.120 The operation of all control functions provided on the theatre control panel should be checked for conformity with the design specification (see Appendix 10).

12.121 If an auxiliary panel has been fitted, its interlocking with the main theatre control panel control functions will be checked for conformity with the design specification.

Panel indicator lights

12.122 The panel indicators should illuminate as appropriate when the control functions are selected, or warning levels are reached (see Appendix 10 for an example “cause and effect” test regime).

BMS interface

12.123 The operation, monitoring and alarm functions should be checked for conformity with those set out in the design specification.

UCV theatre microbiological tests

12.124 There is little value in performing microbiological sampling in an empty operating theatre supplied with ultra clean ventilation. The foregoing filter challenge tests, air velocity measurements and entrainment test will have proved that the system operates satisfactorily and achieves the contracted level of performance. The EPA filters will remove bacteria-sized particles from the air supplied through the UCV canopy. Therefore, there will be an insignificant number of bacterial and/or fungal cfus present until the theatre is actually used.

12.125 Following full validation, in-use microbiological sampling during a surgical procedure will not be required unless specified by the client’s VSG.

UCV operating suite validation report

12.126 Following validation, a full report detailing the findings will be produced and sent to the client’s lead project manager. The report should conclude with a clear statement on whether the UCV operating suite as a whole achieved or did not achieve the standard set out in the agreed design specification.

12.127 The client’s lead project manager should lodge a copy of the report with:

- theatre manager;
- infection prevention and control;
- estates and facilities.

Pharmacy aseptic preparation facilities

12.128 The following regime of inspection and testing should be applied to the validation of new installations. The test regime has been devised to ensure that the system as installed fully achieves the operational requirement for these systems as set out in EUGGMP and the design specification.

Basic requirement

12.129 The validation procedure set out in paragraphs 12.1–12.33 should have been satisfactorily completed prior to attempting to validate the aseptic preparation facility. The suite to be validated should be physically complete with final finishes applied and have been completely cleaned. All ventilation systems serving it should be operating correctly and delivering their design airflow rates.

Aseptic preparation facility validation procedure

12.130 Tests to validate the suitability and performance of the aseptic preparation facility should be undertaken in the order that they appear below. Should an item fail to meet the required standard it should be rectified and successfully retested before passing on to the next test.

Summary of test regime

12.131 Challenge tests should ensure that:

- the supply terminal HEPA filters are sealed in their housings so that no air will bypass them;
- the terminal filters are of a uniform quality and undamaged.

12.132 Differential pressure measurements should ensure the correct pressure cascade.

12.133 Particle counting should be carried out at a specified number of test positions in order to determine the individual cleanroom classification in accordance with ISO EN 14644 and ISO 17141.

12.134 Control system checks should ensure that the system operates as specified.

12.135 Microbiological sampling should check the air quality.

Test and measuring conditions

12.136 While validating the aseptic preparation facility, the conditions in the cleanrooms should be stable and within the given ranges.

Temperature: 19–23ºC dry bulb.

Humidity: 30–70% relative humidity.

Test and measuring equipment

12.137 Any test or measuring equipment used should have a certificate to prove that its calibration has been checked within the previous 12 months at a facility using traceable national standards.

Supply terminal EPA or HEPA filter seal leak test

12.138 The test will confirm that there is no unfiltered air bypassing the EPA or HEPA filter seal.

12.139 Each EPA or HEPA filter seal should be scanned using a light scattering airborne particle counter (LSAPC) to prove that there are no leaks.

12.140 A spot reading will be taken at the face of the filter to determine the background particle level. A leak is defined as a significant and repeatable rise above the background level.

Terminal (EPA or HEPA) filter media leak test

12.141 The test will confirm that the terminal filters have not sustained damage while being installed.

12.142 The face of each terminal filter should be scanned using an LSAPC to prove that there are no leaks.

12.143 A leak is defined as a significant and repeatable rise above the background level.

Cleanroom particle count

12.144 The test will confirm the number and size of particles present and therefore the classification of the cleanroom in terms of ISO 14644 or EUGGMP as specified in the project brief.

12.145 The number of test positions is determined by reference to Table A.1 in ISO 14644-1.

12.146 The complete test methodology will be as set out in ISO 14644.

Cleanroom biocontamination control

12.147 BS EN 17141 gives details on cleanroom biocontamination control.

Radiopharmacy aseptic preparation facilities

12.148 Validation will be as for a pharmacy aseptic preparation facility.

12.149 Additional radiological tests as specified in the project brief will be required. These will be carried out and/or witnessed by the client's appointed specialist.

Inspection, assembly and packing (IAP) rooms in central decontamination units

12.150 Validation will be as for the standard practice described in paragraphs 12.1–12.33.

12.151 The pressure cascade and associated automatic monitoring sensors and alarms should be tested for correct operation in accordance with the design specification.

Note: The detail of the sealing between the instrument washers, transfer hatches and sterilizers that penetrate the walls of the IAP room will be critical in attaining the specified room pressure.

12.152 Following the satisfactory validation, the IAP room should be physically cleaned using specialist contractors. Particle counts at locations related to the floor area as set out in table A.1 of ISO 14644 Part 1, along with instructions from ISO 17141 will then be used to establish whether the room achieves a Class 8 cleanroom standard.

Containment level 3 laboratories

12.153 Validation will be as for the standard practice described in paragraphs 12.1–12.33.

12.154 The room will be subject to a permeability test as set out in paragraph 12.17.

12.155 The pressure cascade and associated automatic monitoring sensors and alarms should be tested for correct operation in accordance with the design specification.

Isolation rooms

12.156 Validation will be as for the standard practice described in paragraphs 12.1–12.33.

12.157 See Scottish Health Planning Note 4 Supplement 1 for details of the test regime.

Microbiological sampling

12.158 It is essential that all parts of the validation test specified above have been successfully completed and the areas thoroughly cleaned prior to any microbiological sampling.

12.159 Microbiological sampling will not normally be required for either general or local exhaust ventilation (LEV) systems unless otherwise specified within the contract.

12.160 The procedure for carrying out microbiological sampling in cleanrooms is set out in ISO 17141.

Microbiological sampling conventional theatres

12.161 The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for 15 minutes. An active air sampler set to 1 cubic metre and mounted on the operating table should then be activated remotely. Aerobic cultures on non-selective media should not exceed 10 bacterial and/or fungal colony forming units per cubic metre (CFU/m3).

12.162 The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation. Precise guidance is inappropriate and will depend on local circumstances.

12.163 It may be appropriate to carry out a check of airborne bacteria during a surgical operation. If required, this should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacterial and/or fungal CFU averaged over any five-minute period, would be unlikely to exceed 180 per cubic metre.

12.164 Information on the microbiological testing of UCV Operating suites is given in clauses 12.124 and 12.125.

13. Information

Records required

13.1 There is a requirement under the Building Regulations to provide documentary evidence of the design, commissioning and subsequent performance of ventilation systems as well as recommended maintenance routines (Building Regulations. 2010, Part 8, Paragraph 39).

13.2 Electronic records should be in a format that is compatible with the client's archive and retrieval system.

Handover

13.3 The following general information is required at plant handover:

- "as fitted" drawings of the plant showing the location of all items and listing the size of ducts, grilles and diffusers together with their factors;
- "schematic" drawing of the air distribution system showing design and actual airflows from all outlets together with the design and actual airflows in each duct. The duct centre correction factors should be given and the grille factors;
- the location of all volume control dampers should be marked on the "as fitted" and "schematic" drawings;
- a floor plan of the area served by the plant showing all doorways, hatches, transfer grilles, pressure relief dampers, pressure stabilisers, supply and extract terminals. The total supply and extract volumes should be shown for each room served by the plant. The volume flow and direction of flow through transfer grilles, pressure relief dampers and pressure stabilisers should also be shown, together with the room pressures in pascals measured with regard to atmospheric pressure. For operating suites the "key" door should be identified;
- a fire plan of the area served showing the fire zone and location of all fire and smoke dampers and detectors. An explanation of the ventilation strategy in the event of an in-zone fire, adjacent zone fire or smoke being drawn into the airhandling unit from an outside source should be provided.
- wiring diagrams for all electrical equipment associated with the air handling systems including motor control circuit details and any interlocking and safety devices such as emergency stop buttons adjacent to the item of plant;
- manufacturer's operating instructions and "setting to work" guidance for all specialist components incorporated in the systems;
  - a schematic of the control system showing the location of all plant sensors;
  - control algorithm(s) of the actual plant operation and the set points entered during commissioning together with the control panel access codes and keys.

Plant design information

13.4 The following plant design information is required at plant handover:

- a simple statement of the design intent;
- a description of the plant's intended mode of operation;
- winter outside design temperature in ºCdb;
- winter outside design humidity in % saturation;
- winter room supply air design temperature in ºCdb;
- winter room supply air design humidity in % saturation;
- winter inside design temperature for each room in ºC;
- winter inside design humidity for each room in % saturation;
- summer outside design temperature in ºCdb;
- summer outside design humidity in% saturation;
- summer room supply air design temperature in ºCdb;
- summer room supply air design humidity in % saturation;
- summer inside design temperature for each room in ºC;
- summer inside design humidity for each room in % saturation;
- winter psychrometric chart showing the condition of the air between all items of plant and the design outside, supply and room air conditions;
- summer psychrometric chart showing the condition of the air between all items of plant and the design outside, supply and room air conditions;
- the design mass airflow rate used to size the plant in kg/s;
- the design volumetric flow rate in m 3/s.

Individual equipment information

Heater-batteries including energy recovery

13.5 The following information concerning heater-batteries is required at plant handover:

- the size of the battery, number of passes and fin spacing;
- the design flow and return temperatures and flow rate in L/s;
- the pressure drop across the water side of the battery in Pa;
- the number of phases, supply voltage, current drawn and number of steps if electric;
- the maximum rated capacity of the battery and actual design rating in kW;
- the design and actual face velocity in m/s;
- the pressure drop across the air side of the battery in Pa;
- the design on and off coil air temperature and humidity at winter and summer design conditions

Cooling coils

13.6 The following information concerning cooling coils is required at plant handover:

- the size of coil, number of passes and fin spacing;
- the design flow and return temperatures and flow rate in L/s if chilled water;
- the pressure drop across the water side of the coil in Pa;
- the supply pressure and mass flow rate if direct expansion;
- the maximum rated capacity of the coil and actual design rating in kW;
- the contact factor;
- the design sensible and latent cooling loads in kW;
- the design and actual face velocity in m/s;
- the pressure drop across the air side of the coil in Pa;
- the design on and off coil air temperature and humidity at summer design conditions.

Humidifiers

13.7 The following information concerning humidifiers is required at plant handover:

- the size of the humidifier and number of lances;
- the supply pressure and mass flow rate of the steam;
- the number of phases, supply voltage, current drawn and number of steps if electric;
- the maximum rated capacity of the humidifier and actual design rating in L/hour;
- the design and actual face velocity in m/s;
- the design upstream and downstream air temperature and humidity at winter design conditions

Filters

13.8 The following information concerning filters is required at plant handover:

- the size of the filter and number in bank;
- its grade;
- the design and actual face velocity in m/s;
- the initial pressure drop across the filter when clean in Pa;
- the final pressure drop across the filter when dirty in Pa;
- the manufacturer's name and filter identification code.

Fans

13.9 The following Information concerning fans is required at plant handover:

- the size of the fan and its type;
- the fan curve;
- speed and direction of rotation;

- the drive motor frame size;
- the number of phases, voltage and maximum design and actual current drawn;
- the design and actual delivered air volume in m3/s;
- the fan suction pressure at high and low speed in Pa;
- the fan delivery pressure at high and low speed in Pa;

Attenuators

13.10 The following information concerning attenuators is required at plant handover:

- the size of the attenuator and number in bank;
- the design and actual face velocity in m/s;
- the initial pressure drop across the attenuator in Pa;
- the upstream sound level in dB(A); the downstream sound level in dB(A).

System information

13.11 The preservation of information and records of ventilation systems and their performance is a legal requirement. It is therefore essential that when new systems are completed, full information as to their purpose, design, layout and actual commissioned performance are handed on to the client. If any derogations were agreed from this standard, they should be noted and the reason for them explained. The system information if electronic (for example, BIM model) should be in a form that is compatible with the client's IT standard and can be accessed and searched by it.

13.12 In new "green field" developments an inventory of the installed ventilation systems should be compiled. In existing developments the client will normally have an inventory of their installed systems, and all new systems should be added to it.

13.13 The inventory will be subdivided into the following categories:

- local exhaust ventilation systems (LEV) – note these are statutory items;
- critical healthcare ventilation systems (CHV).

(These are systems the loss of which would seriously limit the delivery of healthcare – for example, operating suite, SCBU, critical care areas, interventional imaging suite, aseptic preparation facility.)

- general ventilation system [supply and extract] (GVS);
- general extract systems (GES);
- systems installed for smoke clearance in the event of a fire, classed as smoke and heat exhaust ventilation systems;
- – (SHEVS) (for example, smoke extract fans in stairwells, automatic smoke clearance dampers in atria).

Note: During the design and contract process, ventilation systems are often given "construction" codes for drawing reference and site identification purposes. It is

imperative that prior to handover the actual identification codes and labels affixed to the systems conform to the inventory in use at the site or desired by the client. Each system code should be unique and conform to the categorisation format for the client's inventory given above.

For ease of future reference, a list of design and construction references for drawings and plant, cross-referenced to the client's building designations and plant inventory codes, should be produced.

13.14 For each ventilation system the inventory should contain the following details:

- a unique system identification code (for example, LEV 001; CHV 001) as appropriate;
- the location of the ventilation fan unit or supply and extract AHU(s);
- the location of the fresh air inlet;
- the location of the extracted air discharge;
- the specific area(s) served by the system;
- the date the system was installed;
- the date the system was validated and accepted by the client.

13.15 Each ventilation system should have a logbook (physical or electronic) that contains the following information:

- the unique system identification reference;
- purpose of the system;
- date of installation;
- details of the installed equipment and ductwork layout;
- detail of the fire plan and location of fire and smoke dampers;
- design performance parameters (for example, airflow rates, air-change rates, pressures);
- commissioned date and performance;
- record of the system validation and acceptance;
- records of the annual inspection and verification;
- maintenance records and plant information (for example, fan specifications and filter sizes).

13.16 The records should be linked to the inventory and stored in such a way as to be readily available in the event of plant breakdown or other incident.

13.17 Every ventilation system should be clearly identified with a permanent label. The label should show in lettering 100 mm high the inventory reference code of the AHU and clearly identify the area that it serves. The label should be mounted with screws or rivets in an easily visible place near the fan of the unit adjacent to the local electrical isolator. The system control panel should have a duplicate label. Any subsystems and the principal branch ducts should be similarly labelled.

13.18 The nature of air and direction of flow should be clearly marked on all ducts using the symbols given in BS 1710.

13.19 All airflow test-points should be clearly identified with a permanent label and the design information given (for example, TPS 1 – Anaesthetic supply; 400 × 300; Design 185 L/s).

13.20 If two ventilation systems supply a common room or an outlier from another zone, the room identification label should state the relevant ventilation identification codes, for example: Theatres 5&6 Utility; [CHV 012 and CHV 015], as should the labels on their individual AHUs.

13.21 Any ventilation system that conveys a hazardous substance or is affected by a hazardous radiation must be clearly marked with the appropriate symbol.

Fire and smoke dampers

13.22 A complete schedule of dampers fitted, their location and unique identification code should be provided.

13.23 A statement of when they were tested and by whom should be included.

Spares

13.24 Unless otherwise agreed with the site maintenance department, spares should be stored on a rack in the entrance of the relevant plantroom and preserved from casual damage or contamination.

13.25 The scale of spare fans to be provided should relate to the number of AHUs using fans of the same size. The spare fans should be pre-wired with power and control connectors so that when used they are plug and play.

13.26 A complete set of new filters should be handed over.

13.27 A complete set of any other consumable item installed in the installation should be handed over.

BIM status

13.28 If the installation was modelled using BIM during construction, the BIM model should be brought up to date and all asset tags incorporated prior to handover.

13.29 Training for estates staff who will be tasked with keeping the BIM model in date should be given, ideally while the original BIM team is available.

Maintenance routines

13.30 Any product or installation-specific maintenance routines should form part of the handover documentation and, if necessary, training.

13.31 Information on routine inspection and maintenance is given in Part B of Scottish Health Technical Memorandum 03-01.

Expected service life

13.32 Air handling units (AHUs) have an expected service life of 20 years. Part B of this SHTM states that ventilation systems should be taken out of service, deep cleaned, their controls renewed and recommissioned after 10 years. The handover information will both assist this process and help inform the selection of replacement plant.

Additional end user information

13.33 The information itemised above is intended to fulfil the contract requirement and provide a record for the client and their appointed operational management and maintenance teams. There is also a need in some circumstances to provide the end-user with information as to the role that them and their patients from airborne contaminants.

13.34 In operating suites and interventional imaging suites of any type, a simplified plan of the suite showing the principal direction of air movement should be displayed at the entrance to the suite. The following bullet points should be appended to the plan:

- the air supplied to each room is intended to dilute any airborne contaminants;
- the airflow between rooms will ensure that contaminants do not enter;
- people are the main source of airborne contaminants; they disperse such contaminants as they move around: the more people, the more movements, the more airborne contaminants;
- optimum conditions exist when all doors are closed;
- in order to ensure that the system operates correctly and efficiently:
  - routine checks should be carried out of the system performance;
  - the system should be taken out of use periodically to carry out essential maintenance.

13.35 The VSG should advise if other applications require similar explanatory information.

Staff training

13.36 On completion of the project, training in the correct use, operation and routine maintenance of the installed systems should be given as appropriate to the following staff groups:

- the end-users;
- those who will operate and maintain the installed systems.

Specimen store	E	–	–ve	–	–	–	Fan accessible from outside of store

Notes:

For general and UCV operating suites and associated rooms, see specific guidance in Chapter 8 and typical design solutions in Appendix 7

Waiting and circulation areas should be directly or indirectly ventilated to provide a comfortable environment and control airborne contamination and odours.

18–22°C indicates the range over which the temperature may float.

18-22°C indicates the range over which the temperature should be capable of being controlled at any point within that range.

S = Supply

E = Extract

N = Natural ventilation where possible where natural ventilation is used the design must reflect clauses 5.2 to 5.9

SUP refers to the supply air quality as defined in BS EN 16798

Appendix 3: Hierarchy of cleanliness

Table A2 Hierarchy of cleanliness

Class	Room	Nominal pressure (Pa)a	Airflow rate for bacterial contaminant dilution Flow in or supply (m3/s)	Flow out or extract(m3/s)
Sterile	Preparation room lay-up sterile pack store Operating theatre Scrub bay	 35 25 25 25	See standard schemes in Appendix 7 and detailed calculation process in Appendix 8 for recommended design values	
Clean	Sterile pack store Anaesthetic room Scrub room	+ve 15c 15	6 ac/h The greater of 15 ac/h or 0.15 –	– The greater of 15 ac/h or 0.15 0.10 mind
Transitional	Recovery room Clean corridor General access corridor Changing rooms	0 0 0 3	15 ac/he (See note f) (See note f) 7 ac/h	15 ac/he 7 ac/h 7 ac/h 7 ac/h
Dirty	Service corridor Utility room	0 –5 or 0	– –	(See note g) 0.40 or 0.10

Notes:

Nominal room pressures are given to facilitate setting up of pressure-relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not immutable provided the desired airflow rates and movement directions are achieved.

An open or semi-open bay is considered to be part of the operating theatre; a low-level extract under the scrub trough is required. (See Chapter 8 paragraph 8.45 onwards and “Note” for more information.)

For design purposes, anaesthetic should be assumed to be at 15 Pa. When commissioning, equal to or greater than 10 Pa is considered suitable.

May need to be increased if scrub is large to promote scouring.

15 ac/h is considered necessary for the control of anaesthetic gas (see Appendix 9).

Supply airflow rate necessary to make up 7 ac/h after taking into account secondary air from cleaner areas.

No dilution requirement. Temperature control requirements only.

Appendix 4: Leakage flows in m3/s through closed door gaps

Pressure difference (Pa)

Table A3 Leakage flows through closed door gaps

Type	5	10	15	20	25	30	35	40
Single door	0.03	0.05	0.06	0.06	0.07	0.08	0.09	0.10
Single door + half	0.04	0.06	0.07	0.08	0.09	0.10	0.11	0.12
Double door	0.05	0.08	0.10	0.11	0.12	0.13	0.14	0.15

Designers' notes:

The door gaps assumed are 4 mm along the bottom, 3 mm at the top and sides, and 2 mm between double leaves.

If doors are fitted with cold smoke seals, these will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design leakage be factored into the size of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air-gap whistles and doors being held partially open by air pressure.

Factory-assembled door-sets with a steel frame and pre-hung leaves are becoming common. There is effectively no leakage across these doors when closed. Therefore, when this type of door assembly is fitted, the door leakage can be ignored and the design airflow into the room reduced accordingly. The design airflow would then become that required either (i) for open door protection (Appendix 5), or (ii) to achieve the specified air-change rate – whichever is the greater.

Appendix 5: Recommended airflow rates in m3/s through a doorway between rooms of different cleanliness to control cross-contamination

Table A4 Flows through dooorways

Room class		Dirty	Transitional	Clean	Sterile
Sterile	Hatch Single door Double door	0.3 0.47 0.95	0.24 0.39 0.75	0.18 0.28 0.57	 0 or 0.28a 0 or 0.57a
Clean	Single door Double door	0.39 0.75	0.28 0.57	0 or 0.28a 0 or 0.57a	
Transitional	Single door Double door	0.28 0.57	0 or 0.28a 0 or 0.57a		
Dirty	Single door Double door	0 0	Open single door = 0.80 m x 2.01 m high Open double door = 1.80 m x 2.01 m high	Open single door = 0.80 m x 2.01 m high Open double door = 1.80 m x 2.01 m high	Open single door = 0.80 m x 2.01 m high Open double door = 1.80 m x 2.01 m high

Designers' notes:

The degree of protection required at an open doorway between rooms is dependent on the degree of difference in cleanliness between them.

Flow-rate required between rooms within the same class tends to zero as class reduces.

If two rooms are of equal cleanliness, no flow is required (in practice there will be an interchange in either direction) and the design of the air movement will assume zero airflow. In certain cases, however, interchange is not permitted, and a protection airflow of 0.28 is assumed in the design – for example, in the case of a preparation room used as a "lay up".

Appendix 6: Typical approximate pressures in an operating suite when a given door is open

Typical approximate effect on other rooms

Table A5 Pressure in room with open door

Door open between	Typical approximate resultant	Room	Pressure (Pa) pressure in these rooms (Pa)
Operating theatre and corridor or Scrub bay and corridor	0	Anaesthetic Preparation – lay-up Utility Preparation – sterile pack store	0 12 –6 5
Operating theatre and anaesthetic room (or other series room with double doors)	17	Preparation – lay-up Utility Preparation – sterile pack store	26 –9 22
Operating theatre and Utility room or Operating theatre and preparation room	25	No change	
Anaesthetic room and corridor (or other series room with double doors)	0	Preparation – lay-up Utility Operating theatre Preparation – sterile pack store	30 –6 20 25
Preparation room and corridor or Utility room and corridor	0	No change	
Utility room and outer corridor	0	No change	

Notes:

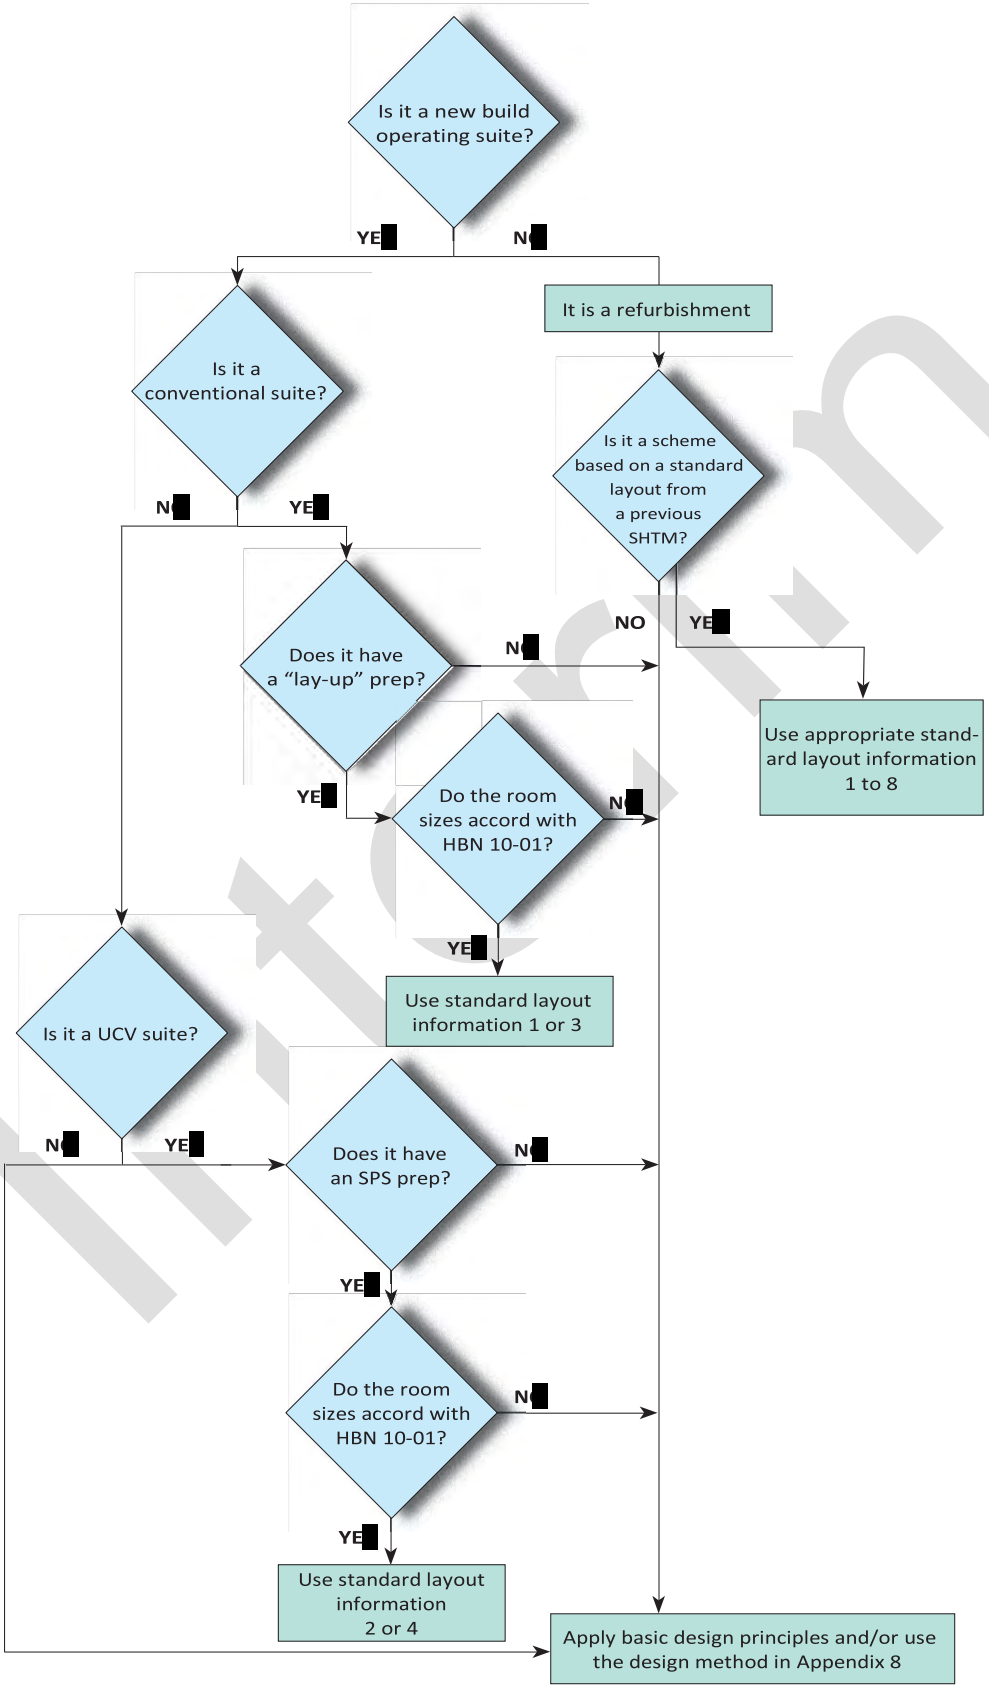
The room differential pressure protects against reverse flows when the door is closed.

The flow of air through a doorway protects against reverse airflow when the door is open.

Pressure stabilisers control flow and ensure a known airflow path between rooms when doors are closed and also reduce backflow between rooms when doors to other rooms are open.

Appendix 7: Operating suite design logic

Figure A5 Operating suite design logic



Standard layout 1 – Two-corridor conventional operating suite with “lay-up” prep

Table A6 Two corridor conventional operating suite with “lay up” prep design criteria

Room	Size (m3)‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m3/s)
Theatre	165	≥22	25	Primary = 0.73 From Prep = 0.28 Total = 1.010
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Lay-up prep	36	≥22	35	0.28**
Scrub	*	–	25	–

Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

*This is a separate scrub and is not considered as being part of the theatre volume.

**Interchange is not permitted between the theatre and lay-up prep; therefore, as in Appendix 5, an airflow protection of

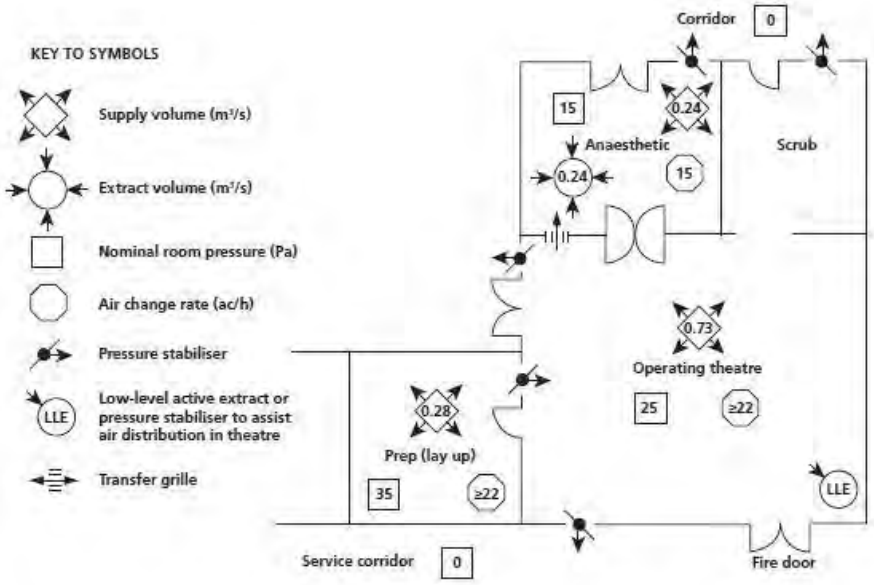
0.28 m3/s is required as a minimum (but see also the “designers’ notes” in Appendix 4).

N.B.If the lay-up prep also has a door or hatch to the corridor, its supply airflow volume would increase to 0.35 m3/s

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the key door from the total air entering the space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A6 Two corridor conventional operating suite with "lay up" prep, schematic layout



Standard layout 2 – two-corridor UCV operating suite with SPS prep

Table A7 Two corridor UCV operating suite with SPS design criteria

Room	Size (m3)‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m3/s)
Theatre	165	≥22	25	# 1.01
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Sterile pack store prep	36	10	25	0.10
Scrub	*	–	25	–

Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

* This is a separate scrub and is not considered as being part of theatre volume.

Primary fresh-air volume to UCV canopy only or ≥22 or door protection

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the key door from the total air entering the space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see

paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

The utility layout design figures will remain the same if a hatch is fitted instead of a door onto the service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

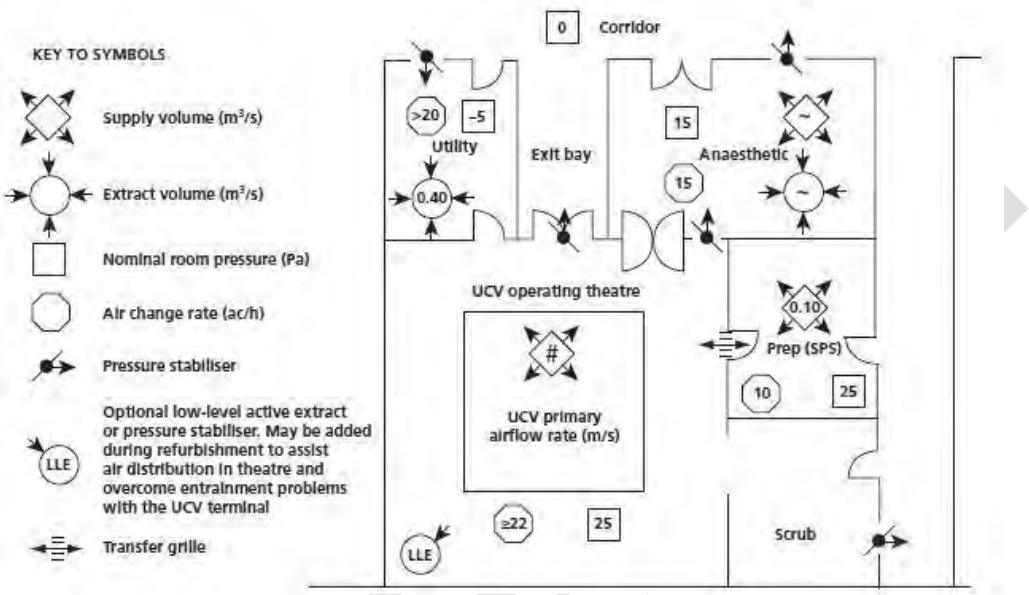
Figure A11 (ex SHTM 2025 Plan 1a): single-corridor UCV operating suite with SPS prep schematic layout



Standard layout 7 – (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with “lay-up” prep

Note: This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning.

Table A12 (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with “lay-up” prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m3/s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Lay-up prep	* See Notes below	≥22	35	0.35**
Scrub	* See Notes below	–	25	–
Utility	* See Notes below	–	0	0.1

Notes:

* Existing theatre suite to be measured on site

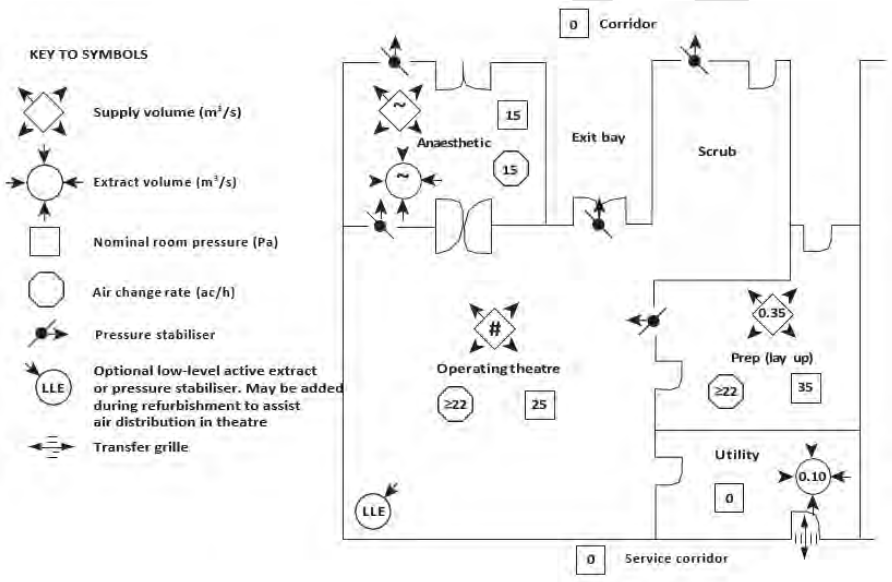
Theatre total airflow related to volume of theatre to give ≥22 ac/h or door protection = primary theatre supply + 0.28 m3/s from Lay-up Prep pressure stabiliser

** See the “designers’ notes” in Appendices 4 and 5

The utility design figures will remain the same if a hatch is fitted instead of a door onto the service corridor. Alternatively, if the operating department has a central waste processing station, the utility room may be omitted and replaced with a hatch between the theatre and service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A12 (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with “lay-up” prep schematic layout



Standard layout 8 – (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep

Note: This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning. If difficulties are experienced with entrainment around the periphery of the UCV, adding a low-level active or passive extract in the location indicated will usually resolve the problem.

Table A13 (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m3/s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Sterile pack store prep	* See Notes below	10	25	0.1
Scrub	* See Notes below	–	25	–
Utility	* See Notes below	–	0	0.1

Notes:

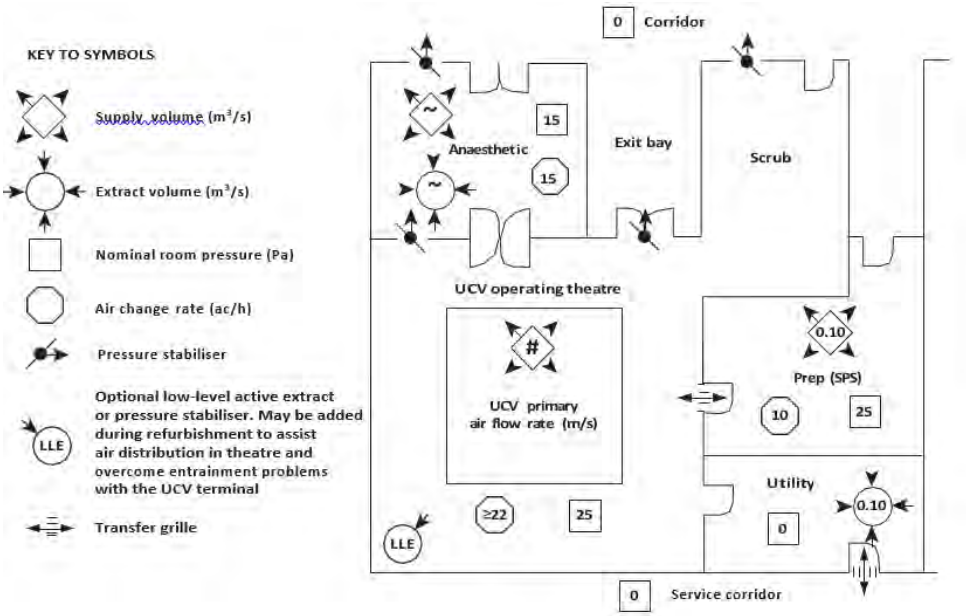
* Existing theatre suite to be measured on site

Primary fresh supply air for the UCV canopy is related to volume of theatre to give ≥22 ac/h or door protection

The utility design figures will remain the same if a hatch is fitted instead of a door onto the service corridor. Alternatively, if the operating department has a central waste processing station, the utility room may be omitted and replaced with a hatch between the theatre and service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A13 (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep schematic layout



Appendix 8: Design of air- movement control schemes for operating theatres

General

A8.1 Standard operating suite design solutions are given in paragraphs 8.27–8.74 and Appendix 7. If these standard solutions cannot be used, the following procedure should be adopted, which will result in an acceptable design. Note that the method employed may equally be used to provide a design solution to a ventilated suite of rooms for any application.

A8.2 The method is concerned with the calculation of air-flow rates to ensure that correct air movement occurs between rooms when any one door is open. Under most circumstances, the air quantities required for air-movement control will approximate to those for either temperature control or bacterial contaminant dilution. This flow rate is sufficient to control the effects of any slight reverse flows occurring when a door is opened.

A8.3 The progression through the design procedure is shown in the air-flow design procedure chart (Figure A24) and is supported by worksheets WS1 to WS7 described in paragraph A8.4. It is recommended that a plan of the suite and an air-flow network be made (Figure A23) to collate all information. Flow rates, air- transfer devices etc should be entered as required. The remainder of this Appendix may be treated as reference data to assist in the various steps. The following symbols are used:

SS – supply air-flow rate for summer temperature control;

SW – supply air-flow rate for winter temperature control;

SD – supply air-flow rate for dilution of bacterial contaminants;

SL – supply air-flow rate for heat loss;

SG – supply air-flow rate for heat gain;

ED – extract air-flow rate for dilution of bacterial contaminants;

SF – final supply air-flow rates

EF – final extract flow rates;

SAMC – air-supply flow rate for air- movement control;

EAMC – air-extract flow for air- movement control;

LOUT – leakage air-flow rate outward;

LIN – leakage air-flow rate inward;

∑OUT - total air-flow rate outward;

∑IN total air-flow rate inward.

A8.4 To simplify the procedure, standard worksheets (WS1 to WS7) have been devised. For each operating suite, a set is required comprising one each of WS1, WS3, WS5, WS6a, WS6b and WS7, one WS4 for each corridor and one WS2 to cover each peripheral room. WS2 has five versions:

WS2a single flow,

WS2b parallel/series multi-flow,

WS2c parallel multi-flow or series multi-flow (unbalanced);

WS2d series multi-flow (balanced); and

WS2e bay (semi-open).

Peripheral room type

A8.5 The rooms in the operating suite other than the operating theatre and corridor are referred to as peripheral rooms. Peripheral rooms have been classified according to the flows in and out. These room classifications are defined in paragraphs A8.6–A8.11.

Single flow

A8.6 This is a room with only one door and a net surplus of supply or extract air.

Parallel multi-flow

A8.7 This is a room with two or more doors through each of which the air flows either outwards (high pressure) or inwards (low pressure) (for example the Prep (lay- up) in standard layout 5 in Appendix 7).

Parallel/series multi-flow

A8.8 This is a room having a net surplus of supply or extract and with two or more doors. One or more doors will be to an area of equal cleanliness and need not be protected; hence, the flow may vary between inwards and outwards, the remaining door being to an area of greater or lesser cleanliness (for example the Prep (SPS) in standard layout 6 in Appendix 7).

Series multi-flow (unbalanced)

A8.9 This is a room having a net surplus of supply or extract and with two or more doors. Air flows inwards through one or more doors and outwards through one or more doors.

Series multi-flow (balanced)

A8.10 This is a room as in paragraph A8.9 above, but having either no mechanical ventilation or no net surplus of supply or extract (for example an anaesthetic room).

Bay

A8.11 A room which has a permanent opening to the operating theatre may be considered as a bay off the latter (for example a scrub). Two categories exist:

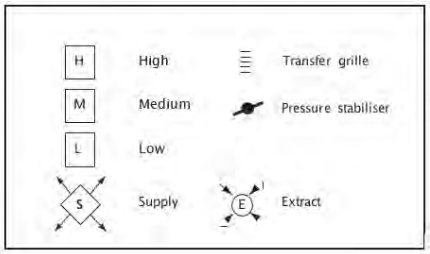
open bay – the opening is larger than a normal single door opening. The bay may be considered as part of the main room;

semi-open bay – the opening is no larger than a normal single door opening. In this case it is possible to protect the bay from the main room by provision of air supply or extract in the bay, or by passing air to or from another area.

Air-movement control in peripheral rooms

A8.12 For the design of air-movement control, two types of air-transfer device are considered. These are transfer grilles and pressure stabilisers. Each has a particular field of application within the design, as described in paragraphs A8.34– A8.43. Air movement is controlled in each of the different room types described in paragraphs A8.13–A8.31.

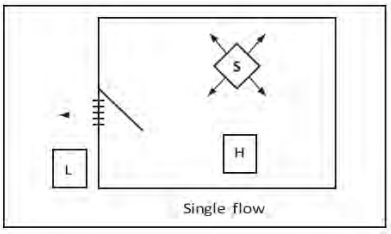
Figure A14 Key to symbols



Single flow rooms

A8.13 An appropriately-sized transfer grille should be located in or adjacent to the door of each single flow room to relieve the pressure differences across the door when closed.

Figure A15 Single flow room solution high–pressure room



Parallel multi-flow rooms

A8.14 The pressure difference across the closed doors should be relieved, but transfer grilles are not appropriate where two doors lead to areas of different pressures, because reverse flow could occur when the other door is open. For this reason, pressure stabilisers are used.

Figure A16 Parallel, multi-flow room solution high-pressure

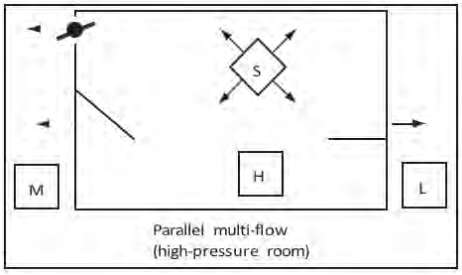


Figure A17 Parallel, multi-flow room solution low-pressure

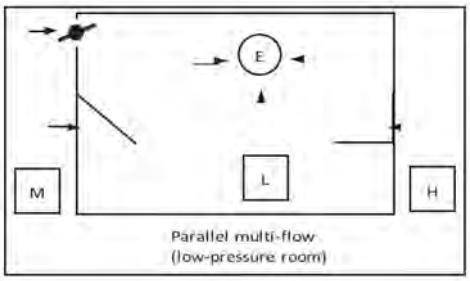


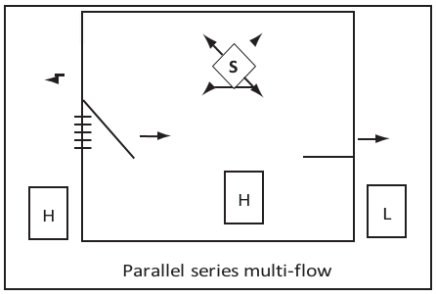
A8.15 These rooms will be either high- pressure or low-pressure with respect to the adjacent areas (see preparation lay-up room and disposal room, respectively, in standard layout 5 of Appendix 7). The pressure-relief damper is always situated between the room and area, which results in the smaller differential pressure to ensure best use of air.

A8.16 Just as reverse flow can occur if transfer grilles are used, it can similarly occur via door gaps when the other door is opened. It is not possible to avoid this, except by using air locks, but due to the low flow rates and short durations involved, this is not considered to be of importance.

Parallel-series multi-flow rooms

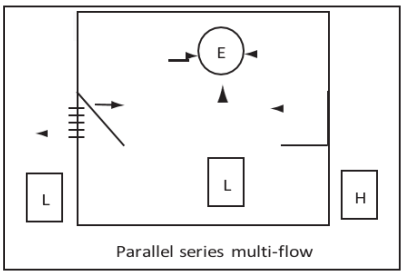
A8.17 These rooms are similar to those in paragraph A8.14 above, but because the room is of equal cleanliness to one of the adjacent rooms, the nominal pressures will be equal and air may flow through the adjoining doorway in either direction (for example the Prep (SPS) in standard layout 6 of Appendix 7).

Figure A18 Parallel, series multi-flow room solution high-pressure



A8.18 Where the nominal room pressure equals that of the higher-pressure adjacent room, the best use of air is by supplying air required for bacterial dilution only and allowing this to exhaust via a transfer grille to the area of equal cleanliness. The doorway to the lower pressure area is protected by the combination of the supply air and the air that will flow inwards through the transfer grille from the area of equal cleanliness.

Figure A19 Parallel, multi-flow room solution low-pressure

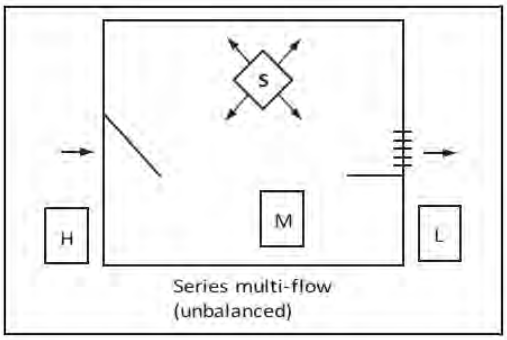


A8.19 Conversely, where the nominal pressure equals that of the lower-pressure adjacent room, extract ventilation and a transfer grille to the lower pressure adjacent room should be provided (for example the disposal room in standard layout 8 of Appendix 7).

Series multi-flow (unbalanced)

A8.20 These rooms are somewhat similar to those in paragraph A8.15 above, but because the pressure lies between that of the rooms on either side, the back-flow problem does not exist.

Figure A20 Series, multi-flow room solution medium-pressure



A8.21 Where the room has a net surplus of mechanical supply air, a transfer grille should be located in or adjacent to the door through which air flows outwards, and the mechanical supply flow rate to the room should be chosen to give protection when this door is open.

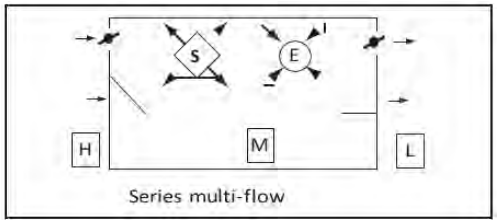
A8.22 Where the room has a net surplus of mechanical extract air, a transfer grille should be located adjacent to the door through which the air flows inwards, and the mechanical extract flow rate to the room should be chosen to give protection when this door is open.

A8.23 The grille should be sized for the protection requirement of the opposing door when open. When the room on the high-pressure side depressurises, there is a possibility of back-flow through gaps around the door, but this problem may be ignored.

Series multi-flow (balanced)

A8.24 In these rooms, a transfer device adjacent to each doorway is required in order to provide a flow path for the air required to protect the opposing door when opened.

Figure A21 Series, multi-flow room solution medium-pressure



A8.25 These transfer devices will normally be pressure stabilisers, although transfer grilles may be used where a large amount of excess air is to be exhausted from the operating theatre when all doors are closed (for example anaesthetic rooms).

A8.26 The calculation procedure is to assume that pressure stabilisers are being used; then – if there is sufficient excess air – change to transfer grilles as described in paragraph A8.50.

Bay

Open bay

A8.27 A bay of the open type (for example scrub-up) is considered to be part of the operating theatre. There should be an active or passive extract/pressure stabiliser under, or directly adjacent to, the scrub trough.

Semi-open bay

A8.28 In a bay of the semi-open type, protection of one area from the other is possible (for example scrub-up).

A8.29 As stated previously, the need for protection between operating theatre and scrub-room is not very great. Better use of air can therefore be achieved in this case by installing a pressure stabiliser between the scrub-room and clean corridor. This will allow a flow of air through the scrub-room at all times, except when a door is opened elsewhere in the suite. The pressure stabiliser will then close and the air will be diverted to the other door. When it is considered necessary to protect the scrub-room at all times, either a transfer grille to the corridor or mechanical extract in the scrub-room should be provided.

Operating theatre

A8.30 Once the peripheral rooms have been considered, the operating theatre requirements may then be decided and the supply flow rate required for air-movement control calculated. This flow rate should be such that, with any one door open, the correct air movement directions are maintained. There will be one door in the suite that will require the largest supply flow rate to the operating theatre for protection when open. This is called the “key door” and is discussed separately in paragraph A8.33. Use of this concept avoids repetitive calculations for each door in turn. Having established the required supply flow rate, a relief route should be provided to the clean corridor for any excess air when the doors are closed. This would be via transfer grilles or pressure stabilisers through a series-flow room or via pressure stabilisers to the clean corridor directly.

Corridors

A8.31 All surplus air from the suite, except that lost through structure leakage and any passing to the outer corridor, will arrive in the patient/staff corridor. Should this air be insufficient to achieve the required air- change rate (see Appendix 3), some additional air supply should be provided. (The air balance should take account of structural leakage.)

A8.32 Whereas the resulting pressures are dependent on ductwork layout, room relationships and characteristics of the fan, the generalisations shown in Appendix 6 may be used to estimate the change in room pressure when a door is opened.

A8.33 The “key door” will be the open double door which leaves the operating theatre at the highest pressure, and/or requires the largest air flow. This should be determined using the procedure in worksheet WS3.

Transfer grilles

A8.34 These may be used to limit the pressure differences across the closed door of a single-flow room or, in some instances, for protection of a series-flow or parallel-series-flow room. They allow air flow in both directions and may not be suitable for all applications.

A8.35 The free area of a grille is calculated from the following equation:

$$A = \frac{Q}{0.84\sqrt{\Delta P}}$$

where:

A is free area (m2)

Q is flow rate (m3/s)

P is pressure difference (Pa)

0.84 is the grille's resistance- correction factor.

A8.36 The flow through a grille at a different pressure may be found from the following equation:

$$Q_2 = Q_1 \sqrt{\frac{\Delta P}{\Delta P^1{}_2}}$$

where:

Q_1 and P_1 are original flow and differential pressure

Q_2 and P_2 are new flow and differential pressure.

A8.37 The transfer grille may be replaced by carefully proportioned door undercuts of the equivalent free area.

A8.38 The function of the transfer grille is to provide a means of air-flow control by which the volume and pressure loss can be established. If a grille is used, it should have an easily removable core to facilitate cleaning.

Pressure-relief dampers

A8.39 The functions of a pressure-relief damper are now carried out by pressure stabilisers. Accordingly, all mention of them has been removed from this document.

Pressure stabilisers

A8.40 Pressure stabilisers can be adjusted to hold the pressure constant over a wide range of flow rates. They are used where requirements exist for accurate room- pressure control or rapid shut-off on pressure fall.

A8.41 The installation of a grille or baffle in association with a stabiliser will alter the operating characteristics. It is recommended that a location be chosen to avoid the need for visual screening, for example, at high level. The location should be chosen to minimise the likelihood of damage.

A8.42 The stabilisers used should be virtually silent in operation, adjustable on site, maintenance-free and of a type which cannot be wrongly inserted. They should not be used in external walls or where the pressure difference is less than 5 Pa. The required size of a pressure stabiliser is dependent on the design pressure difference across it and flow rate through it. The manufacturer should provide data relating pressure difference to mean velocity (or flow rate per unit area). From this, the required area can be calculated and then rounded-up to the nearest size manufactured or nearest combination of smaller sizes.

A8.43 It is sometimes possible to arrange for a pressure stabiliser to perform two tasks. In an anaesthetic room, for example, the two pressure stabilisers may be made to pass the open door protection air, and also control the operating and anaesthetic room pressures with the door closed. To achieve this, the stabilisers are sized for the flow rate required with one of the doors open, but the pressure setting is adjusted to be the value required with the doors closed.

This is shown in Figure A22.

Door leakage flows

A8.44 For an air-movement control scheme to work satisfactorily, it is essential that the estimates of door-gap leakage made at the design stage are closely related to those which are achieved in practice. The calculation of gap-flows is complicated by the fact that such flows generally fall into the transition region between laminar and turbulent flow and hence do not follow the normal flow equations. The gaps assumed are 4 mm along the bottom, 3 mm at the top and sides, and 2 mm between double leaves. Doors should not have wider gaps than these. Tighter gaps would result in lower flow-rate requirements and hence lower fan power, but care should be taken to ensure that all doors in the suite have similar gap dimensions. It may be possible to

ignore the door leakage and so reduce the air-flow requirement (see the “designers’ notes” in Appendix 4).

Room temperature estimation

A8.45 The air-flow rate required to prevent back-flow through an open door is dependent on the temperature difference across the door. The design figures shown in Appendix 6 are based on the temperature differences that will normally occur in practice, assuming heat gains and losses in accordance with Appendix 4.

A8.46 At step 11 of the air-flow design process, the temperature differences across the doors of all rooms classed as “sterile” are calculated. Worksheet WS6 is recommended for the calculations, using the following criteria:

a. assume that the operating theatre is being controlled at 20ºC and calculate the incoming air-supply temperature as shown on worksheet WS6;

b. the calculation should be repeated for both summer and winter conditions, with an operation in progress;

c. assume all doors are closed;

d. use the room supply flow rates from WS1;

e. use the inward air flows through air-transfer devices and closed door leakages from WS2a to WS2E;

f. the formula used in worksheet WS6 is as follows:

$$T = \frac{(t_1 Q_1 + t_2 Q_2 + \ldots + t_n Q_n) + 0.828H}{(Q_1 + Q_2 + \ldots Q_n)}$$

where:

Q = flow rate from source (m3/s)

t = the temperature of source (ºC)

H = the room heat gain (kW).

A8.47 If the evaluated temperature differences between rooms do not exceed 2ºC, the solution is satisfactory; otherwise proceed as follows:

(i) check the assumption on which the heat gains are based;

(ii) take steps to reduce the heat gains;

(iii) if the door is to a corridor, the flow through the open door will be larger than the value given in Appendix 6. Calculate on WS3, assuming it is the “key door” with door-flow unknown, and the supply as known;

(iv) if the door leads to a room with mechanical supply, install a trimmer heater in the supply to the room controlled by either a differential thermostat or a

thermostat slaved to the operating theatre thermostat to ensure that T is minimised;

(v) if the door leads to a room with no mechanical supply, increase the door protection flow as follows:

$$Q_{new} = Q_{old} \quad \frac{2}{[\Delta T + 1]}$$

A8.48 These options should be considered in this order, and (i), (ii) and (iii) should be investigated thoroughly before proceeding to (iv) or (v). The mechanical supply may need to be increased in order to achieve the desired air-change rates.

Relief of excess air from operating theatre when all doors are closed

A8.49 As the mechanical supply to the operating theatre is sized to provide an appropriate flow outwards through any door which is opened, it follows that when all doors are closed, there will be more air supplied to the operating theatre than can exit from it via leaks etc. This “excess” air can be relieved by either of the two methods described in paragraphs A8.50– 8.54.

By transfer devices via the anaesthetic room

A8.50 The transfer device (pressure stabiliser or transfer grille) between the theatre and anaesthetic room needs to accommodate an air volume of 0.46 m³/s at 20 Pa (see Appendix 6) when the door between the anaesthetic room and corridor is open. An additional 0.11 m³/s will pass through the door gaps of the theatre to anaesthetic door to give a total door flow protection figure of 0.57 m³/s through the open door between the anaesthetic room and corridor. The optimum duty for this device with all the doors closed would be 0.33 m³/s at the room differential of 10 Pa. The following equation shows how this figure is arrived at:

$$Q = \frac{Q_1}{\left(\sqrt{\frac{\Delta P2}{\Delta P1}}\right)}$$

$$= \frac{0.46}{\left(\sqrt{\frac{\Delta 20}{\Delta 10}}\right)}$$

$$= 0.33 m^3/s$$

where:

Q = excess air to be vented with doors closed

$Q1$= airflow required for door protection through the transfer device

$\Delta P1$= nominal differential pressure with door to operating theatre closed and door to corridor closed

$\Delta P2$= nominal differential pressure between the operating theatre and anaesthetic room when the corridor door is open.

A8.51 If the excess air is less than 0.33 m3/s, a pressure stabiliser is required to ensure that the correct pressure and protection airflow is available to pass through the door.

A8.52 If the excess air is greater than 0.33 m3/s, a transfer grille is acceptable because at all times the airflow will exceed the flow required for pressure and door protection.

By pressure stabilisers to the corridor

A8.53 If it is undesirable to pass all the extra remaining air volume through the anaesthetic room after the door flow- protection volumes have been achieved, it may be passed from the theatre directly to the corridor via a separate pressure stabiliser.

A8.54 If there is sufficient excess air, the transfer grille solution at paragraph A8.52 should be adopted, as it provides the simplest solution and, once set up, will require no further maintenance. With less excess air, it is recommended that the air be passed through the anaesthetic room via the pressure stabilisers as at paragraph A8.51, thus keeping the number of pressure stabilisers to a minimum. Both these solutions increase the air-change rate in the anaesthetic room, but care should be taken to avoid passing excessive amounts through that would cause discomfort to the occupants.

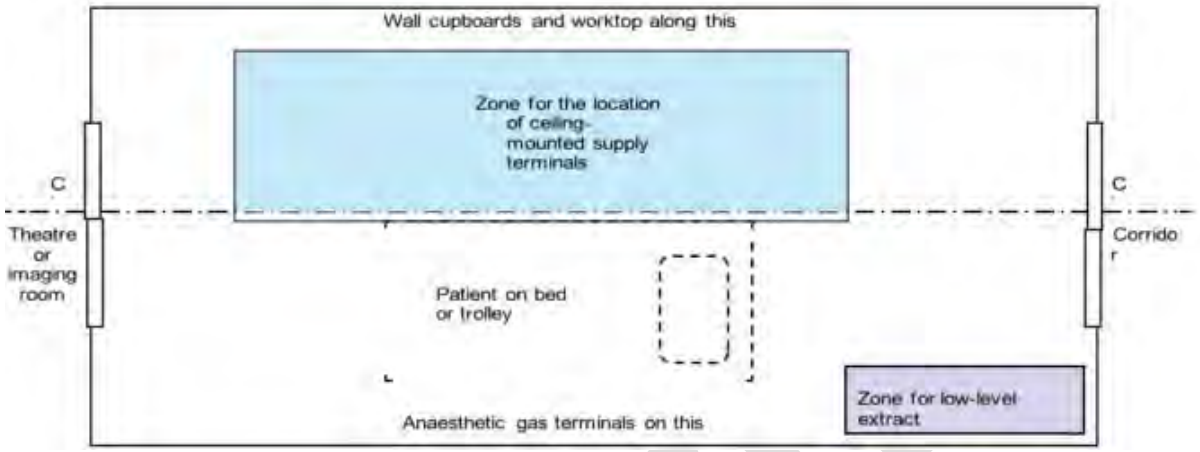
Appendix 9: Design of air- movement control scheme for anaesthetic room

General

Figure A25 Schematic of suitable supply and extract solution



The above shows the typical zones for the positioning of ceiling-mounted supply and low-level extracts in an anaesthetic room. The objective is to comply with the COSHH Regulations and SHTM 03-01 Part A by providing a clean airflow path for staff working in anaesthetic rooms and so reduce their risk of casual exposure to waste/leaking anaesthetic agents.

Note 1: Supply terminals should not be positioned above wall-mounted cupboards as this will prevent their output being measured directly with a balometer. It will also negatively impact on the air distribution within the room.

Note 2: See photographs below for details of the recommended low-level extract installation.

Note 3: Low-level extracts should have a spring-clip-retained pull-off grille face for ease of cleaning.

Low-level extract installation

Traditional installation (not recommended)

- Low-level extract easily obstructed by equipment
- Extra corners to clean around

Figure A26 Low level extract traditional installation (not recommended)

Recommended installation

- low-level extract cut back at 80º and stops short of the floor;
- no added detail to floor covering or coving;
- no additional corners to clean around;
- not easily obstructed by equipment;
- pull-off grille face for ease of cleaning;
- grille still accessible for airflow measurement.

Figure A27 Low level extract recommended installation

The photograph is for illustrative purposes only and shows a cutback of approximately 65º. This was found to make airflow measurement quite difficult, hence the change to an 80º cutback so that measurement can be easily taken with a balometer.

Operating theatre to anaesthetic room air-transfer device

The air-transfer device between an operating theatre and anaesthetic room may be either by a transfer grille or pressure stabiliser. The choice will be determined by the volume of air to be transferred.

Paragraphs A8.51 and A8.52 in Appendix 8 give details.

Appendix 12: Abbreviations used in this document

Table A15: Abbreviations and their meanings

Abbreviation	Meaning
ac/h	Air changes per hour
ACDP*	Advisory Committee on Dangerous Pathogens*
ACOP	Approved Code of Practice
AE(V)	Authorising Engineer (ventilation)
AGP	Aerosol-generating procedure
AHU	Air handling unit
AP(V)	Authorised Person (ventilation)
BESA	Building Engineering Services Association
BIM	Building Information Model
BMS	Building Management System
BEMS	Building Energy Management System
BS EN	British Standard European Number
BSRIA	Building Services Research and Information Association
CCA	Critical care area (Level 2 & 3 care)
cfu	Colony forming unit
CIBSE	Chartered Institution of Building Services Engineers
COSHH	Control of Substances Hazardous To Health
CP(V)	Competent Person (ventilation)
CT	Computed tomography (imaging)
DIPC	Director of Infection Prevention and Control
DOP	Dispersed oil particles
DX	Direct expansion (refrigeration cycle)
EC	Electronicaly commutated (fan)
EPA	Efficiency particulate air filter (E10 to E12)
ErP	Energy related products
EU GGMP	European Guide to Good Manufacturing Process (pharmacy)
GRP	Glass reinforced polymer
HBN	Health Building Note
HEPA	High efficiency particulate air filter (H13 to H14)
HIS	Healthcare Infection Society
SHTM	Health Technical Memoranda
IAP	Inspection, assembly and packing (room)
ISO	International Standards Organisation
Level 0 care	Patients whose needs can be met through normal ward care in an acute hospital
Level 1 care	Patients at risk of their condition deteriorating, or recently relocated from higher levels of care, whose needs can be met through normal ward care with additional advice and support from the critical care team.

Abbreviation	Meaning
Level 2 care	Patients requiring more detailed observation or intervention, including support for a single failing organ system or post-operative care and those 'stepping down' from higher levels of care.
Level 3 care	Patients requiring advanced respiratory support alone or monitoring and support for two or more organ systems. This level includes all complex patients requiring support for multi-organ failure.
LEV	Local exhaust ventilation
LSAPC	Light scattering airborne particle counter
MDR-TB	Multi-drug-resistant tuberculosis
MRI	Magnetic resonance imaging
NICU	Neonate intensive care unit
PFI	Private Finance Initiative
PPVL	Positive pressure ventilated lobby (isolation room)
PVC	Polyvinyl chloride
RH	Relative humidity
SCBU	Special care baby unit
SPATA	The Swimming Pool and Allied Trades Association
SUP	Supply air quality
SVHSoc	Specialised Ventilation for Healthcare Society
TB	Tuberculosis
TCP	Theatre control panel
UCV	Ultra clean ventilation
ULPA	Ultra low particulate air filter (U15 to U17)
UV	Ultraviolet
VAV	Variable air volume
VCD	Volume control damper
VSG	Ventilation Safety Group
WEL	Workplace exposure limit

Table A16: Symbols

Symbol	Meaning
ºC(db)	Degrees centigrade (Dry bulb) temperature
K	Kelvin (temperature difference)
% RH	Percentage relative humidity
L/s	Litres per second
µm	Micrometres, microns
ePM1, 2.5, 10	Particle size in micrometres
≥	Equal to or greater than

* ACDP Containment levels

Category 1 biohazard: a biological agent unlikely to cause human disease

Category 2 biohazard: a biological agent that can cause human disease and may be a hazard to employees; it is unlikely to spread to the community and there is usually effective prophylaxis or effective treatment available.

Category 3 biohazard: a biological agent that can cause severe human disease and presents a serious hazard to employees; it may present a risk of spread to the community, but there is usually effective treatment or prophylaxis available.

Category 4 biohazard: a biological agent that causes severe human disease and is a serious hazard to employees; it is likely to spread to the community and there is usually no effective prophylaxis or treatment available.

Acknowledgements

Health Facilities Scotland would like to thank the principal contributors and the Steering Group led by the Department of Health for their efforts in producing the HTM 03-01 Part A document.

HTM 03-01 Part A has been updated and amended by Health Facilities Scotland for use in NHSScotland as SHTM 03-01 Part A and the contribution from the National Heating & Ventilation Advisory Group is gratefully acknowledged.

Preface

About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Scottish Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.

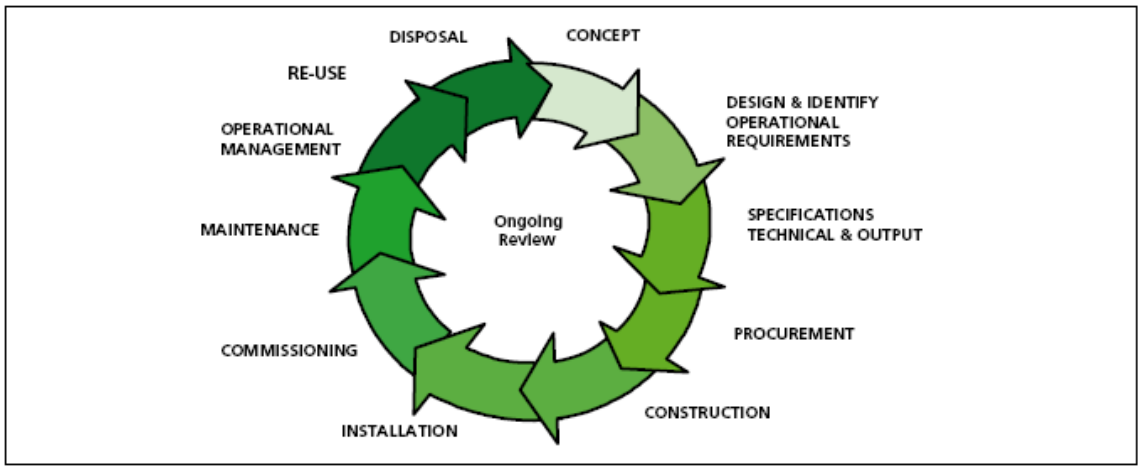
Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.



Healthcare building lifecycle

Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects:

Scottish Health Technical Memorandum 00: Policies and principles (applicable to all Scottish Health Technical Memoranda in this series).

Scottish Health Technical Memorandum 01: Decontamination.

Scottish Health Technical Memorandum 02: Medical gases.

Scottish Health Technical Memorandum 03: Heating and ventilation systems.

Scottish Health Technical Memorandum 04: Water systems.

Scottish Health Technical Memorandum 05: Reserved for future use.

Scottish Health Technical Memorandum 06: Electrical services.

Scottish Health Technical Memorandum 07: Environment and sustainability.

Scottish Health Technical Memorandum 08: Specialist services.

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical Services – Electrical safety guidance for low voltage systems.

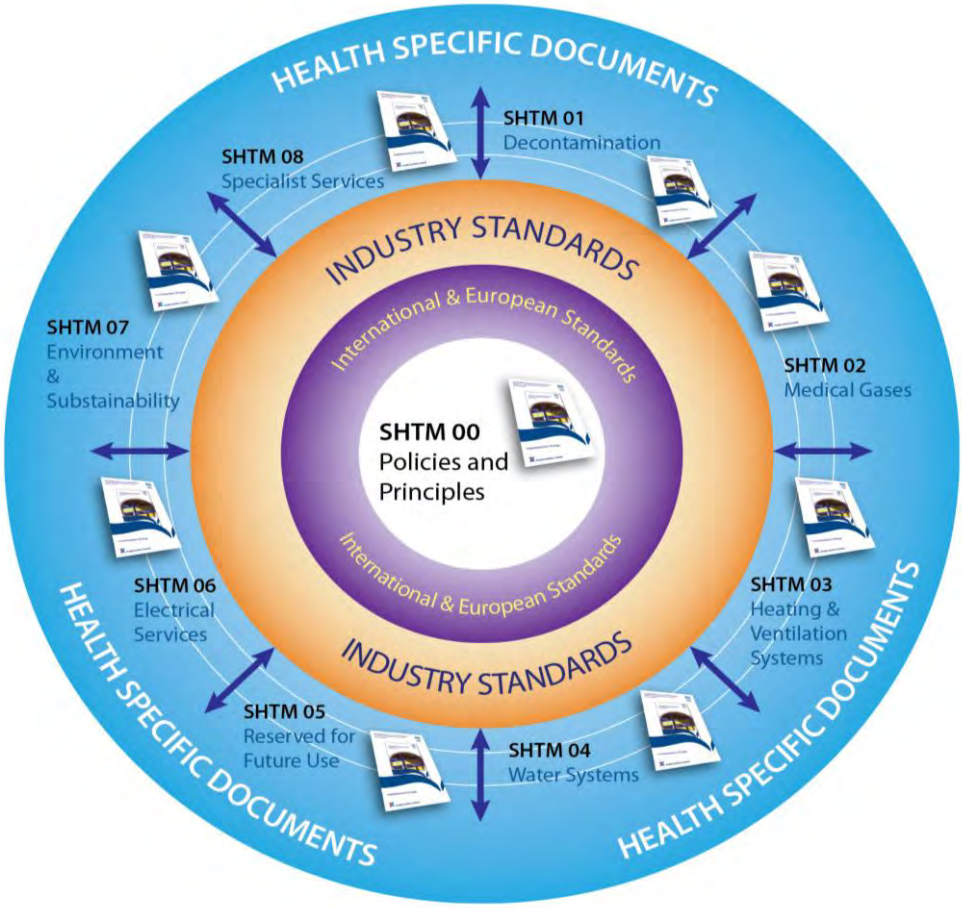
In a similar way Scottish Health Technical Memorandum 07-02 will simply represent:

Environment and Sustainability – EnCO_2de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management

and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.



Engineering guidance

1. Introduction

1.1 Ventilation is used extensively in healthcare premises or primary patient treatment in operating departments, high dependency units and isolation facilities. It is also installed to ensure compliance with quality assurance of processed items in pharmacy and sterile supply departments and to protect staff from harmful organisms and toxic substances, for example, in laboratories.

1.2 This edition of Scottish Health Technical Memorandum 03 'Ventilation in healthcare premises' is published in two sections. It is equally applicable to both new and existing sites. It gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations managers on the legal requirements, design implications, maintenance and operation of general and specialised ventilation in all types of healthcare premises.

1.3 Current statutory legislation requires both 'management' and 'staff' to be aware of their collective responsibility.

1.4 'Ventilation' is also provided in healthcare premises for the comfort of the occupants of buildings. More specialised ventilation will also provide comfort but its prime function will be to control closely the environment and air movement of the space that it serves in order to contain, control and reduce hazards to patients and staff from airborne contaminants, dust and harmful micro-organisms.

1.5 Ventilation systems in themselves present little danger to patients or staff. However, they do possess the ability to transmit hazards arising from other sources to large numbers of people. The danger may not become apparent until many patients and staff have been affected.

1.6 The sophistication of ventilation systems in healthcare premises is increasing. Patients and staff have a right to expect that it will be designed, installed, operated and maintained to standards that will enable it to fulfil its desired functions reliably and safely.

1.7 The Health and Safety at Work etc Act 1974 (HSW Act 1974) is the core legislation that applies to ventilation installations and these installations are intended to prevent contamination, control closely the environment, dilute contaminants or contain hazards. Their very presence indicates that risks to health have been identified.

Statutory requirements

1.8 The Control of Substances Hazardous to Health (COSHH) regulations place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised

ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and safety cabinets.

1.9 The existing requirements to provide ventilation, implicit under HSW Act 1974 and COSHH, have been made explicit by the Management of Health and Safety at Work Regulations 1999, the Workplace (Health, Safety and Welfare) Regulations 1992 and the Provision and Use of Work Equipment Regulations 1998, all issued as a result of European Directives.

1.10 Where specialised ventilation plant is provided as part of the protection measures there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of the COSHH regulations requires that the plant be inspected and tested at least every 14 months by an independent organisation and that management maintain comprehensive records of its performance, repair and maintenance.

1.11 Certain substances have Occupational Exposure Limits (OEL) set out in Guidance Note EH 40 published annually by the Health and Safety Executive. If special ventilation systems are provided in order to achieve these standards they will be subject to the COSHH regulations as above.

1.12 All ventilation systems should conform to the principles set out in the Approved Code of Practice and guidance document entitled “Legionnaires’ disease: the control of *Legionella* bacteria in water systems” (commonly known as ‘L8’) published by the Health and Safety Executive and Scottish Health Technical Memorandum SHTM 04-01: The control of *Legionella*, hygiene, “safe” hot water, cold water and drinking water systems.

1.13 Special ventilation plants installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified organisms, may be subject to particular legislation with regard to their operation in addition to that mentioned above. Further information is given by the Health and Safety Executive Health Services Advisory Committee in:

- safe working and prevention of infection in clinical laboratories;
- safe working and prevention of infection in clinical laboratories: model rules for staff and visitors;
- safe working and prevention of infection in clinical laboratories in the mortuary and post-mortem room.

1.14 Plants installed in units manufacturing medicinal products to the standards set out in the current European Guide to Good Manufacturing Practice may also be subject to particular legislation with regard to their operation in addition to that mentioned above.

1.15 Records should be kept of equipment design and commissioning information. The Health and Safety Executive, Medicines Inspectorate and other interested bodies have a statutory right to inspect them at any time. All records should be kept for at least five years.

1.16 The fire regulations require that if ventilation ductwork penetrates the fabric of a building it should be designed and installed so as to contain the spread of fire. (for further information refer to Firecode Series SHTMs 81, 83 and 85)

1.17 Increased health risks to patients will occur if the more specialised ventilation systems installed to supply high quality air to operating departments do not achieve and maintain the required standards. The link between post-operative infection and theatre air quality has been well established. Plants serving conventional operating departments, for instance, will be required to ensure the separation of areas within the suite by maintaining a specific direction of air flow between rooms, even when doors are opened. They will also maintain the selected operating department environmental conditions regardless of changes in the outside air conditions or activities within the space. In addition ultra-clean operating ventilation systems that are designed to provide an effectively particle-free zone around the patient while the operation is in progress, have been shown to reduce significantly post-operative infection in patients undergoing deep wound surgery. Their use for other forms of surgery may well be required.

1.18 Ventilation systems that can be shown to be inappropriate, inadequate or ineffective and that give rise to proven failures can result in a civil suit by the patient against the operators.

1.19 If the plant has been installed to dilute, extract or contain harmful substances (the definition of which now includes microorganisms) its failure may expose people to unacceptable levels of hazard. Proven failures can give rise to a civil suit against the designers and operators by the individuals who have been affected. This would be in addition to the actions brought as a result of breaching the statutory requirements.

1.20 There is a statutory requirement to provide ventilation in all enclosed workspaces. It may be provided by either natural or mechanical means. The following are some of the factors that determine the ventilation requirements of a workspace:

- human habitation (minimum fresh air requirement);
- the activities of the department, that is, extraction of odours, aerosols, gases, vapours, fumes and dust – some of which may be toxic, infectious, corrosive, flammable, or otherwise hazardous (see Control of Substances Hazardous to Health (COSHH) regulations;
- dilution and control of airborne pathogenic material;
- thermal comfort;
- the removal of heat generated by equipment (e.g. catering, wash-up, sterilising areas, electrical switch rooms, uninterruptible power supply (UPS) cupboards and some laboratory areas);
- the reduction of the effects of solar heat gains where other forms of reducing the solar effect is not available or practical, i.e. solar blinds;
- the reduction of excessive moisture levels to prevent condensation (for

example Hydrotherapy pools);

- combustion requirements for fuel burning appliances (see BS5376, BS5410 and BS5440);
- 'make-up' supply air where local exhaust ventilation (LEV) etc., is installed.

Mechanical ventilation systems are expensive in terms of capital and running costs, and planning solutions should be sought which take advantage of natural ventilation either where the use of the area in question is not critical to airflow patterns or pressures, or where backup systems are available when natural ventilation cannot be achieved.

1.21 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure.

Requirement	Reason	Application
Statutory	Health and Safety at Work etc Act	Operating department Laboratories Pharmacy
	COSHH regulations	Areas containing identified biological or chemical hazards Areas containing oxygen displacing gases
	Local Exhaust Ventilation (LEV)	Enclosed work-spaces Workshops
Functional	Comfort	Situations where the quality of the environment for staff and patients is critical to their general performance and well-being
Clinical	Post-operative infection reduction	Operating suites used for general surgery, casualty, obstetrics/gynaecological and maternity procedures
	Reduction of deep wound sepsis	Ultra-clean operating suites for transplant, deep wound surgery, hip replacement, bone grafting and bone marrow transplant procedures
	Isolation from contact with bio hazards	Isolation units for patients who present a biological, chemical or radiation hazard to others. Isolation units for patients with a reduced immune system

Table 1: Reasons for providing ventilation

Functional overview – Terms in use

1.22 The terms 'ventilation' and 'air-conditioning' are often incorrectly used to describe the same equipment. A general explanation of the terms is given below.

Ventilation

1.23 Ventilation is a means of removing and replacing the air in a space. In its simplest form this may be achieved by opening windows and doors. Mechanical ventilation systems provide a more controllable method. Basic systems consist of a fan and either collection, (extraction) or distribution (supply) ductwork. More complex systems may include the ability to heat and filter the air passing through them. Ventilating equipment may be required in order to remove smells, dilute contaminants and ensure that a supply of 'fresh' air enters a space.

Air-conditioning and mechanical cooling

1.24 Air-conditioning is the ability to heat, cool, dehumidify and filter air. For full air-conditioning, humidification may also be provided. This means that the climate within a space being supplied by an air-conditioning plant can be maintained at a specific level regardless of changes in the outside air conditions or the activities within the space. Mechanical cooling may be provided where close control of 'comfort conditions' within a space is required but humidity control is not needed.

Special ventilation

1.25 In healthcare premises, certain activities will necessitate the provision of ventilation equipment with additional special features in order to achieve and maintain specific conditions. These may be needed in order to assist with the treatment of patients or maintain the health and safety of staff. The precise reason for providing special ventilation will depend upon the intended application. The list below indicates some of the more typical reasons:

- to remove, contain or dilute specific contaminants and fumes;
- to ensure the isolation of one space from another;
- to preserve a desired air flow path from a 'clean' to a 'less clean' area;
- to provide control of the cleanliness of a space;
- to provide 'close' control of temperature;
- to provide 'close' control of humidity.

1.26 The following departments will usually have specialised ventilation requirements, either for a single room or throughout a suite of rooms:

- operating department;
- laser surgery unit;
- intensive treatment unit;
- infectious diseases isolation unit;
- manufacturing pharmacy;
- specialised imaging, X-ray and scanning unit;

- pathology containment laboratories;
- mortuary and dissection suite;
- research laboratory;
- sterilising and disinfecting unit (SDU);
- endoscopy unit;
- renal dialysis suite;
- ultrasound facilities;
- audiology room.

1.27 Ventilation may be provided in a wide variety of ways. These will include:

- extensive purpose-built air-conditioning units housed in their own plant rooms;
- proprietary 'packaged' systems often sited outside on a roof or;
- wall-mounted electric fans located at the point of use.

1.28 A fixed volume of air may be supplied, often expressed in terms of the resulting number of air changes per hour (ac/h) within the space being ventilated. It may also be expressed in terms of litres/second/person. Alternatively the volume of air supplied may be varied in order to maintain a specific pressure relationship between the area supplied and other surrounding areas. In some situations a combination of both methods may be adopted.

1.29 Modern plants are fitted with the means to recover energy from the extract air where this can be justified without causing contamination of the incoming supply air.

1.30 Ultra-clean systems use the same basic plant and equipment as standard air-conditioning but are in addition fitted with a terminal device that supplies the air in a unidirectional manner to the working area. Their standard of filtration will be capable of delivering air with a very low particle count to the space that they serve.

Local exhaust ventilation

1.31 Local exhaust ventilation (LEV) is a term used to describe systems installed to prevent hazardous substances from entering the general atmosphere of the room in which they are being used. Their primary function is to protect staff from the effects of their work activity.

1.32 Simple LEV systems comprise a capture hood, extract ductwork and fan. These are used to contain industrial types of hazard such as fumes from welding processes, gas discharges from standby battery banks and dust from woodworking machinery. The vapour given off when large quantities of chemicals are decanted into ready-use containers and fumes from X-ray film processing units are further examples of chemical hazards often controlled by LEV systems.

1.33 In laboratories, pharmaceutical manufacturing facilities and operating suites, LEV systems usually take the form of semi-open fronted cabinets within which the hazardous substance is manipulated. These cabinets either have their own filtered air supply or are fed with air from the room. The air extracted from the cabinet is passed through a high-efficiency filter before being discharged either to the atmosphere or back into the room. Microbiological safety cabinets, laboratory fume cupboards, cytotoxic drug cabinets and fixed or mobile disinfection enclosures are all examples of this type of facility.

1.34 Mortuaries and dissection suites may have LEV systems incorporated within the dissection table, specimen bench and bone saw.

Management action

1.35 The guidance contained in this SHTM should be applied in full to new installations and major refurbishments of existing installations.

1.36 Ventilation will need to be provided:

- as a requirement for patient care;
- in order to fulfil a statutory duty.

1.37 In assessing the need for more specialised ventilation and the standards desired for patient care, managers will need to be guided by their medical colleagues and by information published by Health Facilities Scotland.

1.38 The statutory need for ventilation falls into two categories:

- in the first, the need for specialised ventilation and the standards to be adopted are clearly set out in specific pieces of legislation. An excellent example of this is the current legislation surrounding the manufacture of medicinal products in the European Community. The managers of the departments affected by this type of legislative requirement should be aware of their needs and be able to advise on the standards to be achieved;
- the second type of statutory requirement arises due to the interpretation of both the Health and Safety at Work etc Act and the Control of Substances Hazardous to Health (COSHH) regulations. The person tasked with conducting COSHH assessments will be able to advise as to the need for, and standard of, ventilation in each particular case.

Design and validation process

1.39 It is essential when undertaking the design of a specialised ventilation system that the project be considered as a whole. The process model set out below should ensure that all relevant factors are considered.

Step	Question	Design statement and information required	Comment
1	Why is the system required?	Healthcare applications Statutory elements Non-healthcare applications	
2	What is the required system performance?	Room air flow pattern Air change rate Differential pressures Air quality Room air condition Noise limits	
3	What are the constraints on the distribution system?	Location, Size, Materials Dampers, Access, Insulation Fire considerations Room terminals	
4	What are the minimum requirements for the AHU(s)?	Intake / Discharge positions *Legionella*, Health and Safety Access, Fire, Electrical safety Leaks, Insulation, Cleanliness Filtration, Drainage	
5	What control functions are required?	User control requirements Estates control functions Energy management Environmental conditions Control sequence logic Run, Set back, Off philosophy	
6	How will the system performance be validated?	Validation methodology Instruments used Design information required [*Design air flow rates* *Design air velocities* *Pressure differentials* *Noise levels* *Air quality* *Installation standard*]	
7	The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.		
8	Handover to client	Basic design information Commissioning results Validation report	

Table 2: Design and Validation process model

Use and function of typical equipment used in ventilation plant

1.40 Typical equipment used in ventilation systems is listed below together with a brief description of both function and use.

General

1.41 The equipment built into the ventilation system and its ductwork should be of a type that will neither cause nor sustain combustion. No materials that could sustain biological activity should be used in the construction or assembly of the system.

Air Intake

1.42 An uncontaminated air supply to the system is essential. In order to achieve this, the air intake will be positioned so that air discharged from extract systems or other dubious sources cannot be drawn in. Exhaust fumes from vehicles can present particular problems. The area surrounding the intake will need to be kept clean and free of vegetation and waste material in order to reduce the possibility of biohazards or fire. The intake itself will be protected by a louvre and mesh screen to prevent rainwater, vermin and insects etc from entering the system.

Damper

1.43 Several types may be fitted:

- automatic dampers fitted immediately behind the air intake and extract louvres. They will automatically close when the system is shut down in order to prevent an uncontrolled circulation of air;
- balancing dampers are fitted into each branch of the air distribution ductwork system so that the design air flow rate can be set during the commissioning process;
- where ductwork passes through a fire compartment wall, ceiling or floor a fire and/or smoke damper may be required;
- plant isolating dampers are fitted so that the main plant can be isolated from its air distribution duct system. They are manually operated and enable cleaning and maintenance of the air-conditioning equipment to be carried out.

Ducting

1.44 The means by which air is conveyed from the intake to its point of use. Ducting is usually constructed of galvanised steel and will normally be insulated to reduce noise and conserve energy. Ducts can also be formed in concrete, brickwork, stainless steel or plastic and may be rigid or flexible.

Fan

1.45 A series of rotating blades that move the air in the direction required. Fans are usually powered by electric motors either directly connected to them or driven through belts and pulleys. A fan may be arranged either to force air into or draw air from a ductwork system.

Attenuator / silencer

1.46 A device that will contain and absorb the noise emitted by a fan. They may be required to reduce disturbance caused by noise breaking out through the air intake and also noise transmitted along the ductwork to the conditioned space.

Filter

1.47 A filter consists of a labyrinth of fibrous material contained in a frame. It is designed to capture and hold particles being carried in the airstream. Because of the size range and number of particles that exist in air no filter can remove them all. The purpose of filtration is to reduce their number and size range to an acceptable level. Filters of progressively higher grades are fitted through the ventilation system:

- primary filters (coarse) are designed to collect the larger particles and are intended to keep the air-conditioning plant clean;
- secondary filters (fine) will remove the staining particles from air and keep the conditioned space visibly clean;
- high efficiency particulate air filters (HEPA/absolute) will remove virtually all particles from air. These may be required in order to reduce contamination in the working area either biologically or in terms of particle count.

Filters may be fitted to extract systems to protect energy recovery devices. They may also be fitted to remove biological, radiation or chemical hazards and if so, are often contained in a 'safe change' facility in order to protect those carrying out maintenance.

Activated carbon filters will reduce odours in extracted or recirculated air.

Heater battery / heater coils

1.48 A series of heater batteries or heating coils with or without fins through which steam or hot water is circulated. Heat is given up to the air passing over the battery thus increasing its temperature. Heating is usually carried out in stages, the final battery being controlled by the end user. Small batteries may be electric.

Humidifier

1.49 A device for increasing the humidity of air by adding moisture. For ventilation in healthcare premises this is normally achieved by releasing 'clean' steam into an air supply duct. The steam will be completely absorbed into the air, increasing its humidity. The level of humidity may be preset or controlled by the end user.

Cooler battery / cooling coil

1.50 A series of finned coils mounted in the air supply duct. Either chilled water or refrigerant is circulated through the coils causing heat to be removed from the air. This will reduce its temperature and may also condense moisture out of the

air. As free moisture in a duct can be a source of contamination the coil will be fitted with an eliminator and drainage system.

Eliminator

1.51 A device for catching and removing water droplets from an air stream. It may form part of a cooling coil or be a separate device.

Drainage system

1.52 A means of removing water from ductwork and disposing of it safely. Typically it will consist of a tray mounted in the duct to catch moisture, a glass water seal trap, continuously falling drainage pipework and an air break in the drain run to prevent waste water returning and contaminating the duct.

Access doors and observation ports

1.53 Doors and removable panels providing access for routine maintenance and cleaning. The doors should be fitted with glazed ports and suitable lighting provided so that the correct operation of devices such as cooling coils, humidifiers and filters can be easily observed without needing to switch off the plant.

Energy recovery

1.54 Many plants are fitted with the means to recover energy from the extract air without causing contamination of the incoming supply air. These devices will be fitted with a drainage system and may incorporate an eliminator. Several types of energy recovery systems are available.

1.55 Precise definitions of ventilation and air-conditioning terms are given in the Chartered Institution of Building Services Engineers (CIBSE) Guide B.

Typical plant

1.56 The layout of a typical plant that conforms to the requirements for healthcare applications is shown in Figure 1 overleaf. It contains most of the equipment described above.

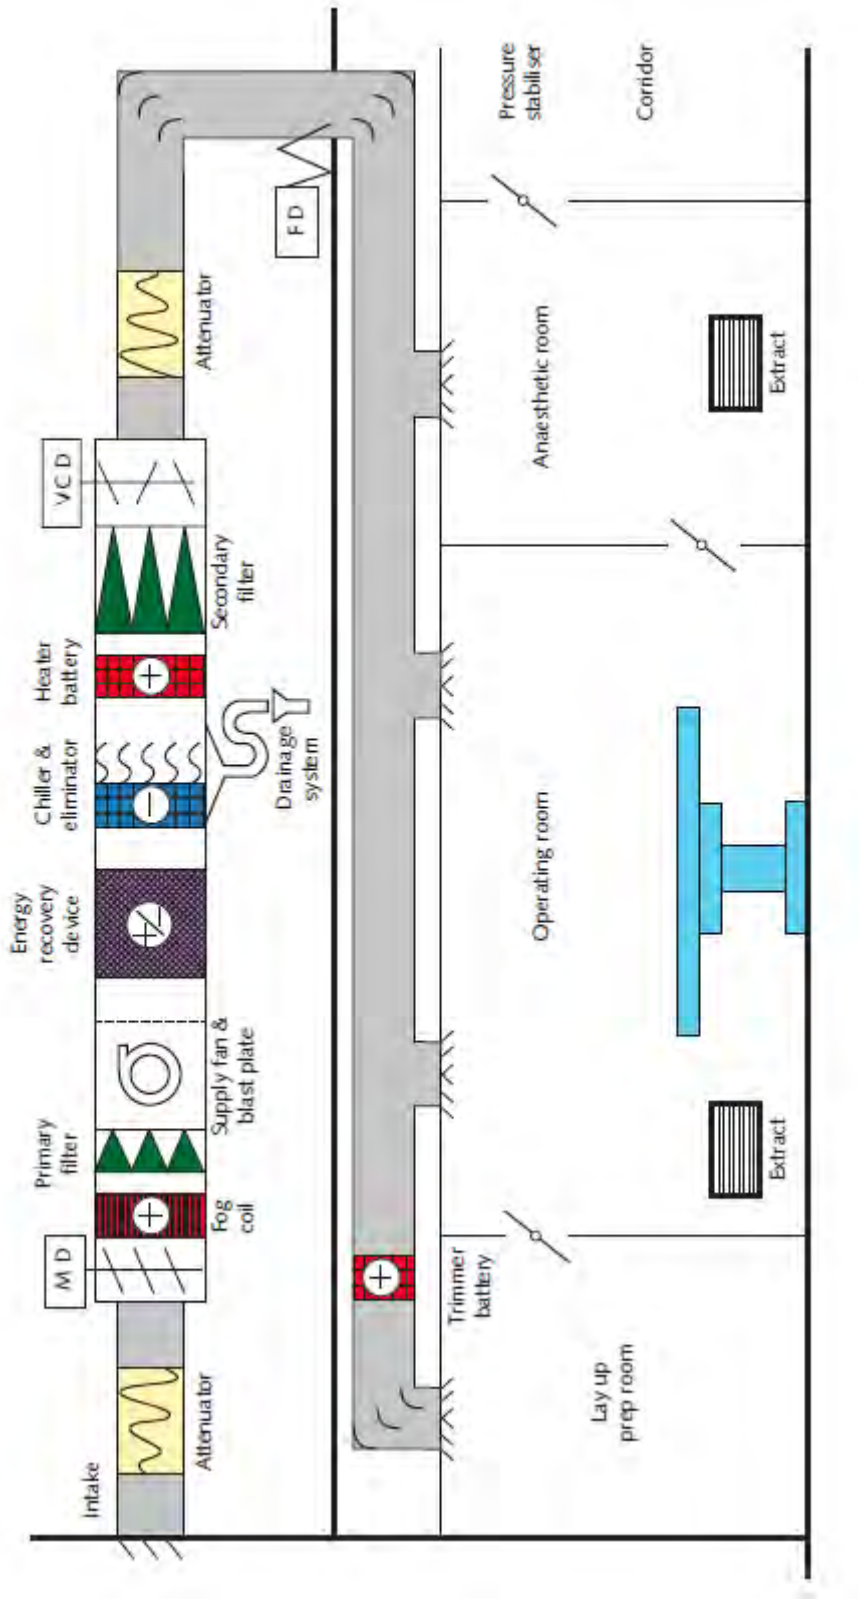


Figure 1: Design and Validation process model

A46676816

2. Provision of ventilation in healthcare buildings

2.1 It is acknowledged that planning constraints imposed by the building shape and/or functional relationships of specific areas will invariably result in some measure of deep planning thus reducing the opportunity for natural ventilation. However, ventilation costs can be minimised by ensuring that where practicable, core areas are reserved for rooms that have a functional requirement for mechanical ventilation. Examples are sanitary facilities, dirty utilities and those rooms where clinical or functional requirements have specific environmental needs; and where for reasons of privacy, absence of solar gain etc., windowless accommodation is acceptable. Other spaces appropriate to core areas are those that have only transient occupation and therefore require little or no mechanical ventilation, for example circulation and storage areas.

Natural ventilation

2.2 Natural ventilation is usually created by the effects of wind pressure. It will also occur if there is a temperature difference between the inside and the outside of the building. The thermo-convective effect frequently predominates when the wind speed is low and will be enhanced if there is a difference in height between inlet and outlet openings. Ventilation induced by wind pressures can induce high air change rates through a building provided air is allowed to move freely within the space from the windward to the leeward side.

2.3 As the motivating influences of natural ventilation are variable, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. This variability is normally acceptable for general areas including office accommodation, general wards, staff areas, libraries rooms, dining rooms and similar areas which should, where possible, be provided with opening windows of a design that facilitates natural ventilation.

2.4 Current guidance restricts the amount windows can be opened for safety reasons and as many designs are top-hung, their ability to permit natural ventilation is limited. It may therefore be necessary to provide dedicated ventilation openings in the fabric of the building to allow a sufficient natural flow of air into and out of the space. Paragraph 2.20 also refers.

2.5 In all cases, excessive heat gain, indoor air quality requirements or external noise may limit or preclude the use of natural ventilation.

Extract ventilation systems

2.6 Separate extract ventilation will be required for sanitary facilities, lavage areas, dirty utilities and in rooms where odorous, but non-toxic fumes are likely, in order to ensure air movement into the space. 10 air changes per hour have been found necessary, particularly in geriatric and psychogeriatric accommodation. This will assist with infection control procedures. A single

fan/motor unit can be suitable for individual rooms, but multi-room systems should be provided with duty and standby fans or motors to meet this need.

2.7 Toilets should have an extract ventilation rate as set out in the building regulations. Where WC's are located in shower and bathroom spaces, the ventilation required for the WC will normally be adequate for the whole space.

Supply only ventilation

2.8 Mechanical supply ventilation will be required in areas where it is important to maintain a positive pressure in order to prevent the ingress of less clean air, e.g. in pharmacy aseptic suites, sterile supply packing rooms, operating theatres and their preparation rooms (air change rates are given in Table A1).

Supply and extract ventilation

2.9 Mechanical supply and extract ventilation should be provided in rooms where there is a need to control room pressure in relation to adjacent spaces. Intensive Care Units, (ICU), isolation suites and treatment areas are typical applications.

Mechanical or comfort cooling

2.10 Cooling is very expensive in terms of energy costs and should be provided only where necessary to maintain a comfortable environment for staff and patient, or to ensure satisfactory operation of equipment. The imaging department in particular may require cooling to offset the equipment load.

2.11 Calculations and thermal modelling should be undertaken to ensure that during the summertime, internal temperatures in patient areas do not exceed 28ºC (dry bulb) for more than 50 hours per year taking into account the level of design risk for the application.

2.12 Certain non-patient areas may also require cooling and will typically include some laboratories, central wash-up and other areas that are subject to high equipment heat gains.

2.13 Where deep planning of other continuously occupied spaces, for example offices, is unavoidable, there will also be occasions when acceptable levels of comfort can only be maintained by cooling. Planning solutions of this type however will be exceptional.

2.14 Refrigeration plant should be of sufficient capacity to offset heat gains and maintain areas at a temperature that does not exceed the external design shade temperatures by more than about 3ºC taking into account the level of design risk for the application.

Air-conditioning

2.15 Full air-conditioning is only required in a very small number of areas within healthcare buildings and due to the capital and running cost its inclusion should be kept to a minimum. Paragraphs 3.14 - 3.15 and 4.91 - 4.93 also refer.

2.16 Areas whose functions may warrant the installation of air-conditioning include operating departments, intensive therapy units, manufacturing pharmacies and areas with particularly sensitive equipment.

Specialised ventilation

2.17 Due to the nature and extent of activities carried out in healthcare buildings, there will be a need for a wide range of specialised ventilation systems. The types of system which are generally required in individual departments and typical arrangements are given in Section 7.

2.18 The activities within some departments will require the provision of local exhaust ventilation (LEV). This is a statutory requirement under COSHH wherever the escape of chemicals, toxic fumes, biological material or quantities of dust into the general area would present a hazard to the occupants.

Ventilation for general areas

2.19 Table A1 provides recommended air change rates, temperatures and pressures for general areas that require mechanical ventilation in healthcare buildings.

Use of natural ventilation

2.20 The air tightness of new buildings has improved to the point that infiltration through building leakage can no longer be relied upon to provide sufficient air-flow. Attention must therefore be given to the provision of purpose-made ventilation openings to achieve the necessary flow rates. The air entering the openings may need to be controlled by motorised dampers linked to temperature and / or occupancy sensors in the ventilated space.

2.21 Internal partitions, fire compartment walls and closed doorways can often impede the flow path, and when this happens, the process will be more dependent on single-sided ventilation. Nevertheless, even with this degree of compartmentation, acceptable ventilation may still be achieved without window openings that would prejudice safety, security or comfort.

2.22 Some types of window, for example, vertical sliding, can enhance single sided air change by temperature difference, and these will improve the overall rate of natural ventilation in protected or sheltered areas where the effect of wind pressure is likely to be minimal.

2.23 It is generally considered that natural cross-flow ventilation is able to give reasonable air distribution for a distance of up to 6 metres inwards from the external façade, provided that reasonably clear air paths are maintained. Beyond this distance in areas where clear air paths cannot be maintained and in areas where high minimum air change rates are specified, mechanical ventilation should be provided.

2.24 Further information can be found in SHTM 55 ‘Windows’, BS5925 ‘Code of practice for ventilation principles and designing for natural ventilation’ and

CIBSE Applications Manual AM10: 'Natural ventilation in non-domestic buildings'.

Mixed mode ventilation

2.25 This comprises an assisted form of natural ventilation. Fans are fitted in the purpose made damper-controlled ventilation openings. Alternatively a separate ventilation unit may be installed. In both cases the dampers and fans are controlled under the dictates of temperature and occupancy sensors to ensure a minimum air flow rate while taking advantage of natural ventilation effects when present.

2.26 Where natural or mixed mode ventilation is adopted with complex air paths, the designer should produce an air flow diagram in order to ensure correct provision of air transfer devices. CIBSE Applications Manual AM13: 'Mixed mode ventilation in non-domestic buildings' gives guidance.

Mechanical extract ventilation

2.27 General extract systems can vary in complexity from a single wall-mounted fan to a ducted air system with dual extract fans.

2.28 Replacement air is generally provided by a central supply system (as described below). Unless special precautions are taken, the latter may result in an unacceptable level of draughts occurring in winter, and possible risk of unacceptable levels of noise transmission.

2.29 If individual systems are used, the ventilation can be operated intermittently, provided it continues to run for at least 15 minutes after the room is vacated, as with light switch-operated fans in individual toilets.

2.30 If general exhaust systems are used; it is recommended that filtered and tempered replacement air is provided via a central supply plant to adjoining lobbies or corridors, to prevent the risk of discomfort caused by the ingress of cold air. Fire compartmentation requirements must be maintained.

2.31 Information on specialised extract systems is given in Section 7.

Mechanical supply systems

2.32 Where mechanical supply systems are required, the fresh air should be tempered and filtered before being delivered to the space, to avoid discomfort.

2.33 The air should be heated using a constant or variable temperature source, but generally only to the space air temperature. In most instances, the low-pressure hot water heating (LPHW) should offset any fabric loss, so that setback room temperatures can be maintained during unoccupied periods without the need for the ventilation system to operate.

Balanced ventilation

2.34 Balanced ventilation systems are merely a combination of a supply and extract systems of equal volume; and either a single space or a whole building may be considered to be balanced. A balanced system is necessary in instances where it is essential to maintain consistent air movement within an area, for example, treatment rooms.

Cascade ventilation

2.35 In operating departments it is normal practice to supply air to the operating room, and allow it to pass through less clean areas – corridors, utility rooms etc. (from where it is eventually extracted).

Recirculation systems

2.36 Due to the nature of the use of mechanical ventilation systems within healthcare buildings, there are few opportunities for the application of recirculation air systems. They are however normally used for HEPA filtered clean room applications where the extract air is significantly cleaner than the outside supply. Recirculation is also routinely used in the canopy section of Ultra Clean Operating theatre ventilation systems.

2.37 Where the designer is considering the installation of a recirculation air system, due account must be taken of:

- minimum fresh air supply volume required by the Building (Scotland) Regulations 2004 (currently 20%);
- prevention of contamination of supply air from vitiated air in extract systems;
- prevention of stratification occurring within plenum chambers and mixing boxes which may result in freezing of downstream coils;
- ensuring sufficient velocities through control dampers (ideally 5-6m/s) to provide suitable authority; and good shut-off;
- modulating control of mixing to provide optimum on-plant conditions;
- use of ‘free cooling’ by cycling the dampers to minimum fresh air when the enthalpy of the outside air is above that of the extract air under conditions when cooling is required.

Chilled beams

2.38 The use of chilled beams for the provision of heating, cooling and ventilation is increasingly common in healthcare premises. The use of Active Chilled Beams providing tempered filtered air to a heating / cooling device within the room can provide effective local control of environmental conditions.

2.39 Care should be taken in positioning chilled beams to ensure the avoidance of cold draughts particularly when used in the cooling mode. The control settings should ensure that the external elements of the beam are always above dewpoint.

2.40 Consideration should be given to the ease with which specific types of chilled beam units can be accessed for cleaning having regard to the need to control the infection risk. The impact of maintenance requirements on room availability should also be considered.

Split comfort air-conditioners

2.41 Split comfort air-conditioners, room conditioners or cassette units are used increasingly where there is a small local requirement for cooling for operational purposes. They can provide an effective economic solution to cooling needs, where a central refrigeration system is not practicable.

2.42 The units re-circulate room air so provision for a fresh air make up, either by natural or mechanical means, to the standard required by the Building (Scotland) Regulations must be provided.

2.43 The recirculation of room air presents problems with indoor air quality (IAQ) and may increase the risk of healthcare associated infection (HAI). Split units should not therefore be used in critical patient areas.

2.44 Split units may be used for single room applications or as multiple linked units that can independently provide either heating or cooling, all served by a single outdoor unit. These systems enable good temperature control of a number of rooms with maximum energy efficiency.

2.45 Whether single or multiple systems are used, it is essential that the designer gives due consideration to the source of electrical supply, location of the heat rejection unit, environmental effects to the refrigerant used and drainage provision for the cooling coil condensate.

2.46 The units will require routine maintenance for filter change and cleaning; they should therefore be installed in an accessible position.

Dilution ventilation and clean air flow paths

2.47 Dilution ventilation has in the past been used to control levels of hazardous substances in a space. This approach is no longer considered acceptable. The COSHH Regulations require that known hazardous substances should be substituted by safe alternatives. If this is not possible then they should be controlled at source by the use of closed systems such as anaesthetic gas scavenging units or exhaust protective enclosures such as fume cupboards.

2.48 The exposure of staff to casual spillages of substances such as medical gases in anaesthetic rooms should in the first instance be dealt with by establishing a clean airflow path. Air should be supplied at high level and extracted at low level directly behind the anaesthetic equipment position. The philosophy of establishing a clean air-flow path from the supply point; to the staff; on to the patient and out via a low level extract would also apply in recovery rooms and maternity delivery rooms including labour, delivery, recovery & post partum (LDRP) Rooms. A suitable air change rate will provide dilution ventilation as an additional safeguard; see Table A1, Table A2 and Note c.

2.49 In operating theatres the patient will be on a closed breathing circuit in a room with a high air change rate. Under these circumstances the dilution effect would be considered sufficient to control any casual exposure to anaesthetic gases.

Mechanical ventilation systems

System selection

2.50 Natural ventilation is always the preferred solution for a space, provided that the quantity and quality of air required, and the consistency of control of ventilation to suit the requirements of the space, are achievable with this method. If this is not the case, a mechanical ventilation system will be required.

Choice of central/local plant

2.51 Mechanical ventilation is expensive to operate, and as such, should be controlled to operate when the space being served requires to be ventilated. In addition, loads on refrigeration plant are rarely constant owing to changes in solar gain, occupancy and use of heat-generating equipment and lights, therefore control of temperature is critical.

2.53 If the ventilation loads throughout a department or building are in phase, or are not significant, a central plant with single zone control can be adopted. However, this is rarely the case, and elsewhere, the condition or quantity of supply air to different areas or zones of the building must be varied accordingly. This can be done by providing either individual plants to each zone, or separate zone terminal control. Where there is a high density of rooms with similar ventilation requirements in an area of a building or department, it is usually economical to combine them into a central system.

2.54 In large buildings, a choice between a single distribution system and multiple smaller systems may arise. Large distribution systems and their plant can have the advantage of lower operating costs, but require more space for vertical shafts and horizontal distribution. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage, and difficulties in balancing during commissioning. As the pressure losses in the long runs will be greater and a higher initial static pressure will be required, this will lead to a more expensive class of ductwork. Multiple smaller distribution systems may be more expensive in capital and operating costs but they avoid long runs, large ducts and vertical shafts, and this may reduce overall building costs. They also provide a more robust service as the failure of an individual system does not prevent the use of the rest of the building.

Zoning of the building

2.55 The efficiency and effectiveness of any ventilation or air-conditioning installation depends largely on the zoning and control of the installation. The factors to consider when determining the zoning of a ventilation system for a building or department are:

- periods of occupancy;

- fresh air/ventilation requirements;
- smoke control.

2.56 Where the ventilation system is not merely tempering the air, but also providing the heating and/or cooling requirements, the following additional factors will need to be considered:

- internal or peripheral location;
- orientation of windows;
- variation in internal loads;
- level of control required.

2.57 For single zone plant in staff areas, local control (with a run-on timer if required) is recommended, as this can be turned off when the space is not in use, thus saving both thermal and electrical energy. Most supply and extract systems, conversely, are required to operate continuously while the department is occupied, thus some form of time or use control is necessary.

2.58 The control of individual plant items is covered in Section 4, with examples of typical control strategies in Section 6. For control of particular specialised ventilation and air-conditioning systems refer to Section 7 of this document.

2.59 On very rare occasions a duplicate standby air handling plant may be justified. If installed it must be provided with a gas-tight damper at its junction with the supply distribution duct, so that no back-flow can occur. Standby plants can become sources of contamination if warm moist air is allowed to dwell within them. Their design and control system must ensure that this cannot happen.

Specific requirements for hospital departments

2.60 Specific requirements for individual spaces and departments are included in the Health Building Notes (HBNs) and Activity Database (ADB) A-Sheets, or Scottish Health Planning Notes (SHPNs).

3. Assessment of service requirement

Selection of design criteria

External design conditions

3.1 The most accurate data that is available for the summer and winter conditions at the site should be used. The Metrological office can supply data for the United Kingdom.

3.2 Healthcare mechanical ventilation systems will normally be 'full fresh air'.

3.3 Local adjustments such as for height above sea level, exposure factor, or other climate peculiarities, should be made as appropriate.

Internal design conditions

3.4 The design conditions selected within patient areas must strike a balance between the comfort requirements of staff and patients, who often have very different levels of clothing and activity.

3.5 Recommendations for the dry resultant temperature and humidity of individual spaces are shown on Activity Database (ADB) A-Sheets. Table A1 gives a summary.

Minimum fresh air requirements

3.6 For most applications involving human occupancy, the dilution of body odours is the critical factor in determining ventilation requirements. Where natural ventilation or mechanical full fresh-air systems are used, all ventilation air will be fresh.

3.7 Where odour dilution is the overriding factor, it is recommended that 10 litres/second/person should be taken as the minimum ventilation rate.

3.8 Smoking is not permitted in healthcare premises. If permitted for example in residential care, it will be confined to designated areas. It therefore follows that these areas will contain a high percentage of smokers so the ventilation rate would be at least 36 litres/second/person for these applications (CIBSE Guide A; Table 1.10 refers).

3.9 In non-standard applications such as laboratories, aseptic suites, operating departments, etc., the particular requirements for each area should be considered independently in order to determine the overriding minimum requirement for ventilation.

Limiting supply air conditions

3.10 For most applications in healthcare buildings, it is the temperature differential between the supply and room air, rather than the actual temperature of the

supply air which is the critical factor. The maximum recommended supply-to-room air temperature differential is:

summer cooling: - 7K

winter heating: + 10K

3.11 It is also necessary to keep supply air humidity below 70% during winter in order to minimise risks associated with condensation.

Air purity

3.12 In healthcare premises, the standard of filtration will depend on the activities within the occupied spaces. With the exception of special areas, (for example manufacturing pharmacies), the requirement for aerobiological needs is not stringent and filtration is only required to:

- maintain hygienic conditions for the health and welfare of occupants, or for processes such as food preparation;
- protect finishes, fabrics and furnishings; to reduce redecoration costs;
- protect equipment either within the supply air system; that is, to prevent blocking of coils, or in the space itself to prevent dust collection.

3.13 Given that almost all viable particles will originate from the occupants of a space and not from the incoming air, dilution is the more important factor aerobiologically. Therefore, for general areas a G4 filter will be suitable. More critical areas will require a F7 filter. HEPA filters will only be required in Ultra Clean systems.

Humidity control requirements

3.14 Providing humidification is expensive in terms of plant, running costs and maintenance, and therefore its use should be restricted to where it is necessary for physiological or operational reasons.

3.15 Humidification was originally required for some healthcare applications, e.g. operating theatres, in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.

Maximum noise levels

3.16 Noise will be generated in an air distribution system by the fan, ductwork fittings, dampers and grilles. The specified maximum noise level will depend on the activities within the occupied spaces.

3.17 The overall noise levels should not exceed the values given in Scottish Health Technical Memorandum 08-01: ‘Acoustics’, although general requirements are given in Table 3.

3.18 Attenuation should be incorporated into the ductwork system or plant arrangement as necessary to reduce noise from fans and plant items in order to achieve the acceptable limits within the rooms at the design air flows.

3.19 Plant noise should not be greater than 80dB(A) within the plant room from the fans, coolers, heaters, humidifiers etc. when starting up or running, and should be reduced to lower noise levels where the plant is near to departments sensitive to noise.

3.20 Attention must be given to the reduction of tonal components. High tonal components from air diffusers etc. can seriously disturb concentration over longer periods even when the overall noise level is low. Broadband noise causes less annoyance. Reference should be made to SHTM 08-01: 'Acoustics'.

3.21 The designer requires knowledge of the total hospital layout and operational policies, to assign acceptance magnitudes to all the possible noise sources, in order to arrive at the correct rating.

Room	Overall noise level - NR	Ventilation plant commissioning - NR	Ventilation plant design - NR
Operating department	50 (55)	45	40
Ward areas	33	30	30
Sanitary facilities	45	40	35
Industrial areas	50	45	40
Circulation areas	50	45	40

Table 3: Interior noise level

3.22 In Table 3, above, the overall noise level takes account of all internal and external noise sources. The commissioning noise level is the level measured with a sound level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use, this commissioning level will constitute a continuous background noise which will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise that must be considered in the overall design, that is, in specifying the attenuation of walls, partitions, ceilings, etc.

3.23 The recommended criterion is measured as the "A" weighted sound pressure level expressed in decibels, which should not be exceeded for more than 10% of the time.

3.24 The designer must also consider noise escaping to the external environment and this must not be unacceptable to occupants of adjacent buildings.

Calculation of building loads

Air infiltration

3.25 Air infiltration occurs due to a complex combination of wind pressure, thermal effects, location relative to other features and the construction standard of the building. The infiltration rate is governed by the size and number of openings in the building envelope and the complexity of internal air paths.

3.26 CIBSE Guide A (2006) Section 4 provides information and formulae for the calculation of air infiltration and natural ventilation of buildings. In all cases the requirements of the appropriate section of the Building (Scotland) Regulations must be met.

Summertime temperatures

3.27 The calculation method for determining the summertime temperature is described CIBSE Guide A (2006) Section 5. However, it is very important to select the time of day and time of year of peak loadings for the calculations. These will be dependent on the orientation and proportion of solar to total heat gain. In establishing outside design values, the design risk having regard to the function and occupancy of the building should be considered.

3.28 Where calculations indicate that internal temperatures will frequently exceed the selected design external shade temperature by more than 3K for a period that exceeds the building design risk, methods of reducing temperature rise should be implemented. Options include: - reducing solar and casual gains, the use of chilled beams or ceilings, increasing ventilation rates or providing mechanical cooling. In some situations it may be possible to alter the thermal mass of the structure to 'move' the peak temperature event time so that it occurs outside of the occupancy period. Calculations and thermal modelling should be undertaken to ensure that during the summertime internal temperatures in patient areas do not exceed 28°C dry bulb for more than 50 hours per year. It has been found that there is a relationship between preferred indoor temperatures and mean outside temperature. Fig A2 in CIBSE Guide A indicates this relationship.

Peak heating load

3.29 Peak heating local calculations are necessary on all mechanical supply systems to establish the size of heater batteries and subsequently the central plant.

3.30 Where ventilation systems provide tempered air to spaces that have supplementary LPHW to offset the building fabric losses, the plant heating load should be calculated based on the external winter design temperature, the design internal air temperature, and the calculated total air volume (including a suitable allowance for leakage).

3.31 Where the ventilation system is the only means of heating a space, an increase in load equivalent to the calculated fabric heat losses from the space should be added to the ventilation load. A check of supply temperature difference should

be made. If it exceeds 10K the ventilation supply volume should be increased to suit.

Condensation risk

3.32 A check should be made to ensure that the selected air condition will not lead to surface condensation on low-temperature elements of the ventilated space.

3.33 Where there are local sources of moisture that would require excessive levels of ventilation to avoid condensation, the designer should consider the capture and removal of moisture at the source of the evaporation via an exhaust hood or similar device.

3.34 In intermittently heated buildings, it is necessary to consider the condensation risk at night setback conditions as well as during normal operation. Calculation methods for this assessment are given in CIBSE Guide A.

Peak cooling load

3.35 In addition to the base data of airflow rates and temperatures, when calculating cooling loads, the designer must take into account:

- solar cooling loads;
- surface conduction cooling loads;
- internal gain cooling loads;
- cooling loads due to high-level humidity control;
- method of control of internal conditions;
- fluctuations in internal temperatures.

3.36 When the peak internal loads have been assessed and a suitable allowance made for non-coincidence, the supply temperature can be calculated.

3.37 Once the lowest required supply temperature of the air handling unit has been established, and an allowance made for temperature rise through the fan and ductwork (usually 1K for low pressure systems), the off-plant enthalpy can be established from a psychrometric chart or table.

3.38 The cooling loads for all plants on the chilled water system should be calculated at each of the individual peak times in order to establish accurately the required (diversified) capacity of the chiller.

Annual energy consumption

3.39 Annual energy consumptions of heating-only ventilation systems are simple to calculate based on supply-to-external air temperature rise, and frequency of occurrence of external temperatures as given in CIBSE Guide A.

3.40 Minimum air volumes are usually fixed by the room loads or fresh air requirements. However, the designer may increase airflow to some rooms or

zones in order to balance loads, as detailed in the following paragraphs on "Calculation of plant requirements."

3.41 The method of zoning and control can significantly influence energy consumption.

3.42 The nature of air-conditioning operation, comprising cooling and reheating for humidity or zonal temperature control, makes prediction of energy consumption very complex. It is imperative that these calculations are performed to ensure optimum energy efficiency.

3.43 The concept of load and plant operation charts is outlined in the CIBSE Guide A. The method requires the designer to establish the minimum and maximum loads on all zones across the range of external temperatures between winter and summer design conditions. Once the load chart is complete, the plant chart converts the loads to supply temperatures, which are then superimposed on external air temperatures.

3.44 When all temperatures for all zones are plotted on the plant operation chart, set points and resetting schedules can be established. From this information, the outputs of individual heaters, coolers and humidifiers can be established at any given external temperature. When those loads are computed against annual frequency of occurrence of external temperatures as given in CIBSE Guide A, the annual energy consumption of individual elements, and thus the air-conditioning system, can be established.

3.45 In order to prevent surface condensation occurring, it is necessary to provide sufficient ventilation to maintain the maximum and ambient dew-point temperature below the lowest surface temperature, the coldest usually being the glazing. Paragraphs 3.33 and 3.34 also refer.

Calculation of plant requirements

Air supply volumes

3.46 The minimum air supply volume for a room is determined by the greatest of these three criteria:

- the minimum fresh-air requirement;
- the minimum supply volume for the room load as determined by the maximum heating or cooling supply temperature differential;
- the desired/required air change rate.

Plant sizing

3.47 Once the design airflow has been established the cross-sectional area of the air-handling unit can be calculated based on a maximum coil face velocity of 2.0 m/s.

3.48 In order to establish the length of the air-handling unit, it will be necessary to refer to manufacturers' literature, ensuring all necessary access panels and components are included as detailed in Section 4.

3.49 The fan duty should be calculated by adding the resistances of all elements that contribute to the pressure drop of the index circuit.

3.50 The main elements that must be considered are:

- inlet or discharge louvres;
- plant entry and discharge;
- attenuators;
- components within the air-handling unit;
- duct-mounted heaters and filters (including a dust allowance);
- ductwork distribution;
- ductwork fittings, including: fire dampers, volume control dampers, bends and sets, tees, changes of section;
- air terminal device;
- discharge velocity.

3.51 Where packaged air-handling units are installed, the fan pressure drop is usually quoted as external plant resistance, and thus the designer does not need to calculate the resistances of individual plant items. The designer should, however, ensure that an allowance has been made for filter clogging; and confirm whether the fan pressure quoted is fan total or static pressure.

3.52 Resistances of ductwork and fittings may be obtained from the CIBSE Guide A. However, the designer should exercise some care when using tabulated pressure loss information for fittings that are relatively close together.

3.53 Upon completion of the resistance calculation exercise, the designer should make allowances for calculation and construction tolerances as indicated in Table 4.

Criteria	Low pressure systems	Medium/high pressure systems
Volume flow rate margin for leaking and balancing requirements	+5%	+5%
Total pressure loss margin A. for increase in volume flow rate (above)	+5%	+5%
B. for uncertainties in calculation	+5%	+10%
Combined total pressure loss margin	+10%	+15%

Table 4: Typical fan volume and pressure margins

Plantroom size and location

3.54 The ventilation plant and associated equipment should be positioned to give maximum reduction of noise and vibration transmitted to sensitive departments; while at the same time, achieve an economic solution for the distribution of services.

3.55 It is not recommended that noise and vibration generating plant be housed either directly above or below sensitive areas (for example, operating or anaesthetic rooms) unless there is no alternative, in which case, additional care and attention must be given to the control measures.

3.56 The plant must also be located so that it is remote from possible sources of contamination, heat gains and adverse weather conditions. The design should ensure that wind speed and direction have a minimal effect on plant throughput.

3.57 Safe access to and around plant is essential to facilitate inspection, routine maintenance, repair and plant replacement.

Provision of primary services

3.58 Where more than one air-handling plant requires cooling, remote central cooling plants with piped chilled water are preferred. In the case of a single plant, a multi-stage direct-expansion cooling coil with refrigerant piped from an adjacent compressor/condensing plant could be considered. If this option is selected, a refrigerant gas detector mounted in the base of the duct and an alarm system audible to the end-user will also need to be provided (as dictated by COSHH Regulations).

3.59 Clean dry steam is preferred for humidification, provided that the boiler water treatment does not render the steam unusable for direct humidification.

3.60 If a suitable supply of steam cannot be obtained from the steam main, a steam generator should be provided locally, or a self-generating humidifier installed. Electric humidifiers require considerable electrical loads and if a gas supply can be derived, this would be preferable. The location of a local steam generator is critical if condensate is to drain back into it.

Inlet and discharge sizing and location

3.61 Air intakes and discharge points should preferably be located at high level, to minimise the risks of noise nuisance to surrounding buildings, contamination and vandalism.

3.62 Intakes and discharges should be designed and located so that wind speed and direction have a minimal effect on the plant throughput.

3.63 Helicopter landing pads in the vicinity of ventilation intakes and discharges can result in large short-term pressure changes. This can cause pressure surges in supply systems and reverse airflows in extracts. Exhaust fumes from the helicopter may also be drawn into intakes. For general information, refer to Health Building Note (HBN) 15-03 – Hospital helipads.

3.64 Intake points should also be situated away from cooling towers, boiler flues, vents from oil storage tanks, fume cupboards and other discharges of contaminated air, vapours and gases, and places where vehicle exhaust gases may be drawn in.

3.65 Where intakes have necessarily to be sited at or near ground level, the area around them should be paved or concreted to prevent soil or vegetation being drawn in. They should also be caged or located within a compound to prevent rubbish being left in the vicinity. The likely proximity of vehicle exhausts should also be taken into account when determining the protected area around the intake.

3.66 The discharge from an extract system must be located so that vitiated air cannot be drawn back into the supply air intake or any other fresh-air inlet. Ideally, the extract discharge will be located on a different face of the building from the supply intake(s). In any event, there must be a minimum separation of 4 metres between them, with the discharge mounted at a higher level than the intake.

3.67 Discharges from LEV systems should preferably be vertical and usually not less than 3m above roof level. They should not be fitted with a cowl that could cause the discharge to be deflected downwards.

3.68 Each intake and discharge point should be fitted with corrosion-resistant weatherproof louvres or cowls to protect the system from driving rain. Louvres should be sized based on a maximum face velocity of 2 m/s in order to prevent excessive noise generation and pressure loss.

3.69 The inside of the louvres should be fitted with a mesh of not less than 6mm and not more than 12mm to prevent leaves being drawn in and infestation by vermin.

3.70 The duct behind louvres should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system.

3.71 Cleaning access must be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a common plenum is provided, cleaning access should be via a walk-in door.

Heat rejection devices

3.72 The design conditions given in Section 2 make no allowance for the elevated temperatures that can occur on the roof of buildings. Refrigeration condensers should, if practicable, be shaded from direct solar radiation, or the design adjusted to take account of the gain.

3.73 Air-cooled condensers must always be the first choice for heat rejection from any refrigeration plant. Evaporative cooling systems must not be used in healthcare premises.

3.74 Reference should be made to Scottish Health Technical Memorandum 04-01: 'The Control of *Legionella*, hygiene, 'Safe' hot water, cold water and drinking

water systems, Part A: Design, Installation and Testing, and Part B: Operational Management, published by Health Facilities Scotland, 2011.

A46676816

4. Air handling unit design and specification guidance

General requirements

Location and access

4.1 Air-handling units should be located in an accessible area secured from unauthorised entry. Siting units in ceiling voids above occupied spaces is not appropriate.

4.2 Units located on roofs must have a safe means of access together with suitable precautions to prevent personnel or equipment falling or being blown off during maintenance activities.

4.3 Units located at ground level should be secured within a locked compound to prevent unauthorised access. Measures should be taken to exclude vehicles from the vicinity to ensure that exhaust fumes will not be drawn into intakes.

4.4 Units may have a working life of approximately 20 years. It can be anticipated that over this period there will be a need to access every element within the unit for deep cleaning. It is also quite possible that the main fan and individual heater and chiller batteries will need replacement. Suitably positioned service connection joints and adequate spacing should permit these items to be withdrawn without the need to dismantle other installed plant or equipment. Batteries significantly wider than 1 metre should be split to permit withdrawal from both sides.

4.5 It is essential that air-handling units are positioned so that all parts are easily and safely accessible for routine inspection and service. If a unit is located against a wall or backs onto another unit then access to all parts must be available from the front. Units greater than 1 metre wide should preferably have access from both sides or access doors large enough to permit the full and safe entry of maintenance personnel.

4.6 Water may be used during routine cleaning or spilt when maintenance is being undertaken. The area around the unit should be tanked to prevent water penetration to adjacent areas and adequately drained.

4.7 Fire precautions should be incorporated in accordance with Firecode. Guidance is available in BS5588: Part 9 and Sections 5 and 6 of this document.

4.8 Combustion equipment must not be located in a fire compartment that houses air-handling equipment.

Technical requirements

4.9 The basic technical requirements of the whole of the ventilation system should meet the relevant clauses of the Model Engineering Specification. It should be noted that the Specification contains a menu of clauses that cover a wide range

of applications, so it is important to select only those that are relevant to the specific application.

Note 1: At the time of writing, Model Engineering Specification C04 was listed for revision in order to bring it into line with the revised standards as set out in this Scottish Health Technical Memorandum. Where conflicts in specification arise, the Scottish Health Technical Memorandum takes precedence.

4.10 It is essential that the main plant/ductwork is located far enough above the floor to permit the correct installation of drainage systems for cooling coils, humidifiers and heat recovery systems. Easy access for maintenance of drainage systems and their associated pipework must be provided.

4.11 Organic materials or substances that can support the growth of microorganisms must not be used in the construction of the plant or its distribution system. The water fittings and materials directory lists suitable materials for sealants and gaskets.

4.12 The plant and its distribution system must not contain any material or substance that could cause or support combustion.

4.13 Plants should have a high standard of air-tightness. The double-skin method of construction with insulation sandwiched between two metal faces is recommended. The panels may be available in a variety of colours at no additional cost. This can aid identification by colour coding of units in a plant room (for example green for general ventilation; blue for theatres; red for laboratories and isolation facilities; grey for extract etc).

4.14 The inside of the plant should be as smooth as possible. Channels, rolled angles or formed sections that could trap or hold moisture should be kept to a minimum. If stiffeners are required, they should be fitted externally. If internal bracing has to be fitted it must be of a design that will not trap or hold moisture.

4.15 Airflow across air treatment components such as filters, heat exchangers and humidifiers will be influenced by the pattern of the approaching airstream. If unsatisfactory conditions are created, the performance of the component will be reduced.

4.16 Access to items that require routine service such as filters, frost batteries and chiller batteries should be via hinged doors. The doors should be large enough (for example 500mm minimum) to allow easy access. Items requiring infrequent access such as attenuators may be via bolted-on, lift-off panels. All doors and panels should be close-fitting and without leaks.

4.17 Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access.

4.18 It can be difficult to turn off AHUs in order to inspect filters and drainage trays. Viewing ports and internal illumination will therefore facilitate routine inspection of such items. Viewing ports should be at a convenient height so that temporary ladders are not required. Internal illumination should be provided by

fittings to at least IP55 rating. Fittings should be positioned so that they provide both illumination for inspection and task lighting. All of the lights in a unit should be operated by a single switch.

4.19 Access to AHUs and items in the distribution system such as filters or heater / chiller batteries should be via fixed ladders and platforms or pulpit-style moveable steps. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow the pulpit steps to be easily wheeled into position.

AHU drainage system

4.20 All items of plant that could produce moisture must be provided with a drainage system. The system will comprise a drip tray, glass trap, air break and associated drainage pipework.

4.21 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent 'pooling', it is essential that the drain connection should not have an upstand; and that a slope of approximately 1 in 20 in all directions should be incorporated to the drain outlet position. The tray must be completely accessible or, for smaller units, easily removable for inspection and cleaning.

4.22 Each drip tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed thus giving an early indication of corrosion, biological activity or contamination within the duct. The trap should have a means for filling and incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting it to the drainage tray should have a continuous fall of not less that 1 in 20.

4.23 Traps fitted to plant located outside or in unheated plant rooms may need to be trace-heated in winter. The trace-heating must not raise the temperature of water in the trap above 5°C.

4.24 Water from each trap must discharge via a clear air gap of at least 15mm above the unrestricted spill-over level of either an open tundish connected to a foul drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish providing each has its own air break.

4.25 Drainage pipework may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22mm and a fall of at least 1 in 60 in the direction of flow. It should be well supported and located so as not to inhibit access to the AHU.

Layout of air handling unit

4.26 The AHU should be arranged so that the majority of items are under positive pressure. Any item of plant requiring a drain should be on the positive pressure side of the fan. A recommended layout is given in schematic from in Figure 3.

4.27 A separate extract unit will generally be required for the area served by each supply unit.

4.28 An energy recovery system will normally be fitted between the supply and extract units.

Provision of dampers

4.29 Fire- or smoke-actuated dampers shall be provided at the locations required by Firecode. (See Paragraphs 5.17 - 5.21).

4.30 Motorised low-leakage shut-off dampers should be located immediately behind the intake and discharge of each supply and extract system respectively. They should be of the opposed-blade type, opening through a full 90° and must close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow.

4.31 The quality of motorised dampers is critical. They should be rigid, with square connections fitted with end and edge seals of a flexible material and with minimal play in linkages. The leakage on shut-off should be less than 2%.

4.32 A manually operated isolating damper should be installed between the main AHU and its distribution system to enable the unit to be isolated when cleaning is in progress.

4.33 Good practice will require the fitting of a main volume control damper so that the design airflow rate can be set at commissioning. The damper should be lockable in any position. If it will also be used for plant isolation, it should be capable of being reset to give the design airflow without the need for re-measurement.

4.34 Internal plant isolating dampers or provision for the fitting of shut-off plates between items within a unit are not required.

Vibration

4.35 Vibration from a remote plantroom can be transmitted by the structure of the building, may be regenerated and may sometimes be magnified many times. Units should be selected to have the minimum vibration generation and installed on suitable anti-vibration mounts. Pipe and ductwork should incorporate anti-vibration couplings, preferably in two planes at right angles, as close to the vibration source as possible. Consideration should be given to the use of anti-vibration pipe hangers and supports.

Sequence of components

4.36 The following arrangement of plant components is typical although in many instances not all elements will be required:

- fresh air intake;
- motorised isolation damper;

- frost / fog coil;
- pre-filter;
- energy-recovery device;
- attenuator;
- fan;
- blast plate;
- attenuator;
- chiller battery;
- eliminator;
- heater battery;
- humidifier;
- final filter;
- isolation / volume control damper.

Note 2: Attenuators may be located in the intake and discharge duct if they are of a suitable type (See Paragraphs 4.159 - 4.162)

There may be instances where the above arrangement is not appropriate and the plant arrangement should be planned accordingly.

Fans

General requirements

4.37 The fan should be selected for good efficiency and minimum noise level, but the overriding factor should be the selection of a fan characteristic such that the air quantity is not greatly affected by system pressure changes due to filters becoming dirty or external wind effects.

Acceptable types

4.38 Fans can be of the axial, centrifugal, cross-flow, mixed-flow or propeller type, depending upon the requirements of the system.

4.39 Where used, centrifugal fans should preferably be of the backward-blade type. Alternatively, where noise levels are more critical and pressure requirements are lower, forward-curved blade fans are acceptable. For high-power applications, aerofoil-blade fans may be appropriate.

Selection

4.40 Generally, large ventilation systems will use centrifugal fans due to their efficiency, non-overloading characteristics, and developed pressures.

4.41 Forward curved centrifugal fans can overload if allowed to handle more air than they are designed for.

4.42 Alternatively, it may be appropriate to use mixed flow fans in high-pressure systems.

4.43 Axial flow or propeller fans are generally only used in local through-the-wall systems, or systems with very low pressure requirements.

4.44 Cross-flow fans have very low operating efficiencies, and thus their use is restricted to applications such as fan coil units.

Location and connection

4.45 Fans are normally positioned to 'blow through' the central plant so that the cooling coil and humidifier drains will be under positive pressure.

4.46 The fan performance figures given by manufacturers in their catalogue data are based on tests carried out under ideal conditions, which include long uniform ducts on the fan inlet/outlet. These standard test connections are unlikely to occur in practice, the designer should therefore ensure as far as is practical that the fan performance will not be significantly de-rated by the system. This objective can be approached by ensuring that the fan inlet flow conditions comprise uniform axial flow velocities with low levels of turbulence.

4.47 Where the outlet duct is larger than the fan discharge connections, there should be a gradual transition, with a following section of straight duct, having a length equivalent to three duct diameters.

4.48 The design of the fan intake connection must be carefully considered to avoid swirl in the airstream. When the air spins in the same direction as the impeller, the performance and power consumption of the fan are reduced. When the air spins in the opposite direction to the impeller the power consumption and noise will increase with hardly any pressure increase. Airstream swirl is usually induced by large variations across the fan intake caused by the air passing round a tight bend immediately before the intake.

4.49 Where a centrifugal fan is located with an open intake, the clear distance between the suction opening and the nearest wall should be not less than half the diameter of the inlet. If two fans with free inlets are positioned within the same chamber, their adjacent suction openings should be at least 1 diameter apart.

4.50 Airtight flexible joints should be provided at fan inlet and outlet connections. They should be equal in cross-section to the points of connection and be neither longer than 200mm nor shorter than 100mm.

4.51 For centrifugal fans, a diffuser screen / blast plate should be fitted immediately downstream of their discharge.

Supply fan drive arrangements

4.52 Where the fan drive is via a motor-driven belt and pulley, it should be external to the air stream. This arrangement has the following advantages:

- the fire risk is reduced;
- the drive is visible so it is simple to check that the belt is still there;
- particles shed from the drive belt are outside of the air stream;
- if the belt slips, the “burning rubber smell” is not transmitted down into occupied areas of the premises;
- noise generated by the motor and drive will not be transmitted along the ductwork;
- waste heat is excluded from the system;
- the drive may be through a vee or toothed belt and pulley. The latter have the advantage of eliminating belt squeal on start up and have a longer service life. They are particularly suitable where the fan drive motor is fitted with a soft start and should be located external to the air stream.

4.53 The drive train should be easily visible without the need to remove access covers. Protecting the drive train with a mesh guard is the preferred option. For weatherproof units designed to be located outside, the fan drive will be external to the duct but enclosed. It should be easily visible through a viewing port with internal illumination and access via a lockable hinged door.

4.54 For direct-coupled fan and motor units, the motor should be out of the air stream.

4.55 For induction drive ‘plug’ motor arrangements (where the motor is fitted within the fan and is integral to it) and in line axial fans with a pod motor; the fan / motor combination may be within the air stream provided the motor windings are protected from over temperature by a thermister and lockout relay.

Extract fan drive arrangements

4.56 The preferred method where the fan drive is via a motor driven belt and pulley arrangement will be to locate it external to the air stream.

4.57 The fan drive and motor may be located inside the duct within the air stream provided the motor windings are protected from over-temperature by a thermister and lockout. The drive train should be easily visible through a viewing port, have internal illumination and access via a lockable hinged door.

4.58 Where the system air is explosive, aggressive or has high moisture content, the extract fan motor must be located outside the air stream. This is generally achieved with axial fans by using a bifurcated unit.

Control

4.59 Fans in healthcare applications are normally either single or two-speed. Where there is a requirement for two-speed operation, this is generally via a local user control (for example, in a hood extract system to provide a boost facility) or via a time schedule for energy saving during unoccupied periods.

4.60 Normally only a single motor is required with a standby motor available for fitting as necessary or fitted but not belted. Twin, run and standby motors - with the standby being jockeyed around - are not required.

4.61 Where there is a specified requirement for standby fans, the system should incorporate an automatic changeover facility activated via an airflow sensor. Fault indication should be provided.

4.62 The control of fans in terms of start-up and run is increasingly being vested in computer software. Inverter-drive, variable-speed, soft-start systems are becoming a standard approach. It should be remembered that most healthcare applications require known amounts of air to be delivered while the system is in use. Constant volume systems that deliver specified air-change rates are therefore the norm. Duct- or room-pressure-controlled, variable-speed systems have a very limited application in healthcare.

4.63 It is necessary to ensure that - should the computer control system or its software develop a fault - then the fan can be switched to a direct-start, fixed-speed, manual operation. This is particularly important for critical care systems serving operating suites, high-dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites. Off-site software support is no substitute for the ability of on site staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff.

Heater batteries / heater coils

General requirements

4.64 Frost batteries are installed to protect the downstream filters from low-temperature, high-humidity intake air conditions. As they handle unfiltered air they should be constructed of plain tubing without fins and be as near to the outside as possible to minimise condensation during cold weather. Access for cleaning will need to be provided to both sides of the coil.

4.65 Where steam coils are used for a frost battery, they may be constructed using spiral-finned copper tube. As they will be prone to fouling the tube layout and spacing should permit easy access for regular cleaning.

4.66 Main and branch heater-batteries should be constructed of solid-drawn copper-tube coils with copper fins, generally connected in parallel.

4.67 Where there is a wet heating system in the areas served, the main heater-battery should be sized for the ventilation requirements only, and not for the fabric loss.

4.68 Access for cleaning must be provided to both sides of all frost batteries and heater-batteries.

Acceptable types

4.69 Electric, water or steam heater-batteries may be considered. However, electric heater-batteries are expensive to operate and where there are alternatives, their use should be restricted to low-power use (for example trimming control).

4.70 Where steam-supplied heater-batteries are used, their control, venting and trapping systems should be designed so that a vacuum cannot occur within the coil. The condensate drainage arrangements should not allow pressure to build in the main resulting in a back-up of condensate in the coil.

Location

4.71 Where possible, wet-trimmer heater-batteries should be located in plant areas.

4.72 Where it is necessary to locate heater-batteries in false ceilings etc, consideration should be given to the use of electric heaters. If this is not practicable, drip-trays should be installed under both the battery and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.

4.73 Auxiliary fan coil units should not be installed in the ceiling above an occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the department that they serve.

Control

4.74 LPHW frost coils should be controlled by an off-coil temperature sensor operating a motorised valve to provide a minimum plant “on temperature” of between 2°C and 5°C. The off-coil temperature of the frost coil is generally sensed by a serpentine thermostat downstream of the coil or upstream of the next plant item. This thermostat will shut the fan down if any part of the air stream is below the minimum set-point.

4.75 Steam-supplied frost coils should be fitted with an on/off control operated by a temperature sensor mounted upstream of the battery. These are normally set to open the control valve fully when the outside temperature drops to +1°C. This will ensure that there is no standing condensate in the base of the coil.

4.76 The main heater-battery should be controlled in the same manner under the dictates of either an off-coil temperature sensor, or a room temperature sensor, depending on the plant configuration and method of control. Trimmer heater-

batteries are generally controlled by one or more averaging temperature sensors within the room or rooms in the zone.

4.77 Heater-battery control valves should drive to a closed position on system shutdown or fan failure. The control system should then automatically set to provide frost protection.

Cooling coils

General requirements

4.78 Cooling coils will need to be decontaminated periodically. They must have good access both up and downstream. Hinged access doors with viewing ports and illumination inside the duct should be provided both sides of the coil.

4.79 An eliminator will be required downstream of all cooling coils. The eliminator may take the form of an extension of the coil fins or be a separate device. If a separate device it should be removable as a unit to permit cleaning of the coil face.

4.81 4.80 All cooling coils must be fitted with their own independent drainage system as specified above. A baffle or similar device must be provided in the drip tray to prevent air bypassing the coil. The tray should be large enough to capture the moisture from the eliminator, bends and headers. Where coils are greater than 1m high, intermediate drip-trays will be required.

4.82 Condensate traps manufactured from Borosilicate Glass will allow easy visual inspection and incorporate a self-cleaning smooth non-porous internal surface, complying with ISO 3585 and BS2589 Part 1.

Selection

4.83 Cooling coils supplied with chilled water are the preferred option. For small loads or where chilled water is not available, direct expansion coils may be used.

4.84 Care must be taken in selection to minimise electrolytic action resulting from condensation on the airside. Coils constructed from copper tubes with copper fins extended on the downstream side in the form of an eliminator and electro-tinned after manufacture are preferred. Aluminium fins should only be used if vinyl-coated.

4.85 All parts of the coil and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Pressed steel coil headers, even if treated, have been shown to be prone to corrosion over time and should not be used. Steel mounting frames and casings present similar problems hence stainless steel is preferred.

Location

4.86 Microorganisms that multiply in moisture cannot be avoided when the coil is dehumidifying. However, locating the final filter downstream of the coils will reduce the risk of infection.

4.87 Cooling coils in AHUs should be located upstream of the final filter.

4.88 Where any cooling coil has to be located above a ceiling, drip-trays should be installed under both the coil and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. To facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.

Control

4.89 There are two basic methods of control for cooling coils:

- off-coil control – used in multi-zone systems or single-zone systems where close humidity control is required, to provide a constant maximum off-plant condition which satisfies the temperature and high humidity requirements of the zone with the highest load;
- sequential control – used in single-zone systems, or multi-zone systems with averaging sensors where close control is not required. A room or duct temperature sensor controls the cooling coil and heater battery in sequence to maintain constant room conditions.

4.90 The advantage of off-coil control is that accurate humidity control can be provided without relying on humidity sensors, which are prone to inaccuracy and drift. Off-coil control is however, expensive to operate in terms of energy consumption, due to the fact that there is no feedback of room loads, and thus at low loads and in systems where there are large zonal variations, significant over-cooling and reheating will occur.

4.91 On systems with two-speed operating, it is usual to isolate the cooling coil upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the cooling coil must be isolated.

Humidifiers

Design need

4.92 Humidification was originally required for some healthcare applications in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.

4.93 Operating-theatre AHUs do not generally require humidifiers but provision for their retrofitting in terms of space provision and a capped drainage system should be provided.

4.94 Where humidification is required, it will be subject to the specific requirements set out below. These are intended to ensure that the unit will operate safely and not become a source of contamination.

General requirements

4.95 The most important requirement for a humidifier is to create complete mixing of the steam with the air. The manufacturers' instructions should be followed regarding minimum distances which should be allowed before bends or other components. This is particularly important with respect to a filter mounted downstream. If it becomes saturated by the humidifier, organisms can grow through the filter and be released into the duct. These may then be carried on the airstream into an occupied space.

4.96 The section of ductwork containing the humidifier may need to be periodically decontaminated. Hinged access doors with viewing ports and internal illumination should be provided. A label warning that the device emits live steam and should be isolated prior to opening should be affixed to the access door.

4.97 All parts of the humidifier and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Stainless steel is preferred.

4.98 The electrodes of self-generating electrode-boiler type humidifiers should be stainless steel.

4.99 All humidifiers must be fitted with their own independent drainage systems as detailed in Paragraphs 4.20 - 4.25 or 4.72 and 4.87.

4.100 For self- and locally-generated steam humidifiers, the cleanliness of the water supply is essential for their safe operation. Provision should be made for draining down supply pipework and break tanks for periodic disinfection and cleaning during periods when they are not required in service.

4.101 The addition of treatment chemicals for continuous control of water quality for humidifier/air handling units should be avoided. Consideration could be given to installing a UV system to control microbiological growth. Given the limitations of UV systems, however, this will require filtration to high quality to ensure the effectiveness of exposure of organisms to the UV irradiation. As with all water treatment systems the unit should be of proven efficacy and incorporate UV monitors so that any loss of transmission can be detected.

Acceptable types

4.102 Only steam-injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. Water humidifiers of any type should not be used.

4.103 Steam may be derived from the central steam supply provided that it does not contain any treatment carry-over, or generated locally either within or adjacent to the humidifier.

4.104 The introduction of steam should be by an appliance specially designed to discharge dry steam into the air-conditioning system without objectionable noise or carry-over of moisture.

4.105 During the design stage, consideration should be given to the proposed methods for the regular cleansing of the humidifier(s) and their components.

Selection

4.106 The number and length of steam-injection manifolds to be used is dependent on various factors such as duct cross-sectional area, air velocity, dry-bulb temperature and manifold design. Guidance from the manufacturer should be followed closely.

4.107 A mains steam humidifier can be noisy and will be difficult to control if it is operated at an excessive steam pressure. It should be sized for an operating pressure of approximately 1 bar. The pipework supplying it should be provided with a dirt pocket, pressure reducing valve and steam trap installed as close as practicable to the humidifier, so that the steam condition at entry is as dry as possible. A temperature switch on the condensate line (or equivalent design provision by the humidifier manufacturer) should be incorporated to prevent 'spitting' on start-up.

4.108 Most operational problems with mains steam humidifiers arise because of back-pressure in the condensate discharge line which will result in flooding into the duct. Unless the condensate from the device can be discharged and collected at atmospheric pressure, it should be discharged directly to drain.

4.109 A local steam generator, where used, must be fed with potable quality water. Additional water treatment to the standard set out above may be required. If the humidifier is unused for a period exceeding 48 hours, it must automatically drain its water content, including that contained in the supply pipework, right back to the running main and leave itself empty.

4.110 Some steam generators are of a type that requires regular cleaning and descaling. The design must allow for them to be installed such that they can be physically isolated from the air duct in order to prevent contamination of the supply by cleaning agents while this is taking place.

Location

4.111 Careful siting of the humidifier injection manifold is required to prevent the steam impinging onto the side(s) of the duct, condensing and generating excess moisture.

Control

4.112 Accurate humidity control can only be provided on single-zone systems, or multi-zone systems with zonal humidifiers. In the above systems, humidity sensors control the humidifier for low-level humidity control, and override the temperature controls to open the cooling coil valve for high-limit humidity control.

4.113 Multi-zone systems are more usually controlled by a minimum humidity sensor located in the supply duct(s) following the last heater-battery.

4.114 Overriding controls separate from the normal plant humidistat should be installed. Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay should be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/plant start-up. In addition, a high-limit humidistat should be installed to limit the output of the humidifier so that the saturation in the duct does not exceed 70%. This humidistat is to control the added moisture. It is not necessary to install a de-humidifier to reduce the humidity of the incoming air if it already exceeds 70%. The humidifier control system should ensure that the humidifier is switched off when the fan is not running.

4.115 On systems with two-speed operating, it is usual to isolate the humidifier upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the humidifier should be isolated.

Filtration

General requirements

4.116 The purpose of filtration is to reduce the level of airborne contamination in an air stream. It is generally carried out in stages.

4.117 Filters must be securely housed and sealed in well-fitting frames that minimise air by pass. Air by pass significantly reduces filter efficiency, the higher the filter grade the greater the effect. Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred.

4.118 Neither the filter media, nor any material used in the construction of the filters, should be capable of sustaining combustion. The filter media should be such that particles of it do not detach and become carried away by the airflow.

4.119 Filters need to be readily accessible for replacement so a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.

4.120 All filters should be provided with a means of visually checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred.

4.121 A complete spare set of filters must be provided at handover.

Definition of filter terms

4.122 Particulate air filters are divided into four categories:

- general ventilation filters grades G1 to G4;

- fine filters grades F5 to F9;
- high efficiency particulate filters (HEPA) graded H10 to H14;
- ultra-low particulate air filters (ULPA) graded U15 to U17.

4.123 General filters are graded in terms of their 'Synthetic dust weight 'Arrestance'. This represents the percentage of a test dust captured by a filter. 'Arrestance' provides a good indication of a filter's ability to remove the larger, heavier particles found in outdoor air. These are of a size to block finned batteries and large enough to settle out in the air distribution system.

BS EN 779 grade (Eurovent grade)	% Arrestance	Notes and typical healthcare application
G1 - (EU1)	< 65	Metal mesh grease filter
G2 - (EU2)	65 to < 80	Coarse primary filter
G3 - (EU3)	80 to < 90	Primary air intake; return air; energy recovery device protection
G4 - (EU4)	> 90	General purpose tempered air supply

Table 4: General Filters

4.124 Fine filters are graded in terms of their 'Atmospheric dust spot Efficiency'. This is a measure of the filter's ability to remove the very fine staining particles found in outdoor air. It will indicate how 'visibly' clean a filter will keep a ventilated space. The staining particles are approximately the same size as most common bacteria so it is also a rough measure of the filter's ability to remove microorganisms.

BS EN 779 grade (Eurovent grade)	% Efficiency	Notes and typical healthcare applications
F5 - (EU5)	40 to 60	General purpose panel / bag filter
F6 - (EU6)	60 to < 80	Basic grade bag filter
F7 - (EU7)	80 to < 90	Medium grade bag or pleated paper Conventional operating theatre supply air
F8 - (EU8)	90 to < 95	High grade bag or pleated paper
F9 - (EU9)	> 95	Basic HEPA filter – Level 8 clean rooms

Table 5: Fine Filters

4.125 High efficiency filters (HEPA and ULPA) are graded in terms of their ability to capture their 'Most Penetrating Particle Size' (MPPS). High-efficiency filters self-select the particle that they are least able to trap, hence the MPPS. They are then tested against that size of particle. These filters are designed to provide very high-efficiency filtration of particles in the sub-micron size range.

BS EN 1822 grade (Eurovent grade)	% Efficiency @ MPPS	Notes and typical healthcare application
H10 - (EU10)	85	Ultra-clean theatre terminal
H11 - (EU11)	95	
H12 - (EU12)	99.5	
H13 - (EU13)	99.95	
H14 - (EU14)	99.995	Pharmacy aseptic suite Category 3 room extract
U15 – U17	-	Not generally used in healthcare

Table 6: High Efficiency (HEPA) Particulate Filters

Selection primary filters

4.126 All filters should be of the dry type. Panel filters are cheap and disposable with relatively low dust-holding capacity. They are generally used as pre-filters to eliminate large particles that would otherwise clog or cause damage to the fan and finned heating and cooling batteries. Stainless steel frames that hold disposable pre-cut filter pads are preferred.

4.127 General ventilation supply plant should incorporate primary air filters of grade G3, sized for a maximum face velocity of 2.0 m/s. Additional coarse pre-filters may be justified where the intake air is exceptionally polluted. They are sometimes fitted as a temporary measure when building work is being carried out in the vicinity of the air intake.

Secondary filters

4.128 Where a higher standard of filtration is required, secondary bag or pleated paper panel filters would be used. Rigid frame filters incorporating pleated paper elements are preferred over bag filters for critical care applications such as operating theatres.

4.129 In urban or other areas of high atmospheric pollution, a higher standard of filtration may be justified to reduce the level of staining to internal finishes.

Extract air filters

4.130 Extract filtration will generally only be required where heat-recovery devices are installed. There are a very limited number of specialised applications (microbiological safety cabinets and similar LEV systems) where contaminated air is required to be filtered prior to discharge to atmosphere. If it is safe for staff to work in a room without wearing respiratory protective equipment, it is safe to discharge the room air to atmosphere without filtration.

Return-air filters

4.131 They are used to reduce the load on HEPA filters in recirculating applications such as Ultra Clean operating suite ventilation canopies and pharmacy aseptic suites.

High-efficiency filters – HEPA and ULPA

4.132 HEPA filters are expensive so their use should be kept to a minimum. Applications requiring HEPA filters include the air supply to aseptic suites in manufacturing pharmacies, the discharges from microbiological safety cabinets and isolation facilities.

4.133 If used, HEPA filters should be of the replaceable panel type with leak-proof seals. They should be installed in a manner that permits on-site validation of the filter and its housing. This may involve the release of a Dispersed Oil Particle (DOP) challenge smoke through an injection point upstream of the filter and a measurement of the DOP penetration across the downstream face. Alternatively a particle-counting method may be used.

4.134 HEPA filters are sometimes fitted in extract systems to capture hazardous substances or organisms. Design provision must be made for the subsequent safe handling of contaminated filters by maintenance staff. This may be achieved by:

- sealing the hazardous substance into the filter before it is removed;
- providing a system to fumigate the filter to kill any organisms;
- housing it in a ”safe change” unit that permits the filter to be ejected into a bag and sealed without staff having to come into direct contact with it.

4.135 In view of the costs and problems associated with placing HEPA filters in extracts, it is recommended that a full risk assessment be carried out at the design stage. This should include defining the true need for HEPA filters in an extract; validation of its performance at installation; the method of safely changing a contaminated filter; and its subsequent disposal.

4.136 ULPA filters are very expensive and are designed to remove particles below a size that are either surgically or aerobiologically significant. There would have to be exceptional circumstances in order to justify their use in healthcare ventilation systems.

Activated carbon filters

4.137 Activated carbon filters are able to remove gases and vapours from an air stream and are graded according to the range of substances they can remove. They are not normally fitted in air-conditioning supply systems.

4.138 They are occasionally fitted retrospectively because the main air intake has been poorly sited and is drawing in traffic fumes. Where used they must be protected by a particulate air filter.

4.139 Activated carbon filters are more commonly used in specialised fume extraction systems when the location of the discharge means that dilution cannot be relied upon to disperse noxious fumes.

Location

4.140 The primary filter should be positioned on the inlet side of the supply fan, downstream of the frost coil. The secondary filter, when fitted, should be on the positive-pressure side of the fan. This will prevent air being drawn into the system after the filter and capture any particles shed by items of equipment within the AHU.

4.141 The filter installation must be arranged to provide easy access to filter media for cleaning, removal or replacement, with side or front withdrawal as required.

Control

4.142 Differential-pressure transducers should be provided to monitor and alarm remotely on excessive filter pressure drop. In critical areas dirty-filter indication lights should be provided at the point-of-use.

Energy-recovery

General requirements

4.143 Energy recovery will normally be fitted to all healthcare ventilation systems. It may be omitted only where it would clearly be uneconomic. Where the economic case is marginal, space should be allowed for the retrofitting of an energy recovery system.

4.144 For systems in healthcare premises, a plate heat exchanger or 'run-around coil' system is suitable. Thermal wheels may be used providing they are fitted with a purge sector. The small amounts of air leakage across those devices are not considered significant. Other systems such as heat pumps or heat pipes are also suitable. Selection should be based on relative locations of the supply and extract units, ease of maintenance and practicality. Cleaning access will be required to both sides of any energy-recovery device.

4.145 The following are the minimum energy transfer efficiencies required for devices handling equal air volumes:

- run-around coil – 45%;
- plate heat exchanger – 50%;
- thermal wheel – 65%;
- any other energy-recovery device – 50%.

4.146 If a plate heat exchanger is chosen, the plates should be constructed of metal. Plastic should not be used for internal bypass dampers and drive gears.

4.147 Whichever energy-recovery device is chosen the extract side will need to be protected by a G3 filter and provided with a drainage system as described in Paragraphs 4.20 - 4.25, to remove condensate.

Location

4.148 Energy-recovery devices should be located downstream of the frost battery and pre-filter, prior to the cooling coil or main heater battery on the supply side.

Control

4.149 It is essential to consider the control of both the energy recovery device and the frost battery when assessing the economics of recovery, as all energy provided by the frost battery will directly reduce the heat exchange of the recovery device. To this end, the off-coil setting of the frost coil should be the minimum possible to protect the primary filter (for example +2°C).

4.150 The energy-recovery device should be controlled in sequence with the main heater battery, and should incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the required plant set point.

4.151 In instances where the plant is cooling the air, it may be possible to remove heat from the supply air at high ambient conditions, under the dictates of enthalpy sensors in the intake and extract ducts.

Attenuation

General requirements

4.152 Noise will be generated in an air distribution system by the fan, plant items and airflow. The ductwork is a very effective transmitter of this noise hence there is generally a need to limit the noise transmission to meet the requirements of the building. This normally involves the provision of sound attenuation treatment as part of the overall ductwork system design.

4.153 A thorough assessment of the design should be made to assess the noise impact. This should take into account the following primary factors:

- fan- and plant-noise generation;
- air-flow generated noise in ductwork fittings and dampers;
- noise generated at grilles, diffusers and other terminals;
- noise break-in and break-out of ductwork;
- cross-talk and similar interference;
- the noise limitations for the building and surrounding areas;
- external noise generation.

4.154 A method of assessment of these factors and the sound attenuation requirements of ductwork systems is given in CIBSE Guide B.

4.155 The fan is usually the main source of system noise. The sound power that it generates varies as the square of the fan pressure, and thus to limit the fan noise level the system resistance should be kept as low as economically

possible. As a general rule the selected fan should operate close to its point of maximum efficiency to minimise its noise generation. Where there is disturbance to the airflow at the fan inlet, the manufacturer's stated fan noise levels should be increased by up to 5 dB(A). More precise guidance on this aspect may be available from the manufacturers.

4.156 Fans radiate noise through both the inlet and outlet connections and it may be necessary to provide attenuation to limit the noise from both of these connections. It is always preferable and more economic to control noise and vibration at source, or as close to source as possible. It should be noted that attenuators offer a resistance to airflow. The resistance must be included in the fan and ductwork calculations.

4.157 Provided care is taken in the design and construction of low-pressure systems to avoid significant noise generation in the ductwork, attenuation should only be needed to absorb fan noise.

4.158 Noise breakout from all equipment housed in the plantroom must be taken into consideration if control is to be satisfactory. Any ductwork within the plantroom after the silencer should be acoustically insulated to prevent noise break-in or the silencer relocated at the point of entry or exit of ductwork to and from the plant room.

4.159 There is no complete means of control over external noise generation from such as road traffic, aircraft, factory and community noise. Consideration must be given to this at the design and planning stage.

Acceptable types and location

4.160 The noise levels produced by ventilation and other plant should be reduced by either lining the inside of the duct with sound-absorbing material or fitting bespoke attenuator units.

4.161 In supply systems, sound-absorbing material should not be applied to the inside surface of a duct system downstream of the final filter, owing to the risk of mechanical damage and the subsequent dispersal of the media into the ventilation system.

4.162 In supply and extract systems, sound-absorbing material must not be applied to the inside of a duct within 1 metre of a fire damper. The material should be non-particle-shedding and fire-resistant (further guidance can be found in SHTM Firecode suite of documents). Where sound-absorbing material is applied in a section of duct that will be routinely exposed during maintenance activities it should be protected from mechanical damage.

4.163 Bespoke attenuator units with a sound-absorbing infill suitable for the quality of air being handled and protected by a perforated sheet metal casing are the preferred option for critical systems. Absorption of moisture, dirt and corrosive substances into the 'in-fill' and the release of fibrous particles into the airstream should be prevented by the use of a membrane. The membrane material should have a declared service life of at least 25 years. If these conditions can be met then the attenuator may be located in the supply ductwork downstream

of the final filter. When so located, cleaning access should be provided at both ends of the attenuator unit.

5. Air distribution system

Air distribution arrangements

Ductwork distribution systems

5.1 Ductwork systems for ventilating and air-conditioning applications are referred to by their velocity or pressure category, that is, as low, medium or high velocity (or pressure) systems. Heating & Ventilating Contractors Association (HVCA) limits are up to 10 m/s or 1,000 Pa; 20 m/s or 1,750 Pa: and 40 m/s or 3,250 Pa in the case of conventional low, medium and high pressure systems respectively. High-pressure systems are disappearing because of the constraints of the Building Regulations but existing systems may sometimes need to be altered or extended.

5.2 For normal applications in healthcare buildings, low velocity systems are recommended. The use of higher velocities than those recommended is not likely to be economical. Future trends are likely to be towards even lower optimum duct velocities; however, velocities below 2 m/s are unlikely to be justified.

5.3 The site will often dictate the main routing of ductwork systems, but in general, the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid regulation and may reduce the number and variety of duct fittings that are needed.

5.4 Main distribution ductwork should not be routed above sleeping areas. Where there is no alternative route, additional acoustic insulation will be required.

5.5 Where auxiliary cooling units, fans, filters or trimming devices are installed in the distribution system, they must be independently supported and fitted with a suitable drainage system where appropriate. If they are a source of vibration they should be linked to the distribution ductwork via flexible connections.

5.6 The fan of a Local Exhaust Ventilation (LEV) system provided under the COSHH Regulations should be located outside of the building so that all of the ductwork within the building is under negative pressure. Where the fan has to be within the building it should be located as close as practicable to the outside with an absolute minimum run of discharge ductwork within the building. The discharge ductwork within the building will be under positive pressure so it must not be penetrated by test holes or inspection hatches.

Ductwork materials and construction

5.7 The choice of duct material should take account of the nature of the air or gas being conveyed and the environment in which the duct will be placed.

5.8 Galvanised-sheet-steel is generally suitable and most economical for normal ventilating and air-conditioning applications. Its inherent mechanical strength

renders it resistant to casual damage both during the construction phase and throughout its service life when mechanical and electrical services around it are altered. It also readily withstands the impacts sustained when rotary equipment is used to for internal cleaning.

5.9 In instances where moisture levels and/or corrosive elements in the air being conveyed are very high, aluminium, stainless steel, PVC or GRP (glass-reinforced plastic) ducts should be used. Stainless or black steel are the only suitable materials for high-temperature ductwork.

5.10 In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in Paragraphs 4.20 - 4.25.

5.11 Where builderwork plenum chambers or ducts are used, these may be constructed of various materials. However all such ducts must be rendered and sealed to prevent dust shedding. A greater allowance may need to be made for leakage.

5.12 Galvanised, black and stainless steel ductwork should be manufactured and installed to the current HVCA specification for sheet metal ductwork DW144, but excluding the use of bolt-through supports.

5.13 GRP and PVC ductwork should be manufactured and installed to the current HVCA specification for plastic ductwork DW154.

5.14 Where phenolic-board ductwork is considered, care should be taken to ensure that it is fabricated to a quality standard and installed strictly in accordance with the manufacturers' instructions. Its pressure rating and degree of support should be suitable for the application and ducts should be fitted with mechanical protection where required. Designers should be fully conversant with installation techniques and Installers should be experienced having received training in the techniques required and certified to this effect by the manufacturers. Due consideration should be given to the impact on ductwork pressures created by the closing of dampers. Phenolic-board ducting should not be installed in plant rooms or any other areas where it could be vulnerable to impact damage. Internal cleaning using mechanical (rotary) means is also liable to cause damage to the integrity of surfaces.

5.15 Flexible ductwork is unsuitable for air distribution in healthcare applications. It should only be used to make the final connection to a terminal (See Paragraphs 5.54 and 5.55).

5.16 The inside of the ductwork should be free from structural projections and as smooth as possible. Flanged, gasketed joints are preferred.

Fire aspects, damper types and locations

5.17 It is essential that all relevant fire aspects of ducting systems are agreed with the fire officer before the design is finalised.

5.18 Ductwork must be fire-stopped where it penetrates fire compartment walls, floors and enclosures, cavity barriers and sub-compartment walls or enclosures, and provided with weatherproof collars where roofs or external walls are penetrated.

5.19 Fire/smoke dampers shall be provided at the locations required by SHTM Firecode. The fire-damper mounting frame must be securely attached to the building fabric. Where a fire-damper is not mounted directly in a fire compartment wall, it must be correctly supported and the ductwork between it and the firewall must posses the same fire rating as the firewall that it penetrates. The fire-rated portion of ductwork must not be penetrated by test holes or inspection hatches. All fire/smoke dampers shall be capable of remote re-setting via the Building and Energy Management System (BEMS) or equivalent, after periodic testing procedures.

5.20 An access hatch shall be provided adjacent to each fire damper so that its correct operation can be directly observed.

5.21 Smoke-diverting dampers must be provided on recirculation air systems to divert automatically any smoke-contaminated return air to the outside of the building in the event of a fire; and arranged so that the normally open smoke-diverting damper on the return-air branch to the input unit closes and all the return air is exhausted through the extract fan. Guidance is available in SHTM 81 and BS5588: Part 9.

Duct sections

5.22 Ducting is generally available in rectangular, circular and flat oval sections, although other sections may be made for special situations.

5.23 Rectangular ducting is most common on low-pressure systems, for the following reasons:

- it can readily be adapted to fit into the space available;
- fittings are cheaper than those for circular or flat oval ductwork;
- it can readily be joined to such component items as heating and cooling coils, and filters.

5.24 When sizing ductwork, the designer should take into account:

- both installation and operating costs;
- space limitations imposed by the structure and other services;
- operating noise levels;
- requirements of regulation at the commissioning stage.

5.25 For overall economy and performance, the aspect ratio should be close to 1:1, since high aspect ratios increase the pressure loss, heat gains or losses and overall cost (for example, changing the aspect ratio from 1:1 to 1:4 can typically

increase the installed cost of the ductwork by 40% and add 25% to the heat gains or losses).

5.26 Rectangular ducting should not be the first choice for high pressure systems, and should be avoided in systems operating at high negative pressures, because the strengthening of the flat sides and the sealing requirements necessary to make rectangular ducts suitable for these high pressures are costly.

5.27 Circular ducting is preferable for high-pressure systems, and for systems operating at high negative pressures. In the case of the latter, additional stiffening rings may be necessary. Machine-formed spirally-wound ducting and a standard range of pressed and fabricated fittings can sometimes make circular ducting more economical, particularly in low pressure systems having a relatively low proportion of fittings.

5.28 Flat oval ducting provides an alternative to circular ducting, principally where there is a limitation on one of the dimensions in the space available for the duct run.

5.29 Other sections may be used, such as triangular sections to pass through roof trusses. Such sections present difficulties in the provision of fittings, and connections to standard plant items, and are likely to be more expensive than traditional sections.

Standard ductwork fittings

5.30 All fittings should conform to current HVCA specification DW144. Wherever possible, long radius bends, large radius main branches, not more than 45° angle sub-branches and long-taper transformations should be used.

5.31 Fittings should be arranged with vanes in sub-branches connected directly to grilles and diffusers, and turning vanes in square bends (when used). When vanes are used, additional cleaning access will be required.

5.32 The number of duct fittings should be kept to a minimum and there should be a conscious attempt to achieve some standardisation of types and sizes. Increasing the number and variety of fittings in a system can markedly raise its overall cost.

5.33 Bad design in relation to air flow can lead to vibration of flat duct surfaces, increases duct-generated noise and pressure loss, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of installed plant items (such as trimmer batteries).

Branches

5.34 There are many designs of branches and junctions in use. The important features are that the flow should be divided (or combined) with the minimum interference and disturbance. Changes in duct sizes should not be made at the branch but a short distance downstream (or upstream). A good dividing branch

design cannot be effective if the flow entering the branch is not uniform across the section.

Changes of section

5.35 The expansion of a duct section should be formed with sides having a total included angle of no more than 30°, and preferably less than 20°. If the angle of expansion is greater, the flow is not likely to remain attached to the walls of the duct and large eddies will be formed with flow reversal at the walls. This leads not only to a high-pressure loss, but also to non-uniform velocity pattern at the outlet. Where there is insufficient space for a gentle expansion and a greater angle is necessary, internal splitters should be used.

5.36 A contraction in a duct section is less critical, but the total included angle of the taper should not exceed 40° (or 20° where the contraction is made on one side of the duct only)

5.37 The most economical way to change the section of a rectangular duct is to restrict the change of duct size to one side only. If the calculated reduction or increase to the side dimension is 50mm or less, it is usually not economical to change the size at the position. The minimum size of a rectangular duct should usually be 150mm x 100mm.

Other fittings

5.38 As a general rule, fittings should avoid abrupt changes in direction and also sharp edges that cause the flow to separate and form eddies, thus limiting pressure loss and causing noise generation. If the fitting leads to the flow preferentially attaching to one side of the outlet, then a significant length of straight downstream duct is necessary before the next branch or fitting; this length should be greater than five equivalent diameters.

Thermal insulation

5.39 Thermal insulation is applied to ductwork to reduce heat exchange, and to prevent condensation.

5.40 In a duct system, the air temperature changes can be significant, especially when passing through untreated space, and these have the effect of reducing the heating or cooling capacity of the air and of increasing the energy input to the system. The heat transmission to and from the surrounding space can be reduced by effective insulation of the ducts. Extract ductwork conveying air from which heat recovery will be derived should be thermally insulated to the same standard as with associated supply ventilation ductwork.

5.41 Condensation can arise in ductwork systems conveying cooled air and, apart from creating conditions conducive to corrosion of ductwork, condensation affects the heat and vapour-resisting properties of insulating materials themselves which may induce further condensation.

5.42 In normal circumstances, the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the

insulation thickness for vapour resistance may be greater than that for heat resistance. When cold ducts pass through areas of high dew-point, carefully selected vapour barriers should be applied externally to the insulation.

Noise generation within the ductwork

5.43 Noise is generated in ductwork at sharp edges, by tie rods, damper blades, duct obstructions and sharp bends etc. This air-flow-generated noise becomes an important factor if it is about the same or greater level than the upstream noise level. (Air-flow-generated noise is often referred to as “regenerated noise”).

5.44 The noise level generated by airflow in ductwork is very sensitive to the velocity. The sound power of this noise is approximately proportional to the sixth power of the velocity; that is, a doubling of the duct velocity will increase the sound power by a factor of 64. The duct velocities should therefore be kept as low as possible. In general, duct fittings that have lower pressure loss factors in similar flow conditions will generate less noise.

5.45 Ductwork serving quiet areas should not be routed through noisy areas where noise break-in can occur and increase the noise level in the ductwork.

5.46 Grille, register and louvre noise should be kept to the minimum by selecting types having low noise-producing characteristics, without high tonal noise, and should be fitted with acoustically treated external inlet and outlet louvres.

5.47 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. They will normally be of the ‘through-the-ceiling, ‘up-and-over’ type and may include a fire damper if required.

Volume control damper locations

5.48 Manually operated balancing dampers are needed generally:

- in the main duct downstream of the fan;
- in branches of zone ducts;
- in sub-branch ducts serving four or more terminals;
- at terminals not covered by the previous item.

5.49 Dampers integral with terminals should only be used for final trimming of air volumes, otherwise noise and air distribution problems may ensue.

5.50 Dampers in rectangular ducts should be single-bladed when the longer side is up to 450mm but be of the opposed-blade multi-leaf type above this size. In circular ducts, iris-type dampers are recommended. Dampers must be accessible, incorporate a position indicator and means of locking in the commissioned position. Dampers should be located as far away as possible from adjacent branches or plant items.

Cleaning and access door locations

5.51 Cleaning and access doors are required to facilitate access to plant items and ductwork components for inspection, maintenance, cleaning and replacement, and must be of sufficient size to permit safe access for the required functions. Consideration should also be given to the number of doors to be provided. Older installations may be deficient in the provision of access doors and consideration will be necessary to have these incorporated in the course of any refurbishment in the accommodation served.

5.52 Recommended locations for access doors are given in the current HVCA specification DW144 and are generally provided to give access to:

- every regulating damper;
- every fire and motorised damper;
- filter (to facilitate filter withdrawal);
- both sides of cooling/heating coils;
- humidifiers;
- fans; and
- motors and impellers.

5.53 Care should be taken when siting access doors to ensure that no other services to be installed will prevent reasonable access.

Flexible ducting

5.54 Flexible ductwork may be used for final connections to grilles and diffusers provided it is constructed to meet the fire precautions recommended in BS8313. It must not pass through fire compartment walls, floors or enclosures of sub-compartment walls or enclosures, or through cavity barriers.

5.55 Flexible ducting will cause a significant frictional loss and may be difficult to clean and should never be used in lieu of a bend. Where installed it should take the most direct route and be as short as possible, never exceeding 1 metre in length.

Diffuser and grille selection and sizing

5.56 The effectiveness of all ventilation and air-conditioning systems depends on the methods by which air is introduced to, and vitiated air is removed from, the space. The usual results of poor air-terminal selection and/or positioning are: draughts, stagnation, poor air quality, large temperature gradients and excessive noise.

5.57 Air can be supplied to a space in a number of ways, although any device can be broadly placed into one of two categories: that producing a diffused supply, or that producing a perpendicular jet. Diffusers may be radial or linear, and normally utilise the Coanda effect (that is, adhesion of the air stream to an adjacent surface), to reduce the risk of excessive room-air movement. A

perpendicular jet is formed by discharging air through grilles, louvres or nozzles, which are generally adjustable.

5.58 Air-flow patterns produced by both types of terminal are dependent to a large extent on the presence of the Coanda effect.

5.59 Supply air terminals can be incorporated into any room surface, for example, floors, walls (high or low level), desktop etc.

5.60 As they operate on the jet principle, the use of sidewall and linear grilles is restricted to areas where air change rates are low, that is, less than 10 per hour. Perforated rectangular diffusers can provide acceptable conditions within the occupied zone at up to 15 air changes per hour. In areas where a higher air change rate is required, square or circular ceiling mounted diffusers should be used.

5.61 The performance of supply air terminal devices is provided, based on three criteria: throw, spread and drop.

- **throw** is defined as perpendicular or parallel distance from the terminal to the point at which the air velocity is 0.5 m/s isovel;
- **spread** is defined as the width of the 0.5 m/s isovel; and
- **drop** is defined as the vertical distance from the centre line of the terminal to the bottom edge of the 0.25 m/s isovel.

5.62 It is necessary to consider each of these parameters in both summer and winter conditions to ensure satisfactory operation of the air-terminal device, as warm jets behave very differently from cold jets.

5.63 A warm jet tends to rise until it attaches itself to a horizontal surface, while a cold jet falls. Care must be taken to ensure that this does not lead to unacceptable temperature gradients in winter or excessive air velocities in the occupied zone in summer.

5.64 In order to ensure satisfactory air movement within a space, it is necessary to consider interaction between air movement from adjacent terminals, and ceiling mounted fixtures (light fittings etc), as well as interaction between air movement and room surfaces.

5.65 If the supply and extract terminals are too close, short-circuiting may occur, while if they are too far apart, stagnant zones may be formed. Where two opposing air streams meet, the individual velocities must not be greater than 0.25 m/s.

5.66 Supply and extract grilles and diffusers should be fitted with opposed-blade dampers for fine balancing purposes.

5.67 Further guidance on the selection of grilles and diffusers is given in the CIBSE Guide B.

5.68 In operating theatres, the supply terminals must be able to produce a down-flow movement of air in the operating zone 1 metre above floor level. Ceiling mounted diffusers with fixed directional vanes that provide a downward turbulent airflow are the preferred option. Plenum boxes fitted with perforated screens to produce a parallel downward flow are also acceptable. Nozzles or jets of any type are not acceptable. Sidewall-mounted linear diffusers that utilise the Coanda effect to send air across the ceiling and 'drop' it into the operating zone are also not suitable. However linear ceiling mounted diffusers that provide a direct downward airflow around the operating zone may be used.

Transfer grille - size and location

5.69 Air-transfer grilles in walls, partitions or doors form an integral part of the building's air distribution system. Modern doorsets have very low leakage rates so cannot be relied upon to permit even quite small airflows. Failure to make adequate provision for air to move from room to room will result in excessive pressure differentials and 'door whistle'.

5.70 Transfer grilles are required in locations where there is a significant imbalance between the supply and extract rates in a room. They will relieve any pressure differentials that may affect the operation of the spaces and/or the ventilation system and permit airflow in a known direction. However, transfer grilles are vulnerable to damage and, in many instances, as long as the equivalent free area is provided, they can be substituted with undercut door.

5.71 Care needs to be taken to ensure that the positioning of transfer grilles does not interfere with the fire or smoke integrity of the building. In general, the air-transfer grilles should not be installed within fire-resisting boundaries, although if this is unavoidable, they should be fitted with fire- or smoke-dampers.

5.72 Where installed, transfer grilles should be of the non-vision type, sized for a maximum face velocity of 1.5 m/s.

5.73 In photographic dark rooms, lightproof transfer grilles will be required.

5.74 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. (See also Paragraphs 5.43 - 5.47).

Pressure stabilisers - size and location

5.75 Pressure stabilisers are required in lieu of air-transfer grilles in areas where it is necessary to maintain pressure differentials between adjacent rooms to prevent reversal of airflows for example, in operating suites, isolation facilities and clean rooms. (See also Paragraphs 7.24 - 7.28).

5.76 Fire precautions for pressure stabilisers are the same as for transfer grilles. For sizing criteria, refer to Paragraph 7.23

5.77 Pressure stabilisers should be of the balanced-blade type, with the facility to make fine adjustment of the pressure setting. They should be silent in

operation and give a seal as tight as practicable when closed. The materials of construction and method of assembly should allow for cleaning and disinfection.

5.78 Pressure stabilisers should be installed in a visible location so that their operation can be readily observed.

5.79 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where confidentiality is required. In these cases, the pressure stabiliser and cross-talk attenuator should be mounted in a short length of ductwork within the ceiling void.

5.80 Pressure stabilisers may need to be fitted with a stand-off baffle on their discharge side to prevent a sight line in situations where a laser will be used. Baffles may also be required to preserve privacy or prevent discharge air causing draughts or disturbing the air distribution pattern in the adjoining room. They are also useful in low-level locations to prevent the airflow path being obstructed by portable equipment.

6. Automatic controls

6.1 Various options for control of single and multi-zone air-conditioning systems are given in CIBSE Guide B.

General requirements

6.2 The basic requirements for an automatic control system are as follows:

- facilities to start, set-back and stop the plant;
- facilities to control the volumetric air-flow;
- facilities to control the system or room pressure;
- temperature control and indication;
- humidity control and indication;
- devices to monitor and indicate the plant's operating state;
- alarms to indicate plant failure, low air-flow, and filter state.

The control functions actually provided will depend on the purpose of the ventilation system.

6.3 There will also be a need to determine the control strategy in the event of a fire either within the zone being served or within an adjoining zone.

6.4 The designer should consider whether it is necessary for the supply and extract fans to be interlocked, either so that the supply fan will not operate unless air-flow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served.

6.5 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratory and pharmacy areas that also contain fume cupboards, safety cabinets and other LEV systems.

6.6 Alarms should be provided to show 'filter fault' and 'low air-flow'. The "filter fault" alarm should be initiated by a predetermined increase of pressure differentials across the filter. The 'low air-flow' alarm should be initiated when the supply air quantity falls to 80% of the design value.

Objectives of control system

6.7 The primary objective of ventilation plant control system is to maintain the space served within the required environmental control limits, at the appropriate times, regardless of external conditions or internal loads and with the minimum energy consumption.

6.8 Often, it is not possible to predict accurately building load variation at the design stage, and thus optimum set points cannot be assessed. Information provided by monitoring the operation of the plant via a Building and Energy Management

System (BEMS) will enable optimum set points to be established and energy consumption reduced. Control of most systems will be via a BEMS. This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system together with that recovered by the energy-recovery device. This will provide a useful check on overall operating efficiency and provide evidence that energy targets are being achieved.

6.9 BEMS incorporating self-adaptive control algorithms that automatically adjust the set-point to the suit the usage and load are preferred. The provision of movement sensors within the controlled space in order to determine the actual occupancy will facilitate this process.

6.10 The failure of specialised ventilation systems can have grave consequences for the delivery of healthcare. Control systems should therefore be simple, robust and reliable.

6.11 Computer-software-driven control systems are becoming the norm in building services. However, it should be remembered that healthcare ventilation systems need to be available to operate outside of normal working periods when software support is not available. Should the software fail, it will be left to site staff, who may have little knowledge of the control algorithms to restart the ventilation system. It is therefore essential to ensure that a simple means of re-starting critical systems in the event of a software failure is provided (see also Paragraphs 4.62 - 4.63)

Location of controls

6.12 Whether within the plant, duct or room, sensors should be located to provide accurate measurement of the condition of the air being monitored.

6.13 Sensors and control items such as control valves should be located close to the element being sensed or plant item being controlled, in order to minimise time lags within the system which may create over-shoot of conditions beyond the design envelope and result in additional energy consumption.

6.14 There are practical advantages in locating all control valves for an air-handling unit in a bank (at a convenient height) at one end of the unit. (This will not normally result in an undue additional control lag.)

6.15 Some applications require intermittent mechanical ventilation, frequently at a high air-change rate, (for example, in bathrooms and treatment rooms.) Local controls to facilitate this mode of operation should be placed in a prominent position to encourage economical use.

6.16 Local controls that enable the user to select more than one mode of operation should be clearly labelled to identify the particular mode selected. Where the system allows different room pressures to be selected then a direct-reading pressure gauge should be fitted within the eye line of the users to provide an independent confirmation of the resultant mode of operation. A clear

description of the selectable modes of operation should be mounted adjacent to the control switch.

Fire aspects

6.17 A fire control panel should be mounted at the entrance of the area that the ventilation serves. The panel should have restricted access for the fire officer and include independent on/off controls and indication of the supply and extract systems.

6.18 In certain critical care departments it is preferable to maintain the supply ventilation in case of a fire within the area. For example, in an operating department, while undergoing surgery, the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department, or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. This will allow time for the patient to be stabilised so that he/she can be safely evacuated if necessary. A similar situation occurs for patients in ITU and other critical care units. In all of these cases the ventilation to the critical area should continue to operate unless the AHU starts to draw in smoke. For these departments, a notice should be affixed to the fire control panel drawing attention for the need to liaise with departmental staff before switching off fan units.

6.19 All supply AHUs should have a smoke sensor mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the supply air fire damper to close and shut down the AHU.

Time switching

6.20 Facilities to start, set-back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location, for example, at the reception or staff base or, in theatres, within the Surgeon's Panel.

6.21 Many ventilation systems may be completely shut down when the area served is not in active use. Alternatively, where there is a need to maintain a background condition, the ventilation output can be reduced by "setting back" the system. This will significantly reduce energy consumption and extend the life of filters and other system components.

Start-up control

6.22 The plant's start control should contain a control logic that will start the plant in the sequence set out in the following algorithms, Figures 2 - 5

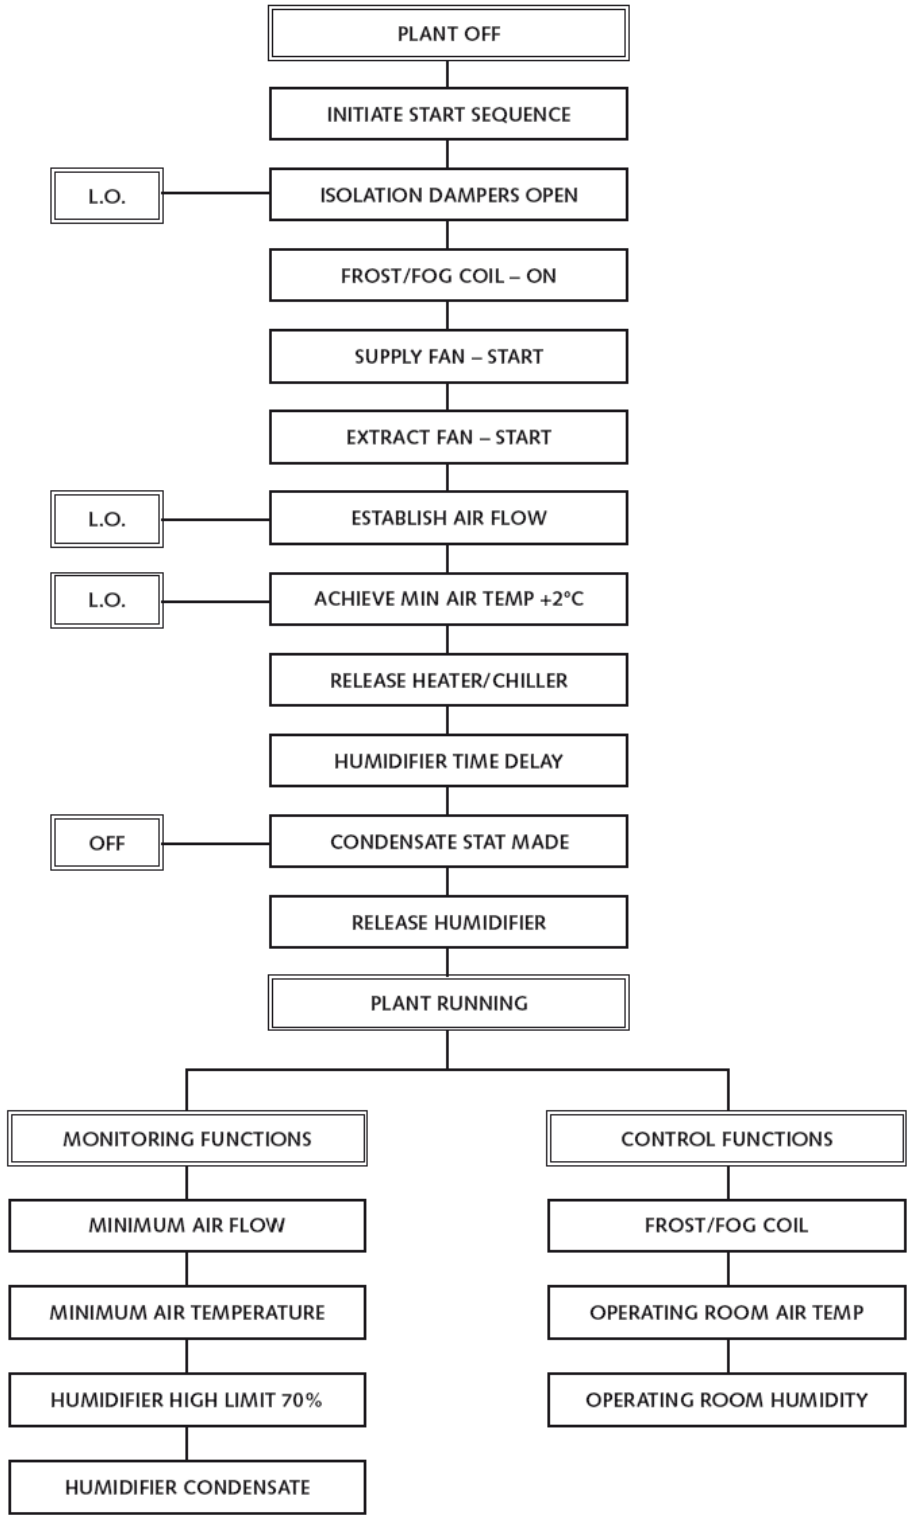

Figure 2: Typical plant control algorithm – normal start-up sequence

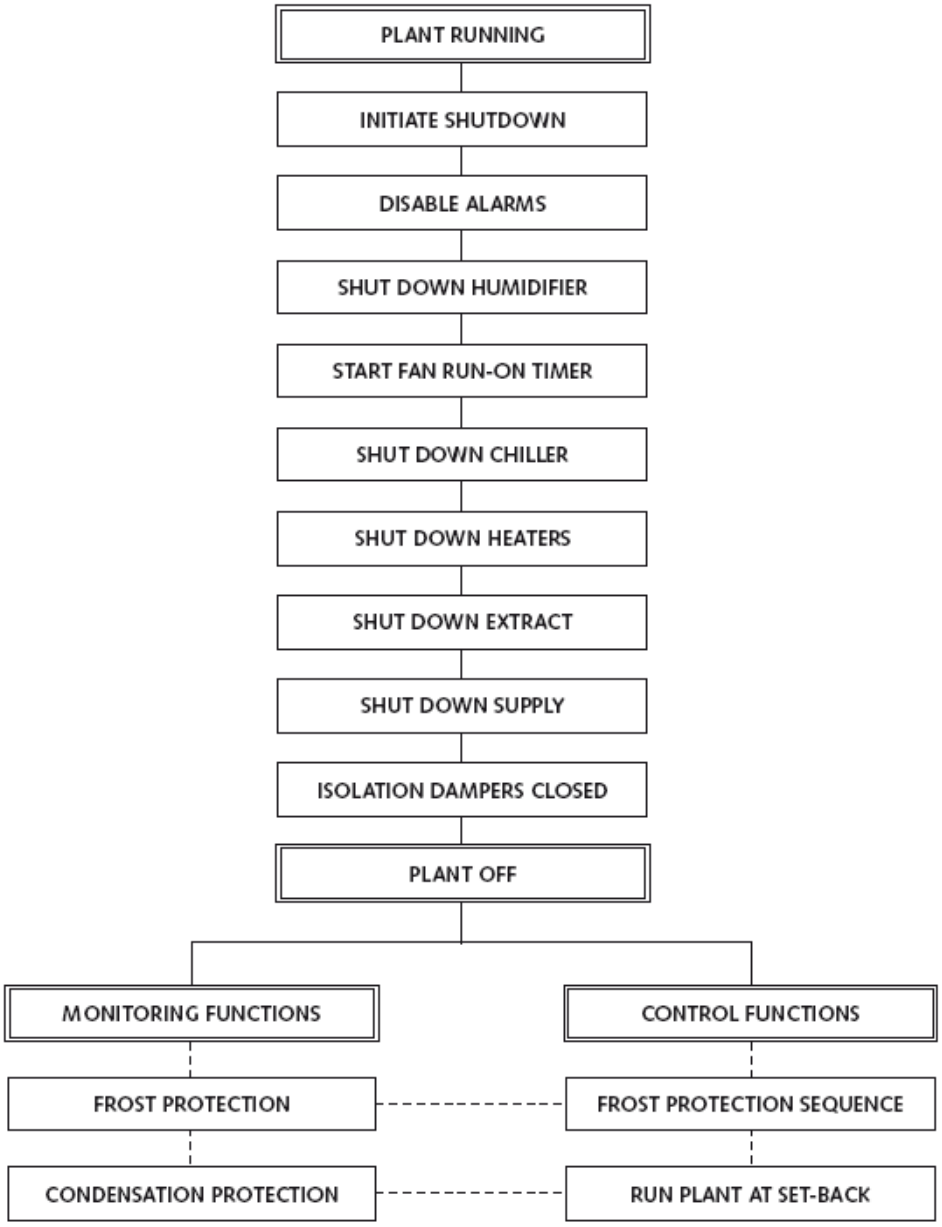

Figure 3: Plant control algorithm – normal shutdown sequence

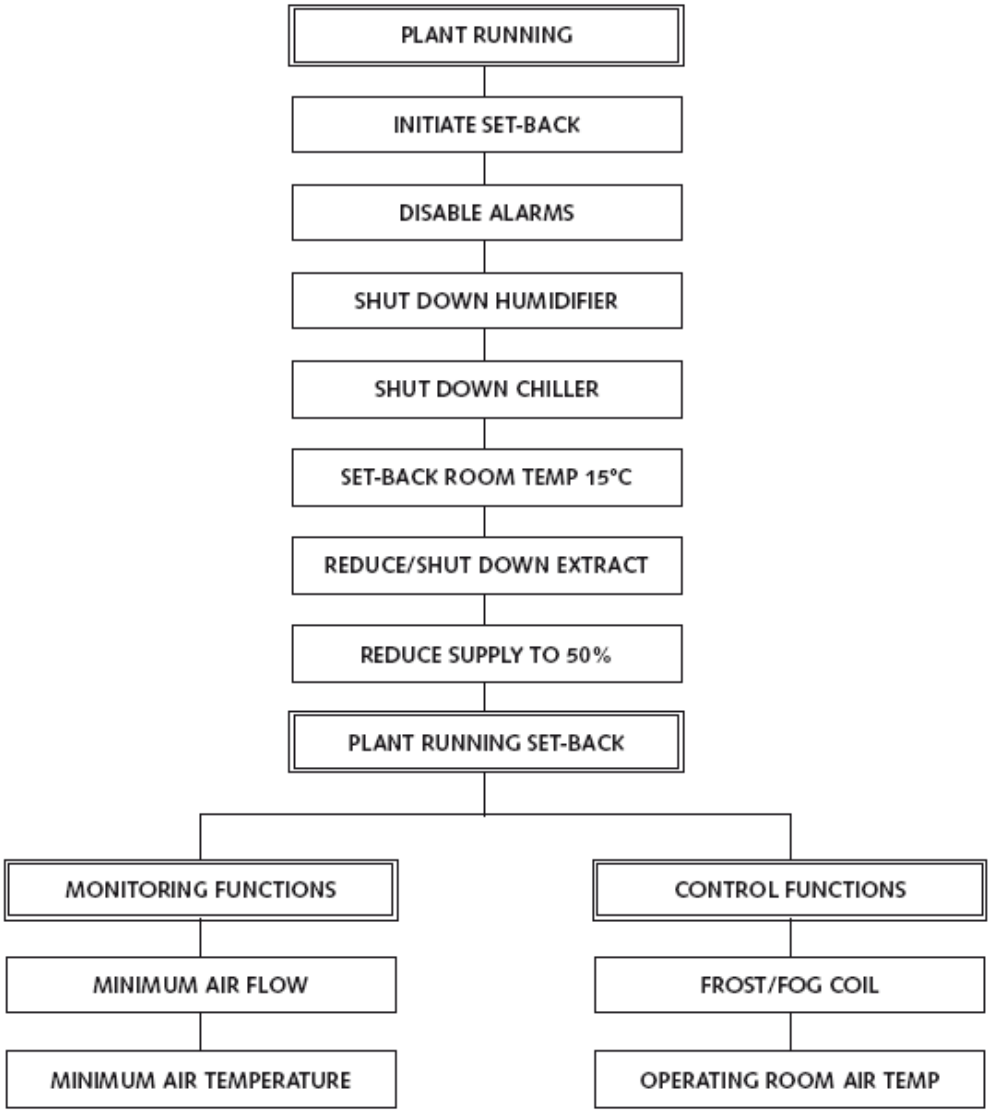

Figure 4: Plant control algorithm – set back sequence

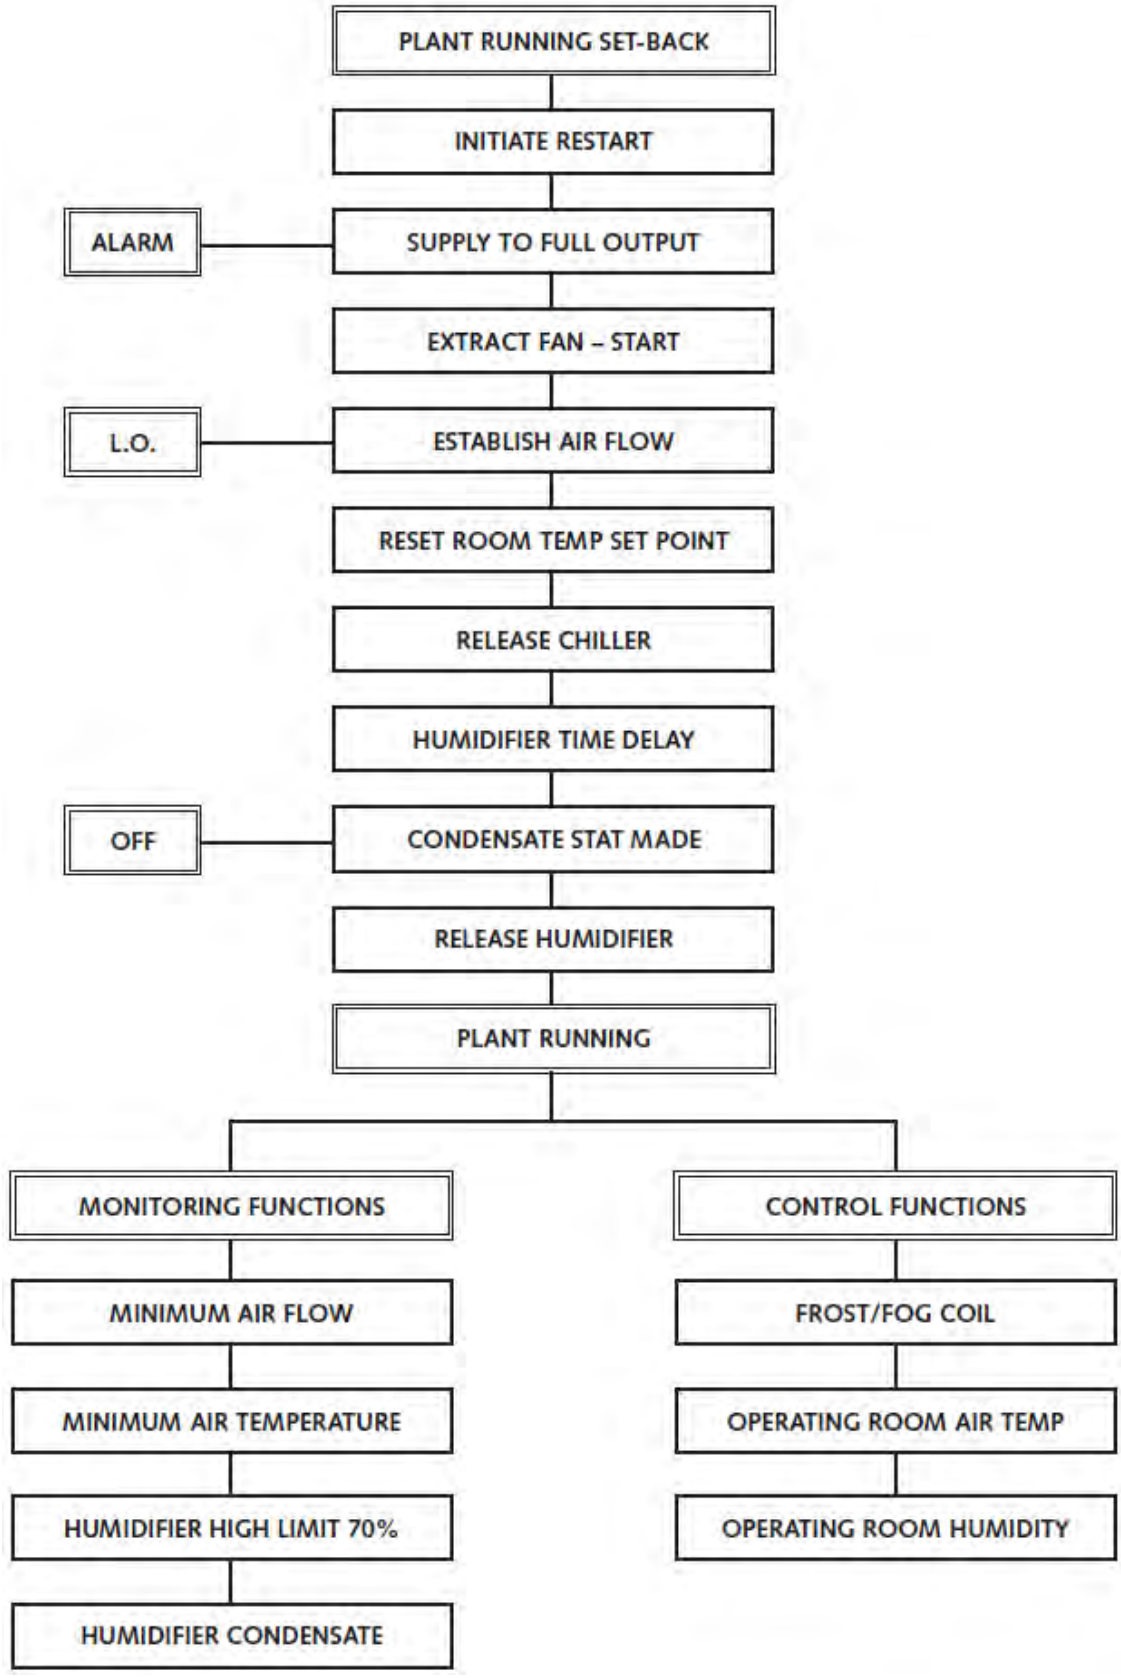

Figure 5: Plant control algorithm – restart from set-back

Set-back control

6.23 Where variable speed controls are installed, the setback facility for each plant should depress the control temperature to around 15°C; exclude any humidification and cooling from the system; and reduce the supply and extract air volumes to around 50%. The extract fan can also be turned off as long as the desired direction of air movement from clean to less clean will be maintained (See also Figures 2 - 5).

Use control

6.24 The installation of movement detectors allows for “use control” of ventilation systems. A simple control logic that reduces the system to a “set-back” condition if there has been no movement detected in the space for, say, 30 minutes and that switches the system “off” if no movement is detected for one hour is recommended for many applications, including operating suites.

6.25 A variation on this can be provided by linking ventilation controls to lighting. For example, in an operating theatre, the system may be off outside of working hours, could run at set-back when the general lighting was switched on and increase to full speed when the operating lamp is switched on. As with movement detection, a 30-minute run-on should be provided at each stage when the lights are turned off.

6.26 Either of the above control strategies may be refined by linking to the BEMS to provide a control logic related to normal working hours and associated ‘real-time’ movement within the zone being controlled. This should result in significant energy savings.

Environmental control

Temperature control methods and application

General

6.27 All control valves must fail safe, that is, close in the event of power or air-flow failure, with the exception of the fog/frost battery control valve, which should open upon power or airflow failure.

6.28 Control valves should be located in an accessible position. Isolation valves should be provided to enable the control valve to be removed for service without the need to drain-down the system.

6.29 Care should be taken to ensure that the installation of control valves and their associated pipework do not obstruct access to the AHU inspection doors and hatches.

Room temperature control

6.30 The limits for room temperature set point are generally between 16°C and 25°C depending on the particular application, and in some specialised instances (for

example, operating departments) are adjustable within a predetermined range by the user.

6.31 The selection of temperature set point for each room or zone may be by a control facility in the room / zone, or remotely at the control panel or BEMS. Where the control device is mounted within the room / zone and adjustable by the user, it should be marked either 'raise' and 'lower' or '+' and '-'. It should control within a specified temperature range to suit the user requirement with a control tolerance of ±1K. All other control set-points should be selectable either on the control panel or at the BEMS interface.

6.32 Where local control is provided, an indication of temperature will be required locally, or at a staff base (if appropriate), using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example, at the operating table in a theatre). This may be mounted in a supervisory or, 'surgeon's' control panel, with the signal repeated on the main system control panel or BEMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

6.33 Where the supply and extraction systems are designed for ventilation only and there is a wet heating system to provide background heating, care must be taken to avoid one system trying to heat the space while the other system is trying to cool the area.

Frost battery control

6.34 Steam-supplied frost batteries must be operated as on/off devices with their sensor mounted upstream of the battery. This will give 'open loop' control. A set point of +1°C is recommended.

6.35 Low pressure hot water (LPHW)-supplied frost batteries should be controlled using the proportional mode. Their sensor should be located downstream of the battery to give 'closed loop' control. A set point of between 2°C and 5°C is recommended.

6.36 If the temperature downstream of the frost battery, as sensed by a serpentine thermostat, falls below the required set point over any part of the coil, the plant must automatically shut down in order to prevent damage to the other batteries. The serpentine thermostat must not be in direct contact with the coil.

Off-plant control

6.37 The control logic must prevent the chiller and pre-heater being on at the same time.

Humidity control methods and application

6.38 In order to prevent excessive condensation when starting up from a total plant shut-down, a time delay should be incorporated into the control system such that the humidifier does not start until 30 minutes after the ventilation plant starts up.

6.39 Irrespective of the method of control, a high-limit humidistat should be installed to ensure that when the humidifier operates, the condition of the air in the duct does not exceed 70% saturated, particularly during plant start-up.

6.40 With certain types of steam humidifiers, it may be necessary to install a thermostat in the condensate line from the humidifier's steam supply, to ensure that the steam at the control valve is as dry as possible before it is injected into the air supply.

6.41 The humidifier and cooling-coil control must be interlocked so that they cannot be on at the same time.

6.42 The humidifier control system should ensure that it is switched off with the fan. It is preferable to design the control system so that the humidifier is isolated for an adequate time before the fan is turned off so as to purge humid air from the system.

6.43 All control valves must fail safe (that is, close in the event of power failure) and the humidifier must be interlocked with the low airflow switch.

Multi-zone control methods and application.

6.44 Close control of all air-conditioning parameters may be difficult to achieve with multi-zone systems, since each zone will in theory require a re-heater and humidifier to give total control of humidity if that is what is required. In reality such close control is rarely required in practice. It is therefore usual with multi-zone systems to provide control of zonal temperature only, with humidity control where fitted being based on average conditions within all zones, or minimum conditions within one zone.

6.45 Where there is a requirement for close control of air-conditioning parameters in a number of zones (e.g. an operating department) separate plants should be provided for each zone in order to avoid the need for expensive over-cooling and reheating of individual zones.

6.46 Most multi-zone systems within healthcare premises are controlled based on off-coil control within the central plant, with trimmer heater batteries on individual zones.

Alarms and indication

6.47 Supply and extract systems should include indicator lamps on the control panels to confirm the operational status of each system. Where the usage is on a regular daily pattern, time control with a user-operated timed manual over-ride should be provided.

6.48 Where a system is provided for a particular space, the indicator should be in, or immediately adjacent to, that space and local controls should be provided with labels clearly defining their function (eg. isolation suites.)

6.49 The 'plant failure' and 'low air-flow' alarms should be initiated by a paddle switch or other device located in the main air supply duct. This should operate when

the air quantity fails to reach or falls to around 80% of the design value and will give indication of fan failure, damper closed, access door left open, or any other eventuality that could cause a reduction of air quantity. Monitoring the current drawn by the fan motor is not a substitute for a sensing device that is directly affected by the air-flow.

6.50 The 'filter fault alarm' should be initiated by a predetermined increase of pressure differential across the filters, thereby indicating a dirty filter.

6.51 Direct-reading gauges or manometers should be installed across filters to give maintenance staff an indication of their condition.

6.52 Visual indication should be provided at a manned staff location (for example, the reception or staff base) and on the main control panel and BEMS to show 'plant failure' and 'low air flow'.

BEMS

6.53 Control of most systems will be via a Building Energy Management System (BEMS). This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system and recovered by the energy recovery system. This will provide a useful check on the overall operating efficiency and provide evidence that energy targets are being achieved.

7. Specialised ventilation systems

7.1 This section contains design information for a range of healthcare ventilation applications.

7.2 The following departments will require a degree of specialised ventilation.

- the Operating department;
  - treatment rooms;
  - endoscopy, day case and minimum invasive suites;
  - cardiology and operative imaging suites;
  - conventional operating theatres;
  - Ultra-clean ventilation (UCV) operating theatres;
  - barn theatres;
  - recovery and ancillary areas.
- Obstetrics;
  - maternity theatres;
  - birthing rooms;
  - LDRP Rooms;
  - SCBU.
- critical areas and high-dependency units of any type;
- Isolation facilities;
  - infectious diseases units;
  - bone marrow and other transplant units;
  - chemotherapy and oncology units.
- Sterile Supply and Decontamination Units;
  - wash rooms;
  - inspection and packing rooms;
  - sterile pack stores.
- the Pharmacy departments;
  - aseptic suites;
  - extemporaneous preparation areas;
  - radio pharmacies.
- the Pathology department;
  - laboratories;
  - cat 3 and 4 rooms.

- the Mortuary and Post mortem suite;
  - mortuaries;
  - post-mortem rooms;
  - specimen stores.
- Hydrotherapy units;
- Burns units;
  - burns theatres;
  - treatment rooms;
  - isolation rooms;
  - tissue banks.
- Emerging specialties;
  - gene therapy units;
  - stem-cell laboratories.
- Infrastructure;
  - plant rooms housing combustion equipment;
  - welding facilities;
  - wood working workshops;
  - electric vehicle charging areas.

7.3 Design information for many of these applications is given in Appendix 1 Table A1, Appendix 2 and in the following Chapters within this section.

7.4 It is not possible within this existing document to give definitive guidance for every healthcare specific ventilation application. Additional detailed guidance may be issued in due course in the form of supplements.

General information

7.5 The section on operating theatres is the most extensive and contains much information that is common to other applications. Each theatre suite should have its own dedicated air-handling unit and extract fan. Where no specific guidance is given the principles set out below should be followed:

- the foregoing sections of the document contain general information on healthcare-specific aspects of ventilation system design and specification;
- a set of standard solutions for the design of general operating theatre suites to conform to past and new standards is given in new standard layouts Nos 1, 3, 5 and 7 and those for UCV theatres in new standard layouts Nos 2, 4, 6 and 8 within Appendix 3;
- the CIBSE Guides A & B contain basic information on ventilation design that can be applied to most applications;

- where a British or European standard exists that is specific to the application (for example, a clean room) it should be used as the basis of the design requirement;
- air should always move from clean to less-clean areas. A hierarchy of room cleanliness is given in Table A2;
- differential pressure will prevent contamination between areas when doors are closed. Information on air leakage through closed doors and hatches for a range of differential pressures is given in Table A3;
- the flow of air will prevent contamination between areas when doors are open. Information on air leakage through open doors and hatches for a range of differential pressures is given in Table A4;
- if anaesthetic gases are used, 15 air changes per hour will be required;
- a methodology for calculating a design solution for a non-standard suite of operating rooms is given in Appendix 4. This may be adapted as necessary to suit other less complex applications where air is required to cascade from clean to less clean areas.

7.6 The supply of air to a room has four main functions:

- to dilute airborne contamination;
- to control air movement within such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
- to control the temperature and if necessary the humidity of the space;
- to assist the removal of and dilute waste gases where used.

7.7 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied will be determined by the number of doors and desired air-change rate.

7.8 There are four routes whereby airborne contaminants may appear in a room:-

- through the supply air;
- shed directly by the room occupants;
- arising as a result of the work activities;
- transferred from adjacent spaces.

7.9 Particles entering with the supply air can be controlled by the selection of suitable filter grades.

7.10 Particles shed directly by the room occupants can be controlled by:

- restricting access to essential persons only;
- the choice of the occupants' clothing;

- the room's air-change rate.

7.11 Particles arising as a result of the work activity can be controlled by:

- enclosing, semi-enclosing or otherwise controlling the work-based source;
- the room air-change rate.

7.12 The transfer of particles from adjacent spaces can be controlled by:

- differential pressure;
- air-flow paths.

7.13 Air change rates are given in Table A1. These figures have been found to give sufficient dilution of airborne contaminants, provided the mixing of room air is reasonably uniform.

7.14 A downward-displacement turbulent air distribution is generally preferred. The supply and extract diffusers should be positioned to ensure that all parts of the room are actively ventilated and that where necessary the staff will be in a clean air-flow path. (See Section 5 for additional guidance on supply terminals).

7.15 Horizontal-flow room-air distribution with or without a Coanda effect can be a source of draughts and difficult to set up correctly. Its use should be confined to non-critical areas.

Air movement control

7.16 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room pressure differentials. When closed they prevent significant reverse air-flow.

7.17 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic airflow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less clean areas. Failure to provide such devices will lead to uncontrolled air flows when personnel move between rooms. They may also result in doors being held partially open by air pressure

Temperature and humidity control

7.18 To achieve the required room conditions, supply flow rates are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the base heating load will be provided by a heating system. In critical systems the room or suite being considered will be within the heated building envelope so the ventilation will be sized to suit the casual gains or losses.

7.19 Temperature differences of up to 10K for winter heating and 7K for summer cooling must not be exceeded.

7.20 It is acceptable for the humidity to swing uncontrolled between 35% and 70% saturation.

Removal and dilution of waste anaesthetic gases

7.21 Anaesthetic gases are subject to occupational exposure limits. Waste anaesthetic gas must be contained and removed by a suitable gas-scavenging system. Some leakage from the anaesthetic equipment and the patient's breathing circuit will occur with all systems, particularly during connection and disconnection; and from the interface with the patient. The air movement scheme should ensure that this leakage is diluted and removed from the room. Anaesthetic agents are heavier than air so placing the supply terminal at high level with an extract at low level, adjacent to the anaesthetic gas terminal units will ensure that staff are in a clean air-flow path.

7.22 In LDRP and delivery rooms the use of anaesthetic gas is controlled on demand by the patient. This may result in significant leakage which, in order to reduce staff exposure, will need to be controlled by establishing a clean airflow path. A supply at high level at the foot-end of the bed with extract at low level at the head-end will provide such a path.

Fire aspects

7.23 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire.

Door protection

7.24 Air should flow from the cleaner to the less clean areas as shown in Table A2. There are several factors that affect the likelihood of a reverse air- flow through doorways:

- when a person passes through a doorway, both the passage of the person and the movement of the door flap cause a transfer of air between the areas separated by the door;
- when a door is left open there is a transfer of air between the two areas separated by the doorway. This is caused by air turbulence, but is greatly increased by any temperature differential between the areas (a 1.4m wide doorway may allow the transfer of 0.19 m^3/s of air in each direction when there is no temperature difference, but when the temperature differential increases to say 2K, the volume transferred may increase to 0.24 m^3/s).

7.25 Two methods of door protection are used in order to reduce the likelihood of contamination of clean area by a reverse air-flow from a less clean area:

- closed door protection – a pressure differential is created across a closed door so that any air leakage is from the clean to the less clean area.

Table A3 gives details of closed door leakage rates for a range of differential pressures;

- open door protection – the pressure differential drops (See Table A5) and is effectively replaced by a flow of air through the doorway from the clean to the less clean area. The flow of air needs to be sufficiently large to ensure that significant reverse airflow cannot occur and will be related to the relative cleanliness of the areas being considered. Table A4 gives air-flow rates for open door protection related to door / opening size and classification of the adjoining areas.

7.26 Pressure stabilisers enable the room differential pressure to be set when the doors are shut, thus providing closed-door protection. When a door is opened the stabilisers will close, forcing air to be directed through the doorway thus providing open-door protection.

7.27 The recommended air-flow rates to achieve this are given in Table A3. Provided that the dilution criteria in Table A1 are met, the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.

7.28 In applications where it is critical to maintain a specific airflow and /or pressure regime (for example isolation rooms) all windows in the zone should be locked shut or sealed. Trickle vents, if fitted, will also need to be sealed.

Systems design

7.29 The design of the ventilation system for an area depends on the overall configuration of the department. Where the department is served by more than one AHU, the control of the units may need to be interlocked so that reverse air-flow patterns do not occur.

7.30 Dual-duct high velocity systems have advantages, but are noisy, costly and may give rise to unacceptable values of humidity. Single-duct, low velocity/pressure systems are preferred.

7.31 Extract grilles should be sited and balanced to promote air movement in the desired direction.

7.0 (a) Operating department ventilation systems

7.32 The information given in this section relates to general operating suites. It will be applicable to other types of theatre suite such as maternity, burns, cardiac, etc. The standard values given may need to be adjusted to reflect non-standard room sizes, pressure regimes and air change rates.

7.33 A method of obtaining a design solution for non-standard theatres is given in Appendix 4.

7.34 Additional information for Ultra-clean ventilation (UCV) theatres is given in Section 7.0 (b).

General

7.35 The supply of air to an operating room has four main functions:

- to dilute airborne contamination;
- to control air movement within the suite such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
- to control the temperature and if necessary the humidity of the space;
- to assist the removal of, and dilute, waste anaesthetic gases.

7.36 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied to the operating room will be determined by the number of doors and desired air-change rate.

7.37 The detailed considerations upon which the supply air-flow rate is based are as follows.

Dilution of airborne bacterial contaminants

7.38 There are four routes that airborne contaminants may appear in an operating room:

- through the supply air;
- shed by operating staff;
- produced by the surgical activities;
- transferred from adjacent spaces.

7.39 Supply flow rates for the main rooms of the operating suite are given in Appendix 3. For the other areas where room sizes and activities vary from site to site, air-change rates are given in Table A1. These figures have been found to give sufficient dilution of airborne bacterial contaminants, provided the mixing of room air is reasonably uniform.

7.40 A downward-displacement air distribution is preferred; it may be either turbulent or laminar flow. For turbulent flow the supply-air diffusers should be positioned either in the centre of each quadrant of the ceiling or along a line between the centres of each quadrant. This should ensure that all parts of the room are actively ventilated and that there will be adequate air movement at the operating table. Laminar flow would be provided by a perforated plenum terminal centred above the operating table. (See Section 5 for additional guidance on supply terminals).

7.41 Suspended articulated equipment is usually fitted in theatres. These require significant structural steelwork in the ceiling void to cater for the loads imposed by the resulting bending moments. It is important to ensure that the void is

deep enough to accommodate both the steelwork and the ventilation ducts. The location of the steelwork must not prevent a suitable layout of the ventilation ductwork and correct positioning of the supply air terminals. It needs to be recognised that the correct ventilation of an operating theatre plays a significant part in controlling healthcare acquired infections and is not subordinate to the desire to make equipment easy to move.

7.42 Horizontal flow distribution with or without a Coanda effect can be difficult to set up correctly and are unlikely to be as effective in Theatre applications. It should not be used in new installations. However space constraints may force its retention or replacement when refurbishing existing installations. Where fitted, the supply grilles will require a means of directional adjustment.

7.43 For general operating theatres, the air supply would be filtered in the AHU. Terminal HEPA filters are not generally required.

Control of air movement within the suite

7.44 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. In older designs suitably dimensioned door undercuts were often used in lieu of transfer grilles. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room-pressure differentials.

7.45 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic air-flow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less-clean areas of the suite. Failure to provide such devices will lead to uncontrolled airflows when personnel move between rooms and doors being held partially open by air pressure.

Temperature and humidity control

7.46 Supply flow rates to achieve the required room conditions, are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the room being considered will be within the heated building envelope.

7.47 Temperature differences of up to 10K for winter heating and 7K for summer cooling must not be exceeded.

7.48 It is acceptable for the humidity to swing uncontrolled between 35% and 60% saturation.

Removal and dilution of waste anaesthetic gases

7.49 Anaesthetic gases are subject to occupational exposure limits. The air-movement scheme should ensure that staff are in a clean air-flow path. (See Paragraph 7.21).

7.50 Air extracted from operating suites should not be re-circulated, as it may contain malodorous contaminants. However an energy recovery system should be fitted in the extract in order to reduce the plant energy consumption. (See Paragraphs 4.142 - 4.147).

Fire aspects

7.51 When considering the overall air-flow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire. However, this is a highly staffed department with a low fire risk/load status and these factors need to be recognised when developing the fire strategy. It is considered satisfactory to treat the complete operating department as a single fire compartment providing there are at least two exits from it. Over-compartmentalisation can lead to difficulties in establishing clean air-flow paths and room-air dilution rates. This will lead to an increased risk of healthcare-associated infections. Staff areas within the department should be treated as a sub-compartment. (See Paragraph 6.18).

Door protection

7.52 Air should flow from the cleaner to the less clean areas as shown in Table A2. The factors that affect the likelihood of a reverse airflow through doorways are discussed in Paragraphs 7.24 - 7.26.

7.53 It is not possible to design an air-movement scheme, within the restraints of the amount of air available that will protect the operating room when two doors are simultaneously opened. The design process that has been used considers that each door is opened in turn and ensures that the direction and rate of air-flow through any open doorway is sufficient to prevent any serious back-flow of air to a cleaner area.

7.54 Provided that the air-change rates in Table A1 are met, dilution will be sufficient to ensure that the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.

7.55 The following general points should be taken into consideration during the design of operating suites:

- Number of exits – the fewer the number of rooms (and therefore doorways) leading from the operating room the better, as traffic is reduced and less complicated air-movement control schemes are required.
- Scrub and hand-wash facilities – these may be a part of the operating room, often in a bay. The bay would count as part of the operating room volume

and should have a low-level active or passive extract to remove the moisture-laden air. Should a separate room be required for the scrub area, a door between the scrub-up room and the operating room is an inconvenience to scrubbed staff, and could be replaced by an opening. This opening should be larger than a normal single doorway, but the scrub would not, in these circumstances, be considered part of the operating room volume.

- If an alcohol scrub regime is employed, individual theatre scrubs may not be required and would be replaced by a common departmental pre-/post-operation scrub position in the corridor. This would require local extract to prevent a build-up of moisture.
- Preparation 'Sterile Pack Store' (SPS) – if it is intended to 'lay-up' instruments in the operating room, the preparation room is then used simply as a sterile pack store. The nominal room pressure can therefore be the same as that of the operating room and the airflow between the two rooms in either direction. Air supplied to the preparation room may be directed into the operating room either through a door mounted transfer grille or if no door is fitted, through the opening. Alternatively, stock ready-use sterile items can be located in a bay within the theatre. In this case, a portion of the total theatre supply air should be provided in the bay to ensure it is actively ventilated.
- Preparation room 'lay-up' – when the preparation room is used as an instrument 'lay-up' room, it should be regarded as being of greater cleanliness than the operating room, and the design should minimise the transfer of air from the operating room to the preparation room. Air supplied to the room may be directed to the operating room through a pressure stabiliser taking care not to compromise the airflow pattern in the operating room. The air may also be directed into a corridor;
- Service corridor – if materials to be disposed of are placed in impervious material for transportation, it is not necessary to have a separate corridor for this purpose. However, a service corridor has many operational advantages it terms of the flow of materials through the theatre suite. It also permits routine service and maintenance access without compromising the use of adjacent theatre suites.

Standard air-movement control schemes

7.56 In the previous versions of this guidance standard air movement control schemes were given that provided a range of design solutions to typical operating suite layouts. These were satisfactory design solutions for 'standard' sized rooms within the suite but were never intended to be universal for any sized room or suite. Guidance on operating suites contained in HBN 26 (2004) has increased the recommended size of operating room from approximately 35m^2 to 55m^2. Associated room sizes and air change rates have also increased. This means that the original standard solutions are no longer appropriate for new-build installations.

7.57 Because of the resulting increase in the volume of air supplied to the theatre, provision needs to be made either to actively remove it or allow it to escape

passively through pressure stabilisers. The increase in room size has also made the number and position of air-supply terminals critical to the effective ventilation of the room.

7.58 Four new standard solutions have been developed to reflect the current guidance on theatre suite layout and room sizes given in HBN 26 (2004) as well as the general increase in air-change rates.

7.59 The most commonly used original standard solutions have been revised and updated. They have been retained in this guidance, as they will remain applicable to older theatre suites that are being refurbished to their original performance standards. They will also be applicable in existing departments where space constrains do not permit the upgrading of suites to the latest standard of performance or where a pre-built "shell" is being fitted out.

7.60 It is important to recognise that in any situation where a "non-standard" room size or theatre suite layout is being considered, the designer must return to first principles when developing a solution. Examples of non-standard configurations would be:

- cardiac theatres that typically have an operating room half as big again as normal, a perfusion laboratory and no anaesthetic room;
- operating departments served by a central instrument lay-up preparation area rather than individual prep rooms;
- balanced-flow theatres for infectious cases.

Appendix 4 contains a methodology for assisting the designer to arrive at a suitable solution.

7.61 The new and revised standard design solutions are as follows:

No 1 – Typical Conventional theatre – room sizes as HBN 26;

No 2 – Typical UCV theatre – room sizes as HBN 26;

No 3 – HBN 26 illustrated Conventional theatre;

No 4 – HBN 26 illustrated theatre with UCV terminal fitted;

No 5 – Pre-2006 Conventional theatre, single corridor (former SHTM 2025; 1b);

No 6 – Pre-2006 UCV theatre, single corridor (former SHTM 2025; 1a);

No 7 – Pre-2006 Conventional theatre, two corridor (former SHTM 2025; 5b);

No 8 – Pre-2006 UCV theatre, two corridor (former SHTM 2025; 5a).

7.62 Details of these standard solutions are given in Appendix 3. They contain diagrams that show the relationship of rooms and the various doors and transfer devices between them, **but should not be regarded as architectural layouts.**

The schemes have been developed using the calculation procedure described in Appendix 4. Important features of the solutions are:

- Zone trimmer heaters – a trimmer heater battery is advocated when calculations indicate that the temperature differential between rooms may be greater than 2K. Generally this will only be the case in the preparation room when designated as a lay-up.
- The preparation room (sterile pack store)/operating room interface – these rooms are deemed to be of equal cleanliness, and thus a transfer grille is required between these rooms or the door can be replaced with an opening wider than a standard door.
- Preparation (lay-up)/disposal room interface – pressure relief dampers are recommended here to provide an air path when doors are closed, while preventing back-flow when a door is opened elsewhere.
- Operating room/anaesthetic room interface – pressure stabilisers, or in some cases, carefully sized transfer grilles are recommended here, and between the anaesthetic room and corridor, and between the operating room and corridor.
- Operating room/scrub room interface – an opening is provided between these rooms. The flow of air through the opening provides protection, and gives bacterial dilution within the scrub room; the air is then exhausted to the corridor via a pressure stabiliser.

7.63 No mechanical supply or extract ventilation is provided in the scrub room, and thus when a door is opened elsewhere in the suite, the stabiliser will close, allowing the air to be re-directed to help protect the doorway. If the scrub is a bay within the theatre then a suitably positioned pressure stabiliser and / or active extract should be provided to ensure air movement and prevent a local build-up of moisture.

7.64 Any other scheme may be used and the standard solutions applied, if the following conditions are met:

- room relationships in air network terms are as shown in the plans;
- door-gap measurements approximate to those given in Scottish Health Technical Memorandum 58: ‘Internal doorsets’, (but see also Table A3 and Note 3);
- casual heat gains are accounted for;
- a trimmer battery is installed in the air supply system to the preparation room;
- leakage through the structure is kept to a minimum.

Note 3: It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design door leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

7.65 It is recommended that every effort should be made to adopt one of the schemes described above.

Air terminals and air distribution within rooms

7.66 The selection and sighting of air diffusers will be critical in establishing an efficient pattern of mixing. To this end the diffusers selected must be fit for purpose. Ceiling mounted circular 'air master' style, square 'four-way blow' or similar diffuser designs that provide a downward displacement, turbulent airflow are the preferred option. (See Paragraph 5.68).

7.67 Plenum-type 'laminar'-flow-style diffusers with a footprint that encompasses the operating site are acceptable but may be prone to buoyancy effects as a result of temperature difference. Manufacturers' type-test data should be consulted to ensure that the terminal will achieve the required performance envelope. Note that these are not true laminar-flow systems in the strict sense of the word but produce a downward-displacement parallel-flow style of air distribution.

7.68 The diffuser equipment chosen should not cause 'dumping' and it should provide a velocity 1 metre above floor level at the operating position of between 0.2 m/s and 0.3 m/s.

7.69 In the operating room, the supply air terminals must be at high level, and should all be adjustable for rate of flow as well as being easily cleaned and silent in operation.

7.70 In order to ensure that all parts of the operating room are actively ventilated, there should be an air-out path on each face or in each corner of the theatre. This may be provided by a pressure stabiliser, transfer grille, active or passive extract terminal. A minimum of three, but preferably four, air-out paths - approximately equally spaced - should be provided.

Automatic control

7.71 The automatic control of ventilation in operating suites needs to be simple and robust. Over-reliance on complex room pressure and flow relationships linked to automatic fan speed control is unnecessary and in the long term have been shown to be unreliable. Complex software algorithms that can only be accessed and interpreted by off-site specialists should not be used. Whichever control strategy is chosen it is important that on-site staff have the facility to override the control system and keep the ventilation operating at least until the surgical procedure is complete. (See also Paragraph 6.11)

7.72 Theatre air-conditioning control sensors should be actively ventilated. They would typically be located in a sampling extract duct mounted in the surgeon's

panel, positioned at normal working height (1.8m above finished floor level) and be accessible for cleaning and the removal of fluff and lint.

7.73 Wall-mounted passive-temperature and humidity sensors are not recommended.

7.74 Controls should be provided to enable operating department ventilation plants to be closed down when the operating suites are unoccupied. (See also Paragraphs 6.24 - 6.26)

7.75 When in the 'off' mode, the control system should ensure that the ventilation plant is automatically reinstated if the space temperature falls below 15°C.

7.76 The theatre control panel should include plant status indication; clearly-readable temperature and humidity indicating gauges; and means of adjusting the set point for temperature. Theatre ventilation plant status indication should be located at the staff control base.

7.77 Where it is considered necessary to fit a humidifier, it should be selected to humidify to 40% saturation at 20°C during the design winter outside conditions. The cooling coil should be able to remove sufficient moisture so that 60% saturation at 20°C is not exceeded during the design summer outside conditions.

7.78 Each operating suite should be served by an independent supply and extract plant.

Ventilation of operating department ancillary areas

General

7.79 There are advantages in providing mechanical ventilation to all areas of the department. Maintaining operating suite airflow patterns is simpler and grilles and diffusers can be sited to eliminate condensation on windows. Where radiators or embedded wall or ceiling panels are installed they should be confined to the corridors and staff-only areas of the department.

Ventilation requirements

7.80 Table A2 gives guidance on the operating department areas in descending order of cleanliness, and this should be considered in the overall design of the department ventilation systems. The specified flow rates of air through doors given in Table A4 for the operating suite are not necessary for other areas of the department. However, the air-flow directions must be maintained from the clean to the less clean areas.

7.81 All windows in the department should be double-glazed and hermetically-sealed in order to ensure that the desired airflow pattern is maintained under all external environmental conditions and to avoid infestation. Trickle vents if fitted will need to be sealed.

Systems design

7.82 The design of the ventilation system for the ancillary rooms depends on the overall configuration of the department. The plant for the ancillary rooms may need to be interlocked to the theatre suite plants so that reverse air-flow patterns do not occur.

7.83 Extract grilles should be sited and balanced to promote air movement along the clean and access corridors towards the reception/transfer areas. This should not affect the air distribution in the operating suite(s).

Reception

7.84 The aim in these areas is to provide comfortable conditions having regard to the movement control requirements of the department as a whole. The number of air changes will depend on the particular design.

Sterile pack bulk store

7.85 The store needs to be maintained at a positive pressure in order to preserve the cleanliness of the outside of the packs; 6 air changes are recommended.

Recovery

7.86 The air-change rate in the recovery room will be rather higher than that needed merely to provide clean, comfortable conditions, as it is necessary to control the level of anaesthetic gas pollution; 15 air changes are recommended, with a balanced air flow.

7.87 The supply air terminals should be ceiling mounted above the foot-end of the recovery bed positions. Extract should be at low (bed height or below) level behind the bed head positions or in the corners. This will establish a clean airflow path so that staff do not inhale anaesthetic gases exhaled by recovering patients.

7.0 (b) Ultra-clean ventilation systems

General requirements

7.88 The design philosophy of a conventionally ventilated operating suite is based on the need to dilute contaminants and control both the condition and movement of air in an operating suite. Ultra-clean ventilation (UCV) is a means of significantly increasing the dilution effect by providing a large volume of clean filtered air to the zone in which an operation is performed and sterile items are exposed. Air is discharged above the operating zone and while not truly laminar, its downward displacement purges the clean zone of contaminants and particles generated by the activities within it. The airflow in and around the clean zone also serves to prevent particles originating outside the zone from entering it. The resulting reduction in contaminants has been shown to reduce significantly post-operative sepsis following certain orthopaedic procedures.

7.89 The number of bacteria that are present in the air at the wound site and exposed surgical items is dependent on the operating team, their procedural discipline, choice of clothing and the type of UCV system. Ultra-Clean air is defined as that containing not more than 10 CFU/m^3.

7.90 UCV systems are very successful in reducing contaminants at the wound site so it is often considered that there is no need for complex air movement control schemes in the rest of the suite. However, when designing the ventilation scheme, it should be noted that the users may switch the UCV terminal to "set-back" when non-orthopaedic surgery is taking place. This is because the high airflow rates can cause increased moisture evaporation of exposed tissue that may be detrimental to the surgical outcome. In recognition of this, the ventilation scheme should be capable of providing operating conditions to at least a "conventional" theatre standard throughout the suite with the UCV in set-back mode. It should also be remembered that suitable levels of ventilation will always be required in the peripheral rooms.

7.91 UCV systems can be designed and built from first principles or a range of bespoke modular units of varying shapes and sizes are available with each manufacturer having a slightly different approach to UCV design. Some systems are fitted with partial or full walls to delineate the clean zone and direct a laminar or exponential downflow of air within it. Other designs utilise slotted linear supply terminals to produce an air curtain around the clean zone together with laminar-flow diffusers to provide a downward-displacement supply within it. **Notwithstanding any variation in the design philosophy, all UCV systems will be required to achieve completely the performance standard set out in the "Validation" section of this document**. (Section 8)

7.92 As with conventional theatres, each UCV operating suite should have its own dedicated air handling unit (AHU) to the standard set out in Section 4 of this document. To ensure operational flexibility and permit routine maintenance, air handling units should not be shared between suites.

7.93 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances an AHU may be shared between not more than two operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre so that the primary air volume to each UCV canopy can be determined. In addition the branch supply and extract should be capable of being physically isolated and the main air-flow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

7.94 An inherent feature of a UCV system is its large airflow so it is essential to re-circulate the air supplied to the operating theatre and/or to recover its energy in order to optimise operating costs.

7.95 The primary fresh-air volume supplied to a UCV suite will be the same as in a conventional suite and it should be dispersed to the rooms in the suite in the same manner. This is an important aspect of the design and requests by UCV suppliers for increased primary air-supply volumes should be resisted.

7.96 Laying-up in the clean zone is preferable for infection control reasons. Where a Sterile Pack Store (SPS) Preparation room is provided a transfer grille will be required in the preparation room / theatre door.

7.97 If the Preparation room is intended to be used for laying-up instruments, a pressure stabiliser will be required between the prep room and theatre. It should be fitted with a stand-off baffle to prevent air transfer interfering with the ultra-clean airflow distribution.

7.98 Separate scrub-up or disposal facilities are not necessary for air cleanliness although operational policy may prefer such a provision. A separate anaesthetic room should, however, be provided.

7.99 There is no aerobiological reason why two or more UCV systems should not be installed in a common area as long as adequate spacing is provided. These are known as “barn theatres” and require special design considerations and operational discipline. The relative positions of the UCV units, temperature control range and location of doors and openings to other areas will all significantly affect the airflow at the operating positions.

Types of UCV system

Remote plant systems

7.100 In a remote plant system, all the air-conditioning equipment is located outside of the operating room, except for the unidirectional air-flow terminal, terminal filter, air diffuser and the return-air grilles (see Figure 6).

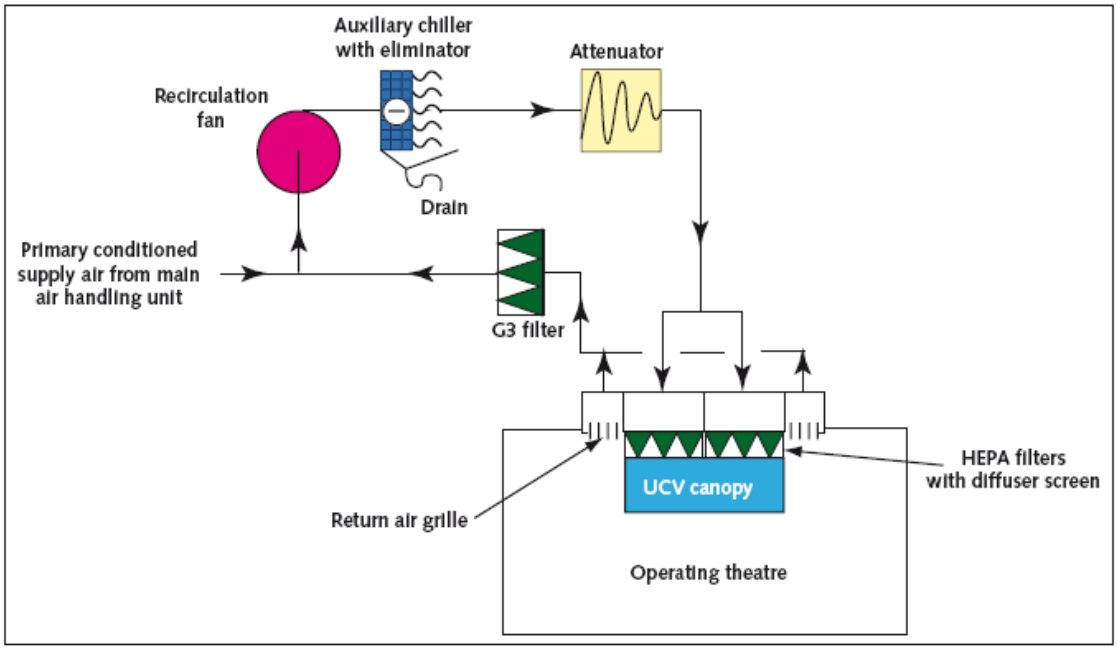

Figure 6: UCV theatre with remote air recirculation

7.101 This arrangement is the preferred option for new installations as it has the following advantages:

- the recirculation fans are out of the theatre thus reducing noise. Multiple recirculation fans can be replaced by a single fan unit with its drive out of the air stream;
- casual heat gains from recirculation fan(s), canopy lights, equipment and people within the theatre can be removed by a chiller battery in the return air stream. This will prevent heat build-up in the theatre;
- the return-air filters can be changed without needing access to the theatre making routine maintenance more feasible;
- the opportunity exists to locate the HEPA filter in the primary supply duct rather than the theatre terminal. This will reduce the number of filters required and allow them to be changed without entering the theatre.

Modular systems

7.102 Modular systems are frequently used in retrofit applications. Vertical or horizontal units are available.

7.103 Vertical-flow modular units comprise a ceiling-mounted air-terminal module containing return-air filters, return-air fans, final filter and air diffuser. Primary air is supplied by a remote air-conditioning unit at the volume and to the standard required for a conventional operating suite. (see Figure 7)

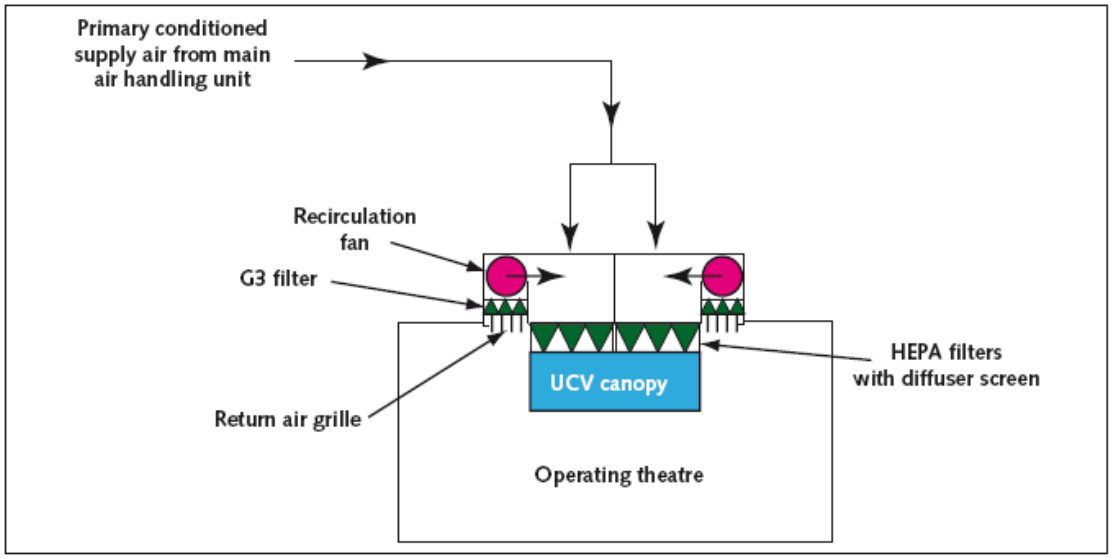

Figure 7: UCV theatre with modular system

7.104 Horizontal or cross-flow modular units comprise a wall-mounted air-terminal module standing vertically to produce a horizontal flow of air and containing final filter/diffuser, return-air filters and fans. The module may incorporate a cooling unit or be supplied with 'fresh air' from a separate primary cooling system.

Vertical flow UCV systems

7.105 Vertical-flow systems have a superior performance and are more effective at reducing infection risks. Air-curtain or partial-wall systems are acceptable, but are known to be more susceptible to problems arising from performance

deterioration, poor operating-team discipline and high occupancy rates than is the case with full-wall systems. A full-wall is considered to be any wall terminating not more than one metre above the finished floor level.

7.106 Because of the large volume of air being moved in a relatively small space, the siting of the return-air grilles can cause short-circuiting of the air discharged through the UCV terminal. If the return-air grilles are positioned at high level, partial walls should be provided to control short-circuiting. The partial-walls shall be not less than 1m from the operating room walls and terminate at least 2m above floor level. The clearance should be increased proportionally for larger terminals (that is, 1.15m for 3.2m x 3.2m units and 1.25m for 3.5m x 3.5m units). In all cases, the sidewalls should terminate at 2m above floor level.

7.107 Siting the return-air grilles around the periphery of the theatre at low level will eliminate short-circuiting, remove the need for partial walls and give an improved airflow path. In any event there should be an air-out path on each face or in each corner of the theatre. These may be provided by combination of pressure stabilisers and passive or active low level extract grilles. Failure to provide air-out paths on all faces of the theatre may result in the surplus air causing entrainment into the clean zone.

7.108 Vertical systems should have a clean zone large enough to encompass the operating site and all of the instrument trays likely to be needed for the surgical procedures to be undertaken. Ophthalmic and minor hand surgery would typically require a 1·4m circular or rectangular terminal. For major orthopaedic procedures a minimum size of 2·8m x 2·8m will be required. This is the area projected on the floor under the supply air terminal within the partial walls, full walls or air curtain. Any air outside this zone cannot be guaranteed to be ultra-clean although given the dilution factor the level of microbiological contamination will be much lower than the general level in a conventional operating room. The use of lines or a coloured area on the floor delineating the extent of the clean zone will assist staff and is therefore essential.

7.109 When upgrading an existing conventional theatre to an ultra-clean standard the only solution may be the installation of a modular system. In these units, the heat gains from the return-air fans and terminal lights may warrant the inclusion of supplementary cooling within the module although modern luminaries contribute substantially less unwanted heat. However issues of cooling coil drainage, condensate removal and maintenance access within the space constraints of the module may make this option impracticable. The additional cooling load should then be catered for by conditioning the primary air to compensate.

7.110 If an existing AHU is to be retained, it may require modification to ensure that it achieves the minimum standards set out in Section 4 of this document. The fan may need re-rating to accommodate the change in system resistance. The cooling coil may also need to be upgraded to cater for the increased load resulting from the return air fans and terminal lights. Failure to make adequate provision for this may make the theatre unusable during prolonged warm spells.

7.111 A factor affecting the air-flow pattern is the supply or room air temperature difference. When the supply-air temperature is significantly above room temperature, buoyancy effects will reduce the volume of air reaching the operating zone. If it is anticipated at design stage that this will be a regular occurrence, then a system incorporating full-walls should be used. Demountable extensions that convert a partial-wall to a full-wall unit are available.

7.112 Convection up-currents from the surgical team and operating lamp tend to counter the movement of clean air towards the operating site, hence the air velocity reaching the operating level is critical. The minimum velocity given below has been selected to take account of these factors and is greater than the theoretical minimum value.

7.113 For all vertical UCV systems the design discharge velocities will be as follows:

Air velocity 2 metres above floor level:

- partial-wall system = 0.38 m/s average;
- full-wall system = 0.30 m/s average.

Air velocity 1 metre above floor level:

- all systems = 0·2 m/s minimum within the operating zone.

The validation Paragraphs 8.75 – 8.86, gives details of the method of measurement.

7.114 Variable-speed recirculation fans with differential pressure control may be the most suitable solution for maintaining consistent performance and energy saving.

Horizontal UCV systems

7.115 Horizontal UCV air-flow systems have been shown to be less effective than vertical systems and are not the preferred solution. There may be occasions, however, where architectural, engineering, economic or workload considerations prevent the installation of a vertical-flow system and only a horizontal-flow system can be installed.

7.116 Horizontal- or cross-flow modular units comprise a wall-mounted air terminal standing vertically to produce a horizontal flow of air across the operating field. The terminal module contains the final filters, air diffuser, return-air grilles, filters and fans. The module may incorporate a full air-conditioning unit or be supplied with 'fresh-air' from a separate primary air-conditioning system. In the latter case the return-air fan power may warrant the inclusion of a supplementary cooling coil within the module.

7.117 The system should have sidewall panels at least 2·4m apart. The panels may fold to facilitate cleaning of the theatre. The minimum height of the terminal should be 2·1m and a deflector at the top of the filter/diffuser will be acceptable

as an alternative to a full roof. These dimensions reflect currently available equipment and may impose operational constraints in addition to a lower level of performance common to these systems.

7.118 In the horizontal flow systems, personnel working between the filter and surgical wound will disperse bacteria that are more likely to contaminate exposed surgical instruments and enter the wound. This may be minimised by the use of improved clothing and operating procedure to reduce dispersion of bacteria. The use of lines on the floor delineating the extent of the clean zone and hatching or colour coding the 'no-entry' zone between the air diffuser and patient will serve to prompt staff and are therefore essential.

7.119 The air discharge velocity as measured 1m from the diffuser face should have a mean value of 0·4 m/s. The validation Section 8 gives details of the method of measurement.

Filters

7.120 The main plant primary and secondary filters should be to the standards and in the location set out in Section 4.

7.121 Terminal filters should be provided within the airflow terminal or in the air supply to it. High efficiency particulate air (HEPA) filters grade H10 as specified in BS EN 1822 will be required as a minimum. There is no aerobiological benefit in fitting filters of a higher grade than this, although for practical reasons most UCV manufacturer recommend the fitting of H12-grade filters.

7.122 In some modular UCV units, the terminal filter is used as a pressure equaliser to balance airflow and filters of a higher grade with a greater pressure drop may be recommended by their manufacturer. The increased resistance may affect the velocity of air reaching the operating level and there will be penalties in terms of installed fan power and higher noise levels.

7.123 The final filters should be installed in a leak-proof housing in a manner that allows the terminal unit, filters and their seals to be validated. A challenge test will be carried out during commissioning to prove the effectiveness of the complete installation.

7.124 Where UCV units are constructed in sections, a means of measuring the pressure drop across the terminal filters in each section should be provided. The pressure test-points should be located outside of the partial wall, capped to prevent air leakage and accessible within the theatre without the need to open the unit inspection panels. Alternatively direct-reading pressure gauges should be fitted.

7.125 The UCV system will require a return-air filter to capture the relatively coarse particles that would otherwise significantly reduce the life of the final filter. This should be at least a G3 grade to BS EN 779. In remote recirculation systems there may be advantages in fitting a higher grade return air filter, as it will reduce the load on the terminal HEPA filters and extend their life.

Noise level

7.126 If sound-attenuating material is used to line any portion of the inside of the UCV unit it should be non-particle-shedding and fire-resistant. (Further guidance can be found in SHTM Firecode suite of documents).

7.127 The maximum noise level in an operating room fitted with a UCV terminal of any type shall not exceed 50 NR. The validation section gives details of the method of measurement.

Lighting and operating lights

7.128 CIBSE lighting guide LG2 and BS EN 12464-1 give detailed information of lighting requirements. Operating luminaires should comply with the photometric requirements detailed in relevant sections of BS EN 60601.

7.129 The position of the UCV light fittings and style of partial walls, where fitted, should neither adversely disturb the airflow nor result in significant spatial variations in illuminance levels.

7.130 In vertical units, specialised task lighting should be provided by toroidal, cruciform or small multiple dome-shaped luminaires as they have good aerodynamic properties. The ideal luminaire will have a minimal effect on the airflow regardless of where it is positioned. Large-diameter saucer-shaped luminaires should not be used in vertical-flow systems as they will occlude the airflow in the critical central zone. It is important to consider the suitability of existing luminaires when retrofitting UCV systems.

7.131 In vertical UCV installations a minimum of 2·75m from floor to underside of the diffuser is required to allow for supporting mechanisms and lamp articulation. When upgrading existing systems this dimension may not be achievable. However, when parked, the lowest point of the central light stem, luminaire and articulation arms should never be less than 2m above floor level.

7.132 The traditional means of light support is a central column that passes through the UCV terminal and is rigidly fixed to the building structure. The position of the support therefore prevents air being supplied at the centre of the terminal. Separate supports displaced from the centre of the clean zone would lead to improved airflow. This approach was advocated in the 1994 version of HTM 2025 but at the time of writing no UK manufacturer has chosen to adopt this solution.

7.133 In horizontal units the size or shape of the specialised task luminaire has little effect on the air-flow pattern.

Controls and instrumentation

7.134 The functions of the supply AHU and extract ventilation should be continuously monitored by a BEMS control unit. The controls and instrumentation for the main plant are set out in Section 6.

7.135 UCV systems will additionally require:

- a set-back facility that can reduce the air supplied through the UCV terminal to a volume that equates to not less than 25 air changes per hour of the operating room gross volume whilst still leaving the supply AHU operating at full speed;
- a facility to turn the entire system, supply AHU and UCV terminal, off. (an emergency stop is not required);
- a read-out sufficiently large to be clearly visible from the operating table that shows the temperature of the air being supplied by the UCV terminal;
- a read-out sufficiently large to be clearly visible from the operating table that shows the relative humidity of the air being supplied by the UCV terminal;
- a red indicator light that will illuminate when either the supply AHU or the UCV terminal fails, either or both are switched off or are at set-back;
- an amber indicator light that will illuminate when the UCV terminal is at set-back and the supply AHU is running;
- a green indicator light that will illuminate when both the supply AHU and UCV terminal are operating at full speed;
- a blue indicator light that will illuminate when the UCV terminal air flow, as detected by a differential pressure sensor, falls below 80% of the design flow rate.

AHU	UVC terminal	Indicator light	Comment
Off or Fault	Off or Fault	Red	Ventilation not operating at a suitable level to commence surgical procedures
Off or Fault	On (set-back)		
Off or Fault	On (full speed)		
On (set-back)	Off or Fault		
On (full speed)	Off or Fault		
On (set-back)	On (set-back)		
On (full speed)	On (set-back)	Amber	Ventilation provided to at least conventional theatre standard
On (full speed)	On (full speed)	Green	Full UCV standard conditions
-	-	Blue	HEPA-filter resistance causing low air flow

Table 7: Indicator light logic table

7.136 The switching devices and indicators should be incorporated in the surgeon's panel and their functions clearly labelled. In retrofit installations an auxiliary panel for the UCV may be the most practical option. If fitted it should be mounted adjacent to the surgeon's panel and their control functions interlocked as necessary.

7.137 When a system is designed to have partial walls with full-wall extensions, a volume control facility may be incorporated to allow the system to be run with reduced velocity when the demountable full-walls are in place. It would be the responsibility of the user to ensure correct operation of the system. To assist the user an explanatory notice should be included on the theatre control panel.

7.138 A direct-reading gauge should be fitted in the theatre to show a representative pressure drop across the final filters. If the UCV control box is located out of the theatre and has a means of manually adjusting the return air-fan speed then it should also be fitted with a direct-reading differential pressure gauge. The means of adjusting the return-air fan speed should be lockable to prevent casual adjustment. The direct-reading gauges should be fitted with a means of indicating the correct operating pressure range.

7.139 The UCV-unit manufacturer's control box should be located in an accessible position preferably in the operating department adjacent to the operating theatre that it serves. A service corridor, if provided, is an ideal location. The control box should be clearly labelled with the identity of the operating theatre that it serves.

7.0 (c) Extract systems

7.140 Extracts may be provided for a variety of reasons including:

- simple odour control (for example in a WC or mortuary);
- to receive and remove moisture-laden air (for example, in a kitchen);
- as part of a combined supply/extract balanced system (for example, in an operating suite);
- to capture a hazardous substance at source (for example a safety cabinet).

7.141 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations.

7.142 An LEV system may comprise a self-contained unit incorporating its own carbon filter such as a simple bench-top fume cupboard. Alternatively it may be a complete "ventilation system" comprising a make-up air supply, multiple-exhaust-protected work stations, branch and central extract ductwork, duplex extract fans and a high-level discharge terminal. It may also incorporate a special filtration system appropriate to the hazardous substance being controlled. Such systems could be required for workshops containing woodworking machinery or large centralised pathology laboratories housing multiple safety cabinets, dissection benches, fume cupboards and specimen stores.

7.143 It is important to recognise at the design stage whether an extract is being provided for comfort or as an LEV system. Typical systems in healthcare include:

- microbiological safety cabinets and Category 3 containment rooms;
- fume cupboards;
- welding-fume extracts;
- woodworking machinery duct collectors;
- battery-charging bay extracts;

- powered plaster and bone saws;
- pharmaceutical preparation cabinets and tablet machines;
- dissection benches, cut-up tables and some specimen stores;
- medium- and high-risk infectious disease isolation facilities;
- decontamination facilities;
- dental furnaces, grinders and polishers.

7.144 General design information and guidance for LEV systems is produced by the Health and Safety Executive (HSE) as HS(G)37. Information on the design and installation of microbiological safety cabinets is given in BS5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.

7.145 LEV systems are statutory items that will be subject to an independent inspection every 14 months.

Hood extract systems

Special requirements

7.146 Extract canopies will be required over steam-and-heat-emitting appliances, for example sterilisers, catering and washing equipment; and for the extraction of toxic fumes over benches used for mixing, sifting and blending procedures.

7.147 Perimeter-drain gulleys and corrosion-proof grease eliminators should be provided on kitchen hoods.

Typical arrangements

7.148 The air-flow rate must be sufficient to ensure an adequate capture velocity in the vicinity of the process; typical values are as follows:

- evaporation of steam and like vapours 0.25 m/s to 0.5 m/s;
- chemical and solvent releases 1.0 m/s;
- vapour of gases 5 m/s to 6 m/s;
- light dusts 7 m/s to 10.0 m/s.

Excessive velocities will be wasteful of power and generate noise.

7.149 The lowest edge of the canopy should be 2m above finished floor level, with a minimum of 300mm overhang beyond the edge of the equipment on all sides.

7.150 A compact arrangement of equipment (but with access for maintenance) will minimise the canopy area, and hence reduce the air volume necessary to achieve the optimum capture velocity.

7.151 Hoods required for the control of heat gain and vapours may be connected to the general extract system when it is convenient to do so, but where non-corrosive ductwork materials are necessary, a separate discharge is preferred.

7.152 Lighting and internal divider plates are often required to be built into the perimeter of large canopies. However, built-in shelving systems are not recommended, as they interfere with the air-flow, and constitute a maintenance problem.

Control of hood extracts

7.153 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the hood extract and any associated supply can be shut down. To this end, local control should be provided.

Bench extract systems

Special requirements

7.154 Bench extract ventilation is required in departments such as pathology and mortuary, where activities involve the release of malodorous or toxic fumes that should not be inhaled. Where hazardous substances are being controlled, the system should be designated an LEV.

Typical arrangements

7.155 Each ventilated position will usually be accommodated in a continuous run of benching, which should not be more than 650mm from front to rear and which should be provided with a continuous upstand at the rear. Each position should have a 1200mm x 150mm linear extract grille mounted on a purpose-designed plenum box (incorporating guide vanes as necessary), with its face flush with the upstand. The bottom of the grille should be as close as practicable to the level of the working surface (usually 75mm above, to allow for cleaning). The minimum velocity across any part of the grille should be 1 m/s. The grille should be readily demountable to allow for cleaning.

Control of bench extract systems

7.156 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the bench extract and any associated make-up supply can be shut down. However, a run-on timer with a minimum setting of 30 minutes must be provided. To this end, local or automatic-use control should be provided.

7.157 Processes that produce hazardous vapours, fumes, dusts or noxious vapours should be enclosed or semi-enclosed in a suitable cabinet or exhaust protected workstation.

Safety cabinet and fume-cupboard extract systems

7.158 Safety cabinets and fume cupboards are devices that use an inflow of air to control exposure of staff to hazardous substances. The units, their exhaust

systems, filters, fans and discharge terminals are all classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations. The make-up air system to a room that contains an LEV system should also be considered as an essential part of the system and be included in the LEV classification. Information on the design and installation of microbiological safety cabinets is given in BS5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.

7.159 The Advisory Committee on Dangerous Pathogens (ACDP) publishes 'The Management, Design and Operation of Microbiological Containment Laboratories' covering the general environment in which they are used and operational considerations.

Special requirements

7.160 The supply-air system should not distort the unidirectional and stable air pattern required for fume cupboards and microbiological safety cabinets. In general, supply-air ceiling diffusers should not discharge directly towards fume cupboards or safety cabinets, unless the terminal velocity is such that the air-flow pattern of the cabinet is unaffected. The design should ensure that high air-change rates, and/or the opening and closing of doors do not have any adverse effect on the performance of safety cabinets or fume cupboards. A damped door-closure mechanism may help.

7.161 In order to safeguard the user, all safety cabinets and fume cupboards must be fitted with a clear indication that they are operating correctly. Direct-reading gauges or falling-ball indicators are preferred (in addition to electronic pressure indicators). The system should be set to alarm audibly if the face velocity falls below the minimum safe operating level.

Arrangements for safety cabinet installations

7.162 The manufacture and installation of microbiological safety cabinets must be in accordance with the relevant national standards and guidance issued by the Advisory Committee on Dangerous Pathogens (ACDP).

7.163 A Class 1 microbiological safety cabinet must be specified for routine work involving Group 3 pathogens. It should be housed in a Category 3 containment room. Specific design information on containment rooms is issued by ACDP in conjunction with the Health and Safety Commission.

7.164 Siting and installation of microbiological safety cabinets are of particular importance because:

- the protection afforded to the operator by the cabinet depends on a specific and stable unidirectional air flow through the open front;
- the protection to the environment by the cabinet depends on the high efficiency particulate air (HEPA) filters. The exhaust air should never be considered as totally free from microbiological hazard.

7.165 Microbiological safety cabinet is HEPA filtered prior to being discharged to outside. The extract ductwork should as far as practicable be kept under negative pressure while inside the building.

7.166 Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2m); such an installation however, is likely to be noisy and is not recommended for use in new buildings.

7.167 The discharge from the cabinet should be fitted with a back-draft damper. In multiple installations where several cabinets discharge into a common extract and discharge duct, it must be possible to isolate each cabinet from the system when not in use.

7.168 Roof-level discharge, wherever practicable, is preferred since it removes much of the uncertainty over air re-entering the building through ventilation inlets and/or windows. In such an installation, the extract fan should be situated separately from the cabinet and close to the discharge outlet, to maintain the duct within the building under negative pressure. The discharge point on a flat roof should be through a 3m high terminal. This is required to safeguard staff who may need to access the roof periodically for maintenance. This requirement will also be applicable to fume-cupboard discharges.

7.169 Where this is impracticable, discharge into the room via a double HEPA filter has been accepted. The preferred method, however, is to discharge 3m above the roofline in line with the similar standard for fume cupboard designs.

Arrangements for fume cupboard installations

7.170 The manufacture and installation of fume cupboards must be in accordance with the relevant national standards and associated guidance.

7.171 The primary factors that contribute to the effective performance of fume cupboards include:

- an adequate volume of supply air;
- an effective exhaust system to promote the safe dispersal of waste products to atmosphere.

7.172 The air velocities through sash openings must be sufficient to prevent hazardous materials from entering the laboratory while avoiding excess flow rates that interfere with the investigation process. Average face velocities should be between 0.5 and 1.0 m/s, with a minimum at any point within 20% of the average, the upper end of the range being applicable to the containment of materials of high toxicity. The design velocity must be maintained irrespective of whether the sash opening is varied, or whether doors or windows are open or closed. Variable Air Volume (VAV) cupboards are available which offer a reduction in energy use.

7.173 The possibility of a fire or explosion that may not be contained by a fume cupboard must always be considered. A fume cupboard should not, therefore,

be sited in a position where exit to an escape route will necessitate passing directly in front of it.

7.174 Fume-cupboard fans should be installed as near as possible to the termination of the duct, thus maintaining the maximum amount of ductwork at negative pressure.

7.175 Where there are adjacent buildings with opening windows, or where downdraughts occur, it may be necessary to increase the height of discharge ducts in order to achieve adequate dispersal. In complex locations, airflow modelling or wind tunnel tests may be required to determine the optimum height of the stack (see also Paragraph 7.167).

7.176 Fume-cupboards for certain processes must have separate extract systems. However, where appropriate, individual fume-cupboard exhaust systems may discharge via non-returning dampers into a single collection duct rather than having a large number of separate stacks. The collection duct should have a large cross-sectional area to minimise its effect on the individual exhaust systems; be open to atmosphere upstream of the first connection; and be designed to discharge a total air volume at least equal to the combined individual extract systems.

7.177 Individual fume-cupboard extract systems, discharging either directly to atmosphere or into a collection duct, do not require duplex fans. However, a collection duct designed to provide dispersal of effluent from a number of individual extracts, should have duplex fans with automatic changeover.

7.178 Some fumes are particularly corrosive, so the choice of material for the ductwork, and type of extract fan fitted should reflect the nature of the fume being conveyed.

Control of extract systems

7.179 It is desirable to provide local control of safety cabinets in order to maximise the life of the HEPA filter, and to permit the sealing of the cabinet and room for fumigation if spillage occurs.

7.180 To cope with the risk of an accident or spillage outside safety cabinets, a ‘panic button’ should be provided to switch off the supply to that area; and discharge all extracted air to atmosphere.

7.181 In pathology departments, it will be necessary to have one or more microbiological safety cabinets and one or more fume cupboards available for use at all times, including weekends, therefore, local overriding controls for all these items and any associated ventilation plant will be necessary.

7.0(d) Plantroom ventilation

General requirements

7.182 Plant rooms are required to be ventilated in order to maintain acceptable temperatures for satisfactory operation of the plant and controls, and for

maintenance activities. In the case of plant rooms housing combustion equipment, a secondary function of the ventilation is to provide make-up air for the combustion process.

7.183 The air required for these purposes should be introduced into the space through inlets positioned to minimise the discomfort to occupants; they should be unlikely to be blocked, closed deliberately (except in the case of fire shutters if required), or rendered inoperative by prevailing winds.

7.184 Plantroom ventilation air should not be used for any other purposes, such as make-up air for extract; and where the plantroom contains combustion equipment, the appliance pressure must not fall below the outside air pressure.

7.185 Specialised healthcare air handling equipment must not be located in a fire compartment that houses combustion equipment.

7.186 Statutory regulations for plantroom ventilation are contained in the Scottish Building Regulations, and further guidance is given in CIBSE Guides A & B.

Assessment of ventilation levels

7.187 Ventilation requirements must take into account all heat sources within a plantroom, and where there are large glazing areas, solar gains. The ventilation rate should limit the maximum temperature within the plantroom to 32°C.

7.188 As the level of equipment operating during mid-season and summer is often lower than the winter condition, and the cooling effect of the outside air is reduced, it is necessary to calculate the minimum volume for each season of operation, and the inlet and outlet grilles or fan sizes should be chosen to cater for the largest seasonal air volume.

7.189 Replacement air should not be drawn through pipe trenches or fuel service ducts. Where metal ducts penetrate walls and floors, effective sealing should be provided to confine the ventilation to the boiler room and to meet fire protection requirements. Penetration of fire barrier walls by ventilation ducts should be avoided if possible.

7.190 Fire dampers in plant room ventilation ducts should be electrically interlocked with the boiler plant.

7.191 Care must be taken to prevent any noise generated in the boiler room emerging from natural or mechanical ventilation openings to the detriment of the surrounding environment. Particular care is necessary with mechanical flue draughts and fan-diluted flue systems.

7.192 Information on required air volumes in contained in the CIBSE Guide A & B.

7.193 Where combustion plant is installed, the high-level (outlet) openings should be sized to cater for the total ventilating air quantity; and the low-level (supply) openings sized to cater for the total combined ventilating and combustion air quantity.

Choice of ventilation system

7.194 Ventilation air may be introduced and exhausted by either natural or mechanical means or a combination of both. However, natural systems are preferred where possible.

7.195 Generally, small installations at or above ground level should have their combustion and ventilation air provided by natural means, employing both high- and low-level openings.

7.196 Basement, internal and large installations at or above ground level will usually require a combination of natural and mechanical ventilation. If the airflow rate is difficult, both supply and extract may require mechanical means.

7.197 Whether natural or mechanical, the system should be designed to avoid both horizontal and vertical temperature gradients. Both inlet and outlet openings should be placed on opposite or adjacent sites of the building to reduce the effect of wind forces.

7.198 Where mechanical air supply is employed, electrical interlocks with the boiler plant should be provided to prevent damage in the event of failure of the supply fan(s) once the air volume is established.

7.199 The necessary free opening areas for a naturally ventilated plantroom may be calculated using either the method in A4 of the CIBSE Guide A or the table in section B13 of CIBSE Guide B.

7.200 A combined natural and mechanical ventilation system should allow for natural extract at high level, to take advantage of convective forces in the room, with mechanical supply at low level. The high level natural ventilators should be sized to cope with the total quantity of ventilation air, as above.

7.201 To prevent leakage of flue gases and to ensure that the flue draught is not impeded at any time, the air pressure in the boiler room must not exceed the prevailing outside pressure. Therefore, the fan duty should exceed the calculated total combined combustion and ventilation air quantity by at least 25%. Fan-powered inlets should be arranged to flow outside air into the space at a point where cross-ventilation will ensure pick-up of heat without causing discomfort to occupiers.

7.202 Where it is impractical to provide sufficient natural ventilation to remove the heat emitted by the plant, both mechanical supply and extract will be required.

7.203 The high-level extract should be sized to cater for the total ventilating air quantity and the low-level supply should exceed the total combined combustion and ventilating air quantity by at least 25%, as above.

7.0(e) Ventilation of hydrotherapy suites

General requirements

7.204 In a hydrotherapy suite heat recovery should be via heat pump.

7.205 The quantity of supply air should be calculated as 25 litres/sec/m^2 wetted surface, with the wetted surface taken as 110% of the pool water surface area.

7.206 A re-circulation plant is recommended, with a minimum of 20% fresh air.

7.207 As far as practicable, re-circulated pool air should be provided to the ancillary changing and recover accommodation, with the only extract from the toilets, laundry/utility room and pool hall.

7.208 Supply air to the pool hall should be introduced at high level and directed towards the perimeter to mitigate condensation, with extract air taken from directly over the pool. Dampers should not be located over the pool water.

Control of hydrotherapy pool installations

7.209 The supply and extract fans should be interlocked so that the supply fan does not operate until flow is established within the extract system.

7.210 Time-clock control should be provided, with a local override switch to extend the normal operating period as required.

7.211 Night setback temperature (in the range of 21°C -25°C) and high humidity control (in the range of 60-75% sat) should be provided to override the time clock in order to prevent condensation. The exact set points should be ascertained post-installation.

7.212 A remote indication panel should be provided in the pool hall, giving a visual display of the pool water and pool air temperature.

8. Validation of specialised ventilation systems

Definitions

Commissioning - Commissioning is the process of advancing a system from physical completion to an operating condition. It will normally be carried out by specialist commissioning contractors working in conjunction with equipment suppliers. Commissioning will normally be the responsibility of the main or mechanical services contractor.

Validation - A process of proving that the system is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that "*The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.*"

Note: Commissioning is often sub divided into sections e.g. air handling unit, automatic controls, airside balance, building fabric and fittings. Each section may be commissioned by its specialist installer and they are often accepted in isolation. Validation differs from commissioning in that its purpose is to look at the complete installation from air intake to extract discharge and assess its fitness for purpose as a whole. This involves examining the fabric of the building being served by the system and inspecting the ventilation equipment fitted as well as measuring the actual ventilation performance.

It is unlikely that 'in house' staff will possess the knowledge or equipment necessary to validate critical ventilation systems such as those serving operating suites, pharmacy clean rooms and local exhaust ventilation systems. Validation of these systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the NHS Board.

It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.

Commissioning general

8.1 Commissioning is an essential process for ventilation systems. It is therefore important that adequate provision for the process be made at the design stage of the project. Procedures for commissioning air-handling systems are given in CIBSE Commissioning Codes and BSRIA Application Guide Set COMPAK 1.

8.2 The duct-sizing procedure should take into account the requirements of system balancing, and the position and number of regulating dampers included in the design should be sufficient for this purpose.

Location of dampers and test holes

8.3 Balancing/commissioning dampers will be required in each branch of the distribution ductwork.

8.4 Test holes for the measurement of air-flow will be required at carefully selected points in main and all branch ducts. The number and spacing of holes are given in the BSRIA Application Guide Set COMPAK 1. Their positions must be identified at the design stage.

8.5 The test positions need to be accessible for commissioning to take place. They may also be required for subsequent annual verification of the system performance, so they should not be covered by permanent lagging.

8.6 The measurement point should be in a straight length of duct as far away as possible from any upstream bends, dampers or other elements that could cause disturbance to the airflow. The actual location should be:

- at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends;
- if this is not possible, 10 diameters downstream of dampers, bends or tees, and 5 diameters downstream of eccentric reducers;
- where there is enough space round the duct to insert the pitot tube and take readings;
- where the duct has a constant cross-sectional area.

8.7 Test holes for measuring total airflow from a fan should be located either 4 diameters upstream or 10 diameters downstream of the fan. Provision should also be made for measuring the speed of rotation.

Information to be provided

8.8 It is essential that the designer should pass on his intentions fully to the commissioning engineer by indicating which parts of the system are high, medium and low pressure, and by providing:

- relevant parts of the specification;
- schematic drawings indicating performance data as indicated in Table 8;
- equipment schedules;
- controller and regulator schedule;
- fan performance curves;
- wiring diagrams for electrical equipment, including interlock details.

Items in system	Information to be provided
Fans	Fan total pressure Volume flow rate at high and low speed Maximum motor current
Plant items	Type and identification numbers from equipment schedules Fluid and air volume flow rates Fluid and air side pressure losses Dry bulb temperatures Wet bulb temperatures Humidity
Dampers, including motorised and fire dampers	Identification numbers from equipment schedules Location Identification number Volume flow rate
Main and branch ducts	Dimensions Volume flow rates and velocities Identification numbers from equipment schedules
Terminal	Location Identification number Grille or diffuser factor Volume flow rate and neck velocity Operating static pressure
Test holes and access panels	Location Identification number
Controllers	Set points

Table 8: Information to be provided on schematic drawings

Notes: For Table 8

1. Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet.

2. Where volume flow rates are variable, maximum and minimum values should be provided.

Commissioning personnel

8.9 As one individual is unlikely to possess all of the required commissioning skills, a commissioning team is therefore usually needed. The objective of commissioning is to ensure that the necessary performance and safety requirements are met.

8.10 During the commissioning process a great deal of information will be generated which will form an invaluable future source of reference about the plant. It is essential to ensure that it is collected together in the form of a commissioning manual and handed over to the client on completion of the contract together with the 'as fitted' drawings. This information should be both in hard copy and electronic format.

8.11 In order to be successful the commissioning process must start before achieving practical completion as many parts of the system will become progressively less accessible. The correct installation of those parts will need to be witnessed and leak-rate tests carried out as construction proceeds. Failure to establish responsibility for commissioning early enough will delay the completion of the project or lead to unsatisfactory plant performance.

Commissioning brief

8.12 The commissioning team will require a detailed brief from the system designer. This should include:

- a 'user' brief comprising a description of the installation and its intended mode of operation;
- the precise design requirements with regard to the scheme of air movement, room static pressures, supply and extract air-flow rates and acceptable tolerances;
- full details of the design conditions both inside and out, for winter and summer together with the control strategy;
- equipment manufacturer's type test data, commissioning, operation and maintenance recommendations;
- drawings showing the layout of the system, positions of air-flow measurement test points, dampers, regulating devices and filters within the duct runs, together with sizes of ducts and terminal fittings. It will save time if these drawings are annotated with the design volumes and static pressures required at each branch and outlet point;
- wiring diagrams for all electrical equipment associated with the air handling systems including motor control circuit details and any interlocking and safety devices such as emergency-stop buttons adjacent to the item of plant.

8.13 The CIBSE Commissioning Code, Series 'A' – "Air Distribution", provides full guidance on the information that will be required by the commissioning team.

8.14 The designer should include in the contract document instructions on verifying the accuracy of test instruments that should be supported by reference to relevant calibration certificates.

8.15 The system, on completion, should be operated by the contractor as a whole and subject to performance tests in accordance with the contract requirements. For critical systems, these may include independent validation of the system performance on behalf of the client.

8.16 Prior to dynamic commissioning, it is essential that builders' work in the area served by the system is complete, all rubbish and dust is removed, concealed plumbing (IPS-type) panels are in position and ceiling tiles are in place and clipped. Floors should be mopped and visible dust removed from all other surfaces.

8.17 Once the system is shown to meet the design intent the handover documentation should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract arrangements.

Pre-commissioning checks

8.18 The pre-commissioning checks consist of visual inspection, manual operation of equipment, static measurements and functional tests of individual components. They should be carried out prior to setting the system to work and undertaking the dynamic commissioning process set out in Paragraph 8.29 onwards of this guidance.

Standard of installation

8.19 During the installation of the system the following must be witnessed:

- that the plant and installations have been provided and installed in accordance with the design specification and drawings;
- that only approved sealants have been used in the installation;
- that all components function correctly;
- that the satisfactory sealing of access doors and viewing ports have been carried out;
- that air pressure tests and air-leakage tests on ventilation ducting have been carried out in accordance with the methods set out in the HVCA's DW/143: Ductwork Leakage Testing. It is usual to carry out these tests, a section at a time, as the ductwork is installed and before its insulation is applied. The results must be recorded in the commissioning manual;
- that gaps around doors and hatches are as specified in the design;
- that the correct operation of pressure stabilisers, control dampers, isolating and non-return dampers have been checked and installed in the correct orientation for air-flow;
- that test holes have been provided in their specified locations and are sealed with suitable grommets;
- that control dampers are secured and their quadrants fitted correctly;
- that any interlocks are operative and in accordance with specification;
- that the electric circuits are completed, tested and energised;
- that electric motors have been checked for correct direction of rotation both at full speed and set-back;
- that cooling and heating media are available at correct temperatures and pressures and in specified quantities;
- that the air-conditioning plant components and controls function correctly;
- that the air-conditioning plant interlocks and safety controls function correctly;

- that the plant is physically complete, insulation is applied and all ducts and pipework are identified as specified;
- that the building housing the ventilation plant is generally in a fit condition for commissioning and performance tests to commence, that is, windows, doors, partitions etc are completed, surfaces sealed and their final finish applied;
- that the areas containing the ventilation plant and those being served by it are clean;
- that access to all parts of the system is safe and satisfactory.

Cleanliness of installation

8.20 During installation it must be established that ductwork is being installed to the 'advanced level' as defined in the HVCA (2005) 'TR/19 – Guide to good practice: internal cleanliness of ventilation systems'. This specifically includes ensuring that ductwork sections arrive on site and are stored with their open ends sealed and that open ends remain sealed during installation to prevent the ingress of builders' dust.

8.21 Should any doubt exist whether the guidance has been observed, the ducts must be cleaned internally to restore them to this standard before being taken into use.

8.22 "Builders work" ducts of brick or concrete must be surface sealed to prevent the release of dust before being taken into use.

8.23 The area around the supply air intake must be free of vegetation, waste, rubbish, builders' debris or any other possible source of contamination.

Certification of equipment

8.24 The following test certificates should be assembled by the commissioning team and be available for inspection at any time during the contract period. They will form part of the handover information and should be placed in the commissioning manual:

- type-test performance certificates for fans;
- pressure-test certificates for:
  - heater-batteries;
  - cooling coils;
  - humidifiers (if appropriate);
- type-test certificates for attenuators;
- type-test certificates for primary and secondary filters;
- individual test certificates for high efficiency particulate air (HEPA) filters.

Equipment tests

8.25 Prior to setting the system to work, the checks in Paragraphs 8.26 - 8.28 should be witnessed, and proving tests should be carried out as detailed.

Filters

8.26 The quality of filter housing and in particular, the seals is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter panels. Therefore, the following checks should be made:

- filter seals should be fitted and in good condition;
- filters should be installed correctly with respect to air flow;
- bag filters should be installed so that the bags are vertical and their pockets free;
- HEPA filters should be installed in a sealed housing and their seals tested to DIN 1946 if specified;
- all filters should be checked to ensure they are free of visible damage;
- the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.

Drainage arrangements

8.27 The drain should conform in all respects to the “Design considerations” of this SHTM. In addition the following must be proved:

- that the drain tray is easily removable;
- that a clear trap is fitted and is easily removable;
- that the drain has a clear air gap of at least 15mm;
- that the pipework is supported so that the air break cannot be reduced;
- that the drain system from each drain tray is independent up to the air break;
- that the operation of the drainage system is proved by introducing water into the duct at the drain tray and observing that it completely drains out. This check is to be repeated both at normal speed and set back once the fans have been commissioned. At this time the clear trap can be marked to indicate the normal water level with the fan running.

Fire dampers

8.28 The following must be witnessed and proving tests should be carried out as detailed:

- the operation of all fire dampers;
- the access provided to enable the dampers’ to be visually inspected and / or re-set should be sufficient for the purpose;

- indication should be provided of the dampers' position (open/tripped);
- indication of the fire dampers' location should be provided both on the ductwork and at a visible point on the building fabric if the ductwork is concealed.

Dynamic commissioning

Air-handling and distribution system

8.29 The fan drive, direction of rotation, speed and current drawn should be set in accordance with their manufacturer's instructions.

8.30 After the installation has been checked to ensure that it is in a satisfactory and safe condition for start-up, it should be set to work and regulated to enable the plant to meet its design specification. The proportional balancing method described in the CIBSE Commissioning Code "A" must be followed. The air-flow rates must be set within the tolerances laid down in the design brief. This will normally be the design airflow rate +10% -0%.

8.31 When combined supply and extract systems are to be balanced and the area that they serve is to be at or above atmospheric pressure then the supply should be balanced first with the extract fan switched off, and then the extract balanced with the supply fan(s) on.

8.32 For combined systems where the area that they serve is to be below atmospheric pressure then the extract should be balanced first with the supply fan switched off and then the supply balanced with the extract fan on.

8.33 On completion of the balance all volume air-flows in supply and extract ducts and from grilles and diffusers must be measured and recorded. The true air change rate can them be calculated from the data obtained.

8.34 The main supply and extract duct volume control dampers must be locked and their position marked.

8.35 All grille and diffuser volume control registers must be locked to prevent alteration and their final position marked.

Room air distribution

8.36 The pressure-relief dampers and pressure stabilisers must be set to achieve the specified room static pressures and locked. The grille direction control vanes and diffuser cones must be set to give the specified air-movement pattern. Visualisation techniques may need to be employed in order to prove that the required air-flow pattern is being achieved. This may be a potential requirement when commissioning LEV systems or rooms that contain them.

Air-conditioning plant

8.37 The specified flow rate and/or pressure drops must be set for all heater batteries, cooling coils and humidifiers. The methods described in the CIBSE

Commissioning Codes “W” and “R” should be followed. On completion their regulating devices must be locked to prevent alteration.

Control system

8.38 The control system should not be commissioned until both the air distribution system and air-conditioning equipment have been commissioned.

8.39 Because of the specialised nature of control systems and the fact that each manufacturer’s system will contain its own specialist components and settings, the commissioning should be completed by the supplier and witnessed by a representative of the user.

8.40 The location of all control and monitoring sensors should be checked and their accuracy proved.

8.41 The control system’s ability to carry out its specified functions must be proved.

8.42 If the plant is provided with a “user’s” control panel in addition to the one located in the plantroom then the operation of both must be proved. This will typically apply to operating departments and laboratory systems.

Specific performance standards

Air movement

8.43 The performance of the system should be measured and compared with information provided by the designer.

Plant capacity and control

8.44 When setting to work and proving the design, both the manufacturer of the air-handling plant and the control specialist should attend site together and jointly commission the system.

8.45 If any doubt exists as to the capacity of the installed system, then its ability to achieve the specified inside design conditions with the plant operating at winter and summer outside design conditions must be proved. Artificial loads will be required in order to simulate the internal gains/losses and the outside design conditions.

8.46 On completion of the plant performance test, recording thermo-hygrographs should be placed in each room/area served by the plant and also the supply air duct upstream of the frost battery. The plant should be run for 24 hours with all doors closed. During this period the inside conditions must stay within the tolerances specified. The BEMS should be used to obtain the information required wherever possible. Periodic tests will be required during the defects liability period.

Noise levels - general

8.47 The commissioning noise level is the level measured with a sound-level meter in the unoccupied room and taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use this commissioning level will constitute a continuous background noise that will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise.

8.48 The noise levels apply at the maximum velocity for which the system is designed to operate. Acoustic commissioning tests should be carried out with all plant and machinery running normally and achieving the design conditions of airflow, temperature and humidity.

8.49 An industrial-grade sound-level meter to BS3489 or IEC 651 Type 2 will normally be sufficient to check the noise level.

8.50 The noise level readings are to be taken at typical normal listening position 1.5m above floor level and at least 1m from any surface and not on any line of symmetry. In critical rooms the noise should be measured at the centre of the room and at the centre of each quarter. The mean of the 5 readings should then be calculated.

8.51 In the event of a contractual deficiency, a Type 1 precision-grade sound-level meter should be used and the noise level determined by the procedure given in Scottish Health Technical Memorandum 08-01 (2011).

Filter challenge

General ventilation filters

8.52 In-situ performance tests will not normally be required for primary and secondary filters and their housings. However the filters should be visually inspected for grade, tears, orientation and fit within their housing. Filters should be clean and a replacement set available. Bag filters should be installed so that their bags are vertical and spaced so that air can move through them freely. Any filter found to be wet should be replaced and the cause investigated.

HEPA filters (for exhaust protective enclosures and laboratories)

8.53 Pathogenic material may be discharged through damaged or badly installed HEPA terminal filters. The complete installation must be tested using the method set out in BS EN: 14644 ‘Method of Testing for the Determination of Filter Installation Leaks’.

8.54 The challenge tests may be carried out using either of the following techniques:

- use Dispersed Oil Generator (DOP) to provide the challenge and a photometer to detect leaks;

- use a Discrete Particle Counter (DPC) to detect leaks. (In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters).

8.55 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.

8.56 A challenge aerosol of inert particles of the type produced by a DOP generator should be introduced into the air, upstream of the HEPA filter. The downstream face of the filter, its mounting seal and housing would then be scanned for leakage using a photometer. A leak should be deemed to have occurred if a steady and repeatable reading on the photometer at any point exceeds 0.01% of the upstream reading.

8.57 Alternatively a Discrete Particle Counter (DPC) may be used. For the Discrete Particle Counter method the filter face is sampled at several points to establish the smallest non-penetrating particle size. If particles at or above this size are detected when subsequent scans of the filter face, its seal and housing are made, then there is deemed to be a significant leak at, or near, the test position.

8.58 Should the HEPA filter fail this test it must be replaced. Should the filter mounting seal or housing fail this test it may be repaired and the test repeated.

Bacteriological sampling

General ventilation systems

8.59 Bacteriological sampling will not normally be required for either general or local exhaust ventilation (LEV) systems unless otherwise specified.

Conventional operating rooms

8.60 The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for 15 minutes. An active air sampler set to 1 cubic metre and mounted on the operating table should then be activated remotely. Aerobic cultures on non-selective media should not exceed 10 bacterial and/or fungal colony forming units per cubic metre (CFU/m^3).

8.61 The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation. Precise guidance is inappropriate and will depend on local circumstances.

8.62 It may be appropriate to carry out a check of airborne bacteria during a surgical operation. If required this should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacterial and/or fungal CFU

averaged over any five-minute period, would be unlikely to exceed 180 per cubic metre.

8.63 Information on the additional validation testing of UCV Operating suites is given in Section 8.0(a).

Ventilation system commissioning/validation report

8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

8.65 The report shall conclude with a clear statement as to whether the ventilation system achieved or did not achieve the required standard. A copy of the report should be lodged with the following groups:

- the user department;
- infection control (where required);
- estates and facilities.

8.0(a) Validation of UCV operating suites

General

8.66 Commissioning of a UCV terminal will normally be carried out by its supplier. Commissioning of the air-handling unit, fire dampers, distribution ductwork and control systems may be undertaken by different teams. It is therefore important to recognise that the UCV terminal is only one element of the specialised ventilation system serving the operating suite and it cannot be accepted in isolation.

8.67 In order to ensure that the complete system operates correctly it will be necessary to validate the system as a whole from the air intake through to the extract discharge. It is unlikely that “in house” staff will possess the knowledge or equipment necessary to undertake this process. Validation of Ultra-Clean operating theatre ventilation systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the client.

8.68 It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.

8.69 The following regime of inspection and testing should be applied to the validation of new installations designed to provide Ultra-Clean conditions in an Operating suite. The test regime has been devised to ensure that the system as installed fully achieves the design requirement for these systems as set out in Section 7.0(b) of this document.

Basic requirement

8.70 The operating suite to be validated should be physically complete with final finishes applied. All ventilation systems serving it should be operating correctly and delivering the design air-flow rates.

8.71 In order to avoid pre-loading the UCV terminal's recirculation ducts and HEPA filters, the Operating suite should be free of any obvious dust and at least "builders clean" before the recirculation fans are set to work.

8.72 The validation procedure for a conventional theatre suite should have been satisfactorily completed to the standard set out in Section 8 prior to attempting to validate the UCV unit. In particular:

- the supply AHU will have achieved the minimum standard;
- the operation of all fire dampers will have been proved;
- the supply and extract air-flow rates as measured in ducts and at room terminals will achieve their design values +10%; -0%;
- room differential pressures will be correct.

Evidence of the satisfactory achievement of the foregoing standard should be available for inspection and independently measured as necessary *prior to validating the UCV unit.*

UCV unit validation procedure

8.73 Tests to validate the suitability and performance of an ultra-clean operating suite should be undertaken in the order that they appear below. Should an item fail to meet the required standard it should be rectified and successfully retested before passing on to the next test.

Summary of test regime

- Challenge tests to ensure that:
  - the UCV terminal unit is correctly assembled and sealed so that no air will bypass the filters;
  - the terminal filters are correctly sealed in their housings;
  - the terminal filters are of the same grade, of uniform quality and undamaged.
- Air velocity measurements to ensure that
  - a sufficient quantity of air is being delivered by the terminal;
  - the terminal quadrants are in balance;
  - the air flow has sufficient velocity to reach the working plane.
- An entrainment test to ensure that contaminants arising outside of the UCV terminal footprint are not drawn into it.

- Visualisation techniques to gain an understanding of the overall system performance.
- Noise measurement to ensure that working conditions are satisfactory.
- Control system checks to ensure that the system operates as specified.
- Biological monitoring to determine how effective the system is in use.

Test and measuring conditions

8.74 While validating the UCV terminal, the conditions in the Operating room shall be stable and within the given ranges.

temperature: – 19°C - 23°C dry bulb.

humidity: – 30 – 65% relative humidity.

Test and measuring equipment

8.75 Any test or measuring equipment used should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards.

8.76 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

Test grid – vertical units

8.77 A test grid should be constructed on the floor within the ultra-clean terminal footprint as projected by the inside dimensions of the sidewalls or boundary air curtain. A suitably marked test sheet will provide a consistent standard of test grid.

8.78 The test grid should comprise test squares of 280mm each side.

8.79 The test grid should be aligned along the centre lines of the terminal footprint with its centre under the centre point of the terminal.

8.80 Any test square with 80% of its area within the UCV footprint should be used as a test position.

8.81 An inner zone should be designated that is not less than 36% of the total footprint. It should be made up of a number of test squares distributed symmetrically about the terminal footprint centre line. Regardless of the shape of the terminal footprint, the inner zone should comprise a minimum grid of 6 x 6 test squares.

8.82 Unless specified otherwise, a test position should be in the geometric centre of a test square.

8.83 Test position 1 should be the leftmost test square in the row nearest to the operating room wall that houses the surgeon's panel.

(For an example of a grid for a 2.8 x 2.8 metre terminal see Figure 8)

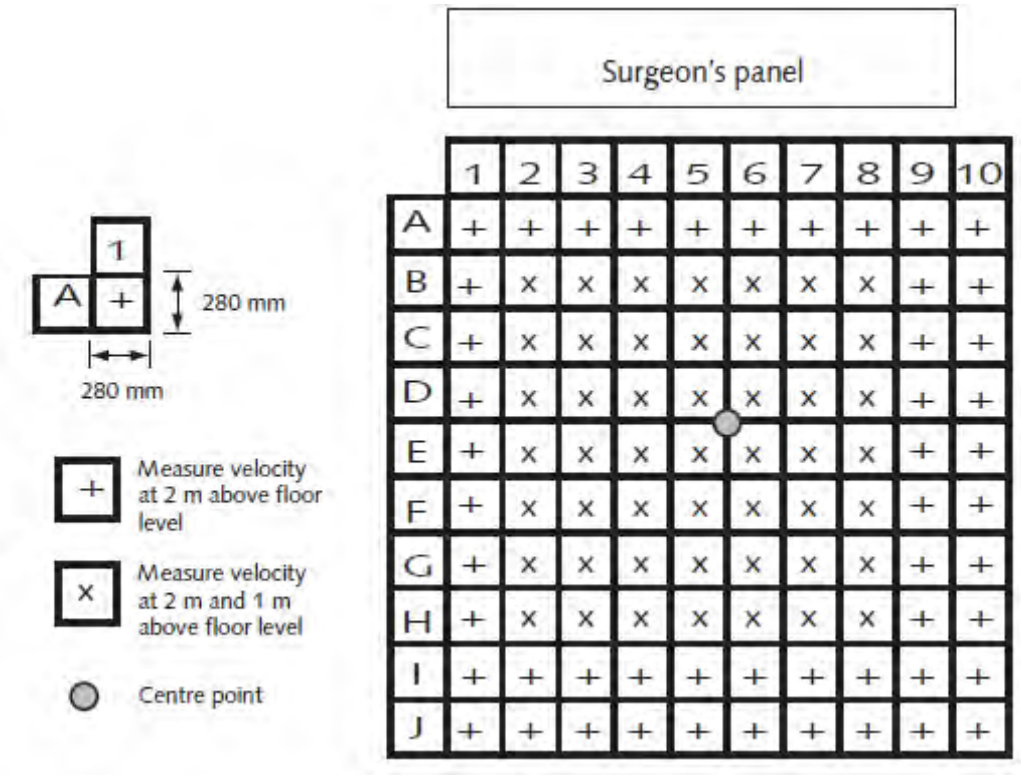

Figure 8: Example of a Test Grid for a 2.8m x 2.8m UCV Terminal

Test grid – horizontal units

8.84 A line of test positions should be marked on the floor 1m in front of the face of the UCV terminal.

8.85 A test position should be marked in the centre of the line. Additional test positions should be marked at 280mm spacing along the line either side of the centre position, up to the full-face width of the unit.

UCV terminal challenge tests (Vertical and horizontal systems)

8.86 The diffuser screen fitted below the face of the terminal HEPA filters should be lowered or removed while the challenge tests are being carried out.

8.87 The installed HEPA filters should be checked to ensure that their grade accords with the design specification and that their performance has been certified by the manufacturer.

8.88 The challenge tests may be carried out using either of the following techniques:

- use DOP to provide the challenge and a photometer to detect leaks;
- use a DPC to detect leaks. In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters.

8.89 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.

8.90 For the DOP test this should be set as the reference level and a leak will be declared significant if penetration greater than 0.01% of the range is detected. (See Paragraph 8.56 for details).

8.91 For the DPC method the filter face is scanned to establish the smallest non-penetrating particle size. If significant particles at or above this size are detected when subsequent scans are made then there is deemed to be a significant leak at, or near, the test position. (See Paragraph 8.57 for details)

UCV terminal unit clean zone leak test

8.92 This test will confirm that there is no unfiltered air bypassing the HEPA filter.

8.93 The joints and service penetration points under the UCV terminal within its side walls or boundary air curtain should be scanned to prove that there are no leaks.

8.94 A leak is defined as a significant rise above the background level.

Terminal HEPA filter seal leak test

8.95 The test will confirm that there is no unfiltered air bypassing the HEPA filter's seal.

8.96 Each HEPA filter's seal should be scanned to prove that there are no leaks.

8.97 A leak is defined as a significant rise above the background level.

Terminal HEPA filter media leak test

8.98 The test will confirm that the HEPA filters have not sustained damage while being installed.

8.99 The face of each HEPA filter should be scanned to prove that there are no leaks.

8.100 A leak is defined as a significant rise above the background level.

Vertical UCV terminal air velocity tests

Test set up

8.101 The terminal face diffuser screen should be in place for these tests.

8.102 Take spot readings to establish that the room is within the specified temperature and humidity test conditions.

8.103 Set out the test grid as described previously.

8.104 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow, are perpendicular to the front edge of the test sheet and face the back edge. Any lamp and equipment heads should as far as practicable be outside of the UCV terminal footprint.

Test instrument

8.105 The measuring instrument should be a hot-wire anemometer with a digital read-out. The instrument resolution should be at least 0·01m/s, have a tolerance of ±0·015 m/s or 3% of that reading and be calibrated down to 0·15 m/s or lower. An alternative instrument may be used providing it is of no lesser specification.

Test method

8.106 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.

8.107 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively they could be downloaded to a computer or data logger at the end of the test.

8.108 The test stand to be positioned on each test point in turn and the reading taken when the instrument has stabilised.

8.109 When taking a reading the test person should not stand within the same quadrant as the test instrument.

8.110 Readings are to be taken at the test positions with the instrument probe facing the wall housing the surgeon's panel, commencing at the first test position. Readings are taken working along the row from left to right and back, or for all text positions in one quadrant at a time.

8.111 When all test positions under one half of the terminal have been covered, readings of temperature and humidity are then taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.

8.112 Having completed one half of the test grid, the operating lamp arms and any other stem arms should be swung round through 180º and the test stand reversed so that the wall housing the surgeon's panel is behind the test person. Readings are recommenced starting at the right of the test row and working from right to left a quadrant at a time, as above.

UCV high-level discharge velocity test

8.113 Measurements of air velocity are to be taken at every test position 2m above floor level and the results averaged.

8.114 The average of the total readings taken is to be not less than:

0.38 m/s for a partial-wall system;

0.30 m/s for a full-wall system.

The average air velocity for each quadrant should not exceed ±6% of the measured average velocity for the terminal

UCV low-level air velocity test

8.115 Measurements of air velocity are to be taken at each of the inner zone test position 1m above floor level.

8.116 The measured velocity at every test position in the inner (operating) zone shall be not less than 0·2 m/s.

Horizontal UCV terminal air velocity test

Test set up

8.117 Set out the line of test positions as described previously.

8.118 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow and are perpendicular to the line of test positions.

Test instrument

8.119 See that specified for vertical systems (Paragraph 8.105 refers).

Test method

8.120 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.

8.121 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively, they could be downloaded to a computer or data-logger at the end of the test.

8.122 The test stand should be positioned on each test point in turn and the reading taken when the instrument has stabilised.

8.123 When taking readings the test person should stand well downstream of the instrument.

8.124 Readings are to be taken at the test positions with the instrument probe facing the UCV terminal, commencing at the first test position on the left and working along the row from left to right at the specified height.

8.125 The instrument should be reset to the next specified height and the test repeated and so on.

8.126 Readings of temperature and humidity should be taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.

UCV discharge velocity test

8.127 Measurements of air velocity are to be taken at all test positions at 1m, 1·5m and 2m above floor level.

8.128 The average of the total readings taken should be no less than 0·4 m/s.

UCV entrainment test (Vertical systems only)

Rationale for the entrainment test

8.129 The performance of UCV systems may be compromised by room air being drawn into the ultra-clean airflow, a phenomenon known as “entrainment.” Significant levels of entrainment could lead to microbial contamination of items left exposed on instrument trolleys laid out beneath the canopy.

8.130 UCV systems having permanently fitted full sidewalls do not need to be tested, as the sidewalls physically prevent entrainment.

Principle of the test

8.131 A source of particles is produced outside of the UCV terminal and is used to challenge the system. A detector is placed within the ultra-clean airflow and used to determine the percentage penetration of the test particles at predefined locations under the UCV terminal footprint. The source and detector are moved in tandem around the UCV canopy and pairs of readings taken, from which the percentage penetration at specified locations is calculated. The degree of penetration should be below specified maximum limits if entrainment is to be declared not significant.

8.132 The entrainment test may be carried out using either of the following techniques:

- use DOPs to provide the challenge source at the specified release position and a photometer to measure the entrainment; or
- duct non-HEPA-filtered air to the specified release position and use a DPC to measure the entrainment.

Test set-up

8.133 The terminal face diffuser screen should be in place for these tests.

8.134 The test should be performed without any equipment in place beneath or closely adjacent to the UCV terminal.

8.135 The theatre lights should be moved to a central position beneath the terminal and raised to 2m above floor level, so as not to interfere with the peripheral airflows.

8.136 Take spot readings at the centre of the canopy, one metre from floor level, to establish that the room is within the specified temperature and humidity test conditions.

8.137 Set out the test grid as described previously.

8.138 For either of the following entrainment tests, a measurement of particle penetration through a representative section of the HEPA filter media is to be taken and used as the reference background level.

Test equipment, challenge source, measuring instrument and detector head

8.139 The challenge and detector equipment should be chosen so that:

- the tracer particles are mainly within the size range 0.3 to 5 microns and thus capable of remaining airborne for a substantial time;
- the particles used should not be able to penetrate the terminal filters in sufficient numbers to cause a background count that is more than 0.1% of the challenge count;
- the choice of particle and detector will enable a minimum of a three-logarithm (1,000-fold) range of counts to be recorded between the highest (that is, source) and lowest (that is, background) readings expected. (A concentration of approximately 10^5 particles per cubic metre of source air has been shown to be adequate.)

Source – Dispersed Oil Particles (D.O.P.)

8.140 The DOP generator should be able to produce a cloud of test particles in the form of a visible smoke. The test smoke should be delivered via an aperture so that it flows vertically downward from the lowermost edge of the partial wall, on the outside of the UCV canopy.

8.141 The test smoke is to be delivered via an aperture.

Note 4: To prevent undue contamination of the theatre and filters with deposits of oil, DOP should only be released for the minimum amount of time necessary to complete the test.

Challenge source – natural particles

8.142 The source unit should be a fan/blower or other method that takes non-HEPA-filtered air and expels it via a delivery head at the specified release position to provide the particle challenge. The challenge air should be delivered vertically downwards from the lowermost edge of the partial wall, on the outside of the UCV canopy, parallel to the airflow coming from the diffusers. The challenge air velocity should be the same as the measured average velocity at 2m from the terminal under test.

Note 5: The use of DOP for testing is gradually being phased out and replaced by a natural challenge measured with a DPC. At the time of writing research is under way to define more precisely a challenge source unit for natural particles. It is anticipated that such a unit, together with a matching test methodology, will become available during the life of this Scottish Health Technical Memorandum.

The detector (defined in terms of range and resolution)

8.143 This may be a photometer or a DPC. It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. The instrument should be capable of sampling a minimum a 28.3 litres of air per minute and in the case of the DPC, provide readings for particle size ranges from 0.3 microns to 5.0 microns and greater. The instrument should be compliant with the requirements of BS EN ISO 14644-1. An alternative instrument may be used providing it is of no lesser specification.

Test positions and orientation of source and detector

8.144 The test positions should be at the centre of each test square, as defined for the velocity test.

8.145 For rectangular UCV terminals, measurements of penetration are to be taken at the four corner test squares of the test grid and at intermediate positions along the line of test squares between the corners. The number of intermediate test positions will be as equally spaced as possible around the periphery with no fewer than 3 and no more than 5 complete test squares between test positions.

8.146 A further series of measurements are to be obtained around the periphery of the inner zone. Measurements of penetration are to be taken at the four corner test squares of the inner zone of the test grid and if necessary at intermediate positions along the line of test squares between the corners as equally spaced as possible, with no fewer than 3 and no more than 5 complete test squares between test positions.

8.147 A single measurement should be taken at the geometrical centre of the UCV terminal footprint. The centre measurement will be taken with the detector head mounted vertically upwards 1 metre above floor level.

8.148 The centre of the challenge particle source should be aligned with the centre of the designated test square, with its longer edge against the outer edge of the partial wall and delivering the challenge from the lower edge of the partial wall. The air containing challenge particles is directed vertically downwards from the lower edge of the partial wall, in a plane parallel to the adjacent partial wall. Where there is physical interference due to obstructions such as gas pendants, the source will be moved to the next available non-obstructed test-square location nearest to the stipulated sampling position. The detector should then also be moved to remain opposite the source.

8.149 In the case of non-rectangular terminals, an interpretation of the above strategy should be adopted that will yield a no less searching examination of the unit's ability to control entrainment.

Test method

8.150 The sampling head of the detector instrument is mounted on a test stand with its sampling orifice facing outwards horizontally from the centre of the UCV canopy, 1m above floor level. The sampling head should be orientated at right angles to the partial wall when sampling along the sides of the test grid but will be set to bisect the angle when measuring at the corner test positions (Figure 88 illustrates the challenge and detector orientations when evaluating a 2.8m x 2.8m UCV terminal).

8.151 The test will commence at the first test position, this being designated the leftmost corner of the test grid when facing the wall housing the surgeon's panel. The penetration will also be measured at the corresponding test point on the inner zone commencing at the corner nearest to the first test position. When these tests have been completed, the source and detector equipment should be moved to the next test positions, working around the test grid in a clockwise direction.

8.152 The test stand should be positioned on each test point in turn and a pair of readings (challenge, then penetration) taken when the instrument has stabilised. The detector should be set to take a reading over a 15 second sample interval.

8.153 When taking a reading the test person should stand within the UCV terminal footprint but not in the same quadrant as the detector head.

Analysis and interpretation

8.154 The following standard is to be achieved:

- penetration to be not greater than 10% of the challenge at each test position in the outer zone;
- penetration to be no greater than 1% of the challenge at each test position in the inner zone;
- penetration to be no greater than 0·1% of the challenge at the centre of the test grid.

If a result is close to, or above the given limits, then a further reading must be obtained using a longer time base (1 minute) and the penetration must not exceed the given limit.

Basis of the test

8.155 Whyte W, Shaw BH, Freeman MAR. An evaluation of a partial-walled laminar-flow operating room. *J Hyg Camb* 1974; 73: 61 – 75.

Whyte W, Lidwell OM, Lowbury EJL, Blowers R. Suggested bacteriological standards for air in ultraclean operating rooms. *J Hosp Infect* 1983; 4: 133 – 139.

UCV visualisation

8.156 The use of smoke to gain an understanding of the overall performance of the system may prove useful at this stage in the validation process but cannot be relied on to produce a contractually definitive measure of performance.

UCV noise level

8.157 An industrial-grade sound-level meter to BS EN 61672 Type 2 fitted with a muff should be used to check the noise level. The instrument should be calibrated using a matched sound source prior to each set of readings.

Vertical systems

8.158 The noise level readings should be taken at typical normal listening positions 1·5m above floor level and at least 1m from any surface and not on any line of symmetry. Measurements should be taken under the centre of each quadrant of the UCV terminal and the four readings averaged.

Horizontal systems

8.159 The noise level readings are to be taken at typical normal listening positions 1·5m above floor level on the test line. The width of the unit should be divided in two and a measurement taken in the centre of each half but avoiding any line of symmetry. The two readings should be averaged.

8.160 Measurements should also be taken in each room of the suite.

8.161 In the event of a contractual deficiency a Type 1 precision-grade sound-level meter complying with BS EN 61672 should be used. Readings should be taken at the positions specified above and in each case the logarithmic mean of the results should be calculated in order to determine the noise level. Further information can be found in SHTM 08-01 (2011).

8.162 For vertical or horizontal systems, the noise level shall not exceed:

- 50NR [55dB(A)] – for UCV operating rooms and spaces without doors that open directly on to it (for example the scrub);
- 40NR [45dB(A)] – for all other peripheral rooms of the suite.

UCV control system checks

Temperature

8.163 The readings of temperature taken under or in front of the UCV unit should be within ±1 K of each other and the read-out on the surgeon's panel.

Humidity

8.164 The readings of humidity taken under or in front of the UCV unit should be within ±5% of each other and the read-out on the surgeon's panel.

Direct-reading differential pressure gauges

8.165 The differential pressure across the terminal filter(s) should be measured to confirm the accuracy of the indicated reading of any gauge.

Control functions

8.166 The operation of all control functions provided on the surgeon's panel should be proved for conformity with the design specification.

8.167 If an auxiliary panel has been fitted then its interlocking with the main surgeon's panel control functions must be proved to conform to the design specification.

Panel indicator lights

8.168 The panel indicator lights should illuminate as appropriate when the control functions are selected or warning levels are reached

BEMS interface

8.169 The operation, monitoring and alarm functions must be proved to conform to those set out in the design specification.

UCV theatre microbiological tests

8.170 There is little value in performing microbiological sampling in a new theatre supplied with ultra-clean ventilation. The foregoing filter challenge tests, air velocity measurements and entrainment test should have proved that the system operates satisfactorily and achieves the contracted level of performance. The HEPA filters will remove bacteria-sized particles from the air supplied through the UCV terminal. Therefore there will be an insignificant number of bacterial and/or fungal CFUs present until the Theatre is actually used.

8.171 Once the theatre has been taken into use, microbial sampling during a surgical procedure should help to confirm the satisfactory performance of the system and discipline of the users. Before commencing bacteriological testing, the room and its ventilation system should have achieved a steady state condition: (see also Paragraph 8.74)

8.172 The installation should be tested during surgical procedure at intervals between the time of the first incision and final closure of the wound. On average, the air sampled within 300mm of the wound should not contain more than 10 CFU/m^3.

UCV validation report

8.173 Following validation a full report detailing the findings should be produced. The report shall conclude with a clear statement as to whether the UCV theatre suite achieved or did not achieve the standard set out above.

8.174 A copy of the report should be lodged with the following groups:

- operating department;
- infection control;
- estates and facilities.

Dirty	Service corridor Disposal room	0 -5 or 0	- -	f 0.41 or 0.10

Table A2

Notes (applicable to Table A2):

a. Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved.

b. An open or semi-open bay is considered to be part of the operating room; provided air movement is satisfactory, no specific extract is required. However if the layout means that air movement is poor, a local extract may be required to control local condensation on the building surfaces, which can result in mould growth.

c. For design purposes, anaesthetic should be assumed to be at 14Pa. When commissioning 10Pa is considered suitable.

d. 15 ac/hr are considered necessary for the control of anaesthetic gas pollution.

e. Supply airflow rate necessary to make up 7 ac/hr after taking into account secondary air from cleaner areas.

f. No dilution requirement. Temperature control requirements only.

Type	Pressure difference - Pa						
	5	10	15	20	25	30	40
Single door (CDB Size 2.4.3.2.6.)	.03	.05	.06	.06	.07	.07	.08
Double door (CDB)	.04	.08	.10	.11	.12	.13	.14
High permanent length of 3mm gap	.004	.008	.010	.011	.012	.012	.013

Table A3: Leakage flows in m^3/s through closed door gaps

Note: CDB = Component Data Base

It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

Factory-assembled door-sets with a steel frame and pre-hung leaves have become common. There is effectively no leakage across these doors when closed. Therefore, when this type of door assembly is fitted, the door leakage can be ignored and the design airflow into the room reduced accordingly. The design airflow would then become that required either (i) for open door protection, or (ii) to achieve the specified air-change rate - whichever is the greater.

Room class		Dirty	Transitional	Clean	Sterile
Sterile	Hatch	0.3	0.24	0.18	
	Single door	0.47	0.39	0.28	0 or 0.28 a
	Double door	0.95	0.75	0.57	0 or 0.57 a
Clean	Single door	0.39	0.28	0 or 0.28 a	
	Double door	0.75	0.57	0 or 0.57 a	
Transitional	Single door	0.28	0 or 0.28 a		
	Double door	0.57	0 or 0.57 a		
Dirty	Single door	0	Open single door = 0.80m x 2.01m high		
	Double door	0	Open double door = 1.80m x 2.01m high		

Table A4: Recommended air flow rates in m^3/s through a doorway between rooms of different cleanliness to control cross-contamination

Designer's Notes:

a. The degree of protection required at an open doorway between rooms is dependent upon the degree of difference in cleanliness between them.

b. Flow rate required between rooms within the same class tends to zero as class reduces.

c. If two rooms are of equal cleanliness, no flow is required (in practice there will be an interchange in either direction) and the design of the air movement will assume zero air-flow. In certain cases, however, interchange is not permitted and protection airflow of 0.28 is assumed in the design, for example, in the case of a preparation room used as a "lay up".

		Effect on other rooms	
Door open between	Resultant pressure in these rooms (Pa)	Room	Pressure (Pa)
Operating room and corridor or Scrub bay and corridor	0	Anaesthetic Preparation – lay up Disposal Preparation – sterile pack store	0 12 -6 5
Operating room and anaesthetic room (or other series room with double doors)	17	Preparation – lay up Disposal Preparation – sterile pack store	26 -9 22
Operating room and disposal room or Operating room and preparation room	25	No change	
Anaesthetic room and corridor (or other series room with double doors)	0	Preparation – lay-up Disposal Operating room Preparation – sterile pack store	30 -6 20 25
Preparation room – corridor Disposal room & corridor	0	No change	
Disposal room & outer corridor	0	No change	

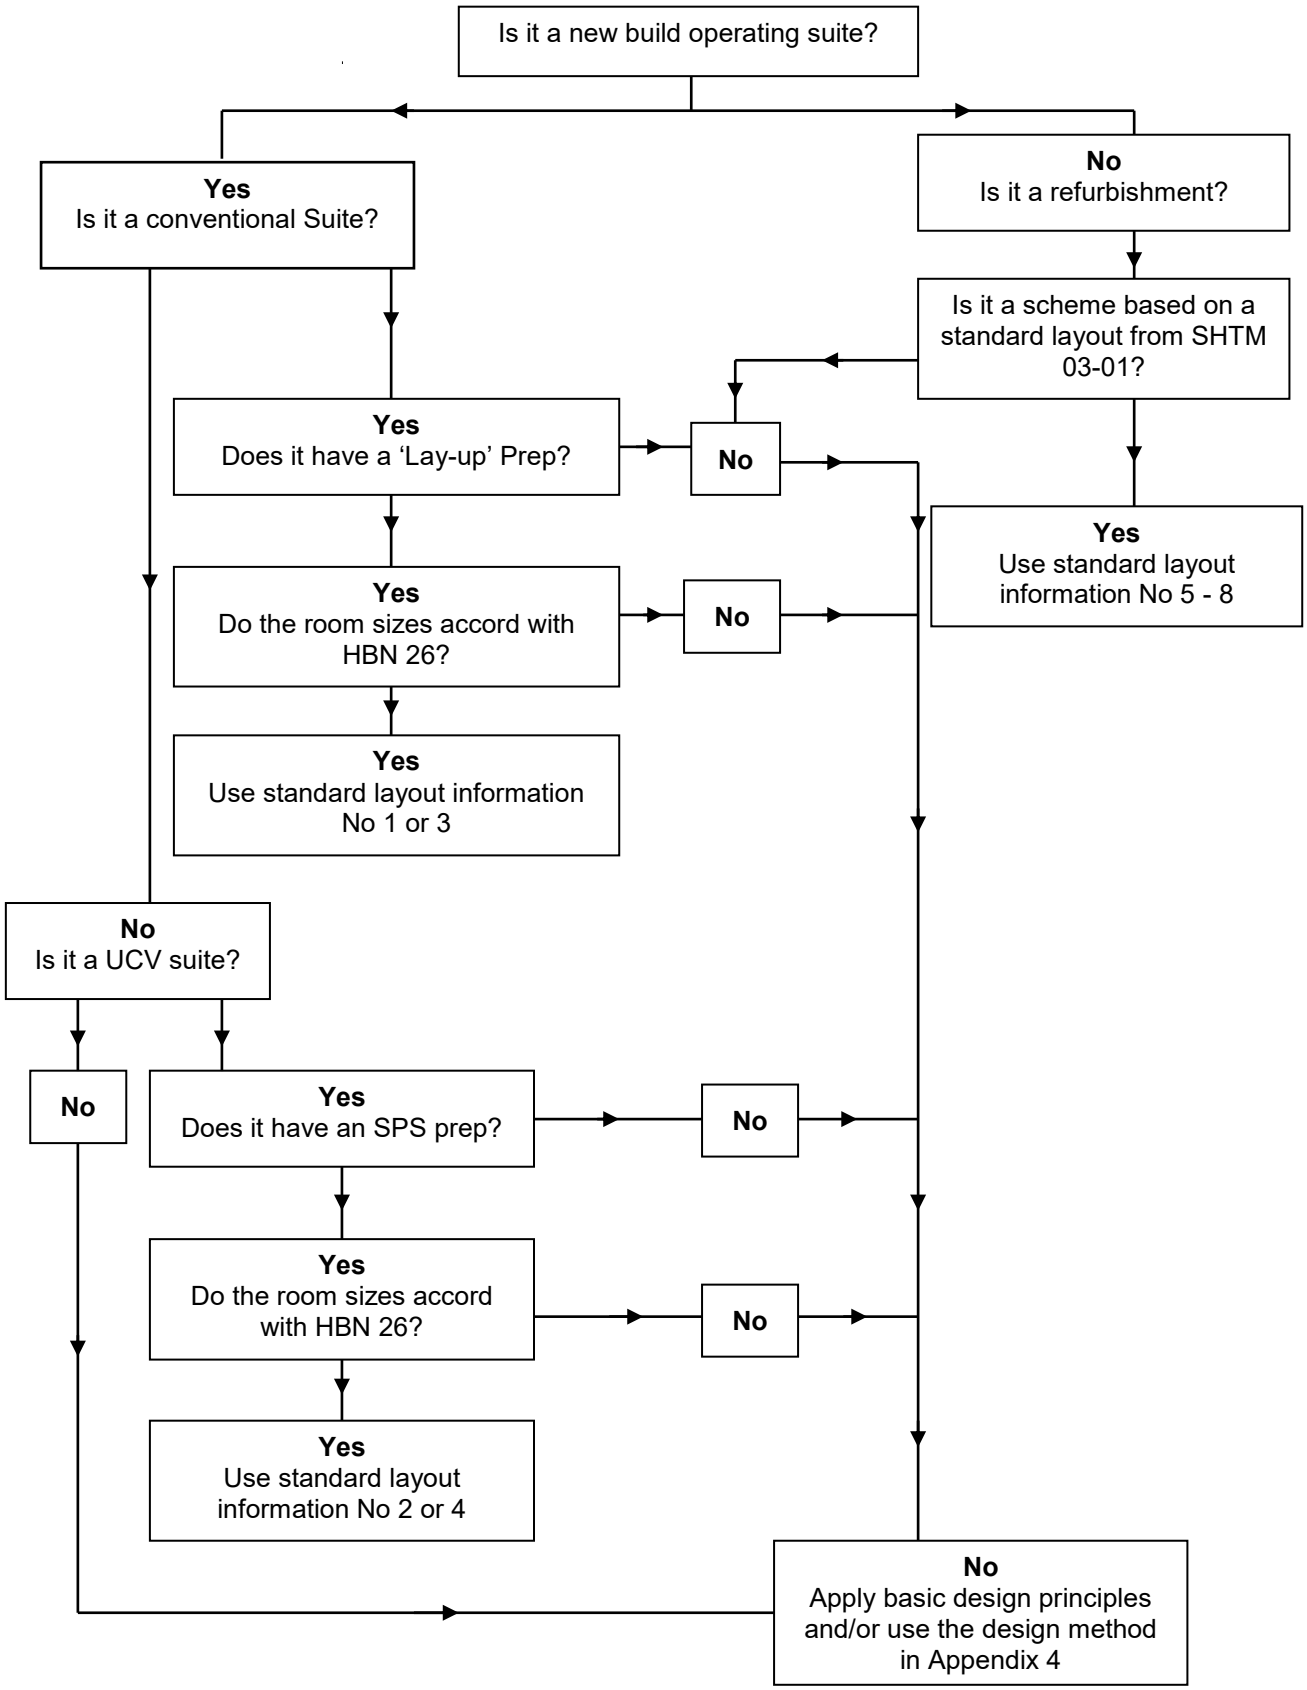
Table A5: Typical pressures in an operating suite when a given door is open

Notes: 1. The room differential pressure protects against reverse flows when the door is closed.

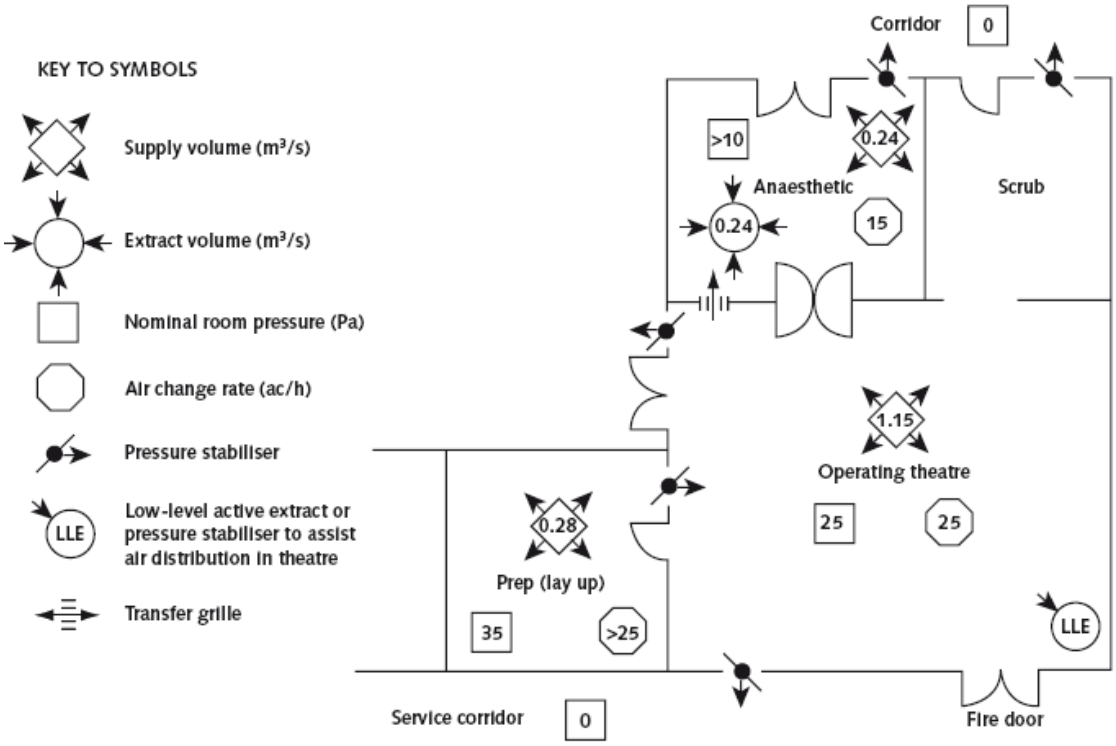
2. The flow of air through a doorway protects against reverse airflow when the door is open.

3. Pressure stabilisers control flow and ensure a known air-flow path between rooms when doors are closed and reduce back-flow between rooms when doors to other rooms are open.

Appendix 3: Operating suite design logic



New Standard Layout N° 1 - Suitable for a typical conventional theatre suite (Room sizes as specified in HBN 26)



Room	Size m³ Derived from HBN26	Air-Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15
Anaesthetic	57	15	>10	0.24
Lay-Up-Prep	36	>25	35	0.28**
Scrub	*	-	25	-

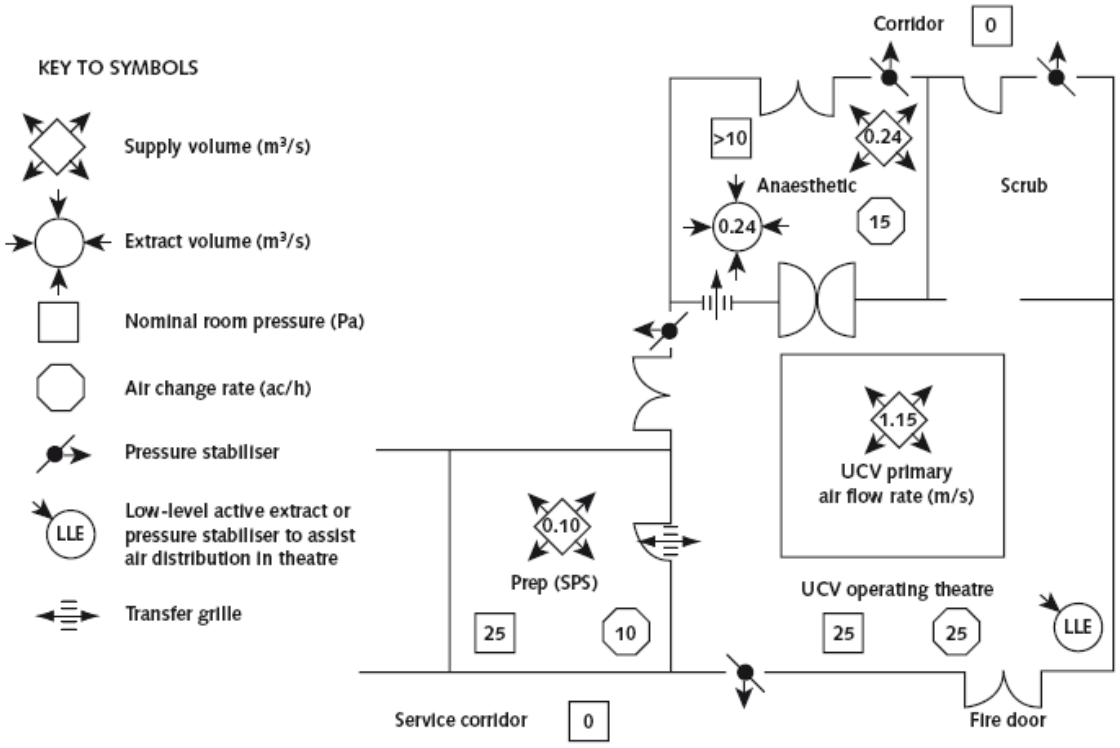
*This is a separate scrub and is not considered as being part of the theatre volume.

**Interchange is not permitted between the theatre and lay-up prep; therefore an airflow protection of 0.28 + 0.06 closed-door airflow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 2 - Suitable for a typical UCV theatre suite (Room sizes as specified in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Prep	36	25	25	0.10
Scrub	*	-	25	-

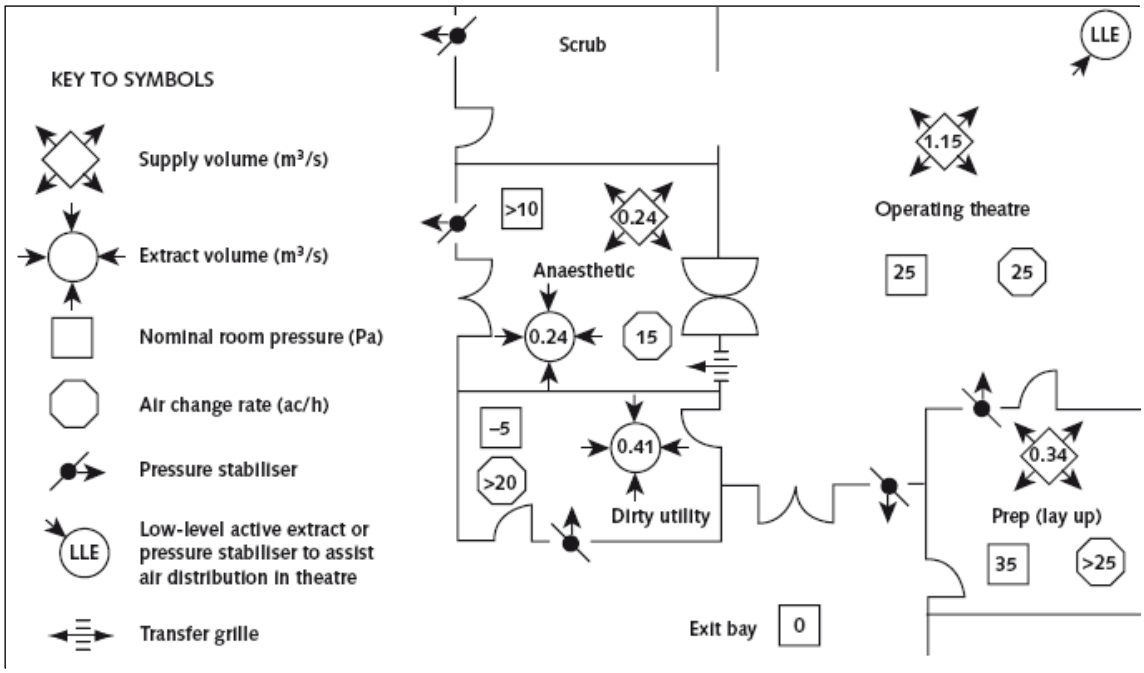
*Separate scrub and not considered as part of theatre volume

**Primary Fresh air Volume Only

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 3 - Suitable for a typical Conventional theatre suite (Layout and room sizes are as illustrated in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15
Anaesthetic	57	15	14	0.24
Lay-Up Prep	36	>25	35	0.34**
Scrub	*	-	25	-
Dirty Utility	36	-	-5	0.41

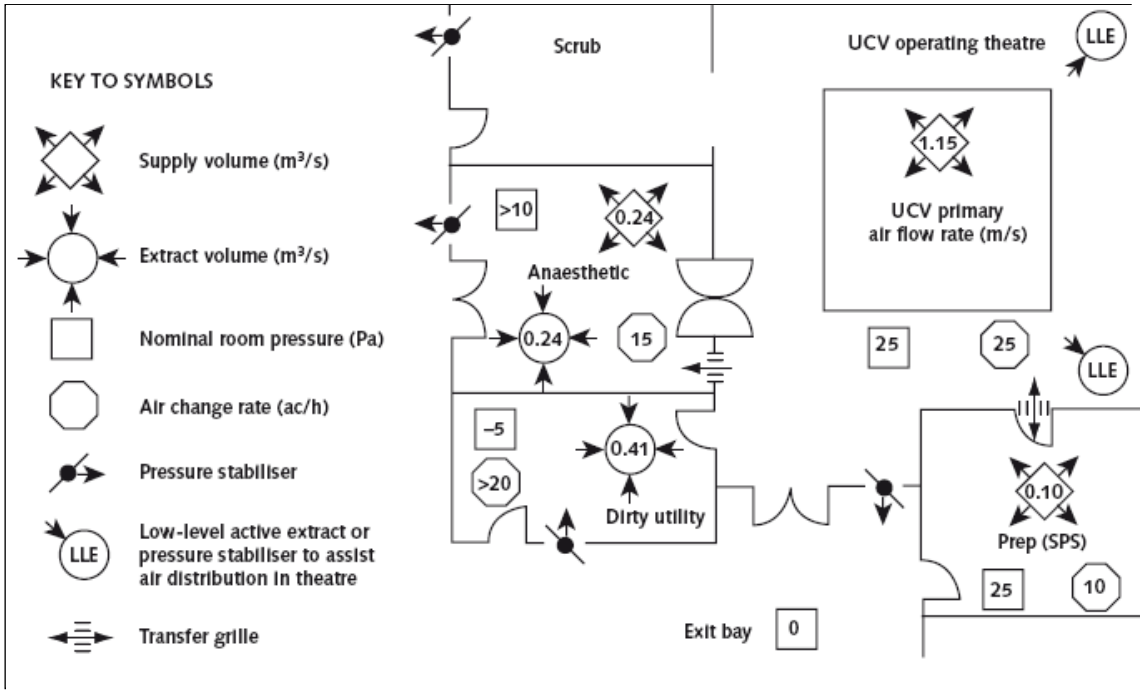
*Separate scrub not considered part of theatre volume.

**Interchange is not permitted between the theatre and lay up prep therefore as Table 4 an airflow protection of 0.28 + 0.06 closed door air flow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 4 - Suitable for a typical UCV theatre suite (Layout and room sizes are as illustrated in HBN 26)



Room	Size m³ Derived from HBN26	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Pack Prep	36	10	25	0.10
Scrub	*	-	25	-
Dirty Utility	36	-	-5	0.41

* Separate scrub not considered part of theatre volume

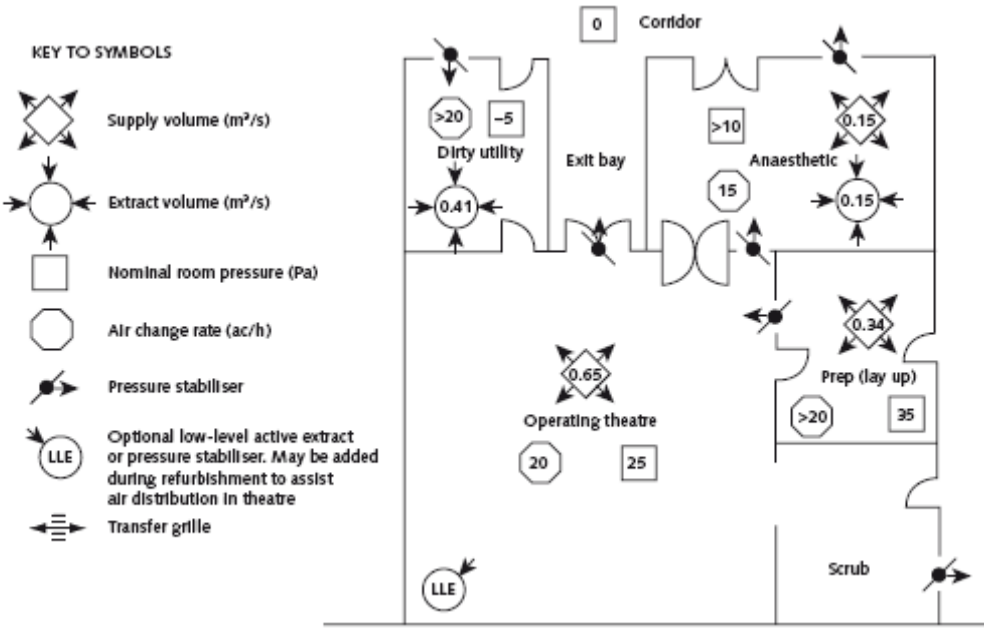
**Primary Fresh air Volume Only

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

New standard layout N° 5 - SHTM 2025 Existing standard plan '1b' typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

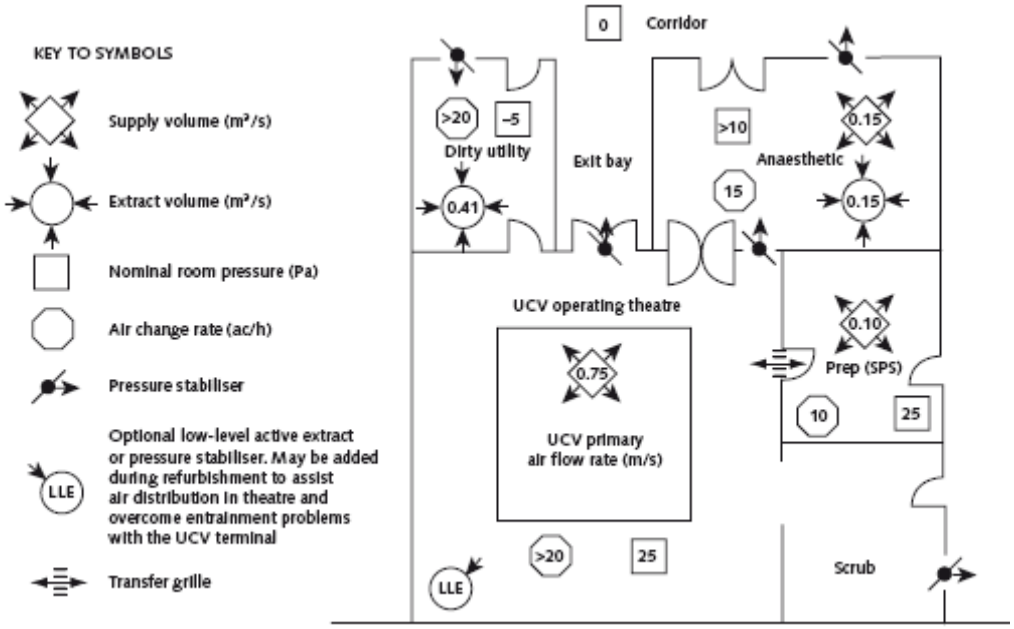


Room	Size m³	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	Existing Theatre Suite to Be measured on site	20	25	0.65
Anaesthetic		15	14	0.15
Lay-Up Prep		-	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

Standard layout No 6 - SHTM 2025 Existing standard Plan '1a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.



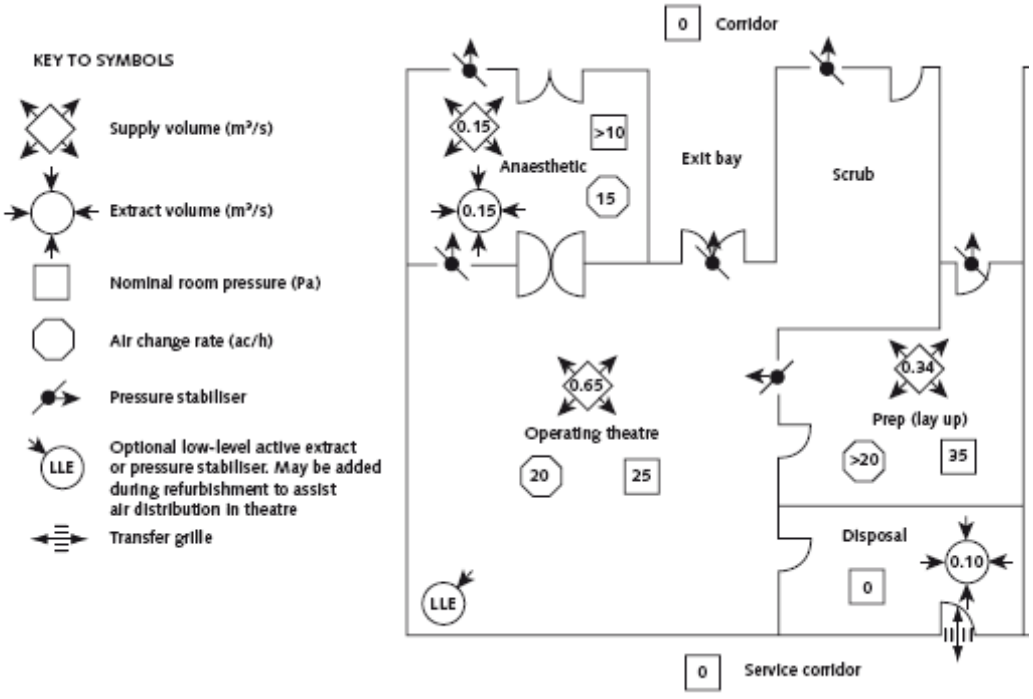
Room	Size m^3	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m^3/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Pack Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

*Primary fresh airflow volume

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

Standard layout N° 7 - SHTM 2025 Existing standard Plan '5b' Typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

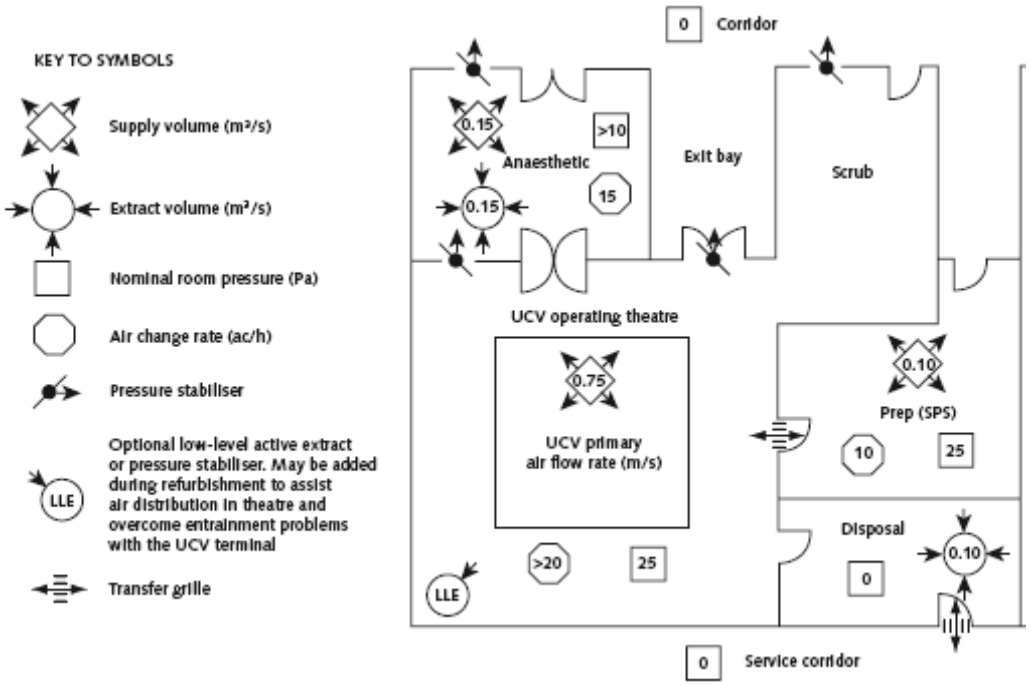


Room	Size m³	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.65
Anaesthetic		15	>10	0.15
Lay-Up Prep		>20	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

Standard layout N° 8 - SHTM 2025 Existing standard Plan '5a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.



Room	Size m³	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m³/s
Theatre	Existing Theatre Suite to be measured on site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

*Primary fresh air-flow volume only

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

A46676816

Appendix 4: Design of air-movement control schemes for operating theatres.

General

A4.1 Standard operating suite design solutions are given in Appendix 3. If these standard solutions cannot be used, the following procedure should be adopted, which will result in an acceptable design. Note that the method employed can equally be used to provide a design solution to a ventilated suite of rooms for any application.

A4.2 The method is concerned with the calculation of airflow rates to ensure that correct air movement occurs between rooms when any one door is open. Under most circumstances, the air quantities required for air-movement control will approximate to those for either temperature control or bacterial contaminant dilution. This flow rate is sufficient to control the effects of any slight reverse flows occurring when a door is opened.

A4.3 The progression through the design procedure is shown in the airflow design procedure chart (Figure A4/3) and is supported by worksheets WS1 to WS7 described in Paragraph A4.4. It is recommended that a plan of the suite and an airflow network be made (Figure A4/2) to collate all information. Flow rates, air-transfer devices etc should be entered as required. The remainder of this Appendix may be treated as reference data to assist in the various steps. The following symbols are used:

S_S – supply airflow rate for summer temperature control;

S_W – supply airflow rate for winter temperature control;

S_D – supply airflow rate for dilution of bacterial contaminants;

S_L – supply airflow rate for heat loss;

S_G – supply airflow rate for heat gain;

E_D – extract airflow rate for dilution of bacterial contaminants;

S_F – final supply airflow rates;

E_F – final extract flow rates;

S_{AMC} – air-supply flow rate for air-movement control;

E_{AMC} – air-extract flow for air-movement control;

L_{OUT} – leakage airflow rate outward;

L_{IN} – leakage airflow rate inward;

$\sum_{OUT}$ – total airflow rate outward;

$\sum_{IN}$ – total airflow rate inward.

A4.4 To simplify the procedure, standard worksheets (WS1 to WS7) have been devised. For each operating suite, a set is required comprising one each of WS1, WS3, WS5, WS6a, WS6b and WS7, one WS4 for each corridor and one WS2 to cover each peripheral room. WS2 has five versions:

- WS2a single flow;
- WS2b parallel/series multi-flow;
- WS2c parallel multi-flow or series multi-flow (unbalanced);
- WS2d series multi-flow (balanced); and
- WS2e bay (semi-open).

Peripheral room type

A4.5 The rooms in the operating suite other than the operating room and corridor are referred to as peripheral rooms. Peripheral rooms have been classified according to the flows in and out. These room classifications are defined below in Paragraphs A4.6 – A4.11.

Single flow

A4.6 This is a room with only one door and a net surplus of supply or extract air.

Parallel multi-flow

A4.7 This is a room with two or more doors through each of which the air-flows either outwards (high-pressure) or inwards (low-pressure) (for example the Prep (lay-up) in standard layout 5).

Parallel/series multi-flow

A4.8 This is a room having a net surplus of supply or extract and with two or more doors. One or more doors will be to an area of equal cleanliness and need not be protected; hence, the flow may vary between inwards and outwards, the remaining door being to an area of greater or lesser cleanliness (for example the Prep (SPS) in standard layout 6).

Series multi-flow (unbalanced)

A4.9 This is a room having a net surplus of supply or extract and with two or more doors. Air flows inwards through one or more doors and outwards through one or more doors.

Series multi-flow (balanced)

A4.10 This is a room as in Paragraph A4.9 above, but having either no mechanical ventilation or no net surplus of supply or extract. (for example an anaesthetic room).

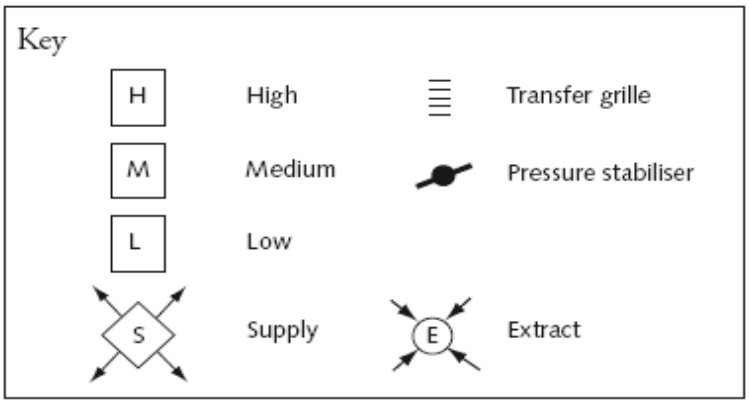
Bay

A4.11 A room that has a permanent opening to the operating room may be considered as a bay off the latter (for example a scrub). Two categories exist:

- open bay – the opening is larger than a normal single door opening. The bay may be considered as part of the main room;
- semi-open bay – the opening is no larger than a normal single door opening. In this case it is possible to protect the bay from the main room by provision of air supply or extract in the bay, or by passing air to or from another area.

Air-movement control in peripheral rooms

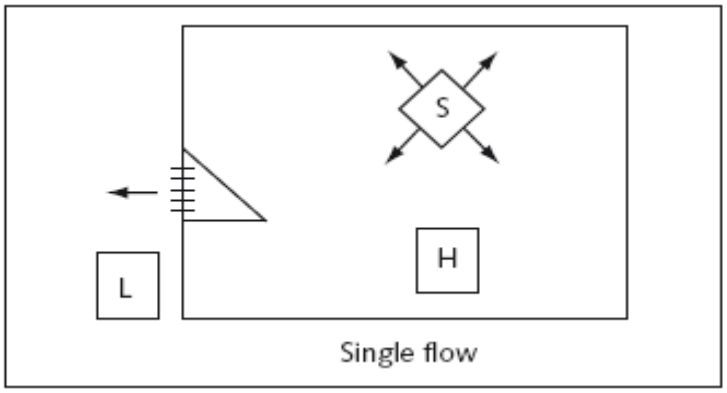
A4.12 For the design of air-movement control, two types of air-transfer device are considered. These are transfer grilles and pressure stabilisers. Each has a particular field of application within the design, as described in Paragraphs A4.34 – A4.43. Air movement is controlled in each of the different room types described in Paragraphs A4.13 – A4.31.



Note: This key applies to each diagram in A4.13 - A4.27.

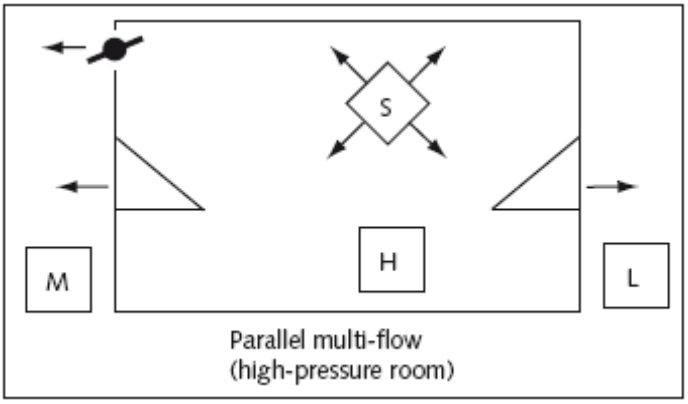
Single flow rooms

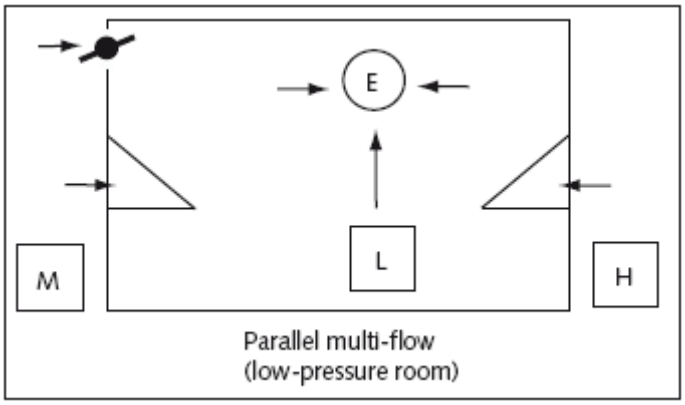
A4.13 An appropriately sized transfer grille should be located in or adjacent to the door of each single flow room to relieve the pressure differences across the door when closed.



Parallel multi-flow rooms

A4.14 The pressure difference across the closed doors must be relieved, but transfer grilles are not appropriate where two doors lead to areas of different pressures, because reverse flow could occur when the other door is open. For this reason, pressure stabilisers are used.



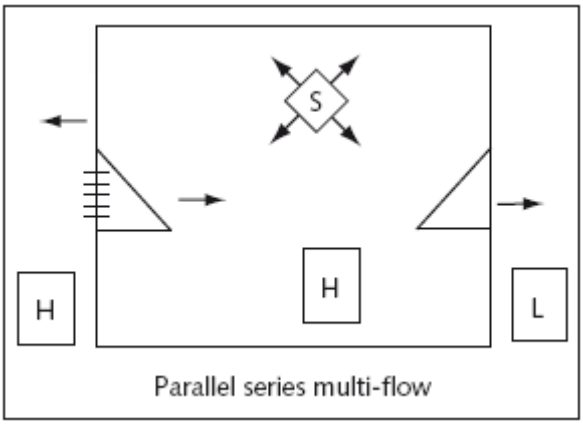


A4.15 These rooms will be either high-pressure or low-pressure with respect to the adjacent areas (see preparation lay-up room and disposal room, respectively, in standard layout 5). The pressure-relief damper is always situated between the room and area, which results in the smaller differential pressure to ensure best use of air.

A4.16 Just as reverse flow can occur if transfer grilles are used, it can similarly occur via door gaps when the other door is opened. It is not possible to avoid this, except by using air locks, but due to the low flow rates and short durations involved, this is not considered to be of importance.

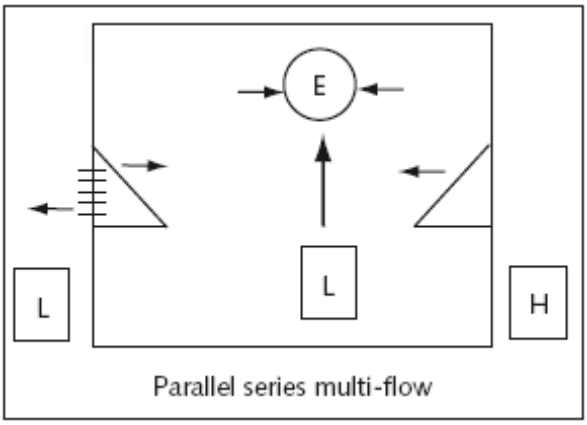
Parallel-series multi-flow rooms

A4.17 These rooms are similar to those in Paragraph A4.14 above, but because the room is of equal cleanliness to one of the adjacent rooms the nominal pressures will be equal and air may flow through the adjoining doorway in either direction. (for example the Prep (SPS) in standard layout 6).



Parallel series multi-flow

A4.18 Where the nominal room pressure equals that of the higher-pressure adjacent room, the best use of air is by supplying air required for bacterial dilution only and allowing this to exhaust via a transfer grille to the area of equal cleanliness. The doorway to the lower pressure area is protected by the combination of the supply air and the air that will flow inwards through the transfer grille from the area of equal cleanliness.

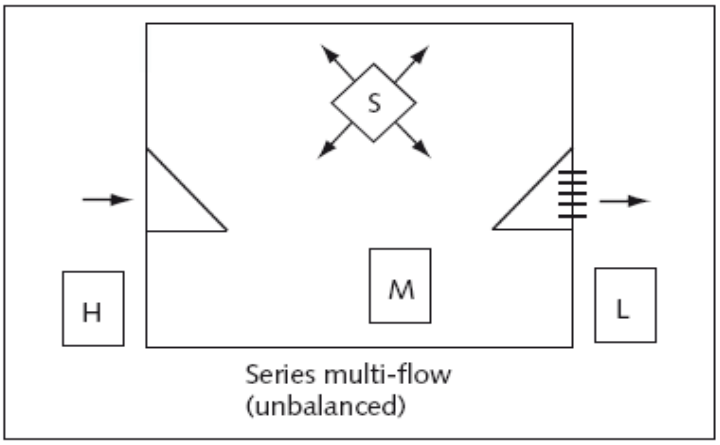


Parallel series multi-flow

A4.19 Conversely, where the nominal pressure equals that of the lower-pressure adjacent room, extract ventilation and a transfer grille to the lower pressure adjacent room should be provided. (for example, the disposal room in standard layout 8).

Series multi-flow (unbalanced)

A4.20 These rooms are somewhat similar to those in Paragraph A4.15 above, but because the pressure lies between that of the rooms on either side, the back-flow problem does not exist.



Series multi-flow (unbalanced)

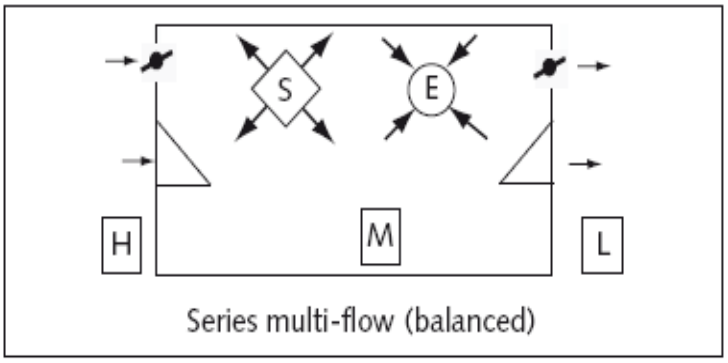
A4.21 Where the room has a net surplus of mechanical supply air, a transfer grille should be located in or adjacent to the door through which air flows outwards, and the mechanical supply flow rate to the room should be chosen to give protection when this door is open.

A4.22 Where the room has a net surplus of mechanical extract air, a transfer grille should be located adjacent to the door through which the air flows inwards, and the mechanical extract flow rate to the room should be chosen to give protection when this door is open.

A4.23 The grille must be sized for the protection requirement of the opposing door when open. When the room on the high-pressure side depressurises, there is a possibility of back-flow through gaps around the door, but this problem may be ignored.

Series multi-flow (balanced)

A4.24 In these rooms, a transfer device adjacent to each doorway is required in order to provide a flow path for the air required to protect the opposing door when opened.



Series multi-flow (balanced)

A46676816

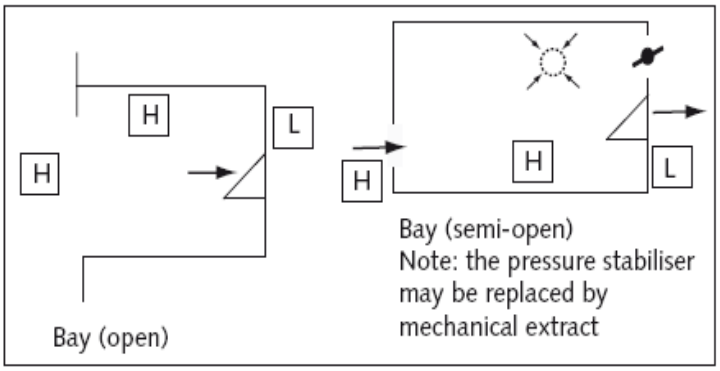
A4.25 These transfer devices will normally be pressure stabilisers, although transfer grilles may be used where a large amount of excess air is to be exhausted from the operating room when all doors are closed. (for example, anaesthetic rooms).

A4.26 The calculation procedure is to assume that pressure stabilisers are being used; then (if there is sufficient excess air) change to transfer grilles as described in Paragraph A4.50.

Bay

Open bay

A4.27 A bay of the open type (for example scrub-up) is considered to be part of the operating room. Provided air movement is satisfactory, no specific extract is required.



Semi-open bay

A4.28 In a bay of the semi-open type, protection of one area from the other is possible. (For example scrub-up).

A4.29 As stated previously, the need for protection between operating room and scrub-room is not very great. Better use of air can therefore be achieved in this case by installing a pressure stabiliser between the scrub-room and clean corridor. This will allow a flow of air through the scrub-room at all times, except when a door is opened elsewhere in the suite. The pressure stabiliser will then close and the air will be diverted to the other door. When it is considered necessary to protect the scrub-room at all times, either a transfer grille to the corridor or mechanical extract in the scrub-room should be provided.

Operating room

A4.30 Once the peripheral rooms have been considered, the operating room requirements may then be decided and the supply flow rate required for air-movement control calculated. This flow rate should be such that, with any one door open, the correct air movement directions are maintained. There will be one door in the suite that will require the largest supply flow rate to the operating room for protection when open. This is called the “key door” and is discussed separately in Paragraph A4.33. Use of this concept avoids repetitive

calculations for each door in turn. Having established the required supply flow rate, a relief route must be provided to the clean corridor for any excess air when the doors are closed. This would be via transfer grilles or pressure stabilisers through a series-flow room or via pressure stabilisers to the clean corridor directly.

Corridors

A4.31 All surplus air from the suite, except that lost through structure leakage and any passing to the outer corridor, will arrive in the patient/staff corridor. Should this air be insufficient to achieve the required air-change rate (see Appendices 1 and 2), some additional air supply should be provided. (The air balance should take account of structural leakage.)

Door opening

A4.32 Whereas the resulting pressures are dependent on ductwork layout, room relationships and characteristics of the fan, the generalisations shown in Appendix 2 can be used to estimate the change in room pressure when a door is opened.

A4.33 The “key door” will be the open double door which leaves the operating room at the highest pressure, and/or requires the largest air flow. This should be determined using the procedure in worksheet WS3.

Transfer grilles

A4.34 These may be used to limit the pressure differences across the closed door of a single-flow room or, in some instances, for protection of a series-flow or parallel-series-flow room. They allow airflow in both directions and may not be suitable for all applications.

A4.35 The free area of a grille is calculated from the following equation:

$$A = \frac{Q}{0.84\sqrt{\Delta P}}$$

where:

A is free area (m^2)

Q is flow rate (m^3/s)

P is pressure difference (Pa).

A4.36 The flow through a grille at a different pressure may be found from the following equation:

$$Q_2 = Q_1\sqrt{\frac{\Delta P_1}{\Delta P_2}}$$

where:

Q_1 and P_1 are original flow and differential pressure

Q_2 and P_2 are new flow and differential pressure.

A4.37 The transfer grille may be replaced by carefully proportioned door undercuts of the equivalent free area.

A4.38 The function of the transfer grille is to provide a means of airflow control by which the volume and pressure loss can be established. If a grille is used, it should have an easily removable core to facilitate cleaning.

Pressure-relief dampers

A4.39 The functions of a pressure-relief damper are now carried out by pressure stabilisers. Accordingly, all further mention of them has been removed from this document.

Pressure stabilisers

A4.40 Pressure stabilisers can be adjusted to hold the pressure constant over a wide range of flow rates. They are used where requirements exist for accurate room-pressure control or rapid shut-off on pressure fall.

A4.41 The installation of a grille or baffle in association with a stabiliser will alter the operating characteristics. It is recommended that a location be chosen to avoid the need for visual screening, for example, at high level. The location should be chosen to minimise the likelihood of damage.

A4.42 The stabilisers used should be virtually silent in operation, adjustable on site, maintenance-free and of a type that cannot be wrongly inserted. They should not be used in external walls or where the pressure difference is less than 5 Pa. The required size of a pressure stabiliser is dependent on the design pressure difference across it and flow rate through it. The manufacturer should provide data relating pressure difference to mean velocity (or flow rate per unit area). From this, the required area can be calculated and then rounded-up to the nearest size manufactured or nearest combination of smaller sizes.

A4.43 It is sometimes possible to arrange for a pressure stabiliser to perform two tasks. In an anaesthetic room, for example, the two pressure stabilisers may be made to pass the open door protection air, and also control the operating and anaesthetic room pressures with the door closed. To achieve this, the stabilisers are sized for the flow rate required with one of the doors open, but

the pressure setting is adjusted to be the value required with the doors closed. This is shown in Figure A4/1.

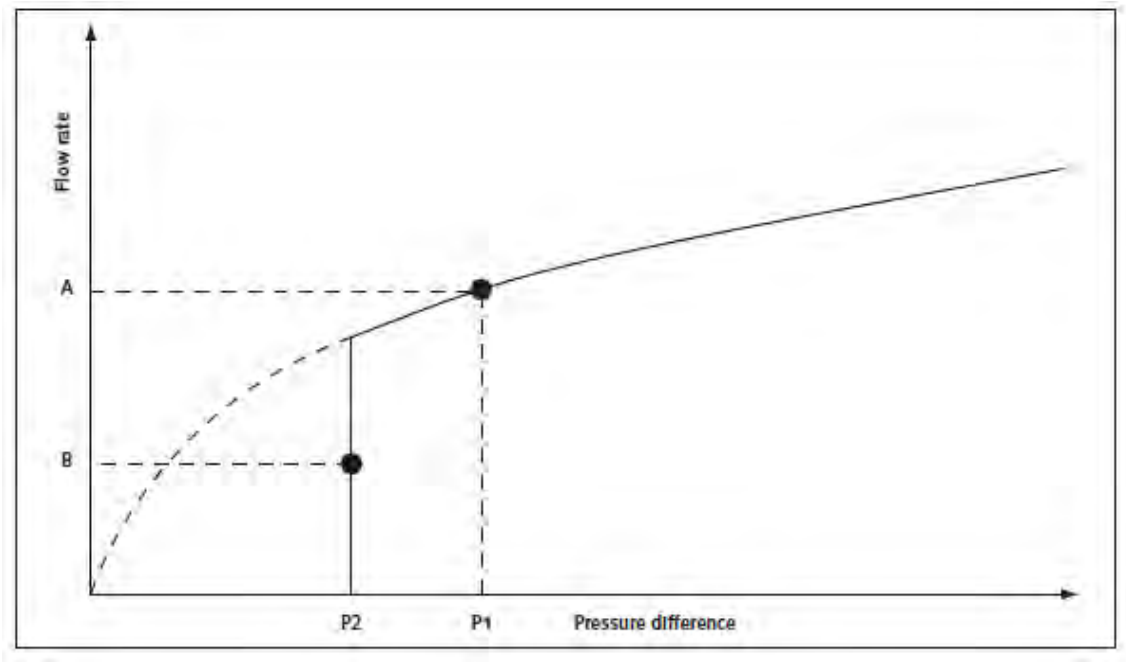


Figure A4/1

Door leakage flows

A4.44 For an air-movement control scheme to work satisfactorily, it is essential that the estimates of door-gap leakage made at the design stage are closely related to those which are achieved in practice. The calculation of gap-flows is complicated by the fact that such flows generally fall into the transition region between laminar and turbulent flow and hence do not follow the normal flow equations. The gaps assumed are 4mm along the bottom, 3mm at the top and sides, and 2mm between double leaves. Doors should not have wider gaps than these. Tighter gaps would result in lower flow-rate requirements and hence lower fan power, but care should be taken to ensure that all doors in the suite have similar gap dimensions. It may be possible to ignore the door leakage and so reduce the airflow requirement (see the notes in Appendix 3).

Room temperature estimation

A4.45 The air-flow rate required to prevent back-flow through an open door is dependent on the temperature difference across the door. The design figures shown in Appendix 3 are based on the temperature differences that will normally occur in practice, assuming heat gains and losses in accordance with Appendix 2.

A4.46 In accordance with the airflow design process, the temperature differences across the doors of all rooms classed as “sterile” is calculated. Worksheet WS6 is recommended for the calculations, using the following criteria:

- assume that the operating room is being controlled at 20°C and calculate the incoming air-supply temperature as shown on worksheet WS6;

- the calculation should be repeated for both summer and winter conditions, with an operation in progress;
- assume all doors are closed;
- use the room supply flow rates from WS1;
- use the inward air flows through air-transfer devices and closed door leakages from WS2a to WS2e;
- the formula used in worksheet WS6 is as follows:

$$T = \frac{(t_1Q_1 + t_2Q_2 + \cdots + t_nQ_n) + 0.828H}{(Q_1 + Q_2 + \cdots Q_n)}$$

where:

Q = flow rate from source (m^3/s)

t = the temperature of source (°C)

H = the room heat gain (kW).

A4.47 If the evaluated temperature differences between rooms do not exceed 2°C, the solution is satisfactory; otherwise proceed as follows:

- check the assumption on which the heat gains are based;
- take steps to reduce the heat gains;
- if the door is to a corridor, the flow through the open door will be larger than the value given in Appendix 2. Calculate on WS3, assuming it is the “key door” with door-flow unknown, and the supply as known;
- if the door leads to a room with mechanical supply, install a trimmer heater in the supply to the room controlled by either a differential thermostat or a thermostat slaved to the operating room thermostat to ensure that T is minimized.
- If the door leads to a room with no mechanical supply, increase the door protection flow as follows:

$$Q_{new} = Q_{old}\left[\frac{\Delta T + 1}{2}\right]$$

A4.48 These options should be considered in the above order, and the first three should be investigated thoroughly before proceeding to the latter two. The mechanical supply may need to be increased in order to achieve the desired air-change rates.

Relief of excess air from operating room when all doors are closed

A4.49 As the mechanical supply to the operating room is sized to provide an appropriate flow outward through any door that is opened, it follows that when all doors are closed, there will be more air supplied to the operating room than

can exit from it via leaks etc. This “excess” air can be relieved by either of the two methods described in Paragraphs A4.50 - 4.54.

By transfer devices via the anaesthetic room

A4.50 For door protection, the transfer devices in the anaesthetic room are typically designed to pass 0.47 m^3/s at a differential pressure of 14 Pa. When the doors are closed, the differential pressure will change to 11 Pa between theatre and anaesthetic room, and 14 Pa between anaesthetic room and corridor; the volume of air passed by the transfer devices will be modified as shown in the following formula:

$$Q = Q_1\left(\frac{\Delta P_1}{\Delta P_2}\right)^{1/2}$$

$$= 0.47\left(\frac{11}{14}\right)^{1/2}$$

$$= 0.42\ m^3/s$$

where:

Q = “excess” air to be vented with doors closed;

Q_1 = air-flow required for door protection through transfer device;

ΔP_1 = nominal differential pressure with door to operating room closed and door to corridor closed;

ΔP_2 = nominal differential pressure between either the anaesthetic room and corridor when the operating room door is open, or the anaesthetic room and operating room when the corridor is open. This differential pressure is used when selecting size of both devices.

A4.51 If the “excess” air is less than 0.42 m^3/s, a pressure stabiliser is required to ensure that the correct protection airflow is available to pass through the door.

A4.52 If the “excess” air is greater than 0.42 m^3/s, a transfer grille is acceptable because at all times the airflow will exceed the flow required for door protection.

By pressure stabilisers to the corridor

A4.53 If it is undesirable to pass operating room air through the anaesthetic room, it may be passed directly to a corridor via a separate pressure stabiliser.

A4.54 If there is sufficient “excess” air, the transfer grille solution at Paragraph A4.52 should be adopted, as it provides the simplest solution and, once set up, will require no further maintenance. With less excess air, it is recommended that the air be passed through the anaesthetic room via the pressure stabilisers as at Paragraph A4.51, thus keeping the number of pressure stabilisers to a minimum. Both these solutions increase the air-change rate in the anaesthetic

room, but care should be taken to avoid passing excessive amounts through that would cause discomfort to the occupants.

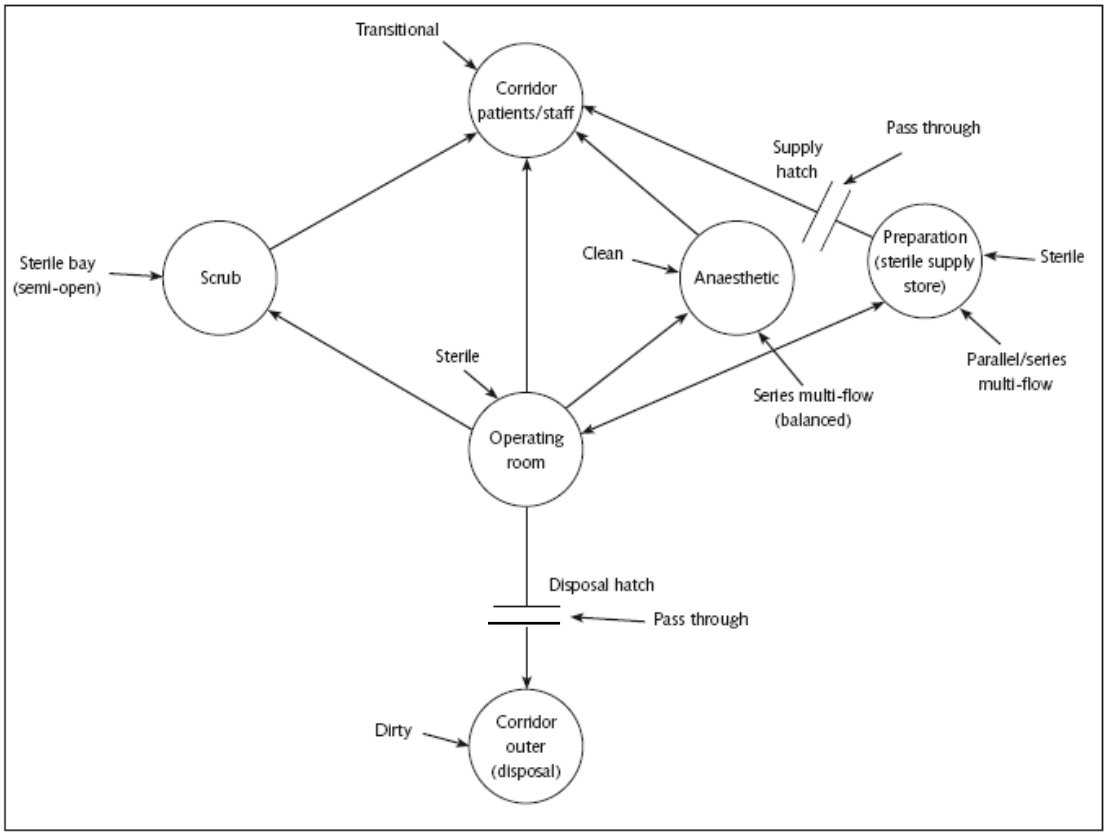

Figure A4/2: An example of an airflow network

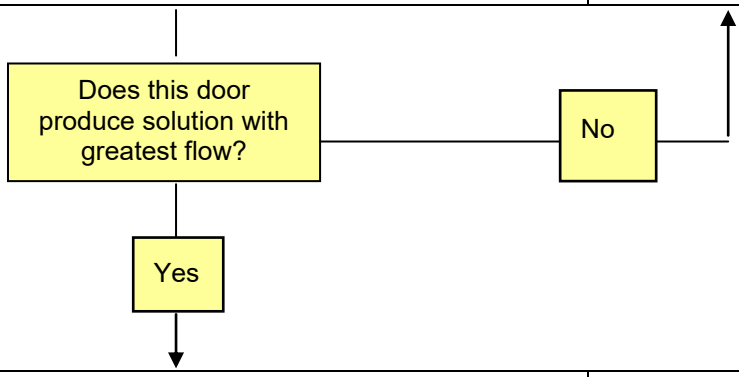
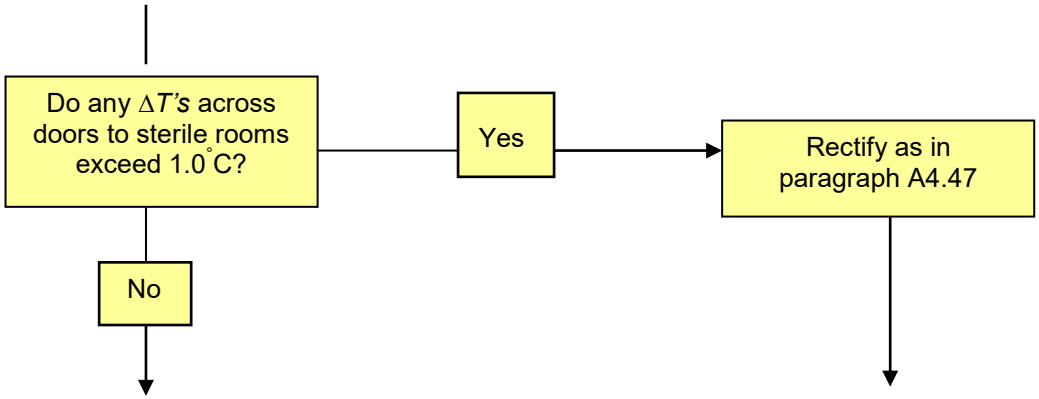
Step	Description	Worksheet
1	Show nominal room pressures and air flow directions on the plan of the theatre suite and WS1	WS1
2	Enter heat/loss/gain data and calculate supply airflow rates for temperature control only. Categorise room types e.g. sterile, clean etc.	WS1
3	Enter airflows required for bacterial contamination control or air change rate whichever is the greater, add supply and extract volumes (S_D, E_D) on the plan.	WS1
4	Define peripheral room types, see paragraphs A4.5 - A4.11, and select appropriate worksheets.	Select from WS2a - WS2e
5	Locate air transfer devices, enter details on worksheets and locate on the plan and Figure A4/2	Selected worksheets from WS2a - WS2e
6	For each peripheral room, determine air flows through doors when open and calculate mechanical supply or extract and transfer device flows	As above
7	Select "Key Door" and calculate air supply for operating room	WS3



8	Transfer to WS1 and select final rate S_F and E_F	WS1. WS3
9	Make provision for relief of excess air with doors closed	Selected Worksheets and WS3
10	Calculate supply and extract flow rates for corridor(s)	WS4, WS5
11	Calculate room temperatures (all doors closed) and ΔT's	WS4, WS5



12	Make summary of flows	WS6a and WS6b
13	Size transfer devices, size ductwork, central plant etc	WS7
14	Design ductwork layout, control plant etc	

Figure A4/3: Airflow design procedures

Note: In the following worksheets WS1, WS2a-e, WS3, WS4, WS5, WS6a&b and WS7 it has been necessary to reduce the font size to 8pt instead of the usual 10pt in order to set out the complete tabular information for each within a single page for ease of use.

Note from the publisher

This publication is primarily intended to provide guidance to those responsible for the design, installation, commissioning, operation and maintenance of building services. It is not intended to be exhaustive or definitive and it will be necessary for users of the guidance given to exercise their own professional judgement when deciding whether to abide by or depart from it.

Any commercial products depicted or describer within this publication are included for the purposes of illustration only and their inclusion does not constitute endorsement or recommendation by the Institution.

Foreword

Guide B provides guidance on the practical design of heating, ventilation and air conditioning systems. It represents a consensus on what constitutes relevant good practice guidance. This has developed over more than 70 years, with the Steering Groups for each edition of the Guide expanding and pruning the content to reflect the evolution of technology and priorities.

Since the last edition of Guide B in 2005, the European Energy Performance of Buildings Directive has been introduced. This requires national building energy regulations to be based on calculations that integrate the impact of the building envelope and the building services systems, formalising what was already recognised as good design practice. In addition, the use of voluntary energy efficiency and sustainability indicators has increased.

These changes have influenced the content of Guide B, but the emphasis remains on system design. The guidance in Guide B is not in itself sufficient to cover every aspect of the effective design of HVAC systems. Energy (and carbon emission) calculations will also be needed, and a range of other environmental criteria may specified by the client. These may, for example, include whole-life costing or assessments of embodied energy or carbon. The balance between building fabric measures and the energy efficiency of HVAC systems is important, as is the balance between energy use for lighting and for heating, ventilation and cooling. More detailed information on energy efficiency and sustainability can be found in Guides F and L respectively. The Guide does not attempt to provide step by step design procedures: these can be found in appropriate textbooks.

Structure of the Guide

Guide B deals with systems to provide heating, ventilation and air conditioning services, and is divided into several chapters which are published separately. It will usually be necessary to refer to several — perhaps all — chapters since decisions based on one service will commonly affect the provision of others.

— Chapter B0: *Applications and activities* focuses on how different types of building and different activities within buildings influence the choice of system. This chapter is not available in printed form, but can be downloaded from the CIBSE website. For many activities and types of building, more detailed design information is available in specialist guidance.

Chapters B1 to B4 address issues relating to specific services. There are usually several possible design solutions to any situation, and the Guide does not attempt to be prescriptive but rather to highlight the strengths and weaknesses of different options.

— B1: *Heating*, including hot water systems and an appendix on hydronic systems, which is also applicable to chilled water systems

— B2: *Ventilation and ductwork*

— B3: *Air conditioning and refrigeration*

— B4: *Noise and vibration control for building services systems* (applicable to all systems)

When all chapters have been published, an index to the complete Guide B will be made available.

The focus is on application in the UK: though many aspects of the guidance apply more generally, this should not be taken for granted. The level of detail provided varies: where detailed guidance from CIBSE or other sources is readily available, Guide B is relatively brief and refers to these sources. Examples of this are the treatment in the Guide of low carbon systems such as heat pumps, solar thermal water heating and combined heat and power. On-site energy generation such as wind power and photovoltaics are not covered.

Regulatory requirements are not described in detail in the Guide – the information varies between jurisdictions and is liable to change more rapidly than the Guide can be updated. Instead, the existence of regulations is sign-posted and their general scope explained. Sometime example tables are shown, but readers should note that these are simply examples of the type of requirement that is imposed and may not be current.

While there is some discussion of relative costs, no attempt is made to provide detailed cost figures as these are too project-specific and variable with time and location.

2 Ventilation and ductwork

2.1 Introduction

2.1.1 Introduction

Ventilation is the process by which fresh air is provided to occupants and concentrations of potentially harmful pollutants are diluted and removed from a space. It is also used to cool a space and as a mechanism to distribute thermally conditioned air for heating and cooling. It is a fundamental component of building services design since it plays a major role in the comfort, health and productivity of occupants. In addition, ventilation can contribute significantly to a building's energy load and, in some cases, can account for 50 per cent or more of total heating or cooling loss. To stem energy loss from uncontrolled air change there is growing demand for airtightness combined with demand-controlled ventilation and heat recovery.

In large buildings, the ventilation system can be extremely complex and is invariably integrated with the heating and cooling system. Hence there is a strong connection between ventilation, heating and cooling systems, building envelope, fire protection and structural design issues (Thomas, 1999). This impinges on the whole-life costs (BSRIA, 2008) and performance (Allard, 2001) of buildings. Since building services are required to operate throughout the life of the building, their operating costs are a very significant element of the whole-life costs of the system.

For all these reasons, there is a need for up-to-date guidance on the design of ventilation systems. The overall process of design development, from the initial outline design through to system selection and detailed equipment specification, is summarised schematically in Figure 2.1. Cooling systems are separately covered by CIBSE Guide B3 (2016a) and heating systems are covered in CIBSE Guide B1 (2016b).

2.1.2 Scope

This guide is intended to be used by practising designers who hold a basic knowledge of the fundamentals of building physics and building services engineering.

Section 2.2 sets out the criteria for the design of ventilation systems, covering the contribution of ventilation to providing a safe and comfortable indoor environment, including indoor air quality, thermal comfort and noise. This chapter should be read in conjunction with chapter 1 of CIBSE Guide A (2015a).

Section 2.3 reviews the principal methods of providing ventilation: natural, mechanical and mixed-mode systems. It also describes the basic principles of related systems for air distribution, filtration, heat recovery and control.

Section 2.4 sets out the principles for designing natural, mechanical and mixed-mode systems and includes the design of ductwork, calculation techniques and methods of measuring the performance of ventilation systems.

Section 2.5 discusses other design considerations closely related to ventilation and covers noise, air leakage, fire and smoke protection. Noise and fire protection are dealt with in more detail in CIBSE Guides B4 (2016c) and G (CIBSE, 2014) respectively.

Section 2.6 covers the components of a ventilation system and includes fans, air control units, mixing boxes, terminal devices, extract hoods and duct equipment. Also included is equipment for natural ventilation.

Section 2.7 covers the important areas of testing, commissioning, maintenance and cleaning.

2.1.3 Definitions

The meaning of key terms used in this Guide are summarised below.

— *Natural ventilation*: this is the process by which airflow through ventilation openings is driven by the natural driving forces of wind (wind effect) and temperature difference (stack effect). Natural ventilation systems are described in section 2.3.2.2.

— *Mechanical ventilation*: these systems incorporate fans and control systems to drive the ventilation process. They are thus able to provide ventilation irrespective of the availability or suitability of natural forces. In many countries large buildings including city centre offices, public buildings and shopping malls are almost universally mechanically ventilated. In addition to providing fresh air, mechanical systems are also often used to distribute thermally conditioned air as part of the building's heating and cooling (air conditioning) system. There are various configurations of mechanical ventilation; these are described in section 2.3.2.3.

— *Mixed-mode or hybrid ventilation*: this utilises a combination of both natural and mechanical ventilation. The various modes of operation are described in section 2.3.2.4.

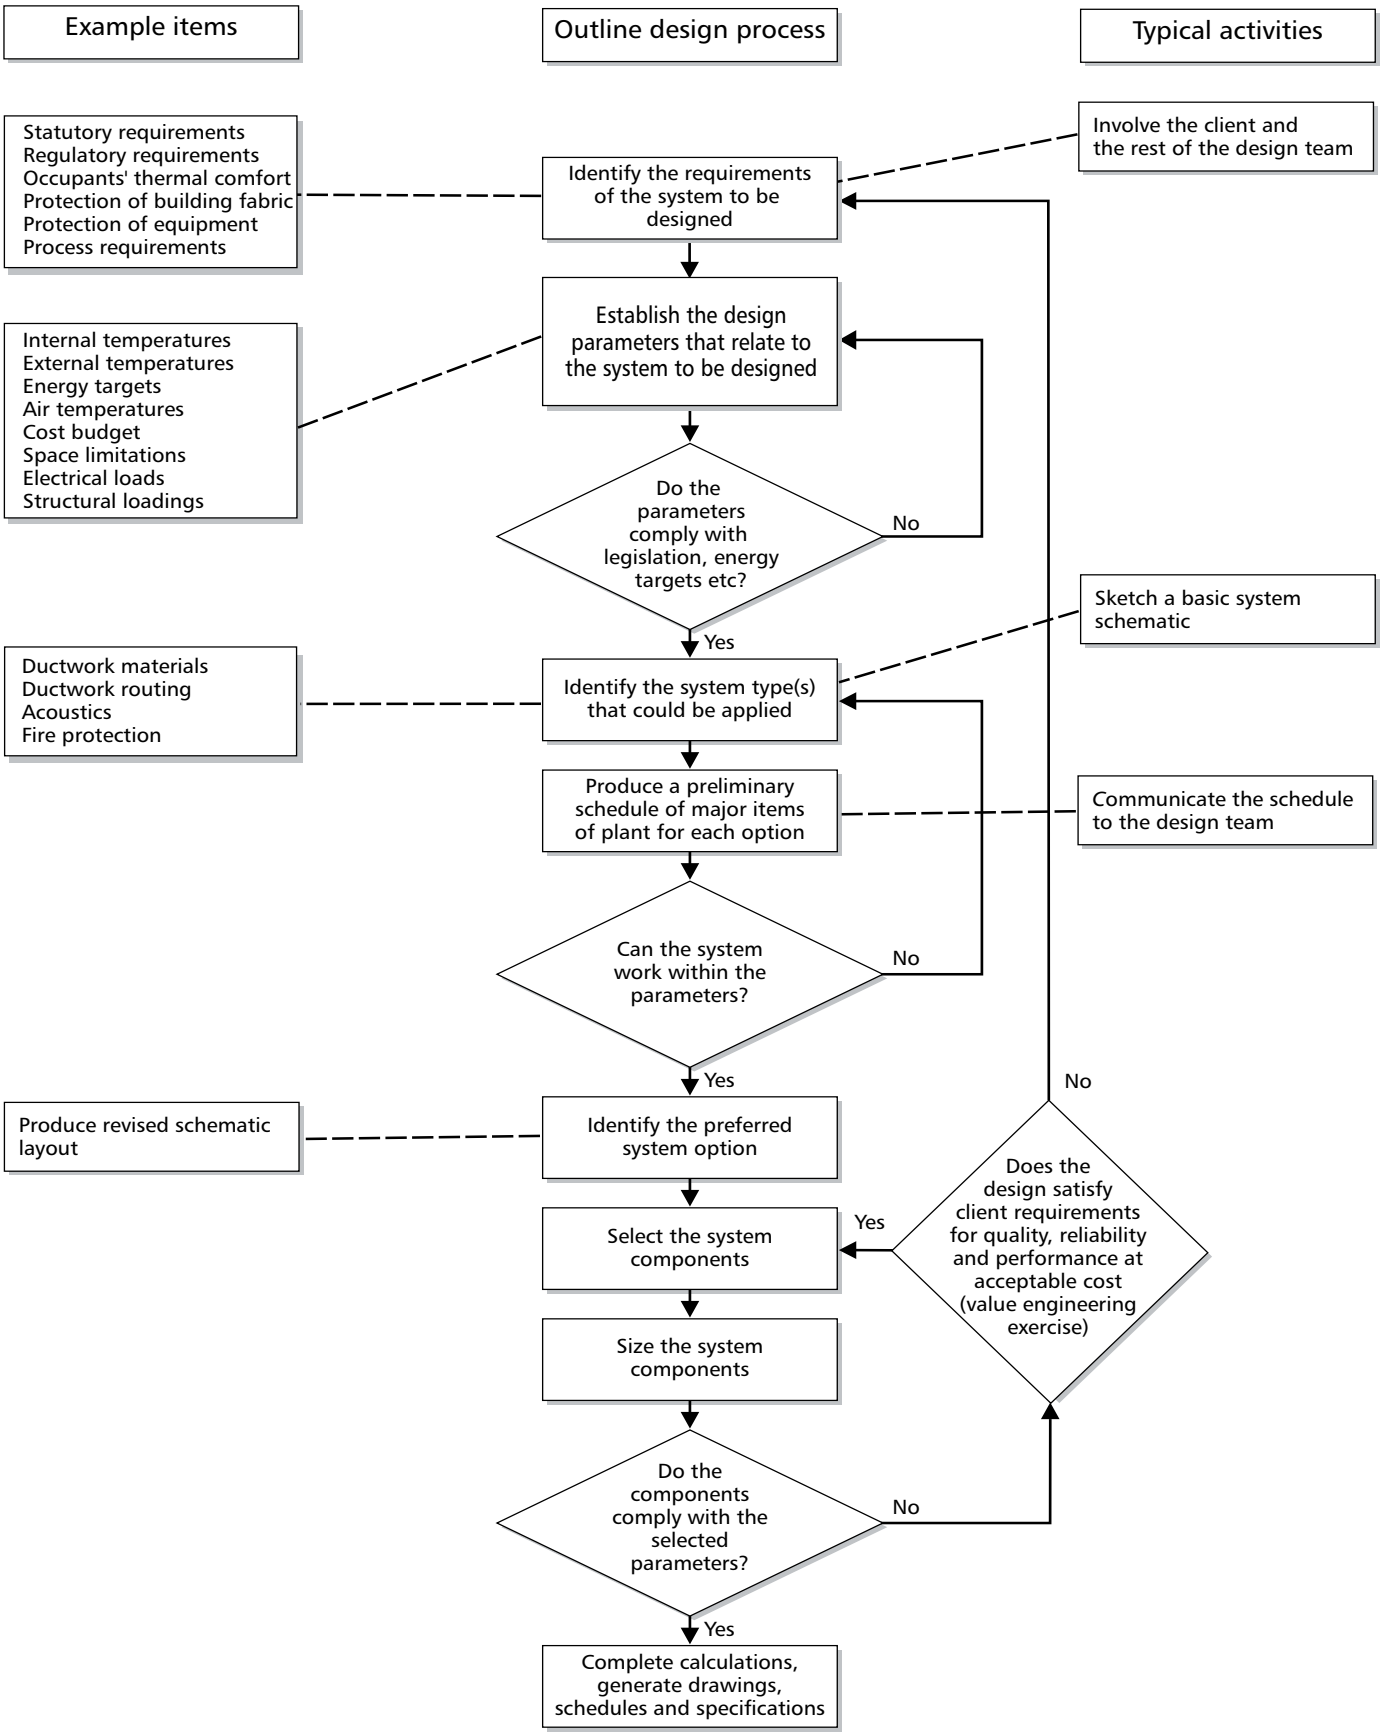

Figure 2.1 Outline of the ventilation design process

— *Air change rate*: this is the ventilation rate in m^3/h divided by the volume in m^3 of the enclosed space expressed in air changes per hour (ACH).

— *Air infiltration*: this is defined as the air ingress, under ambient conditions, that enters a building through adventitious cracks and gaps in the building envelope. The corresponding air loss is defined as air exfiltration.

— *Airtightness*: this is a measure of the air leakage rate through the building envelope for a given test pressure (typically at 50 Pa) (see section 2.4.7.2).

— *Blower door*: a device for pressure testing building airtightness.

— *Contaminant removal efficiency*: this is a term used to describe the efficiency of the removal of contaminant in a space by ventilation. It can relate to the space as a whole or to individual locations.

— *Dilution ventilation*: see 'mixing (or dilution) ventilation'.

— *Displacement ventilation*: this is a mechanism by which fresh air is introduced to a location without mixing the fresh incoming air with the room air.

— *Heat recovery*: a process by which sensible 'dry' heat from the exhaust air supply is recovered and normally used to pre-heat the supply air (see section 2.3.4). Latent heat can also be recovered with some systems.

— *Latent heat recovery*: a process by which latent heat from moisture in air is recovered.

— *Mixing (or dilution) ventilation*: a system by which incoming fresh air is thoroughly mixed with the air already in a space. This is a common approach for air-driven heating and cooling systems.

— *Percentage persons dissatisfied (PPD) thermal comfort parameter*: the percentage of people expressing dissatisfaction with the thermal environment in which they are exposed (e.g. too hot or too cold).

— *Predicted mean vote (PMV) thermal comfort parameter*: a measure by each occupant of their perception to thermal comfort varying from –3 for too cold to 0 for neutral and +3 for too hot.

— *Pressure test*: a method for testing the airtightness of a building or a component such as ductwork.

— *Recirculation*: the blending of fresh air with extract air for recycling back into a ventilated space. This forms an important part of an air-driven heating or cooling system.

— *Specific fan power*: the electrical energy used to drive each litre/second of air through a ventilation system (measured in watts per $l \cdot s^{-1}$).

— *Task ventilation*: a system by which fresh air is ducted directly to the point of need.

— *Ventilation effectiveness*: a term used to describe the degree that fresh air is mixed in a space (see section 2.4.7.5).

2.1.4 Energy and carbon considerations

Many countries are committed to significantly reducing carbon emissions with the aim of achieving carbon neutrality. There is also strong demand to improve the energy performance of existing buildings. Within Europe, energy conservation requirements for buildings are covered by the Energy Performance of Buildings Directive (EU, 2010). This requires member states to apply minimum requirements covering the energy performance of both new and existing buildings. There is currently a commitment to achieving carbon-neutral buildings by 2020. In the UK, the Government has also introduced a Climate Change Levy (HMRC, 2012), effectively a specific tax on energy use. To encourage energy efficiency it has also introduced an enhanced capital allowance scheme for certain energy-efficient measures (Carbon Trust, 2012). It is intended that these measures will stimulate a greater interest in energy efficiency amongst building owners and operators and that energy efficiency will be given a greater prominence in decisions about building design. Allied to this has been the introduction of revised Part L of the Building Regulations in England as well as revisions to Welsh and Scottish Regulations. Similarly, more demanding energy-efficiency requirements for buildings are being introduced into the regulations of many other countries. These set significantly more challenging targets for energy-conservation aspects of buildings than has hitherto been the case. The combined effect of these regulatory measures is expected to be a significant improvement in energy performance, certainly in new buildings and those undergoing major refurbishment.

As insulation and construction techniques steadily improve, ventilation losses account for an ever-greater proportion of the total building energy consumption. Therefore, there is much emphasis on improving building airtightness and regulating the rate of ventilation. However, these need to take place in conjunction with providing sufficient ventilation for air quality. Fan systems must also be energy efficient to ensure that mechanical systems operate at optimum efficiency. Part L of the Building Regulations for England and Wales (NBS, 2013a) therefore imposes requirements on airtightness performance and on the overall specific fan power of a system (see section 2.3.5.2). Where thermal ventilation losses are significant, increasing use is being made of ventilation heat recovery systems. In some instances these form a major component in reducing energy consumption and, in some countries are compulsory for some building types.

A further method for improving energy efficiency is to allow indoor temperature to drift in response to adaptation to climate conditions. Again, ventilation can play an important role by offering a degree of passive cooling and air movement.

2.1.5 System costing

System costing is inevitably a major consideration, especially in relation to payback periods and overall strategic benefit of carbon and energy reduction. Basic guidance is included in CIBSE TM30: *Improved life cycle performance of mechanical ventilation systems* (2002) and BSRIA *Rules of Thumb* (5th edition) (2011).

2.2 Design criteria

2.2.1 Introduction

The selection of a ventilation strategy is affected by location, plan depth, heat gains, internal and external pollutant sources, economics, energy and environmental concerns and internal layout. Ultimately it is the use and occupancy of a space that determines the ventilation needs. There is no universal economic solution, although there are some best practice indicators. It is essential that the client understands and accepts the ramifications of the selected strategy. Full details on the operational performance and selection of individual systems are covered in section 2.3. In selecting an appropriate ventilation strategy thought must be given to meeting the requirements of the people and processes that occupy the building without being excessive and therefore wasteful. However, the pursuance of an integrated design approach to achieve this also links the ventilation strategy with the design of the building fabric in that, as a prerequisite, all reasonable steps should be taken to maximise the potential of the fabric.

The design process must be based on a clear understanding of client and end-user needs and expectations and must be followed by effective commissioning, handover and building management. Close collaboration between the architect, services and structural engineers and the client is essential from the earliest stages of the outline design process. In each case, initial agreement should be reached on the needs required. Checks should be carried out continuously by the design team to ensure that the implications of any changes made during design, construction or subsequent fit-out are understood and mutually acceptable.

This section considers basic design criteria. More specific information about ventilation techniques and components are given in subsequent sections.

2.2.1.1 Purpose of ventilation systems

In designing any ventilation system it is necessary to understand the functions required of it. These are summarised in Table 2.1.

During periods of heating or active cooling, any fresh air ventilation above that needed to control air quality has an energy penalty. During summer, in non-air-conditioned spaces, ventilation rates above those required for air quality may reduce the demand for mechanical cooling, although this will only be possible when the outside air temperature is lower than the room temperature. Even if inside and outside temperatures are similar, increased air movement can improve comfort as described in CIBSE Guide A, chapter 1 (2015a).

2.2.1.2 Occupancy performance

There is much evidence showing that the effectiveness of building ventilation has a significant effect on the performance of those working in the building. Poor indoor air quality impairs the performance of employees in a workspace (Andersson *et al.*, 2006). It has also been shown to result in poor health in the home (Bornehag *et al.*, 2005).

Evans *et al.* (1998) have estimated that design, build and operating costs are in the ratio 1:5:200. Therefore, poor standards of building ventilation can have a significant negative effect on operating costs through their adverse effect on employee performance, given that the cost of running and staffing the business is the most significant to users. Over a system life of 10–15 years, a 1 per cent reduction in productivity may easily equal any savings made on the design and installation costs of the system. So it is worthwhile for building owners and operators to ensure that buildings are ventilated to provide a healthy and effective environment.

Table 2.1 Purposes of ventilation

Purpose	Explanation
To provide sufficient 'background' ventilation for occupants in terms of air quality for breathing and odour control	Typical rates need to be increased where smoking is permitted or additional sources of pollution are present. Most pollutants originate from sources other than people but in such cases general ventilation has been shown to be much less effective than treating the problems at source: e.g. by specification, cleanliness and local extraction.
To provide natural cooling during the occupied period	Care must be taken to avoid excessive air change rates that may cause draughts or disturb documents. Higher rates may be practicable in spaces occupied transitionally, such as atria. The balance point above which mechanical cooling will provide a more effective solution should be considered.
To provide natural cooling outside the normal occupied period	Night cooling or 'night purging' can remove heat built up in a structure and its contents and provide some pre-cooling for the following day. Practical limitations will exist in terms of acceptable secure openable areas in the case of natural ventilation and on duct size and fan energy consumption for ducted mechanical systems.
To exhaust heat and/or pollutants from localised sources or areas	Examples are kitchens, toilets, vending areas and equipment rooms. This enables adjacent areas to be more comfortable, with less conditioning of the air. Such systems often need to operate for longer hours than those serving the main spaces, therefore independent extract systems are preferred.
To act as a carrier mechanism for mechanical cooling and/or humidity control	This can be either via an all-air system in which the air is treated centrally or via air/water or unitary systems in which the air is recirculated and treated locally.
To prevent condensation within the building fabric	Adequate ventilation for condensation control exceeds the minimum rate of fresh air necessary for health and comfort. There is a specific need to address the ventilation of areas where moisture-generating activities occur.
To enable the efficient operation of processes	Needs are entirely dependent on the process. Ventilation may be required to ensure safe combustion or to ensure that machinery is maintained within a suitable temperature range, e.g. lift motor rooms.

2.2.1.3 Establishing key performance requirements

The key performance requirements that need to be clarified before a ventilation strategy can be selected are summarised in Table 2.2. Ideally, where the issues highlighted in the table have not been covered within the specification documents, the design team should expect to agree requirements with the client at the outset of the project to optimise the choice of strategy. If the client is unable to advise on the precise needs, they must at least be made aware of any limitations of the chosen design.

The design team should also be able to advise the client of the cost implications of meeting their stated requirements, on a whole-life basis (BSRIA, 2008) if requested. Requirements may be adjusted over the course of the project to meet financial constraints or changing business

Table 2.2 Establishing performance requirements

Issue	Requirement/comments
Client brief	To be developed in the context of the other issues.
Integrated design	Co-ordinated approach by the architect and other specialists from outline design.
Energy/environmental targets	Use of existing specifications or appropriate advice from the design team required. Compatibility with indoor environment standards.
Indoor environmental standards	Use of existing standards or appropriate advice from the design team required. Areas or objects with special requirements.
Provision of controls	Individual, local, team, zone or centralised basis. Required closeness of control (e.g. of temperature, humidity, air quality, airflow). The required interaction of the end user with the building services. The required basis of control, e.g. temperature, CO_2, CO or other.
Demands of the building occupants and activities	The business process(es) to be undertaken in the building may demand specified levels of availability of ventilation. Work patterns over space and over time (regularity, shifts, team structure). Cellular and open-plan mix with associated partitioning strategy and likelihood of change. Occupancy numbers and anticipated maximum occupancy over the building lifetime that might need to be taken into account. Average occupancy density and any areas of high or low density. Functions of space use, processes contained therein and subsequent internal loads (e.g. standard office space, meeting rooms, lecture theatres, photocopying rooms, sports hall, laboratories, manufacturing environments, retail space). Anticipated diversity of internal loads.
Investment criteria	Constraints imposed by 'letability' requirements.
Value engineering and whole-life costs	Understanding of the client's priorities towards capital cost and issues of whole-life costs. Requirements for calculations to be carried out on systems or system elements and the basis for these calculations. Has the client been involved in discussions of acceptable design risk? The importance of part load performance.
Reliability	The business process(es) to be undertaken in the building may demand specified levels of reliability of the ventilation systems.
Maintenance requirements	Understanding of the client's ability to carry out, or resource, maintenance. Client willingness for maintenance to take place in the occupied space. Any requirement for 'standard' or 'familiar' components.
Associated systems	Implications of any particular requirements, e.g. fire, security, lighting, acoustic consideration.
Security	Restrictions on size and location of any openings.
Future needs	Adaptability, i.e. the identified need to cope with future change of use. Flexibility, i.e. the identified need to cope with future changes in work practices within the current building use. Acceptable design margins: it is important to distinguish, in collaboration with the client, between design that is adequate for current requirements (which may not be currently accepted best practice), design that makes sensible agreed allowances for future changes and over-design.
Aesthetic considerations	The need for system concealment. Restriction on placement of grilles, diffusers etc. Restrictions imposed by local authorities, building listing etc.
Procurement issues	Time constraints. Programming constraints, particularly for refurbishment projects.

Table 2.3 Issues affecting the choice of ventilation

Issue	Comments	Reference
Location	Adjacent buildings can adversely affect wind patterns. The proximity of external sources of pollution can influence the feasibility of natural ventilation. The proximity of external sources of noise can impact on the feasibility of natural ventilation.	CIBSE AM10 (2005)
Pollution	Local levels of air pollution may limit the opportunity for natural ventilation. It may not be possible to provide air inlets at positions suitable for natural ventilation given the inability to filter the incoming air successfully.	CIBSE TM21 (1999)
Orientation	Buildings with their main façades facing north and south are much easier to protect from excessive solar gain in summer. West façade solar gain is the most difficult to control, as high gains occur late in the day. Low sun angles occurring at certain times of year affect both east and west facing façades.	CIBSE Guide F (2012)
Form	At building depths greater than 15 m the ventilation strategy becomes more complex; the limit for daylighting and single- sided natural ventilation is often taken as 6 m. An atrium can enhance the potential for natural ventilation.	Section 2.3.2.2 CIBSE Guide F (2012)
	Tall buildings can affect the choice of ventilation system due to wind speeds and exposure. Adequate floor-to-ceiling heights are required for displacement ventilation and buoyancy-driven natural ventilation; a minimum floor-to-ceiling height of 2.7 m is recommended.	CIBSE Guide F (2012) Section 2.2.8
Insulation	Insulation located on the external surface de-couples the mass of the structure from the external surface and enables it to stabilise the internal environment. In well-insulated buildings provision must be made for the removal of excess heat, for example through night cooling.	Section 2.4.2
Infiltration	Ventilation strategies, whether natural or mechanically driven, depend on the building fabric being appropriately airtight. This implies a good practice standard of 5 $m^3 \cdot h^{-1}$ per m^2 of façade (excluding consideration of the ground floor) and requires suitable detailing. Site quality checks should be followed by air leakage pressure testing as part of the commissioning requirement.	CIBSE TM23 (2000a) Approved Document B (NBS, 2013f)
Shading	The appropriate use of external planting or other features can reduce solar gain. In terms of effective reduction of solar gain, shading devices can be ranked in order of effectiveness as follows: external (most effective), mid pane, internal (least effective).	CIBSE Guide F (2012)
	Horizontal shading elements are most appropriate for reducing high angle solar gains, for example in summer time on south facing façades. Vertical shading devices are most appropriate for reducing low angle solar gain, e.g. on east and west façades. Control of solar shading devices should be linked with that of the ventilation system. Glare must be controlled to avoid a default to 'blinds-down' and 'lights-on' operation.	CIBSE AM10 (2005)
Window choice	Openable areas must be controllable in both summer and winter, e.g. large openings for still summer days and trickle ventilation for the winter time. Window shape can affect ventilation performance; deep windows can provide better ventilation than shallow. High-level openings provide cross-ventilation; low-level openings provide local ventilation, although draughts should be avoided at working level. The location of the opening areas affects the ability of the window to contribute to night cooling (see section 2.4.2). Window operation must not be affected by the choice of shading device. See section 2.6.9 for details of window characteristics.	CIBSE TM21 (1999a)
Glazing	Total solar heat transmission through window glazing can vary over a sixfold range, depending on the combination of glass and shading mechanisms selected.	CIBSE TM21 (1999a) Baker and Steemers (1994)
	At concept stage the percentage of glazed area (normally 20–40 per cent of façade area) and selection of glazing type must balance thermal, ventilation and lighting needs. The choice includes single, double and triple glazing with selective coatings or gaseous fill. The type of coating may have a greater influence than the glazing type. Ideal glazing is transparent to long-wave radiation and reflective to short-wave radiation. Selective low-emissivity double-glazing is equivalent to air-filled triple-glazing.	
	The use of tinted glazing may increase the use of supplementary electric lighting, increasing internal heat gains and energy use. Window frame construction and detailing must also be considered.	
Thermal mass	Thermal mass is used to reduce peak cooling demands and stabilise internal radiant and air temperatures. The first 50–100 mm of the structure is most effective on a 24-hour basis. Thermal mass can be introduced into the ceiling/floor slab (most effective), walls or partitions, but must be 'accessible' in all cases. Heat transfer can be via the surface of the material or via cores/channels within it. The exposure of thermal mass has architectural and other servicing implications, although these effects can be reduced, e.g. by the use of perforated ceilings. See section 2.4.2.4 for further details of incorporating thermal mass.	

needs. The design team must also be able to advise on the impact of any such changes on building performance.

An appreciation of the issues shown in Table 2.2 is an essential part of the briefing process. Further guidance on briefing as it applies to building services is given in the *Building Services Job Book: A Project Framework for Engineering Services* (BSRIA, 2009a)

2.2.1.4 Interaction with fabric/facilities

Building fabric

The required ventilation rate is based on fresh air requirements and any additional ventilation required for comfort and cooling purposes. Additional needs for comfort and cooling must take into account:

— internal heat gains generated by the occupants, e.g. occupancy itself, lighting and small power loads such as office equipment, including computers, screens and photocopiers

— solar heat gains

— the thermal properties of the building fabric including insulation, glazing and thermal mass.

Although the architect is associated with making many of the fabric-related decisions, the building services engineer must be able to advise on their implications for ventilation, energy use etc. and must, therefore, be involved in the decision-making process as far as is practical and at as early a stage as possible. The building services engineer should also be consulted prior to any changes that could affect ventilation system performance.

In instances where designs seek to take full advantage of ventilation to maximise natural cooling, the architect and the building services engineer must be able to enter into a dialogue on the issues introduced in Table 2.3, as a minimum. (Note that this table focuses solely on issues relating to the interaction between the building fabric and services. To these must be added, for example, consideration of the building function and broader issues, as raised in Table 2.2.) Where the ventilation strategy for the building depends on its thermal mass (see section 2.4.2.4 and Braham *et al.*, 2001), early consultation with the structural engineer is also needed to consider, for example, the implications for roof design. At some point it may also be necessary to involve a façade specialist, who could advise the client accordingly.

It is important to note that maximising the 'passive contribution' to be gained from the building fabric itself requires an understanding of both the advantages and disadvantages of this approach. For example, external shading reduces the need for cooling but increased insulation and airtightness may lead to the need for increased ventilation and cooling.

For a detailed explanation of the role of the building fabric in contributing to an energy-efficient solution, see CIBSE Guide F: *Energy efficiency in buildings* (2012) and other publications cited in Table 2.3.

Airtightness

It is also important to consider the risks of air leakage through the building fabric and its subsequent impact on infiltration rates and heat loss calculations (see section 2.5.4.4). The most common locations susceptible to air leakage are:

— junctions between the main structural elements

— joints between walling components

— periphery of windows, doors and roof lights

— gaps in membranes, linings and finishes

— service penetrations, e.g. gas and electricity entry points and overflow pipes

— access and emergency openings

— some building materials, e.g. poor quality brickwork, may be permeable.

Airtightness is becoming a mandatory requirement in an increasing number of countries. Full guidance on achieving airtightness is available in Jaggs and Scivyer (2011). In the UK, airtightness requirements are incorporated in Part L of the Building Regulations (NBS, 2013a). The pressurisation test for determining whole-building airtightness is described in 'Building airtightness' in section 2.4.7.2. Optimum duct performance is also dependent on effective duct airtightness (see 'Duct airtightness' in section 2.4.7.2).

Internal heat gains

Heat gains impact on the ability of a ventilation system to meet thermal comfort needs efficiently. In the absence of information from the client, the British Council for Offices (BCO, 2009) recommends the following allowances for internal gains when specifying ventilation systems:

— solar gains not to exceed 60–90 $W \cdot m^{-2}$ depending upon façade orientation

— occupancy based upon 1 person per 12 m^2, but diversified wherever possible to 1 person per 14 m^2 at the central plant

— lighting gains of not more than 12 $W \cdot m^{-2}$

— office equipment gains of not more than 15 $W \cdot m^{-2}$ when diversified and measured over an area of 1000 m^2 or more, but with an ability to upgrade to 25 $W \cdot m^{-2}$. Local workstation levels are quoted as typically 20–25 $W \cdot m^{-2}$.

Interaction with the lighting system

The design strategy for daylight provision forms part of the selection process for window and glazing types and shading devices. Integration of the electric lighting system to minimise its impact on the design and operation of the ventilation system requires that internal heat gains from the lighting be minimised by:

— maximising the use of daylighting

— the selection of light levels, differentiating between permanently occupied workspaces and circulation areas (guidance on lighting levels can be found in CIBSE Guide A1 (2015a))

— the selection of efficient light fittings (decorative fittings may have a lower efficiency)

— the installation of an effective lighting control system, relative to time of day and occupancy level

— the use of ventilated light fittings (see section 2.6.4).

Consideration should be given to the impact of the chosen ventilation strategy on the lighting system, for example the use of uplighting with exposed thermal mass (Braham *et al.*, 2001).

Small power loads

Small power loads, arising from IT and other office-type equipment, are an increasingly significant component of internal heat gains. Accounting for them in the design of the ventilation system requires a realistic calculation of their impact in terms of peak load and anticipated diversity. In order to reduce internal heat gains the designer should:

— encourage the client to select low-energy equipment and introduce power cut-off mechanisms

— locate shared equipment, e.g. vending machines and photocopiers, in a space that can be readily cooled

— where possible separate IT equipment and servers from occupied spaces such that the heat from this equipment does not impact on the occupied space.

2.2.1.5 Solar gain

Solar gain primarily occurs through glazing. Short-wave infrared radiation from the sun enters into the space and warms solid surfaces, often making them hot to touch. These then re-radiate into the space at much longer wavelengths that are impermeable to the glass. As a result, the heat becomes trapped causing overheating and indoor air temperatures to rise above the outdoor value. Solar gain is, potentially, a substantial component of excess heat load and can cause serious overheating, especially in a naturally ventilated or non-air-conditioned space. Hence solar gain must be accurately determined and, where necessary, reduced. Mitigation methods include choice of glazing and the use of external shading. While internal shading may reduce glare and the direct impact of radiant heating on a person, it rarely reduces the overall heat gain into a space This topic is covered in greater detail in CIBSE Guides A (2015a), B1 (2016b) and B3 (2016a).

2.2.1.6 Provision of controls: end-user perspective

The provision of easy-to-use and quick-acting controls is fundamental to occupant comfort satisfaction. Any requirements of the client must be considered in the light of the designer's own experience of end-user behaviour. Control systems are covered in section 2.3.6.

2.2.1.7 Whole-life cost

In the UK it is now a requirement that public sector purchasers move to whole-life cost-based procurement. The UK Private Finance Initiative (PFI) has stimulated a marked increase in interest in whole-life costing and there has been a growth in the availability of data to support the activity (CIBSE, 2002; BSRIA, 2008).

The proper design of ventilation systems can significantly reduce the whole-life costs. Additionally costly modifications and alterations can be avoided by ensuring that the system requirements are properly defined and the design fully addresses the requirements.

Buildings have to adapt and change in response to business needs. Taking account of this at the design stage can also help to ensure that the system is designed to enable such adaptations to be carried out in the most cost-effective manner, again reducing the whole-life costs of the system.

2.2.2 Contaminant control

A fundamental role of ventilation is contaminant control. It is important therefore to understand the characteristics and significance of key pollutants and pollutant sources. Indoor pollutants are derived from both outdoor and indoor sources and each of these sources imposes different requirements on the ventilation control strategies needed to secure good health and comfort conditions. This topic is covered in more detail in sections 1.7 and 8.4 of CIBSE Guide A: *Environmental design* (2015a).

2.2.2.1 Outdoor air pollution

Clean outdoor air is essential for achieving good indoor air quality. Although air cleaning by filtration is possible, it is costly and not appropriate in the many buildings that are naturally ventilated, leaky or ventilated by mechanical extract systems. Also, general filtration is less effective at controlling respirable fine particulates (e.g. at less than 2.5 μm) and gaseous pollutants. Filtration is covered in more detail in section 2.3.3.

Some air quality problems are global and can only be controlled by international effort. Other pollutants are more regional and may be associated with local industry and traffic. Nature, too, presents its own problems, with large volumes of dust and gaseous emissions being associated with volcanic activity, while naturally occurring radon can penetrate buildings from the underlying geological strata. Even rural areas are not immune to pollution, where the presence of pollen and fungi spores can result in allergic reactions. Typical sources of airborne pollutants are:

— industrial emission

— construction dust

— traffic pollutants

— emissions from buildings (boiler exhausts, cooling towers, etc.)

— rural pollution (pollen, insecticides, etc.)

— soil-borne pollutants (radon, methane, etc.).

Increasing concern about outdoor emissions has resulted in the introduction of emission controls and 'clean air' regulations in many countries. In the US, legislation is covered by the Clean Air Act. In Europe, emissions controls fit within the Air Quality Framework Directive (EC, 2008). Implementation in the UK is set out in the Air Quality Strategy for England, Wales, Scotland and Northern Ireland

(DEFRA, 2007). This report explains the measures being undertaken to reduce pollutant concentration in the air including the designation of Air Quality Management Areas at locations identified as having particularly poor air quality. This is based on the nationwide monitoring of key outdoor pollutants. Building developers must check with local authorities for local air quality conditions and must also provide information on how a proposed development will affect the local air quality. UK guidelines on minimising the risk of pollutant ingress into buildings have been published by BRE (Kukadia and Hall, 2011).

Mitigation within buildings of outdoor pollutant sources is not easy but methods include:

— airtightness to prevent the uncontrolled ingress of outdoor pollutant (see section 2.5.4)
— locating air intakes to avoid outdoor sources (CIBSE, 1999)
— filtration (section 2.3.3)
— temporarily reducing ventilation during transient periods of high pollution (CIBSE, 2015a).

2.2.2.2 Indoor pollutants

Pollutants emitted inside buildings are derived from metabolism, the activities of occupants and emissions from materials used in construction and furnishing. Major pollutants include:

— carbon dioxide from metabolism and gas appliances
— carbon monoxide (highly toxic and emitted from poorly maintained gas and other combustion)
— formaldehyde from fibre boards and foam insulation
— moisture (principally generated by occupant activities such as cooking, washing and clothes drying)
— odour (generated as part of metabolism and emitted from furnishings and fabrics)
— ozone (from electrical appliances normally associated with poor maintenance)
— particulates, including dust, organic fragments, fibres and smoke particles
— volatile organic compounds (VOCs) from furnishing fabrics and household chemical products
— laboratory contaminants (chemicals, biohazards, radioactive products).

CIBSE no longer provides recommendations covering ventilation for tobacco smoking. In public buildings in the UK smoking is banned and toxic pollutants generated by smoking are largely regarded as unacceptable, regardless of ventilation rate. Harmful indoor pollutant emissions should always be eliminated where possible. Restrictions on emissions, particularly of VOCs and particles generally apply. More information is given in CIBSE Guide A: *Environmental design* (2015a).

2.2.2.3 Exposure limits

Exposure limits for particular airborne pollutants depend upon a range of factors, including the length of exposure and the general level of health of the person exposed. A detailed discussion is provided in CIBSE TM40: *Health issues in building services* (2006a) and limits for specific pollutants are set out in chapter 8 and Table 1.5 of CIBSE Guide A (2015a).

2.2.2.4 Metabolic carbon dioxide

In densely occupied spaces, metabolic carbon dioxide is widely used as a marker for the adequacy of ventilation. Even at quite high concentrations it is generally regarded as a non-toxic gas that, in itself, is unlikely to cause injury except under extremely unusual conditions. However a build-up of CO_2 in a room leads to a feeling of stuffiness and can impair concentration. Elevated levels of CO_2 in the body cause an increase in the rate of respiration. Slightly deeper breathing begins to occur when the atmospheric concentration exceeds 5000 ppm (0.5 per cent by volume). This is the maximum allowable concentration of CO_2 for 8-hour exposures by healthy adults (HSE, 2011). Within the UK, a CO_2 figure of 800–1000 ppm is often used as an indicator that the ventilation rate in a building is adequate. A concentration of 1000 ppm approximately equates to a 'fresh air' ventilation rate of 8 $l \cdot s^{-1}$ per person (CIBSE, 2015a). The actual ventilation value depends on the local outside concentration (approximately 350 to 400 ppm outside urban areas) and the level of metabolic activity. Carbon dioxide monitoring for ventilation control is becoming increasingly more common and relatively inexpensive (see section 2.3.6).

2.2.3 Fresh air supply rates

2.2.3.1 Introduction

Ventilation reduces the concentration of harmful pollutants emitted within a space. It is for this reason that higher ventilation rates are usually associated with improved health. Commonly applied methods for determining suitable outdoor air ventilation rates are:

— a prescriptive method
— a calculation method for the control of a single known pollutant being released at a known rate.

These are briefly described below. More details are provided in section 1.8 of CIBSE Guide A: *Environmental design* (2015a).

2.2.3.2 Prescriptive method

In occupied spaces, the fresh air requirement is increasingly specified in terms of flow rate per person. Where ventilation is needed to dilute room pollutants not arising from occupancy, fresh air requirements may be expressed as a volumetric flow rate for the space (e.g. $m^3 \cdot s^{-1}$ per m^2). Formerly, much use was made of expressing ventilation rate in terms of air changes per hour (ACH). This is now falling out of favour because of its high dependency on room volume, which fails to reflect the physical need to provide fresh air or remove heat.

European Standard BS EN 13779: *Ventilation for non-residential buildings. Performance requirements for ventilation and room-conditioning systems* (BSI, 2007a) provides basic definitions of air quality standards in occupied spaces and

Table 2.4 Ventilation requirements (reproduced from BS EN 13779: 2007 (BSI, 2007a), by permission of the British Standards Institution)

Classification	Indoor air quality standard	Ventilation range ($l \cdot s^{-1}$ per person)	Default value ($l \cdot s^{-1}$ per person)
IDA1	High	>15	20
IDA2	Medium	10–15	12.5
IDA3	Moderate	6–10	8
IDA4	Low	<6	5

relates these to fresh air ventilation rates required for each occupant (in terms of $l \cdot s^{-1}$ per person), using a methodology set out in BS EN 15251: 2007: *Indoor environmental input parameters for design and assessment of energy performance of buildings addressing indoor air quality, thermal environment, lighting and acoustics* (BSI, 2007b). These are summarised in Table 2.4.

It is important to note that these rates relate to comfort air quality and do not necessarily reflect the purity of air with respect to health-related contaminants. They are most applicable for spaces that are relatively free from sources of pollution and for ventilation air that is itself pure.

Building Regulations Part F (NBS, 2013b) require a minimum ventilation rate of 10 $l \cdot s^{-1}$ per person for office applications. This fits between classes IDA2 and IDA3 in Table 2.4.

General minimum fresh air requirements for specific building types are given in CIBSE Guide A (2015a).

2.2.3.3 Calculating the ventilation rate to control a single pollutant

Where a single known pollutant is emitted at a known rate the required ventilation rate is based on risk assessments, for example in the UK, pollutants under the Control of Substances Hazardous to Health (COSHH) Regulations.

For a single contaminant under steady conditions, the steady dilution equation 2.1 may be applied to determine the flow of outdoor air that, with good mixing, would maintain the contaminant concentration at a specified level.

$$Q = \frac{q\,(10^6 - C_i)}{(C_i - C_o)} \qquad (2.1)$$

where Q is the outdoor air supply rate ($l \cdot s^{-1}$), q is the pollutant emission rate ($l \cdot s^{-1}$), C_o is the concentration of pollutant in the outdoor air (ppm) and C_i is the limit of concentration of pollutant in the indoor air (ppm). Full details are given in CIBSE Guide A (2015a).

This equation can be adapted for:

— pollutant thresholds quoted in $mg \cdot m^{-3}$ and situations where C_i is small or the incoming air is free of the pollutant in question (see CIBSE Guide A, section 1.8.3.1 (2015a)).

— situations where the ventilation results in a non-uniform concentration so that higher than average concentrations exist in the occupied zone and the outdoor air supply rate requires to be increased (see CIBSE Guide A, sections 1.8.3.1 and 1.8.4 (2015a)).

— non-steady state conditions that might allow the outdoor air supply rate to be reduced (see CIBSE Guide A, section 1.8.3.2 (2015a)).

A more comprehensive analysis of the relationship between contaminant concentration and ventilation rate is given in BS 5925: 1991: *Code of practice for ventilation principles and designing for natural ventilation* (BSI, 1991).

Note that the existing guidelines for the calculation of outside air ventilation rates are based on the assumptions that the air outside the building is 'fresh' and that the pollutant load is inside the building. For buildings in city areas or adjacent to busy roads the quality of the outside air needs to be assessed, as this can also be a source of pollutants. Where specific problems are anticipated, an air quality survey should be undertaken. This should include measurements at likely times of peak pollution. This is covered in more detail by Kukadia and Hall (2011).

Ventilation should not be used in place of source control to minimise pollutant concentrations in a space.

2.2.4 Ventilation for thermal comfort

Ventilation provides an essential means to control thermal comfort. This includes the use of air-conditioning systems for the distribution of heated and chilled air (see CIBSE Guide B3 (2016a)) as well as the use of ventilation to passively cool a space. In the case of natural or passive cooling the ventilation rate required to maintain thermal comfort in a space is often far higher than that needed to meet minimum ventilation rates for air quality. A detailed discussion of the factors that affect thermal comfort is given in chapter 1 of CIBSE Guide A (2015a).

2.2.5 Humidity

The role of humidity in maintaining comfortable conditions is discussed in section 1.3.1.3 of CIBSE Guide A (2015a) where an acceptable range of 40–70 per cent relative humidity (RH) is suggested. However, to minimise the risk of mould growth or condensation and maintain comfortable conditions, a maximum design figure of 60 per cent RH is suggested for the design of air-conditioning systems. Within naturally ventilated buildings, humidity levels as low as 30 per cent RH (or lower) may be acceptable for short periods of time. However, low RH can result in unpleasant static electricity shocks, especially when touching metallic objects.

2.2.6 Ventilation to avoid interstitial condensation

Many structures are vulnerable to interstitial condensation, which can cause rotting of wood-based components, corrosion of metals and reduction in the performance of thermal insulation. Condensed water can also run or drip back into the building causing staining to internal finishes or damage to fittings and equipment. The traditional view has been that these problems are caused by water vapour generated in the building diffusing into the structure. Avoidance measures have therefore concentrated on the

inclusion of a vapour control layer on the warm side of the structure, appropriate placing of insulation and ventilating the structure to intercept the water vapour before it can condense. In the UK guidance and requirements are given in Part C of the Building Regulations (NBS, 2013c). Ventilation is specifically required in cavities above the insulation in cold pitched and flat roofs, behind the cladding of framed walls and below timber floors. Commonly this is achieved by using natural ventilation openings, which are often required by building codes. Many problems can occur from water entrapped within materials moving within the structure under diurnal temperature cycles. Under these circumstances it is helpful to distinguish between 'ventilated' and 'vented' air spaces. A ventilated space is designed to ensure a through flow of air, driven by wind or stack pressures, whereas a vented space has openings to the outside air that allow some limited, but not necessarily through, flow of air. As the air in the space expands and contracts under diurnal temperature cycles, water vapour will be 'breathed' out of the structure. This mechanism can be very effective in large span structures where it can be very difficult to ensure through ventilation of small cavities.

Detailed design guidance for the provision of ventilation within structures is available in CIBSE Guide A (2015a), BS 5250: 2011: *Code of practice for control of condensation in buildings* (BSI, 2011a) and BRE Report BR 262: *Thermal Insulation: Avoiding Risks* (BRE, 2002).

2.2.7 Air movement: limiting air velocities

Excessive air movement creates uncomfortable draughts. Guidelines and standards have been developed to provide guidance on maximum values. Draughts are a particular problem in the vicinity of cold air diffusers and in the presence of uncontrolled cold outdoor air ingress. In warmer weather, the draught caused by air movement can be beneficial and adds to the sensation of cooling. It also reduces the operative temperature on which thermal comfort criteria are largely based. For this reason circulation fans are commonly used to provide comfort in a non-air-conditioned environment. The effect of air movement is function of both mean airspeed and a measure of the fluctuating component, usually turbulence intensity. BS EN ISO 7730 (BSI, 2005a) defines a draught rating (DR) for mechanically ventilated and air-conditioned buildings that combines the effect of velocity, turbulence intensity and air temperature. Discussion of acceptable levels of draught rating and other aspects of air movement is included in CIBSE Guide A, section 1.6.6.5 (2015a).

2.2.8 Air distribution

Fresh ventilation air needs to be draught free and maintain a safe level of pollutant concentration in the vicinity of occupants. Important air distribution techniques are used to achieve this, each with a particular purpose. The main approaches are described in the following sections.

2.2.8.1 Mixing (or dilution) ventilation

Mixing ventilation is based on the air being supplied into the room in a manner that creates sufficient turbulence for the contaminants within the space to be equally distributed. The extraction of air then dilutes the concentration of pollutants within the space. Mixing systems are particularly used with conventional warm air heating and cooling systems since this is able to distribute the thermally conditioned air uniformly. Because the amount of air needed to provide thermal conditioning is usually much greater than that needed to provide fresh air, recirculation is widely used (see section 2.4.3). Mixing system performance is not dependent upon room height or room layout. Air can enter the space via either the floor or the ceiling (see Figure 2.2(a) and (b)). Guidance on diffuser design to create mixing is given in section 2.4.3

2.2.8.2 Displacement ventilation

This is based on the provision of low-velocity air supply that does not mix with the room air. Air is supplied at a low velocity from low-level, wall-mounted or floor-mounted supply air terminal devices directly into the occupied zone, at a temperature slightly cooler than the design room air temperature, see Figure 2.2(c). The air from a wall-mounted terminal flows downward to the floor due to gravity and moves around the room close to the floor, creating a thin layer of cool air. Natural convection from internal heat sources, such as occupants and equipment, causes upward air movement in the room. The warm, contaminated air forms a stratified region above the occupied zone, which is then exhausted at high level. The depth of this layer depends upon the relationship between the incoming airflow and the rate of flow in the plumes. The boundary

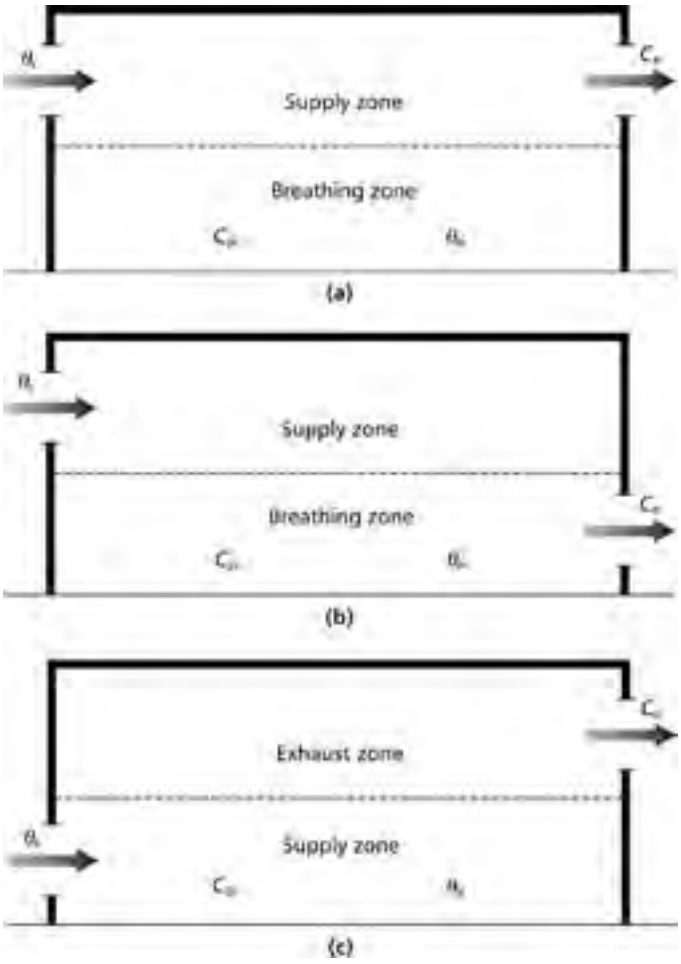

Figure 2.2 Supply/extract arrangements for ventilation: (a) mixing, supply and exhaust at high level, (b) mixing, supply at high level, exhaust at low level, (c) displacement

will stabilise at a level at which these two flow rates are equal.

The airflow in displacement ventilation has both horizontal and vertical air movement characteristics. Horizontal air movement occurs within the thermally stratified layers that are formed between the upper (warm) and lower (cool) air layers in the room. Vertical air movement is caused by the presence of cold and warm objects in the space. Warm objects, such as people, create upward convection currents; cold objects, such as cold windows and walls, cause downward currents.

For given rates of ventilation and pollutant discharge, the air quality in the occupied zone of a room with displacement ventilation can be higher than that using a mixed-flow ventilation method. In displacement ventilation, air movement above the occupied zone is often mixed and it is when this mixed region extends down into the occupied zone that the air quality becomes similar to that in a mixed-flow system.

There is limited cooling capacity unless it is combined with active cooling systems such as chilled ceilings or beams (see CIBSE Guide B3 (2016a)). Heating must normally be provided using hydronic radiators. In the true meaning of displacement ventilation, natural ventilation is not possible since it cannot provide the precision control that is necessary. Sometimes, however, the definition is loosely applied to the situation where an airflow pattern is established across a building in which fresh air enters through one side and propagates across the building to exhaust openings elsewhere.

With displacement ventilation, a vertical temperature gradient is unavoidable. BS EN ISO 7730 (BSI, 2005a) recommends a vertical temperature gradient for sedentary occupants of less than 3 K. This equates to approximately 3 $K \cdot m^{-1}$ if workers are assumed to be seated, although a limit of 1.8 or 2 $K \cdot m^{-1}$ is often proposed for offices (i.e. 5 K limit for a typical floor-to-ceiling height of 2.5 m). However, as 30–50 per cent of the overall supply-to-extract temperature difference occurs between the supply air and that at ankle level in the main space, a limiting difference between floor and ceiling height for typical office applications can be taken as 7–10 K. The supply air temperature should not be lower than 18 °C for sedentary occupancy and 16 °C for more active occupancy. It is also recommended that the limits of variation of temperature across the room should be within a temperature range of 3 K, i.e. ±1.5 K about the mean room air temperature.

A combination of near-floor temperatures below 22 °C and airflows in excess of 0.15 $m \cdot s^{-1}$ may cause discomfort due to cold feet, so occupants should be located a sufficient distance from diffusers. Equipment manufacturers should be consulted for detailed performance characteristics.

The zone around a supply air diffuser within which the supply air conditions have the greatest effect is labelled the near-zone. The permitted near-zone extent together with the maximum allowable comfort temperature at the near-zone perimeter for a given supply air temperature dictates the air volume per diffuser and its size. In an office the near-zone may be 1 m, in a commercial application or in a foyer it may be 3 m. The maximum cooling load that can be delivered by displacement ventilation is therefore limited to 25 $W \cdot m^{-2}$ due to discomfort considerations (Sandberg and Blomqvist, 1989).

There are conditions under displacement systems that are less effective than traditional mixed-flow ventilation strategies. These include (Jackman, 1990):

— where the supply air is warmer than the room air (except under particular circumstances where cold down-draughts exist over the supply position)

— where contaminants are cold and/or more dense than the surrounding air

— where surface temperatures of heat sources are low, e.g. <35 °C

— where ceiling heights are low, i.e. <2.3 m (the preferred height is not less than 3 m)

— where disturbance to room airflows is unusually strong.

2.2.9 Noise

Noise is generated by mechanical systems or can enter into the building from outside sources. Naturally ventilated buildings can be particularly prone to outside noise through open windows while mechanically ventilated buildings can be prone to system noise. Guidance on maximum noise thresholds are given in chapter 1 of CIBSE Guide A (2015a). Noise is considered in more detail in section 2.5.2 and CIBSE Guide B4 (2016c).

Solutions to minimising noise include the following.

— Naturally ventilated buildings:
  — acoustic vents
  — noise barriers (vegetation and fences)
  — location of intakes away from noise zones; reduced noise locations can include high-level intakes (e.g. by using wind towers), courtyards and at locations away from busy roads.

— Mechanically ventilated buildings:
  — control of external noise sources
  — limitations on mechanical duct flow velocity
  — use of silencers.

2.3 Systems

2.3.1 Introduction

A wide range of ventilation systems and associated technologies is needed to meet the air-quality needs of buildings. Ventilation solutions vary from basic natural ventilation systems to complex mechanical approaches. In addition, the maintenance of air quality may often require air cleaning methods, while energy efficiency demands efficient fans, low-loss systems and good control technology. Providing fresh air to complex spaces also requires the use of duct systems, which must meet the often conflicting requirements of restricted space while providing ducting of sufficient cross-section to minimise pressure losses. This

chapter describes the systems needed to accomplish effective ventilation.

2.3.2 Ventilation systems

2.3.2.1 Background

The variability of building type and climate conditions results in the need for a wide variety in the type of ventilation system required to maintain good indoor air quality. Within the UK, large city-centre office buildings tend to be mechanically ventilated. On the other hand, many smaller buildings and public buildings, such as schools and hospitals, tend to be predominantly naturally ventilated. Almost all the existing housing stock is naturally ventilated, although modern airtight housing is increasingly being fitted with mechanical systems incorporating heat recovery (see section 2.3.4). Demand for improved thermal comfort, combined with large internal heat gains, is resulting in an increasing requirement for mechanically ventilated air-conditioned spaces. In some buildings a combined 'mixed-mode' or 'hybrid' approach to ventilation is used in which natural ventilation is applied for some of the time or to some of the spaces while mechanical ventilation is used when and where natural ventilation is unsuitable.

2.3.2.2 Natural ventilation

Natural ventilation may be defined as ventilation that relies on moving air through a building under the natural forces of wind and buoyancy. A building can be considered to be naturally ventilated when most of the space is ventilated by such forces for most of the period during which ventilation is needed. Some spaces, such as bathrooms, kitchens, WCs and other polluting areas, may be required to incorporate intermittent mechanical extractor fans. Full details on natural ventilation theory and design are given in CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005) (see also section 2.4.2).

In a mild and warming climate, such as the UK, there is still very strong demand for natural ventilation. The Carbon Trust (2007) stated that 'average overall energy consumption of air conditioned buildings is approximately twice that of similar sized naturally ventilated buildings'. It also stated that 'making the most of natural ventilation is a simple and cost-effective way of achieving big savings' (Carbon Trust, 2006). In the case of schools, the UK Commission for Architecture and the Built Environment (CABE, 2009) requires that natural ventilation be used wherever possible. Similarly, the carbon reduction strategy of the UK National Health Service (NHS, 2009) states that 'Buildings designed with passive ventilation have improved resilience to energy supply failure and are more energy efficient than mechanically ventilated buildings. In an acute hospital up to 70 per cent of net floor space could be entirely or partially naturally ventilated.' However, natural ventilation may not always be the best choice and it is important that the economic benefits are properly assessed and compared with alternative solutions.

Typical natural ventilation configurations are summarised in Figure 2.3. Purpose-provided ventilation openings can consist of a combination of vents, stacks, wind towers and openable windows. Traditionally, the provision of an openable area equivalent to 5 per cent of floor area has been regarded as a satisfactory default minimum for fulfilling occupant ventilation needs and general purging by natural ventilation. This, however, does not necessarily satisfy requirements for special air quality needs or satisfy all the requirements needed for natural summer cooling.

A prerequisite for the use of natural ventilation to provide cooling for thermal comfort is the control of heat gains into the occupied space. Natural ventilation cannot provide a constant flow rate but the important parameter is the time-averaged flow, rather than the instantaneous flow rate. This means that, within reason, the fresh air rate can vary without there being any significant variation in indoor air quality because of the fresh air quality reservoir provided by the volume of the space.

Wind-driven natural ventilation

Wind pressure acting on a building drives airflow through windows, natural vents or mechanically controlled openings, as well as through adventitious leakage openings in the building fabric. Wind-driven ventilation is caused by varying surface pressures acting across the external building envelope see (Figure 2.4). The distribution of pressure depends on:

— the terrain

— localised obstructions

— the wind speed and its direction relative to the building

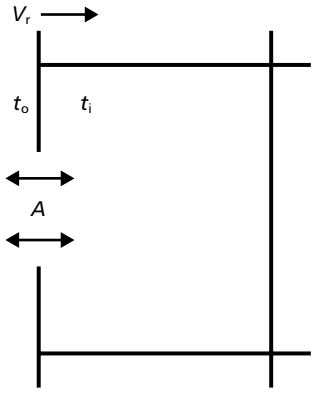
— the shape of the building.

Air will flow through the building from areas of high pressure to areas of low pressure. In very general terms, building surfaces facing into the wind will experience positive pressures; leeward surfaces and those at right angles to the wind direction will experience negative pressure (suction). Since wind velocity increases with height and the wind pressure increases as the square of wind speed, the top of high-rise buildings can therefore experience relatively large wind pressures compared with ground level.

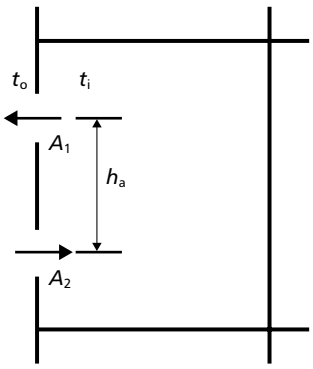
By locating openings in the positive and negative pressure regions, a suitable flow pattern through the building can be planned. Knowledge of local climate conditions is essential. Suitable openings include windows vents and wind towers (see section 2.6.9).

Stack or buoyancy-driven ventilation

Stack-driven ventilation is driven by the pressure differences created between the inside and outside of a building by temperature difference (see chapter 4 of CIBSE Guide A (CIBSE, 2015a)). Warm air inside a space rises to be replaced by colder air, as shown in Figure 2.5. In the normal situation, where the inside of the building is warmer than outside, the pressure difference acts inwards at the lower levels of the building and outwards at the high levels. The driving pressures created by stack effect can often be similar in magnitude to wind-driven ventilation pressure, especially in sheltered locations. Stack ventilation is therefore an important contributor to natural ventilation design. Systems can be applied to both single-storey and multi-storey buildings by utilising interconnected openings



(a) Single sided single opening



(b) Single sided double opening

placed at different heights. Design details are covered in section 2.4.2.

Stack-driven ventilation is enhanced by maximising the vertical distances between openings. This may be accomplished by atrium design (see 'Atrium ventilation' in section 2.3.2.2) or by the use of passive stacks (see section 2.6.9.12).

Combined wind and stack-driven ventilation

Combined wind and stack systems can provide ventilation irrespective of driving force. Good designs of natural ventilation should seek to utilise both forces. This is accomplished by optimising the location of openings to benefit from wind effect and temperature difference. In particular wind pressure can enhance stack effect by placing stack outlets in the negative pressure region above the roof (see 'Wind-driven natural ventilation' in section 2.3.2.2). An example of the interaction of wind and stack pressure is given in Figure 2.6.

Atrium ventilation

An atrium is a variation on the chimney ventilation principle (see Figure 2.7) The essential difference is that the atrium serves more functions than the chimney; for example it can also provide space for circulation and social interaction. These can restrict the flexibility to locate the atrium to maximum advantage for ventilation purposes. The design of atria is discussed in detail by Saxon (1986).

With a centrally located atrium, the air can be drawn from both sides of the building, thereby doubling the plan width of the building that can be ventilated by natural means (see 'Cross-flow ventilation: maximum penetration depth' in section 2.3.2.2). Note that the same effect could be achieved by a central spine of chimneys and wind terminals.

The atrium also provides an opportunity for introducing daylight into the centre of a deep-plan building. Because atria are designed to capture natural light, they are by definition solar assisted. To promote natural ventilation, the air temperature in the atrium should be as high as possible over as great a proportion of the atrium height as possible. If the atrium is open to the surrounding space, or if it provides high-level walkways between floors, then excess temperatures at occupied high levels may be unacceptable. The design should therefore seek to allow solar energy to be absorbed by surfaces such as:

— elements of the structure

— solar baffles or blinds that act as shading devices.

As stack ventilation, roof vents must be carefully positioned within the form of the roof so that positive wind pressures do not act on the outlets thereby causing reverse flow. This is achieved by:

— designing the roof profile so that the opening is in a negative pressure zone for all wind angles

— using multiple vents that are automatically controlled to close on the windward side and open on the leeward side

— using dampers on the outlets to control the air path in high winds

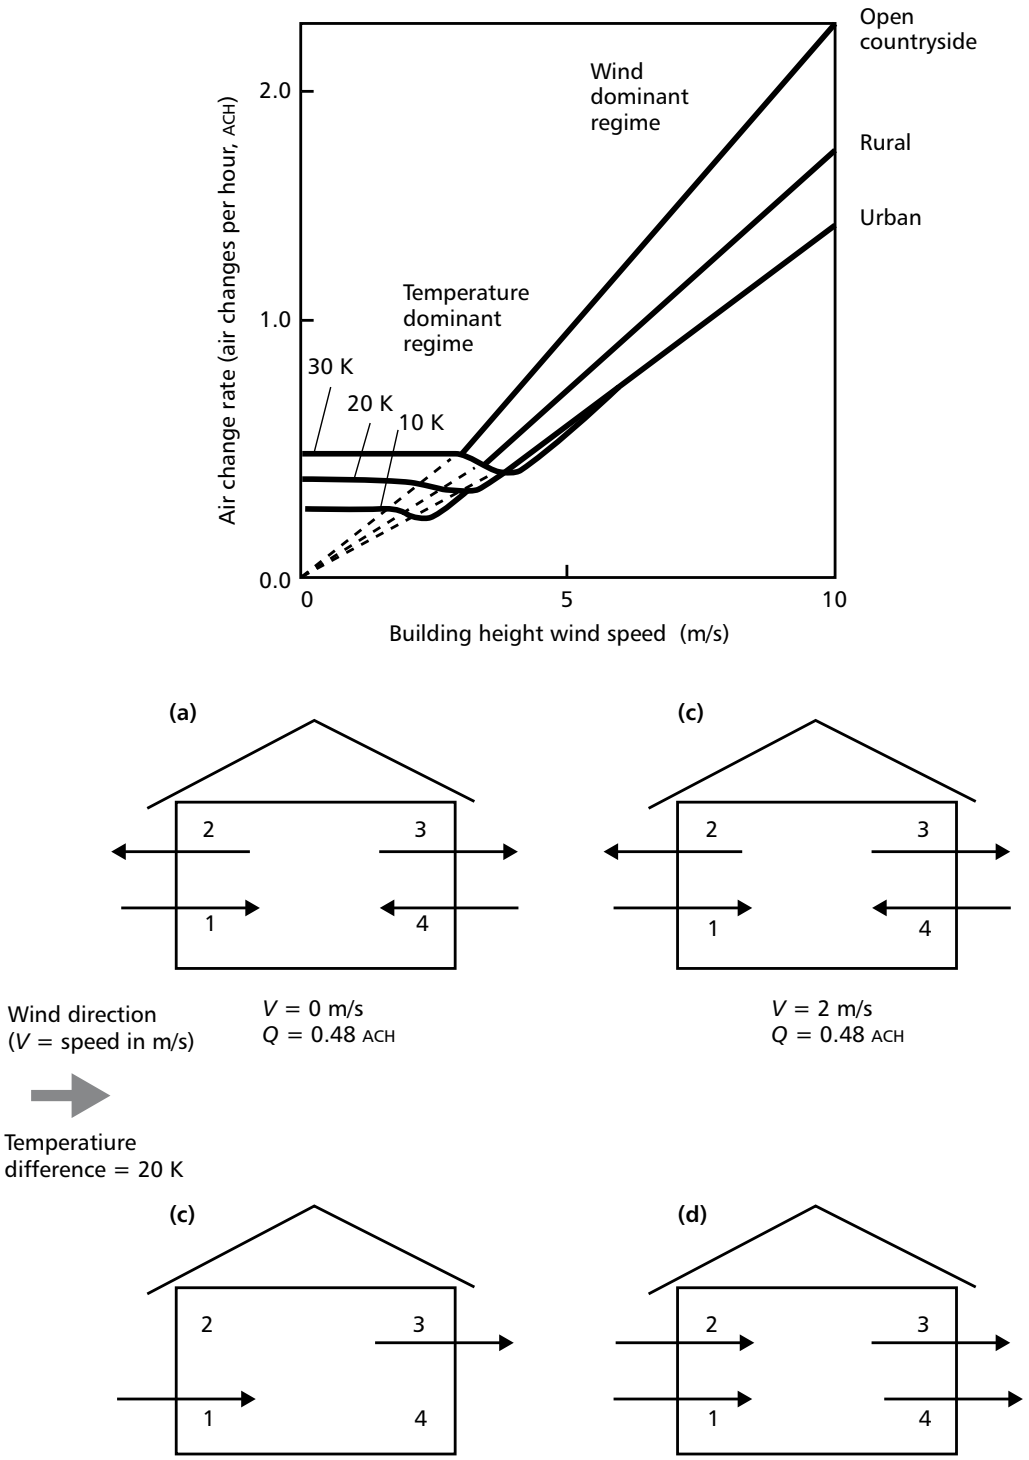

Figure 2.6 Combined effect of wind and temperature difference on ventilation rate and airflow pattern (from *Guide to Ventilation* (AIVC, 1996) reproduced by kind permission of AIVC)

Notes

While the rate of ventilation can be held almost constant for a range of weather conditions, the pattern of airflow changes.

In (a), ventilation is dominated by temperature (temperature dominant regime). Air enters through the lower openings (1 and 4) and leaves through the upper openings (2 and 3).

As wind increases in situation (b), wind pressure reinforces stack pressure at the windward lower opening (1) and leeward upper opening (3), while opposing the stack pressure at the other openings (2 and 4). Although the pattern and magnitude of flow essentially remains unaltered, the flow rate through each opening changes.

At (c) the wind exactly opposes stack pressure at openings 2 and 4, leaving flow only through 1 and 3. The effective reduction in the number of openings reduces slightly the overall air change rate. This effect is less pronounced as the number of openings increase since it is unlikely that a significant proportion of them would simultaneously experience exactly opposing pressures.

At greater wind speeds (d), flow enters the building through the windward side (1 and 2) and leaves through the leeward openings (3 and 4). This marks the start of the wind dominant regime.

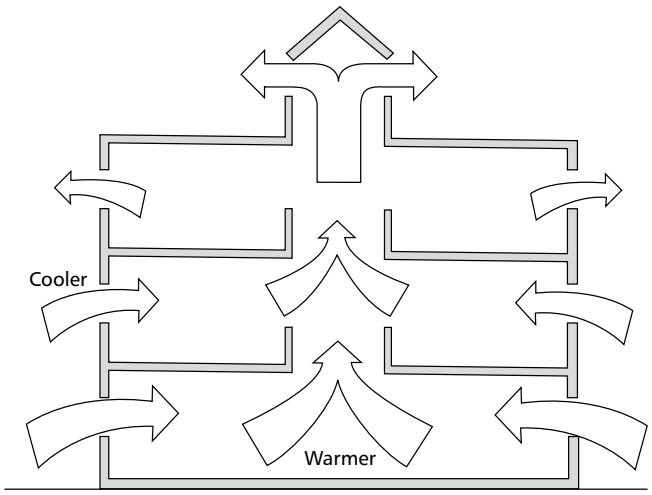

Figure 2.7 Buoyancy-driven ventilation

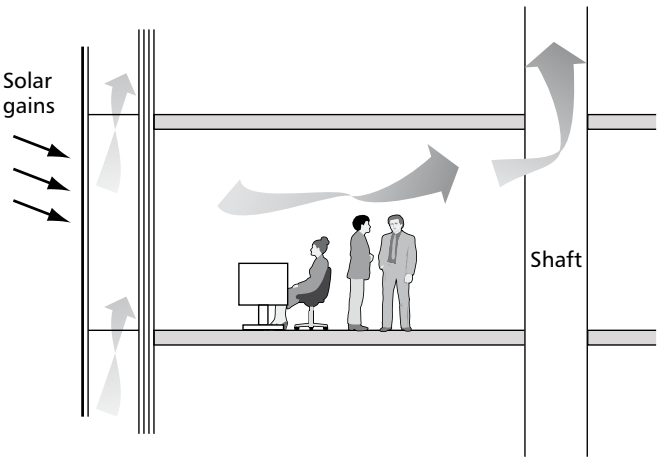

Figure 2.8 Double façade ventilation

— using multiple dampers in a controls philosophy to open and close on the windward or leeward side as necessary.

Natural ventilation can be supplemented on hot still days by the use of extract fans in the atrium roof. Subject to approval by the fire officer, these can also form part of the smoke control system. It is likely that any components used in such a system should have fire or smoke classifications (see section 2.5.3).

Double façade natural ventilation

The double façade is a special form of solar chimney, where the whole façade acts as an air duct (see Figure 2.8). It can act as an extract plenum similar to a solar chimney. In order to provide absorbing surfaces to promote convective flow in the façade, cavity blinds are used. These also prevent direct solar gain passing through the façade to the occupied space.

Alternatively, the cavity could be used as a supply plenum. Outside air is introduced into the cavity at low level and the cavity acts as a solar collector, pre-heating the outside air. The warmed air is then supplied into the occupied zones via ventilation openings between the cavity and the space. If the air in the cavity is too hot, then it can be exhausted to outside or to a heat recovery device.

The efficiency of the solar collector mode can be significantly reduced if the conduction losses are too high. The possibility of condensation should also be checked based on the conditions of the air entering the cavity and the temperature of the glass.

Single-sided natural ventilation: maximum penetration depth

Sometimes natural ventilation may only be provided through openings on a single side of a space (e.g. a row of windows, see Figure 2.9). This can restrict the impact of wind-driven ventilation since the same openings must provide for both supply and extract. To ensure that the full depth of a single-sided space is adequately ventilated, the depth of a single-sided ventilated room should not generally exceed 2.5 times the ceiling height (see Table 2.5).

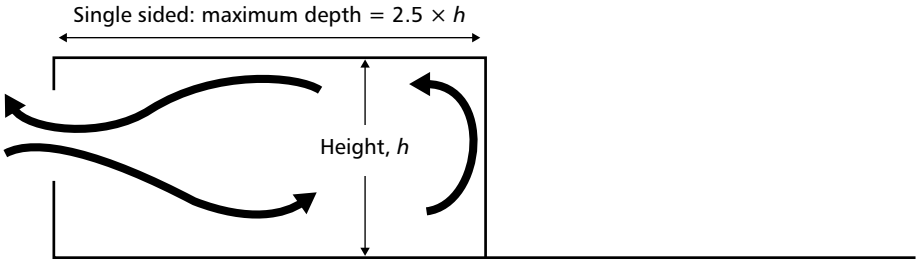

Figure 2.9 Single-sided ventilation maximum penetration (from *Guide to Ventilation* (AIVC, 1996) reproduced by kind permission of AIVC)

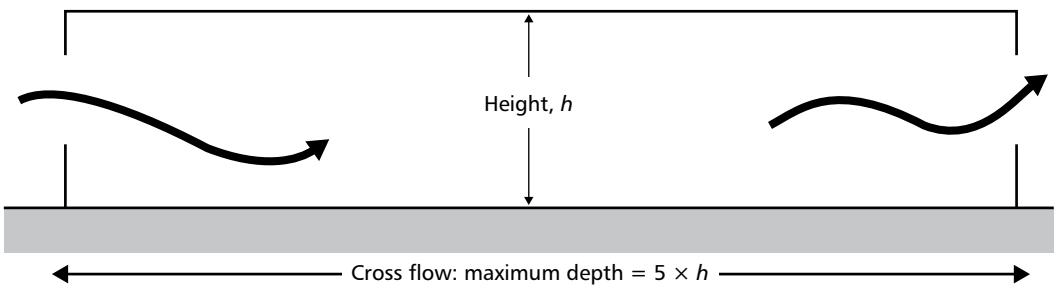

Figure 2.10 Cross-flow ventilation (from *Guide to Ventilation* (AIVC, 1996) reproduced by kind permission of AIVC)

Cross-flow ventilation: maximum penetration depth

Cross-ventilation occurs where there are ventilation openings on both sides of the space concerned (see Figure 2.10). Depending on weather conditions and the configuration of openings, cross-ventilation can be driven by wind or stack pressure or a combination of both. As the air moves across the zone, there will be an increase in temperature and a reduction in air quality as the air picks up heat and pollutants from the occupied space. Consequently there is a limit on the depth of space that can be effectively cross-ventilated. This implies a narrow plan depth for the building, which has the added benefit of enhancing the potential for natural lighting. Cross-ventilation is only generally effective up to a maximum of five times the floor-to-ceiling height (see Table 2.5).

In the case of an atrium, passive stack or a wind tower it may be possible to extend the building depth to 10 times the ceiling height by creating fresh air cross-flow paths towards or from the centre of the building. More information about natural ventilation components is given in section 2.6.9.

Advantages and limitations of natural ventilation

Natural ventilation offers many advantages, especially in a mild climate. However, there are also important limitations that can restrict its use, especially in urban environments and where energy efficiency can be improved by heat recovery.

Advantages include the following points:

— It can provide acceptable levels of thermal comfort and indoor air quality under many seasonal conditions and can also meet acoustic requirements for the internal conditions with a minimum use of energy.

— User control: anecdotal evidence suggests that users are reported to favour access to openable windows or some form of local override facility.

— It is relatively inexpensive to install, however costs are heavily influenced by the complexity of window or ventilator design and by the building form necessary to achieve effective natural ventilation.

— Minimal maintenance needs: natural ventilation systems are generally more accessible for cleaning and maintenance than mechanical systems, and there are no components subject to high humidity, such as cooling coils or humidifiers, which can harbour biological growth.

— There is no plant noise.

— It can be integrated with cooling systems to prevent overheating.

— Wind towers, stacks and atria can increase the depth of space that can be naturally ventilated.

— There is no need to house mechanical plant rooms therefore there is more floor space available for occupation.

Limitations include the following points:

— Under-ventilation can occur at low driving forces.

— Inadequate control could lead to excessive winter heat loss. Although close control over temperature and humidity is possible, it requires a tight control strategy. Poor control could lead to inadequate ventilation.

— Risk of draught: poorly located openings could result in cold draughts. Cold back-draught is possible from passive stacks if the air in the stack is not heated to room temperature.

— Restrictions on the maximum penetration depth of natural ventilation could result in limitations on building and/or room size.

— Flexibility is difficult to achieve if extensive partitioning is introduced.

— Overheating risk: natural ventilation may reach its limits if heat gains increase and no mechanical cooling is installed. This limit will depend on many factors including indoor heat gain, solar gains and outdoor temperature. A full thermal analysis is needed to assess the potential of passive cooling. The long-term impact of global warming also needs to be considered.

— Mechanical heat recovery is not possible.

— Predictability: performance can be modelled in theory, but in practice is subject to variation in the motivating forces of wind and weather.

— Noise: there may be problems associated with external noise or the transmission of internal noise.

— Ability to deal with polluted outdoor environments: protection from outdoor pollutants by filtration is not possible but effects of transient pollutants can be mitigated by closing windows and other types of opening during times of pollution (e.g. periods of peak traffic movement).

— Where air is passed from one zone to another the flow of fresh air must be sufficient to provide acceptable air quality in the downstream zone.

Table 2.5 Natural ventilation options and maximum recommended depths (from CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005))

Strategy	Maximum effective depth relative to floor-to-ceiling height
Single-sided opening	2.5 × floor-to-ceiling height
Cross flow	5.0 × floor-to-ceiling height
Stack ventilation	5.0 × floor-to-ceiling height
Atria	10 × floor-to-ceiling height if centrally located

2.3.2.3 Mechanical ventilation

Mechanical ventilation strategies

Mechanical ventilation systems incorporate fans and control systems to drive the ventilation process. They are thus able to provide ventilation irrespective of the availability or suitability of natural forces. Large buildings including city centre offices, public buildings and shopping

malls are almost universally mechanically ventilated. In addition to providing fresh air, mechanical systems are also commonly used to distribute thermally conditioned air as part of the building's heating and cooling or air-conditioning system.

The main roles for mechanical ventilation are:

— to provide fresh air ventilation

— to assist in naturally cooling a building when the outside air temperature is less than the indoor air temperature, e.g. night cooling by mechanical ventilation assistance

— to distribute thermally conditioned air from a heating and air-conditioning system.

There are several possible arrangements for the supply and extraction of air in mechanical ventilation systems. These are summarised in Figure 2.11.

Large building 'balanced' mechanical ventilation

A schematic of the main elements of a typical large commercial building ventilation system is illustrated in Figure 2.12). This arrangement forms the basis of mechanical systems in large buildings throughout the world and is fundamental to modern heating, ventilation, and air conditioning (HVAC) design. This approach incorporates a separate network of fans and ducts to supply fresh (and often thermally tempered) air to a space and extract polluted air from a space.

Supply air is drawn from the outside via an air intake. This may be pre-heated or cooled by an exhaust air heat recovery unit (see section 2.3.4) before being blended with recirculated air in a mixing box. The air is then filtered and thermally conditioned (heated or cooled) before being supplied to the ventilated space via an air terminal unit and diffuser. Additional heating or cooling may be applied at the air terminal unit. The characteristics of a diffuser depend on the type of ventilation system. In the case of mixing systems (see section 2.6.4) the diffuser is designed to maximise the level of turbulence and hence encourage the rapid mixing of supply air with room air. The orientation of the flow jets and the flow velocity must be designed such that the heat or cooling characteristics of the supply air is rapidly dispersed into the occupied zone without causing draught or thermal discomfort.

Displacement systems (see section 2.2.8.2)

In the case of displacement systems the diffuser must be designed to avoid mixing. Detailed information is given in section 2.4.3.5. Primary thermal treatment may be minimal in the case of a displacement ventilation system. Recirculation is also usually avoided with displacement systems since thermal needs are not provided by the supply air.

Advantages

This is a well-established ventilation approach, which has the following advantages:

— It can control indoor climate irrespective of outdoor conditions.

— Control can be provided at an individual level, regardless of location.

— Closeness of control: close control over temperature and humidity is possible (subject to air being at a suitable temperature), but with higher energy use.

— Flexibility: this can be achieved but with cost penalties.

— Predictability: performance can be predicted subject to commissioning and maintenance.

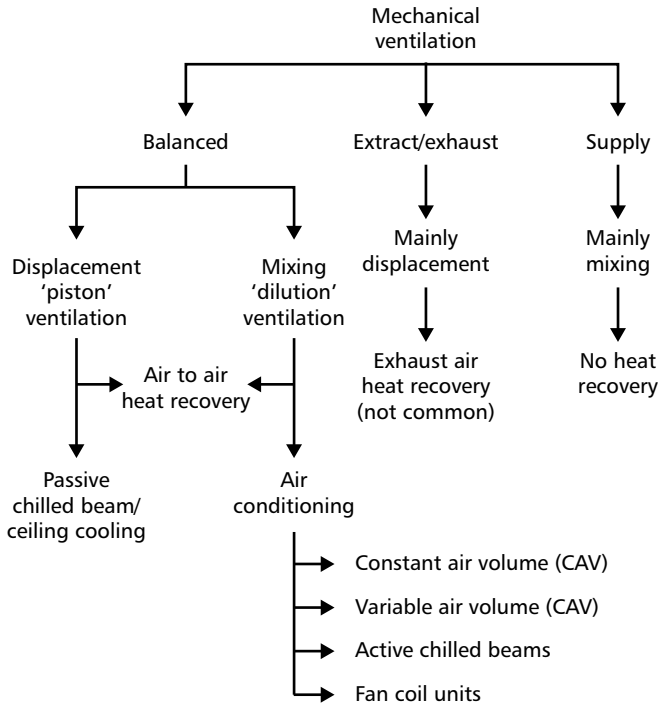

Figure 2.11 Summary of mechanical systems

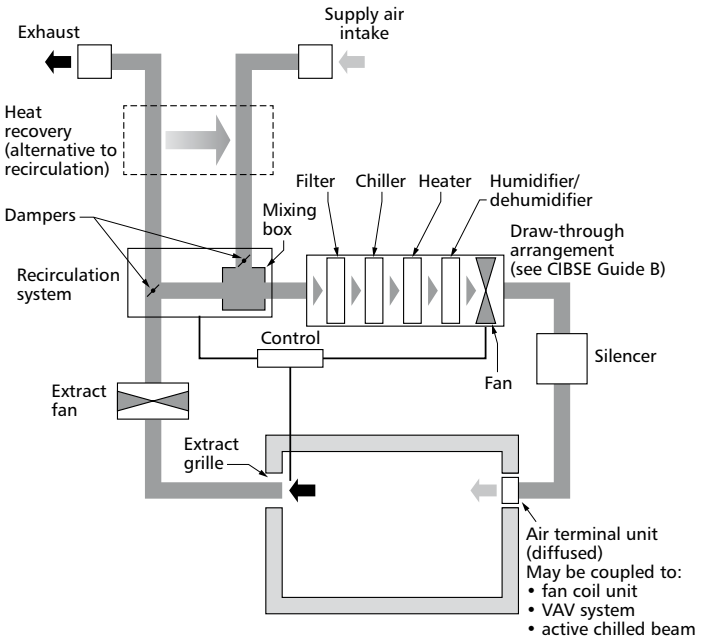

Figure 2.12 Mechanical balanced ventilation for non-residential building (source: Good Practice Guide GPG 257 (Action Energy, 1997) (Crown copyright))

— Ability to deal with polluted environments: there is control of air intake positioning. These should be located away from pollutant sources (see CIBSE, 1999 and BSRIA, 2000). Filtration is possible in harsh environments (see section 2.3.3). However, gaseous and fine particle control may involve considerable expense and regular maintenance.

— It is suitable for hot and cold climates.

— It is suitable for large buildings.

— It is suitable for urban and city centre locations.

Disadvantages

Disadvantages are as follows.

— *High capital costs*: costs are heavily influenced by the amount of mechanical plant and the need for a dual duct system, i.e. one for supply and one for extract.

— *High running costs*: the system incurs electrical energy demand and regular maintenance costs; power is now limited by regulation (NBS, 2011d/e).

— *Risk of draught from displacement units*: poor design may lead to draught risk.

— *High space demand*: space is needed for ductwork and equipment.

— *Building airtightness*: for the associated heating and cooling system to work at maximum efficiency the building needs to be as airtight as possible.

Mechanical extract ventilation

In smaller commercial buildings and dwellings, the complexities of balanced systems may be reduced by installation of an extract only system (Figure 2.13). In this case air is extracted from 'wet' or contaminated areas such as process areas, kitchens, toilets and bathrooms.

Clean, make-up fresh air is provided by a network of purpose-provided 'passive' supply openings to occupied zones as well as natural leakage openings. Because air is extracted from the space, the enclosure will be at a negative pressure relative to the ambient outdoor atmospheric pressure.

When the pressure generated by the mechanical system is greater than the pressures generated by the natural driving forces of wind and stack pressure, the airflow rate is dominated by the mechanical ventilation rate (this process is covered in more detail in CIBSE Guide A (2015a)). Thus this system can inhibit the impact of air infiltration driving forces. However, for full control of ventilation the building should be reasonably airtight.

In the domestic setting, extract ventilation is placed in 'wet' rooms such as WCs, bathrooms and kitchens. The resultant suction pressure prevents moisture, generated in wet spaces, from entering the living area thus reducing the risk of condensation. In addition, cooking fumes and other pollutants are prevented from spreading to occupied zones. In the commercial setting extract ventilation is used for containment. Examples include industrial fume hoods, commercial kitchens and laboratory applications (see CIBSE Guide B0 (2016b)).

A further important advantage of extract ventilation is that contaminants from the exhaust air can be centrally collected and removed by filtration before discharge into the atmosphere. Waste heat can also be extracted using 'run-around' coils for use as supply air pre-heat or, in the case of low-grade heat, for use in conjunction with a heat pump.

Excessive under-pressures will lead to high fan energy consumption and could cause back-draught from flued appliances in adjacent spaces. Hence a full risk assessment will be needed to identify any problem. Part F of the Building Regulations (NBS, 2013b) provides guidance on the avoidance of back-draught when using extract systems.

Fans can be window, ceiling or wall mounted but are most effectively located at a high level away from the source of fresh air such as an internal door or trickle ventilator. In a kitchen they are ideally combined with a cooker hood. Ceiling-mounted fans should be ducted to outside; however, it should be noted that ductwork lengths of as little as 1 m can considerably impair performance due to pressure

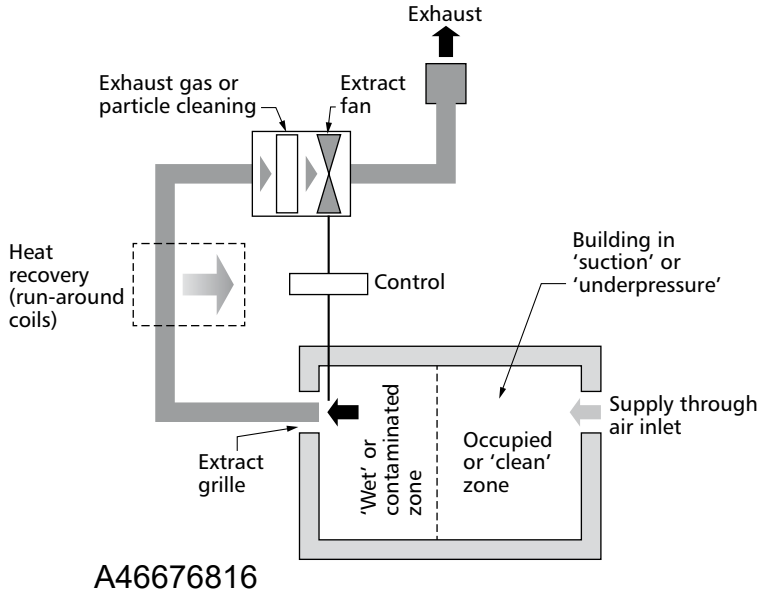

Figure 2.13 Mechanical extract ventilation system (source: Good Practice Guide GPG 257 (Action Energy, 1997) (Crown copyright))

losses, hence correct selection is imperative. In all cases, manufacturers' data on pressure drop should be applied.

Fans should be located so as not to produce draughts or draw combustion products from open-flue appliances. Guidance is covered in Part J of the Building Regulations (NBS, 2013f), BS 5864: 2010: *Installation in domestic premises of gas-fired ducted-air heaters of rated input not exceeding 70 kW* (BSI, 2010a) and BRE IP 13/94: *Passive Stack Ventilation in Dwellings* (BRE, 1994). Note that cooker hoods require permanently open vents as close as possible to the hood. Control can be by manual switching or through being wired into a door or light switches. Another option is humidity control with manual override, although the sensor may cause the fan to operate when moisture generation is not taking place, for example on warm, humid summer days. The sensor needs to be positioned with consideration to where the major source of moisture is located. It may be more suitable to install cowled shutters to avoid noise problems with external gravity back-draught shutters rattling in the wind.

When exhaust air is ducted and discharged at a single location, it is possible to recover heat using a run-round coil (see section 2.3.4.3). This recovered heat may be used to pre-heat hot water systems or provide space heating pre-heat by means of a heat pump

Advantages

— It is simple and widely applicable.

— There is a reduced duct demand compared with a combined supply-and-extract system.

— It provides the possibility of rapid extract.

— The system is easily understood.

Heat recovery is possible for secondary purposes using a run-around coil or heat pump to absorb heat from the exhaust air (see section 2.3.4.3).

Disadvantages

— The distribution of fresh air supply can be uncertain, depending on the size of the opening area servicing a space and the resistance to flow in the paths leading to the extract system.

— It can be perceived by occupants to have high running costs and is prone to tampering by occupants.

— Noise can be an issue.

— The system requires maintenance.

— Air cleaning not is possible.

— Risk of back-draught: resultant under pressure makes this system unsuitable in locations that use open-flue heating appliances.

Mechanical supply ventilation

Mechanical supply systems incorporate mechanical fans to supply fresh air to a space (see Figure 2.14). Air is exhausted through purpose-provided passive vents and air infiltration openings. Because air is supplied to the space, the enclosure will be at a positive pressure relative to the ambient outdoor atmospheric pressure

Mechanical supply ventilation provides fresh air directly to a space. The positive pressure inhibits infiltration ingress from outdoors and adjacent spaces. Additionally, the supply air can be cleaned by filtration (see section 2.3.3) and therefore this method has important applications in clean room design. However, in hot, humid climates, supply ventilation can force moisture-laden outdoor air into the building fabric.

In dwellings the supply fan is typically mounted in the roof space and delivers air that has been filtered and tempered by the roof space into the dwelling. The system works on the principle of continuous dilution, displacement and replacement of air in the dwelling. Air discharge from the dwelling is via purpose-provided extract vents and/or leakage paths. Fans typically run continuously at low speed,

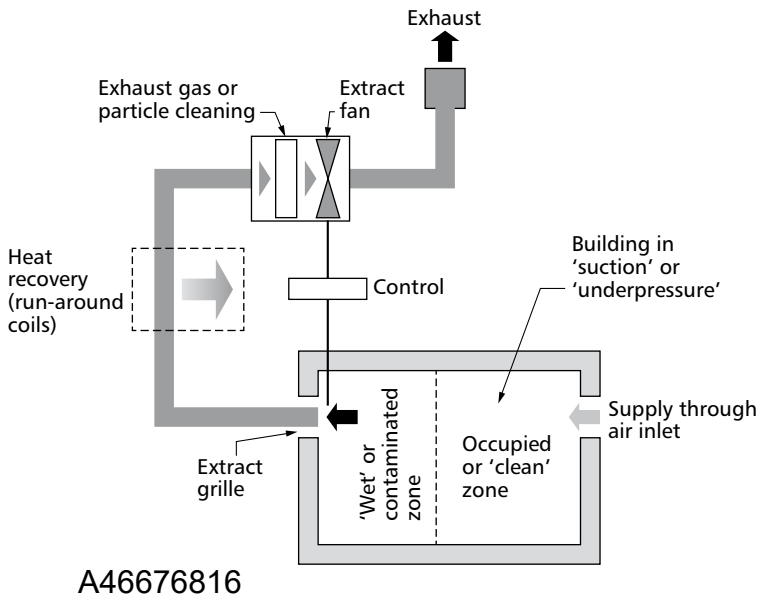

Figure 2.14 Mechanical supply ventilation (source: Good Practice Guide GPG 257 (Action Energy, 1997) (Crown copyright))

with manual or humidity controlled boost to a higher speed when required. Temperature controls can incorporate single roof space sensors or sensors in both the roof and living spaces. The latter system adjusts the flow rate of the unit to suit the temperatures in both spaces, thereby providing the optimum energy benefits for the occupants. Fan units incorporating highly efficient motor technology can provide a significant net energy gain to the dwelling.

Advantages

— It is simple and well established as a means of controlling condensation.

— It is compatible with open-flued appliances.

— It utilises any heat gain in the roof space.

— It allows filtration of the air before it enters the space.

Disadvantages

— Occupants perceive the systems to have high running costs.

— Noise can be an issue.

— Systems are prone to tampering by occupants.

— Maintenance (particularly filter replacement) is required.

— Effectiveness depends on building shape/layout.

— Since there will usually be multiple extract vents it is not possible to recover heat or pollutants from the exhaust air

Domestic 'balanced' mechanical ventilation system with heat recovery

A scaled-down version of the commercial balanced system is becoming increasingly common in dwellings. A schematic is presented in Figure 2.15.

Almost invariably, the fundamental benefit of a balanced ventilation system is to combine it with an air-to-air heat recovery system (see section 2.3.4).

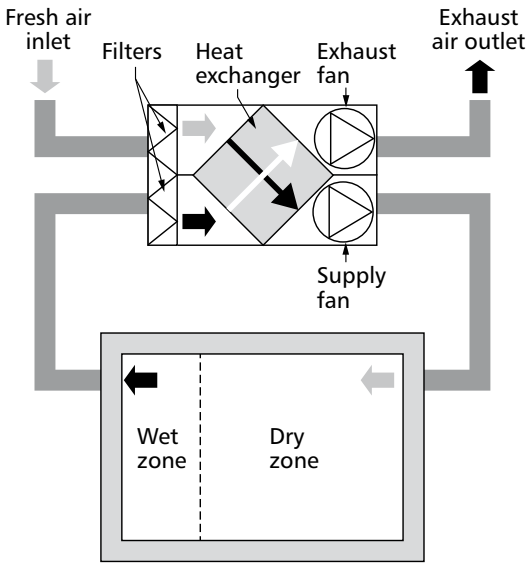

Figure 2.15 Domestic heat recovery system

In operation, warm, moist air is extracted from kitchens, bathrooms, utility rooms and toilets via a system of ducting and passed across a heat exchanger before being exhausted. Fresh incoming air is pre-heated and ducted to the living room and other habitable rooms.

Ducts may be circular or rectangular and typically range in size from 100 to 150 mm in diameter. Air velocities should be kept below 4 $m \cdot s^{-1}$. Vertical exhaust ducts should be fitted with condensate traps; horizontal exhaust ducts should slope away from fans to prevent condensate running back. Both supply-and-extract grilles should be located at high level as far as practical from internal doors but at a sufficient distance from each other to avoid 'short circuiting', i.e. a minimum of 2 m. Suitable louvres or cowls should be fitted to prevent ingress of rain, birds or insects.

Such systems can provide the ideal ventilation almost independent of weather conditions. During normal operation the total extract airflow rate will be 0.5–0.7 air changes per hour (ACH) based on the whole dwelling volume, less an allowance for background natural infiltration if desired. Individual room air change rates will be significantly higher, possibly 2–5 ACH, in rooms with an extract terminal. To be most effective a good standard of air tightness is required, typically the permeability should be better than 5 $m^3 \cdot h^{-1}/m^2$ at 50 pa. Airflows need to be balanced at the time of installation. Extract rates from bathrooms and kitchens can be boosted during times of high moisture production although care should be taken not to cause draughts. The system can be acoustically treated to reduce noise ingress. Commissioning should follow CIBSE Commissioning Code A: *Air distribution systems* (2006b).

Transfer grilles or clearance beneath internal doors are necessary. Part F of the Building Regulations (NBS, 2013b) requires bottom edges of internal doors to be clear of the floor surface by 10 mm. Transfer grilles are usually positioned not more than 450 mm above the floor. If placed higher they may allow the rapid movement of toxic combustion products or facilitate the spread of fire. Fire dampers should be inserted where the ductwork passes through separating walls and floors, and are desirable in kitchens, for example cooker hoods. In dwellings, the principal requirement is to maintain the separation of fire compartments, for example where ducts pass through protected escape routes. The most common approach is to use a means of preserving the partition, such as intumescent duct sleeves. Dampers should not be used in kitchen extracts, instead protection is required through fire-resisting ductwork (see section 2.3.5).

It is claimed that such systems are effective in reducing condensation due to the controlled ventilation and airtight structure reducing cold air draughts. Manufacturers also claim that they improve indoor air quality and help in controlling dust-mite populations.

Advantages

— It provides controlled pre-heated fresh air throughout the house.

— It reduces the heating demand in very airtight dwellings (typically effective in dwellings with infiltration rates < 5 $m^3 \cdot h^{-1}/m^2$).

— It reduces the risk of condensation.

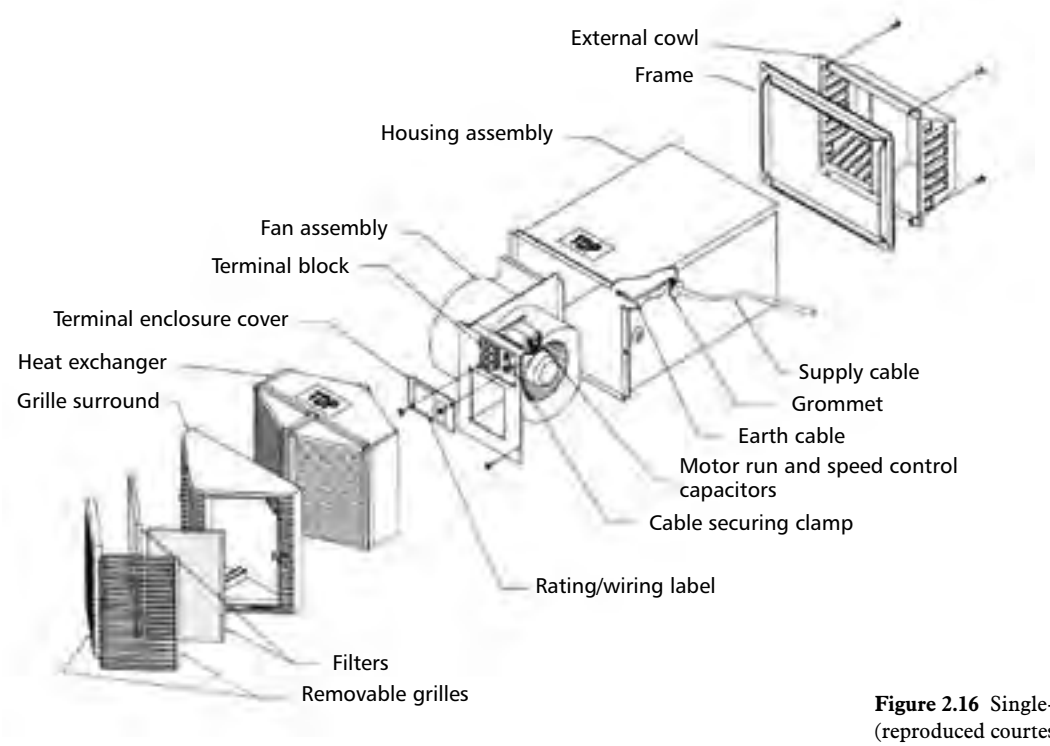

Figure 2.16 Single-room ventilation heat recovery unit (reproduced courtesy of Vent-Axia)

Disadvantages

— Ductwork can be difficult to accommodate.

— Initial costs are high.

— The systems have an ongoing maintenance liability.

— A suitable level of airtightness must be provided.

— Installation and commissioning is more complex than for other systems.

— Because of increased electrical demand to offset fossil fuel heating, a carbon benefit must be demonstrated.

— Systems can freeze and cease to function below 0 °C. Anti-frost measures include switching off, heating or operating at reduced efficiency. All these impact on cost and energy performance.

In cold climates heat recovery systems have become popular for dwellings since considerable energy saving is possible with heat recovery efficiencies of up to 92 per cent being attainable. In milder climates payback periods become more difficult to justify. However, at low temperatures the performance of heat recovery can be hampered by the need for frost protection.

Heat recovery room ventilators

This is a single-room version of a mechanical ventilation heat recovery system, which is mounted in an external wall (often to replace an extract fan, see Figure 2.16). These ventilators incorporate a heat exchanger that recovers approximately 60 per cent of the heat from the outgoing air. This is passed across to the incoming air to pre-heat it. The extract fan is often dual speed, providing low-speed, continuous trickle ventilation or high-speed extract. High-speed extract can be under manual or humidity control. This system is principally designed for wet rooms although versions are now available for living and bedrooms.

Advantages

— It provides continuous low-level ventilation.

— It provides the option of rapid extract.

— It recovers heat energy.

— It allows filtration of the supply air.

— It is almost silent in operation at trickle speed.

Disadvantages:

— Occupants perceive the systems to have high running costs.

— Regular maintenance is required.

— Some recirculation is possible, due to the close proximity of supply-and-extract grilles.

— It is ineffective unless the building is airtight

2.3.2.4 Mixed-mode or hybrid ventilation systems

Mixed-mode ventilation may be defined as the combination of natural and mechanical ventilation and/or cooling systems. These systems are described in full detail in CIBSE AM13: *Mixed mode ventilation* (2000a).

Sub-classifications of mixed-mode systems given in CIBSE AM13 are as follows.

— *Contingency designs*: contingency designs are usually naturally ventilated buildings that have been designed to permit the selective addition of mechanical ventilation and cooling systems where these may be needed at a later date. Occasionally the passive measures may themselves be the contingency plan, with an initially fully air-conditioned building designed to be amenable to subsequent naturally ventilated operation, either in part or in whole.

— *Complementary designs*: natural and mechanical systems are both present and are designed for integrated operation. This is the most common variety of mixed-mode system. Complementary designs can operate in two modes.

  — *Concurrent operation*: the most widely used mode, in which background mechanical ventilation, with or without cooling, operates in parallel with natural systems. Often the mechanical system suffices, controlling draughts and air quality and removing heat, but occupants can open the windows if they so choose.

  — *Changeover operation*: natural and mechanical systems are available and used as alternatives according to need, but they do not necessarily operate at the same time. Changeover may be on the basis of a variety of conditions as suggested below under Control (see section 2.3.6). The chosen control strategy must guard against the risk that changeover systems may default to concurrent operation. Problems of this kind tend to increase with the complexity of the proposed operating strategies.

— *Zoned systems*: these allow for differing servicing strategies to occur in different parts of the building. The zoned approach works best where the areas are functionally different. Many buildings operate in this manner, e.g. a naturally ventilated office with an air-conditioned computer room and a mechanically ventilated restaurant and kitchen. Mixed-mode increases the range of options available, e.g. offices with openable windows at the perimeter and mechanical ventilation in core areas. The zoned approach works best where the areas are functionally different or where the systems are seamlessly blended.

A selection process for choosing a mixed-mode approach is illustrated in Figure 2.17. The mixed-mode approach should not be seen as a compromise solution. It needs to be chosen at a strategic level and the appropriate option selected. The ability to provide general advice on applicability is limited because the final design can range from almost fully naturally ventilated with a degree of fan assistance for still days, to almost fully air conditioned with the option to revert to natural ventilation at a later date. Selection issues to be considered are listed below.

— *Costs*: capital and operating costs are highly variable. A balancing factor is to what extent supplementary mechanical systems have been installed.

— *Maintenance*: poor designs could result in excessively complex maintenance requirements.

— *Operability*: as above, poor designs in terms of controls complexity can result in inefficient and misunderstood system operation.

— *Window design*: a mixed-mode approach might allow this to be less complicated and more robust than in buildings designed for natural ventilation alone.

— *Energy efficiency*: in relation to fully air-conditioned buildings, mixed-mode systems should use less energy for fans, pumps and cooling. However, this is dependent upon the savings in mechanical plant that have been attained.

— *Occupant satisfaction and comfort*: mixed-mode buildings offer the potential for a high level of occupant satisfaction in that they provide more options for correcting a situation.

Advantages

— It can take advantage of natural ventilation to reduce mechanical energy consumption.

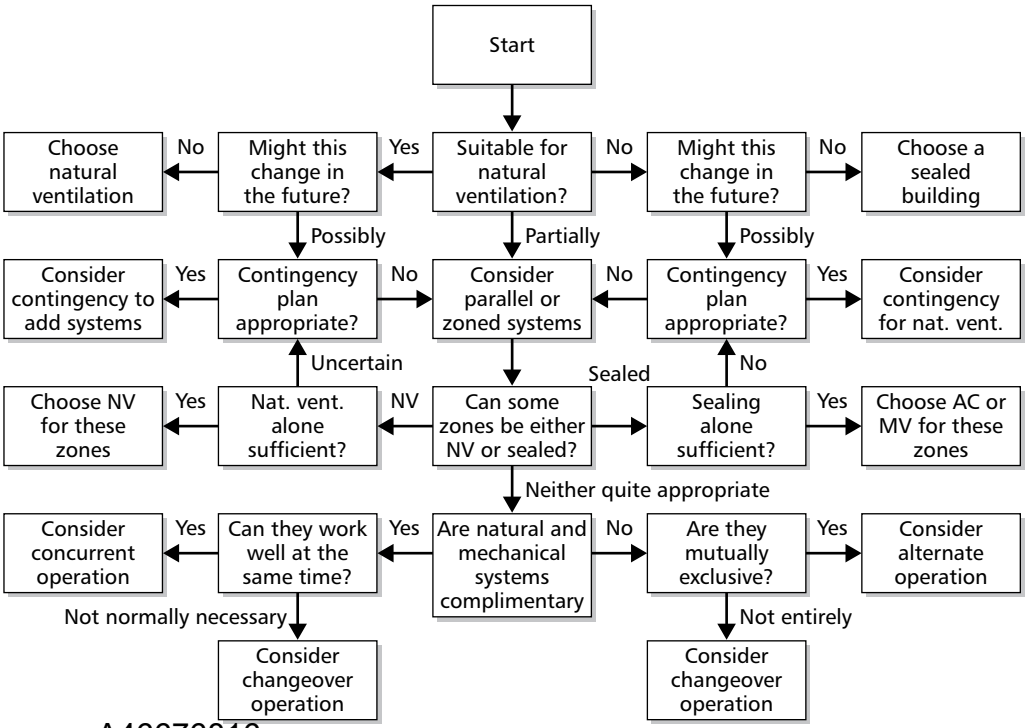

Figure 2.17 Decision chart for selecting mixed-mode ventilation

A46676816

— Mechanical components are usually quite basic, hence costs can be lower than a full mechanical system.

— It can be incorporated with mechanical or passive cooling systems.

Disadvantages

— It is less controllable than a full mechanical system.

— Complementary systems could be expensive.

2.3.3 Filtration systems

In mechanically ventilated buildings, effective air filtration relies on good maintenance (see CIBSE TM26: *Hygienic maintenance of office ventilation ductwork* (2000b)). Poor filtration performance can allow dirt and dust to accumulate within a ductwork system, reducing the efficiency of heat exchange equipment and providing potential sites for microbiological activity. Spores and bacteria can then be released into the occupied space, causing potential comfort and health problems. Natural ventilation systems, on the other hand, are generally more accessible for cleaning and maintenance, and there are no components subject to high humidity, such as cooling coils, or humidifiers, which can harbour biological growth.

2.3.3.1 Nature of airborne contaminants

Atmospheric dust is a complex mixture of solid particulate matter, comprising dusts, smokes, and fumes and non-particulate vapours and gases. A sample of atmospheric dust may contain minute quantities of soot and smoke, minerals such as rock, metal or sand, organic material such as grain, flour, wool, hair, lint and plant fibres and, perhaps, mould spores, bacteria and pollen. Particles are not generally called dust unless they are smaller than 80 μm.

Smokes are suspensions of fine particles produced by the incomplete combustion of organic substances, such as coal or wood, or by the release into the atmosphere of a wide variety of chemical compounds in a finely divided state. Smoke particles vary considerably in size from about 0.3 μm downwards. Fumes are solid particles, predominantly smaller than 1.0 μm, formed by the condensation of vapours.

Non-particulate contaminants consist of vapours condensable at normal pressures and temperatures and gases, of which the most damaging to plants and buildings is sulphur dioxide. Carbon monoxide and various oxides of nitrogen are also present in minute quantities. There is a wide variation in atmospheric solids between rural, suburban and industrial areas, as shown in Table 2.6.

Table 2.7 shows an analysis of a sample of atmospheric dust, in terms of the total numbers of particles for the size range. The figures may be considered typical for average urban and suburban conditions, but wide variations may be encountered in particular cases. Current emphasis in office and other 'standard' accommodation is on the removal of particles smaller than 10 μm. These, along with chemicals outgassed from carpets and furnishings in modern workspaces, have been linked with reports of sick building syndrome and are able to penetrate into the lungs, causing respiratory problems.

2.3.3.2 Definitions

The following definitions, drawn from BS EN 779: 2012: *Particulate air filters for general ventilation* (BSI, 2012a), are commonly used in describing the properties of air filters.

— *Test airflow rate*: volumetric airflow rate through the filter under test. Expressed in $m^3 \cdot s^{-1}$ (for a reference air density of 1.20 $kg \cdot m^{-3}$).

— *Face velocity*: the airflow rate divided by the face area ($m \cdot s^{-1}$).

— *Initial pressure drop*: the pressure drop (Pa) of the clean filter operating at the test airflow rate.

— *Final pressure drop*: the pressure drop (Pa) up to which the filtration performance is measured for classification purposes.

— *Average efficiency* (E_m): weighted average (%) of the efficiency of 0.4 μm particles for the different specified dust loading levels up to final pressure drop.

— *Average efficiency* (E_{ij}): average efficiency (%)for a size range i at different loading intervals j.

— *Minimum efficiency*: lowest efficiency among the discharged efficiency, initial efficiency and the lowest efficiency throughout the loading procedure of the test.

— *Initial arrestance* (%): arrestance of the first 30 g loading dust increment.

— *Average arrestance*: ratio of the total amount of loading dust retained by the filter to the total amount of dust fed up to the final pressure drop.

2.3.3.3 Filter testing

Applicable standards

The applicable test standard for particulate air filters for general ventilation is BS EN 779: 2012: *Particulate air filters for general ventilation* (BSI, 2012a).

These filters are classified according to their performance as measured in this test procedure.

In order to obtain results for comparison and classification purposes, particulate air filters are tested against two synthetic aerosols—a fine aerosol for measurement of filtration efficiency as a function of particle size within a particle size range 0.2 μm to 3.0 μm and a coarse one for obtaining information about test dust capacity and, in the case of coarse filters, filtration efficiency with respect to coarse loading dust (arrestance).

This European Standard applies to air filters having an initial efficiency of less than 98 per cent with respect to 0.4 μm particles. Filters should be tested at an airflow rate between 0.24 $m^3 \cdot s^{-1}$ (850 $m^3 \cdot h^{-1}$) and 1.5 $m^3 \cdot s^{-1}$ (5400 $m^3 \cdot h^{-1}$).

The performance results obtained in accordance with this standard cannot by themselves be quantitatively applied to predict performance in service with regard to efficiency and lifetime.

For higher efficiencies, BS EN 1822-5: 2009: *High efficiency air filters (EPA, HEPA and ULPA). Determining the efficiency of filter elements* (BSI, 2009a) is applicable.

The BS EN 779: 2012 classification system previously in use (comprising groups F and G filters) has been changed to three groups (F, M and G filters). Filters found to have an average efficiency value of less than 40 per cent of 0.4 μm particles are allocated to group G and the efficiency reported as '<40%'. The classification of G filters (G1–G4) is based on their average arrestance with the loading dust.

Filters found to have an average efficiency value from 40 per cent to less than 80 per cent of 0.4 μm particles will be allocated to group M (M5, M6) and the classification is based on their average efficiency (0.4 μm). The filter classes F5 and F6 have changed to M5 and M6, but with same requirements as in the old classification system.

Filters found to have an average efficiency of 80 per cent or more of 0.4 μm particles will be allocated to group F (F7–F9) and the classification is based on their average efficiency (0.4 μm) as in the old system and the minimum efficiency during the test.

Filters are classified according to their average efficiency or average arrestance under the following test conditions.

— The airflow shall be 0.944 $m^3 \cdot s^{-1}$ (3400 $m^3 \cdot h^{-1}$) if the manufacturer does not specify any rated airflow rate.

— 250 Pa maximum final test pressure drop for coarse (G) filters.

— 450 Pa maximum final test pressure drop for medium (M) and fine (F) filters.

If the filters are tested at 0.944 $m^3 \cdot s^{-1}$ and at maximum final test pressure drops, they are classified according to Table 2.6, for example G3, F7. Filters tested at airflows and final test pressure drops different from those above shall be classified according to Table 2.6, and the classification should be qualified by test conditions in parentheses, e.g. G4 (0.7 $m^3 \cdot s^{-1}$, 200 Pa), F7 (1.25 $m^3 \cdot s^{-1}$).

Test for high efficiency filters

The preferred pan-European test method for testing high efficiency EPA (efficient particulate air filter), HEPA (high efficiency particulate air filter) and ULPA (ultra-low particle arrestor) filters is BS EN 1822-5: 2009: *High efficiency air filters (EPA, HEPA and ULPA). Determining the efficiency of filter elements* (BSI, 2009a). This test method is based on scanning by a particle counter at the most penetrating particle size (MPPS) of the filter. MPPS is variable and is determined by testing samples of the filter medium used in the manufacture of the filter being tested. The challenge aerosol is di-ethyl-hexyl-sebacat (DEHS) mineral oil or equivalent, but other oils are permitted. Condensation nucleus counters (CNC) are used for monodispersed aerosols and laser particle counters (LPC) for polydispersed aerosols.

The most recent version of the standard introduced a category of EPA grade filters, formally H10 to H12. This was done because the previous classification did not fully represent the test method employed for all the H grades, particularly regarding leak testing. It was decided that the filter grades should be grouped by test method. The grades are now as follows.

— Group E: EPA filters

— Group H: HEPA filters

— Group U: ULPA filters.

Filters are classified in 'groups' and 'classes'. For each group a slightly different test procedure applies. All filters are classified according to their filtration performance.

Group E filters are subdivided in three classes:

— Class E10

— Class E11

— Class E12.

Group H filters are subdivided in two classes:

— Class H13

— Class H14.

Group U filters are subdivided in three classes:

— Class U15

Table 2.6 Classification of general ventilation filters

Group	Class	Final test pressure drop / Pa	Average arrestance (A_M) of synthetic dust / %	Average efficiency (E_M) of 0.4 μm particles / %	Minimum efficiency* of 0.4 μm particles / %
Coarse	G7	250	$50 \le A_M < 65$	—	—
	G2	250	$65 \le A_M < 80$	—	—
	G3	250	$80 \le A_M < 90$	—	—
	G4	250	$90 \le A_M$	—	—
Medium	M5	450	—	$40 \le E_M < 60$	—
	M6	450	—	$60 \le E_M < 80$	—
Fine	F7	450	—	$80 \le E_M < 90$	35
	F8	450	—	$90 \le E_M < 95$	55
	F9	450	—	$95 \le E_M$	70

* Minimum efficiency is the lowest efficiency among the initial efficiency, discharged efficiency and the lowest efficiency throughout the loading procedure of the test.

Table 2.7 Classification of EPA, HEPA and ULPA filters

Filter group/class	Integral value		Local value (see BS EN 1822-4)*	
	Efficiency / %	Penetration / %	Efficiency / %	Penetration / %
E10	≥ 85	≤ 15	Group E filters not leak tested for classification purposes	
E11	≥ 95	≤ 5		
E12	≥ 99.5	≤ 0.5		
H13	≥ 99.95	≤ 0.05	≥ 99.75	≤ 0.25
H14	≥ 99.995	≤ 0.005	≥ 99.975	≤ 0.025
U15	≥ 99.9995	≤ 0.0005	≥ 99.9975	≤ 0.0025
U16	≥ 99.99995	≤ 0.00005	≥ 99.99975	≤ 0.00025
U17	≥ 99.999995	≤ 0.000005	≥ 99.9999	≤ 0.0001

* Local penetration values lower than those given here may be agreed between the supplier and purchaser.

— Class U16

— Class U17.

After testing, filter elements are classified according to Table 2.7 on the basis of their integral efficiency (Group E) or their integral efficiency and local (Groups H and U) MPPS efficiency or penetration. The other addition is that filters with filter media having an electrostatic charge are classified according to the table on the basis of their discharged efficiency or penetration as per Annex B of BS EN 1822-5: 2009: *High efficiency air filters (*EPA, HEPA *and* ULPA*). Determining the efficiency of filter elements* (BSI, 2009a).

On-site testing

The efficiency of a filter installation depends not only on the filter efficiency but also on the security of the seal between the filter and the air system. This is particularly vital in HEPA filter installations; hence penetration must be established immediately prior to use and at regular intervals throughout the working life of the system.

A common methodology utilises an oil-based aerosol to challenge the installed filter. Concentrations are determined using photometry:

— DOP (an abbreviation for di-octylphthalates) is an oily liquid with a high boiling point. Normally, DOP vapour is generated at a concentration of 80 $mg \cdot m^{-3}$ and the downstream concentration is determined using a light scattering photometer via a probe that scans the entire downstream face of the filter installation.

Gas and vapour removal

Most manufacturers quote efficiencies for removal of a wide range of gases and vapours based on upstream and downstream concentrations. Adsorption filters are also rated in terms of the mass of gas/vapour that can be adsorbed before saturation of the adsorbent.

Specification and testing methods have been developed for gas and vapour removal by filters and recirculating air cleaning units (Gilbert, 1999). This work has looked at the performance of a wide range of systems including active bonded carbon units and electrostatic filters. Specialist advice should be sought on any requirements.

Dry testing

In applications such as cleanrooms used for the production of semi-conductors, testing for local leaks with an oil-based aerosol would result in filter contamination and subsequent production problems. In these circumstances filters are tested using atmospheric air or polystyrene latex spheres (PSL).

2.3.3.4 Filter application and selection

Table 2.8 presents a broad classification of air cleaners and Figure 2.18 illustrates the various characteristics of dusts, mists etc., together with other relevant data.

Table 2.9 provides recommended filter specification data drawn from the National Engineering Specification Y42: *Air Filtration* (NES, 1996) and promoted within BSRIA guidance (Pike, 1996; Bennett, 1996). CIBSE TM26: *Hygienic maintenance of office ventilation ductwork* (2000b) considers other means of reducing the admittance of micro-organisms other than just the installation of a HEPA filter. Under certain conditions, air filters can support the growth of micro-organisms and act as a source of contaminants. Standard air filters can be obtained with an anti-microbial coating that is reported to kill or inhibit the growth of micro-organisms on the filter material and any trapped dust and debris. However, due to the potential for the active biocide to outgas from the surface, the user of such systems should take steps to ensure that they are safe for building occupants. Anti-microbial ductwork coatings are also available, however they also have a potential for the active biocide to outgas from the surface.

Ultraviolet germicidal irradiation (UVGI) is provided by ultraviolet lamps mounted in the supply ductwork. The ultraviolet (UV) light causes inactivation of micro-organisms by disrupting their DNA. This system is claimed to be effective against all types of bacteria and fungi, as well as spores and viruses that are normally found in the air. The user of such systems should ensure that staff are protected from exposure to the UV radiation. Photo-catalytic oxidation technology involves the action of low-energy UV on a catalyst in the presence of water vapour that generates hydroxyl radicals that destroy micro-organisms. As this is

an oxidation process, the microbial hydrocarbons are reduced to carbon dioxide and water. This technique can be used against bacteria, fungi/spores, viruses and allergens.

2.3.3.5 Filter maintenance

The life of a filter depends upon the:

— concentration and nature of contaminants

— filter efficiency

— dust-holding capacity corresponding to rise in pressure loss between clean and dirty conditions

— face velocity at the filter.

A maintenance regime can be based on time intervals or on condition. Details of external conditions that may affect filter life, such as the entering pollution concentration, may be determined in consultation with the local environmental health officer. Alternatively, a local survey may be undertaken. Some filter manufacturers provide prediction data for hours of use for different localities. Tables 2.10 and 2.11 give typical data on the amount and nature of solids in the atmosphere. Issues of external air quality, including sulphur dioxide and particulate matter (PM_{10}), are discussed in CM 4548: *Air Quality Strategy for England, Scotland, Wales and Northern Ireland* (DEFRA, 2007), which is subject to periodic review.

If condition-based maintenance is being used, the filter pressure differential should be monitored. Replacement filters are installed when a specific differential is attained. If the filter represents a significant proportion of the total pressure loss of the system, and there is no provision for automatic fan duty adjustment (e.g. a variable air volume (VAV) system), then the rise in pressure loss due to filter soiling should not exceed 20 per cent of the total system loss with a clean filter. This differential can be reported via a building energy management system (BEMS). Note that a method of alerting maintenance staff of filter failure or blockage is also required for the time-based replacement method.

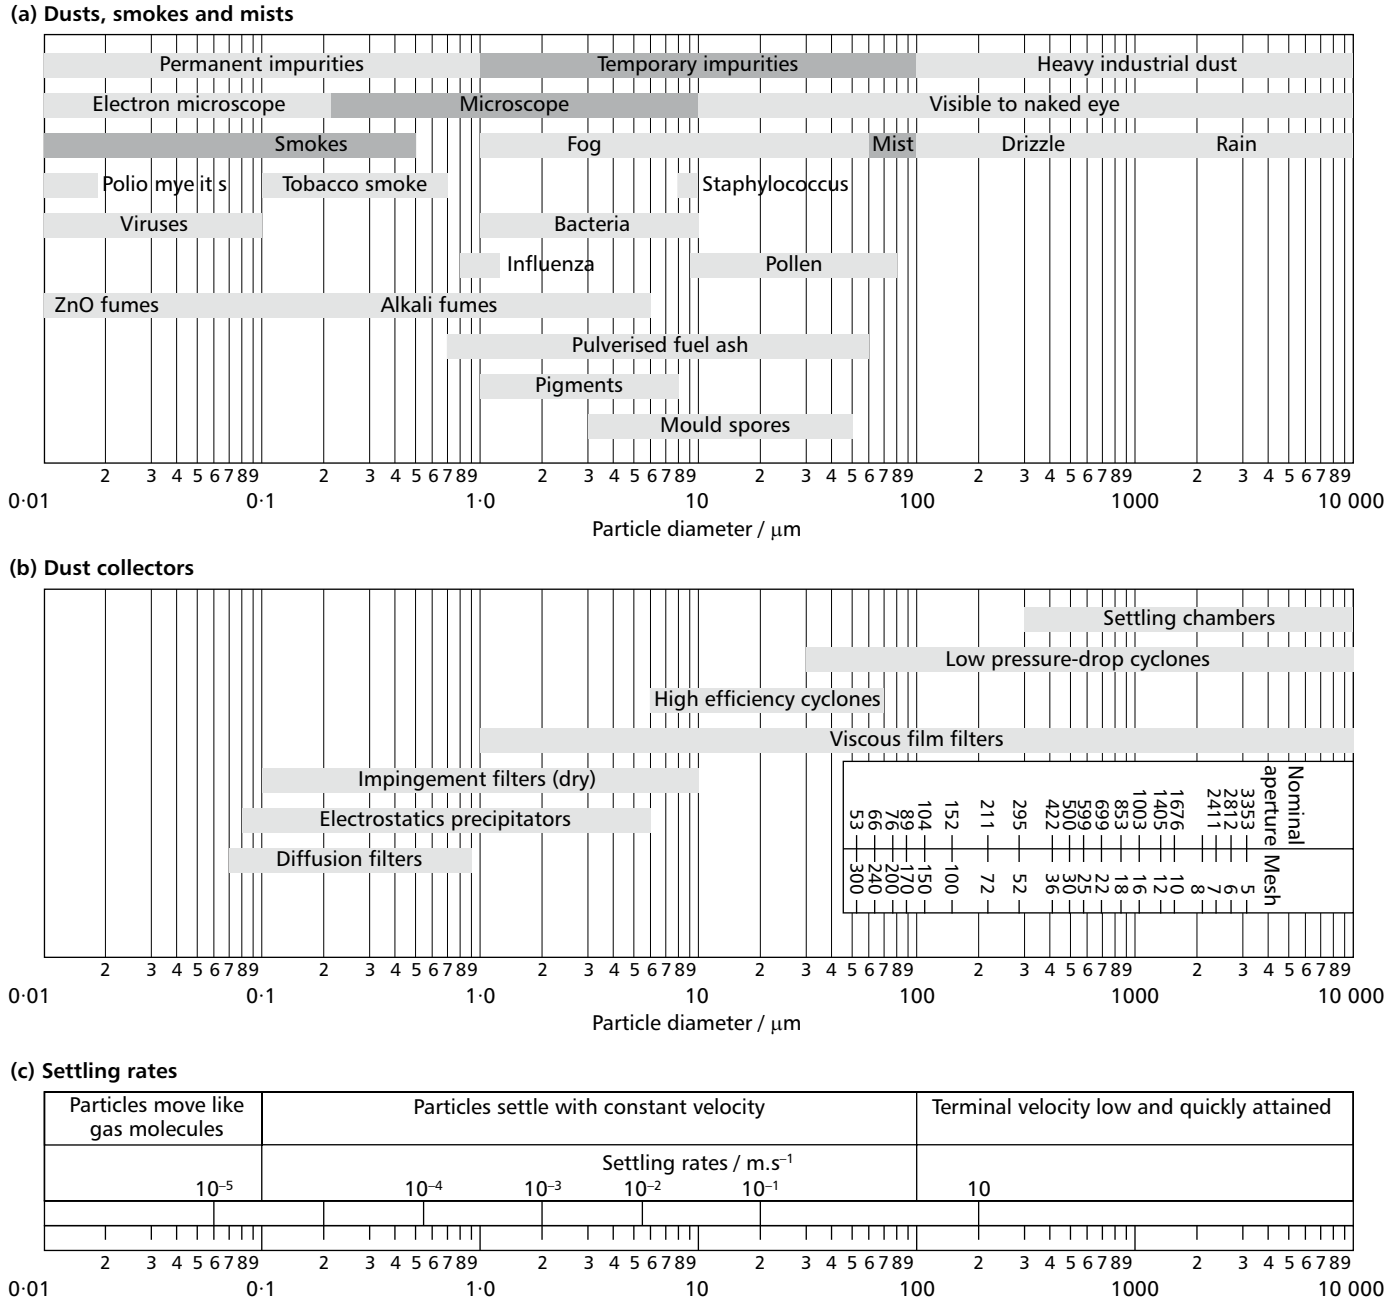

Figure 2.18 Characteristics of dusts and mists

Table 2.8 Classification of air cleaners

Type	Remarks	Method of cleaning	Face velocity / m·s^{-1}	Resistance at face velocity / Pa		Dust holding capacity	Relative efficiency / %		Relative cost
				Initial	Final		Sodium flame	Synthetic dust	
Viscous impingement:									
— panel or unit	Thickness ranges 12–100 mm; small or intermediate air volumes; good for particles > 10 μm diameter; efficiency decreases with dust loadings; used as after-cleaners	Permanent (washable) or disposable	1.5–2.5	20–60 (depending on thickness)	100–150	High; can be critical	10	> 85	Low
— moving curtain	Will handle heavy dust loads; intermediate or large air loads; used as precleaners etc.	Continuous or intermittent; can be automatic	2–2.5	30–60	100–125 (operating)	Self-cleaning by immersion	10	> 85	Medium
Dry:									
— panel, bag, cartridge or unit with fabric or fibrous medium	Small or intermediate air volumes	Usually disposable	1.25–2.5	25–185 (depending on efficiency)	125–250 (depending on efficiency)	Generally not as high as viscous impingement; can be critical	30–80 (depending on filter type, medium and face velocity)	96–100 (depending on filter type, medium and face velocity)	Low to high
— moving curtain	Intermediate or large air volumes	Continuous or intermittent; can be automatic or disposable	2.5	30–60		Self-cleaning	Can be selected over a wide range		Medium to high depending on efficiency
— absolute or diffusion (HEPA)	Pre-filter necessary; small air volumes; particles down to 0.01 μm diam.	Disposable	Up to 2.5	Up to 250		Low	> 99.9	100	High
Electrostatic:									
— charged plate	Pre-filter desirable; after-filter used to collect agglomerates; power-pack and safety precautions necessary (up to 12 kV); particles down to 0.01 μm diam; intermediate to large air volumes	Washable or wipeable; can be automatic	1.5–2.5	Negligible; resistance added (40–60 Pa) to improve uniformity of air distribution	Negligible; resistance added (40–60 Pa) to improve uniformity of air distribution	Can be critical	—	Not suitable over 5 μm diam.	High; low maintenance costs
— charged medium	As for charged plate	Disposable	1.25	25	125	High	55–65	Not suitable over 5 μm diam.	High; low maintenance costs
Adsorption units	Should be protected from dust, oil and grease; used for odour removal*	Can be reactivated	Low	Low; can be selected; constant	Low; can be selected; constant	Medium adsorbs up to half its own weight of many organic substances	95 (dependent on gas to be removed)		High
Mechanical collectors	Not suitable for particles less than 0.01 μm diameter	To be emptied	Varies with design	50–100	Constant (some act as air movers)	High	—	—	High; low maintenance costs

* Odours can also be removed by combustion, masking or liquid absorption devices

Note: air washers used for humidification or dehumidification purposes sometimes also act as air cleaning devices. These include capillary air washers, wet filters, adsorption spray chambers etc., for which manufacturers' data should be consulted.

Table 2.9 Recommended filter specification data

Filter data to be specified	Essential	Desirable
Air flow rate ($m^3 \cdot s^{-1}$)	*	
Air velocity ($m \cdot s^{-1}$)		*
Initial filter pressure drop (Pa)	*	
Final filter pressure drop (Pa)	*	
Average arrestance (%)	*	
Initial dust spot efficiency (%)	*	
Average dust spot efficiency (%)	*	
Minimum dust holding capacity (g)	*	
Class of filter (EU number)		*
Size of filter (height, width, limiting depth (mm))	*	
Casing		*
Test standards	*	
Access		*
Filter medium		*

Further details on filter maintenance can be found in guidance produced by BSRIA (Pike, 1996) and BESA (2012). Designers are also referred to CIBSE TM26: *Hygienic maintenance of office ventilation ductwork* (2000b).

2.3.3.6 Filter installation

BSRIA has analysed the whole-life performance of filter systems (Pike, 1996; Bennett, 1996) (i.e. the balance between space and capital costs and the operating costs such as inspection, change, energy and costs of associated equipment, e.g. duct cleaning and redecoration). The conclusion is that filter performance depends not only on the filter specification but also on the design and installation of the filter system.

Poor filter installation will neutralise the benefits of specifying good filters. The overall efficiency for the filter installation must be not less than that specified for the filter. It is suggested that:

— air intakes are located at a high level away from the direction of the prevailing wind to prolong filter life and improve the quality of the intake air

— air filters should be protected from direct rain by using weather louvres to prevent waterlogging

— filters should be installed upstream of mechanical equipment to provide protection for that equipment; a final filter should be located downstream of the fan under positive pressure to reduce the risk of dust entering the system downstream of the filter

— adequate access for cleaning should be provided

— filter frames should be of good quality to prevent leakage and distortion; side withdrawal will make this difficult to achieve.

For filters installed in air-handling units (AHUs), and with specific fan power (SFP) in mind, lower filter pressure drops are necessary. Table 2.12 gives maximum 'dirty' conditions.

Table 2.10 Typical amounts of solids in the atmosphere for various localities

Locality	Total mass of solids / $mg \cdot m^{-3}$
Rural and suburban	0.05–0.5
Metropolitan	0.1–1.0
Industrial	0.2–5.0
Factories or work rooms	0.5–10.0

Table 2.11 Analysis of typical atmospheric dust in relation to particle size

Range of particle size (diameter)/mm	Amount of solid as percentage of number of particles and total mass of particles / %	
	Number of particles	Total mass of particles
30 to 10	0.005	28
10 to 5	0.175	52
5 to 3	0.250	11
3 to 1	1.100	6
1 to 0.5	6.970	2

2.3.4 Ventilation heat recovery systems

2.3.4.1 Background

Heat recovery devices used in ventilation systems generally provide heat recovery from exhaust to supply air in winter and can also recover cooling in peak summer conditions. They are also used in specific system configurations such as indirect evaporative cooling (see CIBSE Guide B, Chapter 3 on air conditioning. Devices used to recover heat from process applications (e.g. dryers, flues) may transfer the heat to the process or to another application. Selection of equipment should be suitable for process exhaust temperatures. Where the recovered heat is fed to a ventilation system, modulation control is normally required to prevent overheating in warm weather.

Buildings should be airtight, as infiltration has a significant impact on the viability of heat recovery (AIVC, 1994).

Technical considerations for design and selection of heat recovery devices include:

— heat recovery efficiency (sensible and total)

— airflow arrangement

Table 2.12 Maximum final pressure drops for filters (reproduced from Table 9 of BS EN 13053 (BSI, 2006c), by permission of the British Standards Institution)

Filter class	Final pressure drop / Pa
G1–G4	150
F5–F7	200
F8–F9	300

The final pressure drops are the typical maximum values for AHUs in operation and lower than those used in BS EN 779: 2012 (BSI, 2012a) for classification purposes, for reasons of energy saving, and the performance obtained from tests according to BS EN 779 are not necessarily met at these lower pressure drops.

— fouling (filters should be placed in both supply and exhaust airstreams)
— corrosion (particularly in process applications)
— cross-leakage
— condensation and freeze-up
— pressure drop
— face velocity
— construction materials (suitability for temperatures, pressures, contaminants)
— maintenance (in particular cleaning of surfaces)
— controls.

2.3.4.2 Efficiency analysis

The heat recovery efficiency (or effectiveness) of a device is normally defined as follows:

$$\text{Efficiency} = \frac{\text{Actual heat transfer}}{\text{Maximum possible heat transfer}}$$

The maximum theoretical efficiency is a function of the exchanger flow configuration; counter-flow exchangers have a higher theoretical efficiency than parallel flow exchangers. Practical considerations often favour cross-arrangements that lie between the two (ASHRAE, 2008).

Sensible heat recovery devices do not transfer moisture. Latent heat is only transferred when the warmer airstream is cooled below its dew-point and condenses. Total heat recovery devices transfer both sensible heat and moisture between the airstreams. Moisture transfer is desirable in hot, humid climates to reduce the moisture in the supply air and in cold, dry climates to raise the moisture in the supply air.

Drains should be included to collect and dispose of the condensate. In extreme conditions, where the temperature also drops below 0 °C, frosting or icing can occur. This can be prevented by pre-heating the supply air or reducing the effectiveness of the heat exchanger. Alternatively, the heat exchanger may be periodically defrosted.

Pressure drops depend on a number of factors including exchanger design, airflow rates, temperatures and connections. These pressure drops should be minimised, as they impose a fan energy penalty that will need to be balanced against the recovered energy. Face velocities are normally limited by the need to avoid excessive pressure drops. Larger devices will have lower pressure drops and higher efficiency but will cost more and require more space. The selection and evaluation of heat recovery devices should include the following parameters:

— cost expenditure on device, filters etc. and savings on other plant (e.g. boilers) due to heat recovery
— energy, both recovered and required to operate the system (e.g. fan, pump, wheel)
— maintenance requirements
— space requirements of device, filters etc.

Energy analysis may be undertaken using simulation modelling or spreadsheet calculations based on hourly conditions (see CIBSE AM11: *Building performance modelling* (2015c)). Table 2.13 compares a number of heat recovery devices as described below. Recent guidance on heat recovery is also given in BSRIA HRS 1/2009: *Heat Recovery Systems* (2009b).

Heat recovery within mechanical ventilation systems becomes economic when the value of the recovered heat or cooling outweighs the increase in fan capital and running costs, as well as those of the heat recovery equipment. The viability of heat recovery increases:

— as the number of air changes per hour increases and the heating/cooling season lengthens
— as the temperature difference between supply-and-extract airstreams increases
— with increased proximity of the supply-and-extract airstreams, although it can still be considered when they are not adjacent through the use of a run-around coil.

Table 2.13 Comparison of heat recovery devices (based on 'Chapter 8: Air-to-air energy recovery' in *ASHRAE Handbook: HVAC Systems and Equipment* (ASHRAE, 2008))

Device	Typical heat recovery efficiency / %	Typical face velocity / $m \cdot s^{-1}$	Cross-leakage / %	Typical pressure drop / Pa	Modulation control	Features
Recuperator	50 to 80 (sensible)	1 to 5	0 to 5	25 to 370	Bypass	No moving parts Easily cleaned
Run-around coil	50 (sensible)	1.5 to 3	0	100 to 500	Pump or bypass valves	Flexibility; exhaust airstream can be separated from supply
Thermal wheel	65 to 90 (total)	2.5 to 5	1 to 10	100 to 170	Wheel speed or bypass	Latent transfer Compact large sizes Cross air contamination possible
Heat pipe	50 to 65 (sensible)	2 to 4	0	100 to 500	Tilt angle down to 10% of maximum	No moving parts except tilt High cost, few suppliers
Regenerator	85 to 95 (sensible)	1.5 to 3	<1 to5	70 to 300	Regulating changeover period	Relatively high capital cost but high efficiency Self-cleaning action from flow reversal

Heat recovery can increase the overall pressure drop and subsequent fan power used by 50 per cent, although options such as double accumulators offer high heat recovery efficiencies and lower pressure drops.

When heat recovery devices are used in full fresh air systems, parasitic losses should be avoided in summertime operation by the use of a bypass. Effective damper control for minimum fresh air and free cooling on recirculation systems should be provided through enthalpy control.

2.3.4.3 Types of systems

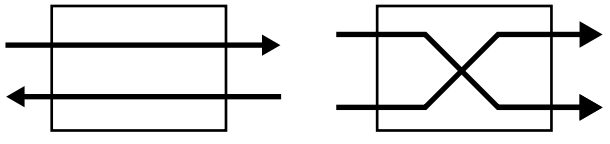
Various heat recovery systems are available, including the following.

Plate heat exchangers

These contain no moving parts and consist of separated interleaved flow channels through which the exhaust and supply air flows. The channel walls have high thermal conductance to facilitate the rapid transfer of heat (this makes little difference due to the limiting effect of the boundary layers). Maximum heat transfer is achieved with a counter-flow configuration (see Figure 2.19 (a)) in which the direction of flow of the exhaust air is in the opposite direction to the flow of the supply air. Practical heat transfer efficiencies of up to 90 per cent are possible from this configuration only with low velocities. In practical systems a cross-flow arrangement is commonly used in which the flow direction of the exhaust air is at right angles to the supply air (Figure 2.19 (b)). This results in slightly lower efficiency (typically up to 70 per cent) but permits a simple layout.

Run-around coils

Finned air-to-water heat exchangers are installed in the ducts between which the heat is to be transferred. A water or water/glycol (for freeze protection) circuit is used to transfer heat from the warm extract air to the cooler supply air (or vice versa in summer) (see Figure 2.20). An expansion tank is required to allow fluid expansion and contraction. Overall heat transfer efficiencies are relatively low, as it is a two-stage heat transfer process, and pump energy (in addition to the fan energy penalty) and maintenance costs need to be taken into account. However, the system is flexible in application, as it places no constraints on the relative location of the two airstreams and can be extended to include multiple sources and uses. They are suitable for applications where contaminants in the exhaust airstream prohibit recirculation.



(a) Counter-flow heat exchanger; theoretical heat transfer 100%

(b) Cross-flow heat exchanger; theoretical heat transfer 70%

Figures 2.19 Heat recovery devices: (a) counter-flow and (b) cross-flow (from *Guide to Ventilation* (AIVC, 1996) reproduced by kind permission of AIVC)

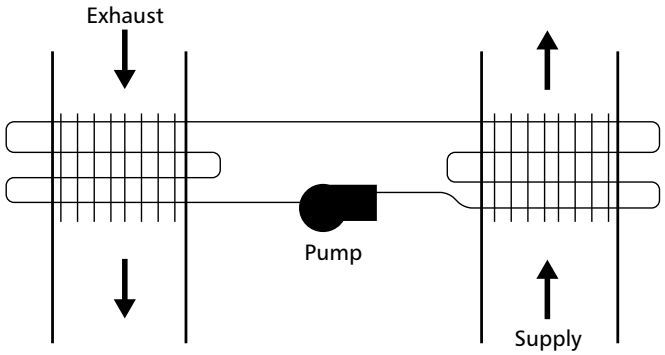


Figure 2.20 Run-around coil heat recovery method (from *Guide to Ventilation* (AIVC, 1996))

Modulation control can be achieved by pump operation and/or valve bypass arrangements on the coils. These consist of finned heat exchangers located in the supply and exhaust ducts. Heat transfer efficiencies can vary between 40 and 60 per cent.

Thermal wheels

A thermal wheel comprises a cylinder packed with a suitable heat transfer medium, which rotates slowly within an airtight casing that bridges the ducts between which heat is to be transferred (see Figure 2.21). Thermal wheels are generally quite compact and achieve high efficiencies due to a counter-flow configuration. The heat transfer properties are determined by the material contained in the wheel, i.e:

— *corrugated, inorganic, fibrous, hygroscopic material that transfers both sensible and latent heat:* air flows through the channels formed by the corrugations

— *corrugated metal (aluminium, stainless steel or Monel):* latent heat transfer is restricted to that resulting from condensation when the temperature of the heat transfer medium falls below the dew-point temperature of the warm airstream.

Maintenance requirements for the thermal wheel need to be taken into account, since they can be difficult to clean (Hamilton, 1986), as do the additional energy penalties due to the drive (although these are usually low).

Cross-contamination occurs by carryover and leakage. Carryover occurs as air entrained within the wheel is transferred to the other airstream. A purge section can be installed where recirculation is undesirable. Leakage occurs due to the pressure difference between the two airstreams. This can be minimised by avoiding large pressure

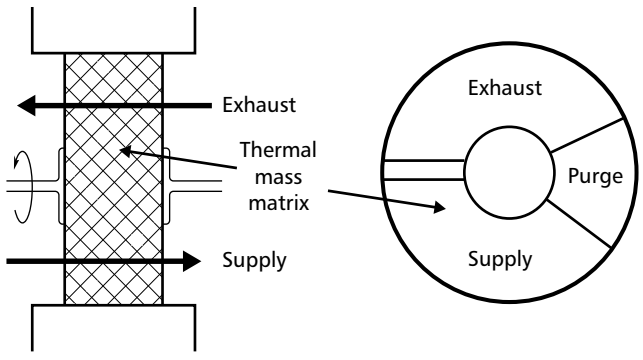

Figure 2.21 Thermal wheel (from *Guide to Ventilation* (AIVC, 1996) reproduced by kind permission of AIVC)

differences, providing an effective seal and placing the fans to promote leakage into the exhaust airstream. Hygroscopic media may transfer toxic gases or vapours from a contaminated exhaust to a clean air supply.

Modulation control is commonly achieved either by the rotational speed of the wheel or by bypassing the supply air. Heat recovery efficiency increases with wheel speed but is ultimately limited by carryover. This consists of a revolving cylinder packed with a coarse mesh of metal or other highly conducting medium. The cylinder passes through the extract and supply streams with the metallic medium passing heat from one to the other (see Figure 2.21). Some thermal wheel media are designed to absorb moisture thus enabling latent heat as well as sensible heat recovery. Thermal wheels are usually used in large building systems.

Heat pipes

The heat pipe is a passive heat exchanger of which there are two main types:

— *horizontal:* in which a wick within the tubes transfers liquid by capillary action

— *vertical:* in which heat from the warmer lower duct is transferred to the cold upper duct by means of a phase change in the refrigerant (see Figure 2.22).

Finned tubes are mounted in banks in a similar manner to a cooling coil. Face velocities tend to be low (e.g. 1.5 to 3.0 $m \cdot s^{-1}$) in order to improve efficiency. Modulation control is normally achieved by changing the slope, or tilt, of the heat pipe.

Regenerator

A regenerator (see Figure 2.23) consists of two accumulators (or a single unit split into two halves) with a damper arrangement to cycle the supply and exhaust airflows between the two. In the first part of the cycle, the exhaust air flows through and heats one of the accumulators. The dampers then change over so that supply air flows through and absorbs the heat from that accumulator. The second accumulator acts in reverse to match, heating the supply air in the first part of the cycle and absorbing heat from the exhaust air in the second. The changeover period is normally of the order of one minute.

Claimed sensible efficiencies for these systems can be quite high at 85 per cent. Latent efficiencies are normally significantly lower and vary with flow velocity and accumulator material. Modulation of the heat recovery efficiency can be achieved by regulating the changeover period.

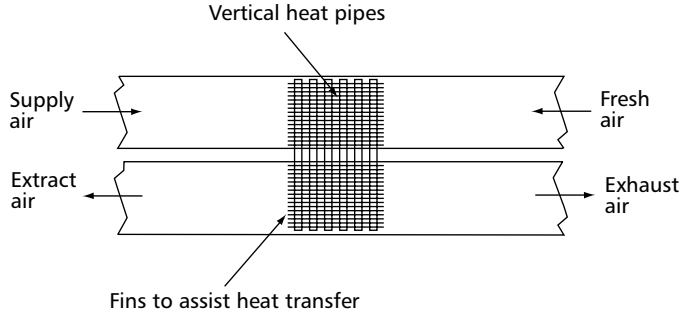

Figure 2.22 Vertical pipe heat arrangement

On damper changeover, the exhaust air contained within the damper, accumulator and exhaust ductwork reverses and becomes supply air. The length of exhaust ductwork should be minimised to limit this cross-leakage. The time required for damper changeover should be kept to a minimum using high torque dampers. Cross-leakage can range from below 1 per cent on well-designed systems to up to 5 per cent and above. Typical face velocities are 1.5 to 3.0 $m \cdot s^{-1}$. Reducing the velocity will reduce the pressure drop, but will have only a limited heat transfer benefit, as efficiencies are normally high anyway.

2.3.4.4 Advantages and disadvantages

Advantages

— Heat recovery efficiencies of up to 90 per cent means that a substantial proportion of lost heat from ventilation systems can be recovered. For this reason, significant importance has been attached to heat recovery systems.

— Flat plate heat exchangers are very reliable.

— Performance is best for very cold climates.

— Thermal wheels can be used to recover latent heat and can therefore have valuable applications in air-conditioned spaces.

— Run-around coils enable complex configurations to be considered. Also exhaust heat can be used for other purposes such as the pre-heat of water or connection to a heat pump.

— Properly sized systems can equal the efficiency performance of other system types.

Disadvantages

— Buildings need to be very airtight since infiltration adds to the overall air change rate and heat loss through infiltration is not recovered. This can adversely affect overall heat recovery performance. In addition, the quality of airtightness must be maintained throughout the operational lifetime of the building

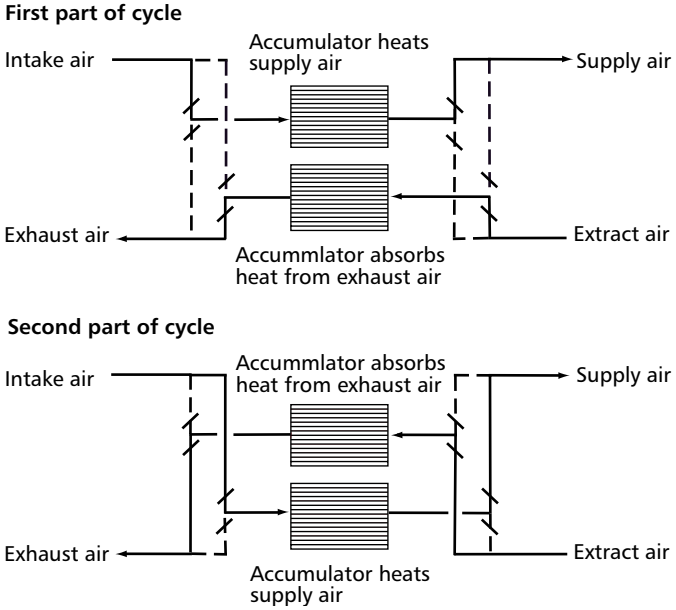

Figure 2.23 Regenerator

— The building must be mechanically ventilated; heat recovery does not work with natural ventilation.

— There are extra costs associated with installation, operation and maintenance.

— Leakage can occur between the supply and exhaust air in the case of thermal wheels. This can be reduced by including a purge zone.

2.3.5 Duct systems

2.3.5.1 Background

The purpose of duct systems is to convey air to and from spaces as part of a ventilation or air-conditioning system. Designers will need to ensure that the design criteria chosen for ductwork systems, associated air pressurisation devices and other in-line equipment can meet the requirements of Part L of the Building Regulations (NBS, 2013a). Any fire safety issues must also be considered to meet the requirements of Part B of the Building Regulations (NBS, 2013g). It is necessary, by law, to pass on all design, installation and actual position details for any fire protection under regulation 38 of the Building Regulations 2010 (TSO, 2010).

This section is intended to be used by practising designers who hold a basic knowledge of the fundamentals of building physics. As such, rigorous mathematical derivations of formulae are not given. Chapter 4 of CIBSE Guide C: *Reference data* (2007) provides detailed information on pressure drops in ducts and duct fittings. The quantitative data apply to the flow of clean air in ducts, but these may also be used for vitiated air where the concentration of contaminant gas is low. The airflow data should not be applied to the conveyance of particulates in ducts.

Constructional aspects of ductwork are not covered in detail. For the UK, reference should be made to the ductwork specifications published by the Building Engineering Services Association (BESA).

The designer must first fully map the design process that is being undertaken. The process for each application will be unique, but will follow the general format, as follows:

— problem definition

— ideas generation

— analysis

— selection of design solution.

Ductwork types and components are described in detail in section 2.6.7.

2.3.5.2 Strategic design issues

Background

The aim of this section is to provide a source of information on current practice in the design of ductwork for ventilation and air-conditioning systems. The information is intended to provide an overview of design criteria and application requirements.

Duct design must balance the need to minimise energy use and noise generation against space availability and the costs of materials and installation, whilst providing adequate means of access for installation, cleaning and maintenance. Materials, equipment and construction methods should be chosen with respect to the whole-life cycle cost of the installation. This is particularly important for new installations for which Part L of the Building Regulations (NBS, 2013a) sets down strict requirements for maximum fan power. The developing sustainability agenda is imposing new constraints on system performance and therefore designers need to look carefully at energy-efficiency issues.

Users of the environmental space serviced by the ductwork will require:

— sufficient air volume for ventilation

— sufficient air volume delivered and removed to provide either comfort conditions or conditions that satisfy the requirements of the process being served

— satisfactory temperature of delivered air

— satisfactory noise levels within the occupied space due to the ductwork installation

— visual impact of the ductwork in keeping with the internal environment and décor

— that on entry to the space, the air is well diffused and does not cause draughts

— satisfactory air quality

— access to fire-protection systems and equipment, such as fire dampers for cleaning and maintenance; under the Regulatory Reform (Fire Safety) Order (RRFSO) (TSO, 2005), records need to be kept of all such positioning, how to clean and maintain and records of such maintenance.

Classification of ductwork

Ductwork systems for ventilating and air-conditioning applications can be divided into low-, medium- and high-pressure systems.

High-pressure systems permit smaller ductwork but result in greater friction pressure drop, requiring the fan to generate higher pressures and noise generation. They are more expensive to install and, because of their greater input power requirements, are more expensive to run. This has led to a trend towards lower design pressures in systems.

Table 2.14 sets out the classification of ductwork systems followed in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a). The table also gives air leakage limits (see 'Air leakage limits' in section 2.3.5.2).

The duct air velocity is not a major factor in the constructional specification of ductwork. Recommended velocities for particular applications using these three system classifications are given in Tables 2.16 and 2.17.

It is permissible to operate these systems at velocities higher than the recommended values. DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) limits are up to 10 $m \cdot s^{-1}$, 20 $m \cdot s^{-1}$ and 40 $m \cdot s^{-1}$ in the cases of conventional low-, medium- and high-pressure systems respectively.

Table 2.14 Maximum positive and negative pressures and velocities for low, medium and high-pressure ductwork

System classification	Design static pressure / Pa		Maximum air velocity / $m \cdot s^{-1}$	Air leakage limit per m^2 of duct surface area* / $litre \cdot m^{-2}$
	Maximum positive	Maximum negative		
Low pressure (Class A)	500	500	10	$0.027 \times p^{0.65}$
Medium pressure (Class B)	1000	750	20	$0.009 \times p^{0.65}$
High pressure (Class C)	2000	750	40	$0.003 \times p^{0.65}$
High pressure (Class D)	2000	750	40	$0.001 \times p^{0.65}$

* where p is the static gauge pressure in the duct (Pa)

However, since pressure losses go up by square of velocity, thus impacting substantially on fan power, the use of higher velocities than those recommended is not likely to be economic, and the trend is towards lower air velocities.

Two factors influence velocity selection. First, for a given volume flow, velocities should fall as the size of the duct is reduced, to avoid increasing pressure gradients. Second, noise generation increases rapidly with increases in velocity at grilles, bends and other fittings where the flow separates from the walls, leaving turbulent eddies in its wake. The noise generated at grilles and terminals is of particular importance. High-velocity systems require noise control by using sound-absorbent units between the duct system and the room outlets and inlets.

Systems with design pressures outside the values given in Table 2.14 or where the mean duct velocity exceeds 40 $m \cdot s^{-1}$ should be treated as special and the designer will need to refer to the original references or other source material to confirm the appropriate design parameters.

Layout

In most installations, the constraints imposed by the building or other structures (e.g. single or multiple plant rooms, split systems based on tenancy arrangements etc.) and the siting of fans, plant items and terminals can lead to the adoption of an overall duct layout that is not ideal. Room must be given for the installation of fire dampers at compartment boundaries. This should also allow for access for maintenance. The performance of a system can also be adversely affected by a lack of care and thought in the arrangement and detailing of the ductwork. The designer and installer should be aware of the characteristics of airflow in ducts and fittings so that the objectives of the design are compromised as little as possible by the constraints imposed and by space restrictions. In general, good design should ensure that the air velocities are relatively uniform across the duct section and that the generation of eddies in ducts is minimised.

The site will often dictate the main routing of ductwork systems but in general the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid regulation and may reduce the number and variety of duct fittings that are needed.

The number of duct fittings should be kept to a minimum and there should be a conscious attempt to achieve some standardisation of types and sizes. Increasing the numbers and variety of fittings in a system can markedly raise its overall cost.

The shorter the ductwork length, the lower is the pressure drop. Distribution lengths are influenced by:

— the shape of the building

— the number and location of plant rooms

— the provision of space for distribution.

In large buildings or industrial plants a choice between a single distribution system and multiple smaller systems may arise. Large distribution systems and their plant can have the advantage of lower operating costs but require more floor space for vertical shafts. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage and difficulties in balancing during commissioning. Also, the pressure losses in long runs are likely to be higher, and a more expensive class of ductwork may be needed. Multiple smaller distribution systems may be more expensive in capital and operating costs but they avoid long runs, large ducts and vertical shafts, and this may reduce overall building costs.

Spatial requirements

Provision of sufficient space for ductwork is essential and must be addressed at an early stage in the design process of the building.

Laying out the space required for ductwork is, to an extent, an amalgam of experience, skill and three-dimensional visualisation. Adequate space must be provided for installation and maintenance of the ductwork and associated equipment, such as fire dampers at compartment boundaries. The designer should ensure that ductwork is co-ordinated with the other engineering services to be accommodated in the same space, particularly in false ceiling voids and riser spaces where there may be several distribution systems vying for restricted space.

Branches from vertical risers to serve horizontal distribution routes should be considered with care, as this is likely to be the most congested area of the service core. If the service core is enclosed on three sides (e.g. by a lift shaft and an external wall) the horizontal distribution from the core will be extremely difficult, with little space for installation and maintenance.

The area served by a single riser will dictate the size of the horizontal branch duct. The depth selected for a branch duct will have a significant influence on the false ceiling or raised floor depth. It will also affect the overall floor-to-floor heights and hence have significant influence on building costs.

The depth of the horizontal element is a function of the number of vertical risers, generally:

— maximum number of vertical risers equates to minimum horizontal element depth

— minimum number of vertical risers equates to maximum horizontal element depth.

Adequate space must be allowed around ducts for fitting of insulation, hangers and supports during installation and for access during subsequent maintenance. Access will also be dependent on the clearance from adjacent objects such as structural items and the type of jointing method. Suitable allowances are given in Appendix 2.A2, which also shows examples of common problems associated with ductwork access.

Adequate space must also be allowed at compartment boundaries for the installation of fire dampers using a tested installation method. The fire damper installation method to be used should be clearly defined as part of the ductwork/supporting construction design, so that it meets the fire classification of the boundary.

Ductwork clearances can be reduced with care, providing jointing, insulation and maintenance of any vapour barrier is achieved. Consideration should also be given to how the ductwork will be tested and how it will eventually be replaced.

Further information is available in Design and Maintenance Guide 08: *Space requirements for plant access, operation and maintenance* (DEO, 1996), BSRIA TN 10/92: *Spatial Allowances for Building Services Distribution Systems* (1992) and BS 8313: 1997: *Code of practice for accommodation of building services in ducts* (BSI, 1997).

Aesthetics

Where ductwork is hidden in risers, ceiling voids and below the floor it will not have an effect on the visual environment. In some situations, ducts can be large (e.g. 1–2 m in diameter) and difficult to locate within the overall building design. In such circumstances the ductwork may be exposed and possibly made an architectural feature. The design, including the shape, location and visual appearance, will need to be addressed to ensure sympathy with the visual environment.

Shopping centres, airports, auditoria, display galleries and large office complexes are possible examples where exposed ductwork may be used. Installation standards and sealing systems for such ducts may require more attention to the final appearance of the duct system than with ducts in concealed spaces.

Approximate sizing

Because ductwork can be large, it will often be necessary to assess the size of individual ductwork in critical locations, particularly where horizontal branches leave the main vertical risers. It is often possible to adjust the size of the vertical space well into the detailed design. Horizontal branches, however, cannot encroach on the necessary headroom.

To make a preliminary estimate of a branch size, calculate the airflow rate required in the area served by multiplying the zone volume by the number of air changes per hour and divide by 3600 to obtain the zone flow rate in $m^3 \cdot s^{-1}$. Two air changes an hour may be appropriate for offices with a separate heating system for fabric losses. Where the air is used for heating, four air changes an hour may be required or six air changes or more for an air-conditioned space. Dividing this flow rate by the velocity given in Tables 2.16 and 2.17 (in 'Duct air velocities' in section 2.3.5.3) gives the duct cross-sectional area required. For conventional systems, the aspect ratio (long side to short side) of rectangular ducting should not exceed 3:1.

Interaction with structure/building form

Because ductwork is likely to be the most space-intensive service provided, it is important that the ductwork design is fully co-ordinated with the design of the building structure to minimise the number of bends and other fittings, each of which will increase the resistance to airflow. The selection of the AHU is also critical (see section 2.6). This is particularly important for new installations for which, for example, Part L of the Building Regulations (NBS, 2013a) sets down strict requirements for maximum specific fan power. The structural design may have reached beyond an outline design and shape by the time that ductwork design commences.

Provided they are allowed for early in the design, it is usually possible to accommodate vertical ducts of any desired size without great difficulty from both structural and planning viewpoints. Horizontal ducts present more problems; if they are located between floors, headroom will be restricted and there will be limits on the floor area that a horizontal duct can serve. Early checks should be carried out to ensure that the vertical main ducts enable horizontal distribution without compromising the performance of the installation or the available headroom and that structural members allow branch ducts to leave the main ducts.

Distribution of the engineering services within a building are likely to follow a pattern associated with the main building circulation route, which represents the main functional pattern of the building. This may not be the most efficient route for the ductwork. The large space requirements for ductwork mean that it can be desirable to locate plant close to the areas they serve.

Sufficient space needs to be provided for ease of fitting the ductwork. Providing access for maintenance is also important since it will be expensive to install retrospectively, whether ducts are horizontal or vertical. Space should also be allowed for additions and alterations. This should include space to fit fire dampers that are suitable to any supporting construction used. The requirements of Part B of the Building Regulations (NBS, 2010g) should be followed. Details of fire damper installation methods are given in DW/145: *Guide to Good Practice for the Installation of Fire and Smoke Dampers* (BESA, 2010) and *Fire Dampers (European Standards)* ('the ASFP Grey Book') (ASFP, 2010).

Co-ordination of the engineering services should ensure that the area for removal of access panels and covers and entry into the ductwork is free of services and readily accessible without obstructions.

Zoning

Loads due to mechanical ventilation of a space are likely to be constant, and zoning, if appropriate, should be based on siting plant as centrally as possible to minimise the distance that the air has to travel. Strategic issues such as availability

of space for multiple plant rooms or the need for separate systems to service different tenants in the building may determine the zoning arrangements.

The ductwork system may be providing heating, cooling or air conditioning, in which case the load will change due to factors such as solar gain, occupancy and the use of lights.

If the loads throughout a building vary together (i.e. are in phase), or the variations are not large enough to cause the internal conditions to drift outside the acceptable limits, a single zone can be adopted. However, if different areas experience load changes that are out of phase, supply air must be provided at a rate or condition appropriate to each zone.

Most deep-plan buildings require division into perimeter and internal zones. The depth of perimeter zones mainly depends on the penetration of sunlight and daylight, which is determined by orientation, external shading, shape and size of windows, characteristics of the glass and the type and pattern of use of blinds. The depth of a typical perimeter zone is 3–6 m.

For a typical multiple-zone system with heating and cooling application, the following should be noted.

— For a constant volume flow rate to be maintained to each zone, the system must be capable of supplying air at various temperatures at any one time; this may involve simultaneous heating and cooling of supply air.

— All rooms with similar solar gain patterns can be zoned together provided that other variables are in phase. However, the number and position of the zonal sensors will be important. Corner rooms pose further problems.

— North-facing rooms experience less variation and can be grouped with internal zones for cooling provided that heating is dealt with by other means.

— Gains through poorly insulated roofs are similar to gains on south-facing surfaces but, if adequately insulated, they may be treated as intermediate floors.

The success of an air-conditioning system depends largely on appropriate zoning and careful positioning of sensors in relation to the sources of heat gains.

Air leakage limits

It is recommended as good practice that all significant installations (e.g. those with a fan capacity greater than 1 $m^3 \cdot s^{-1}$) should be tested in accordance with DW/143: *Guide to Good Practice: Ductwork Air Leakage Testing* (BESA, 2013b). Air leakage testing is required by Part L2A of the Building Regulations (NBS, 2013a). Air leakage testing of high-pressure ductwork is mandatory. Refer to BESA (2013b) for details of the testing procedure. Air leakage limits for the four classes of ductwork are given in Table 2.14. The leakage factors given for classes A, B and C are those for the classes similarly designated in European Standards BS EN 12237: 2003: *Ventilation for buildings. Ductwork. Strength and leakage of circular sheet metal ducts* (BSI, 2003a) and BS EN 1507: 2006: *Ventilation for buildings. Sheet metal air ducts. Requirements for strength and leakage* (BSI, 2006a).

Leakage from ducted air-distribution systems is an important consideration in the design and operation of ventilation and air-conditioning systems. A ductwork system having air leakage within defined limits will ensure that the design characteristics of the system can be maintained. It will also ensure that energy and operational costs are not greater than necessary.

Leakage from sheet metal air ducts occurs at the seams and joints and is therefore proportional to the total surface area of the ductwork in the system. The level of leakage is similarly related to the air pressure in the duct system and, whilst there is no precise formula for calculating the level of air loss, it is generally accepted that leakage will increase in proportion to pressure to the power of 0.65.

The effect of air leakage from high-pressure ductwork is critical in terms of system performance, energy consumption and the risk of high frequency noise associated with leakage. These problems are less critical with medium-pressure systems, but should be considered. Low-pressure ducts present the lowest risk in terms of the effect of leakage on the effective operation of the system.

It is important that ductwork should be made as airtight as possible. Conventional sheet metal ductwork is formed by seaming sheets and jointing sections; these seams and joints, penetrations made by damper spindles, control sensors, test holes, access doors etc. all give rise to air leakage. The designer should accept that some leakage will occur in conventional ductwork and make an assessment of the acceptable level in a given system. In some cases it may not be important, for example for a general extract system where the ducting is all in the space being served. In others it may be very important, for example where obnoxious or hazardous contamination is being handled. In the latter case a completely airtight system may be necessary, where fully welded ducting with airtight enclosures at all penetrations could be the basis of a special specification, outside the scope of DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a).

For most ventilating and air-conditioning applications, compliance with the construction and sealing requirements of DW/144 (BESA, 2013a) will ensure acceptably low leakage rates. For sheet metal ductwork, the specification requires sealant to be applied to all longitudinal seams (except spirally wound, machine-made seams) and cross-joints; for plastic and resin bonded, glass fibre ductwork, similar sealing requirements are specified. The sheet metal specification also gives details of an air leakage test procedure. Recommended acceptable leakage rates in $l \cdot s^{-1}$ per square metre of surface area are given in Table 2.14.

Appendix 2.A3 shows these limits for a range of duct static pressure differentials. These rates are in accordance with the comparable classes in BS EN 12237 (BSI, 2003a) and BS EN 1507 (BSI, 2006a) but these provisional European Standards do not cover the full range of high-pressure ductwork.

Whilst leakage occurs at seams, joints and penetrations, the purpose of giving acceptable leakage rates in terms of surface area of ductwork is to require that the airtightness is of a consistent standard for air leakage test systems. It does not follow that the total leakage of a system that meets specified leakage requirements will always be a set percentage of the total flow rate; the percentage leakage

from short runs can be substantially less than that from long runs. The design therefore plays a very important part in the likely total leakage loss from ductwork systems, since long runs not only provide more crackage and penetration, but also require higher working pressures to operate. Where limitation of air leakage is important, the designer should first ensure that the duct runs are as short as possible, that the operating pressure is as low as possible, that the number of seams, joints and penetrations is kept to a minimum and that there is adequate room around the ducts for site-made joints to be effectively sealed.

Items of equipment and plant installed in ductwork systems can also leak, and particular attention should be paid to the sealing of these items. Where leakage testing is required, the designer should ensure that suppliers of these items can demonstrate that their equipment meets the required airtightness standards. The designer should make adequate allowance in the fan selection for some air leakage so that the completed installation can meet its intended purpose without subsequent adjustments to the fan(s) and motor(s). Table 2.15 gives some recommendations for margins that should be included for complete installations (i.e. ductwork and equipment).

System leakage loss

There is no direct relationship between the volume of air conveyed and the surface area of the ductwork system. It is therefore difficult to express air leakage as a percentage of total air volume. Operating pressure will vary throughout the system and, since leakage is related to pressure, the calculations are complex. However, it is generally accepted that, in typical good-quality systems, the leakage from each class of duct under operating conditions will be in the region of:

— *low pressure* (Class A): 6 per cent

— *medium pressure* (Class B): 3 per cent

— *high pressure* (Class C): 2 per cent

— *high pressure* (Class D): 0.5 per cent.

Designer's calculations

The designer can calculate with reasonable accuracy the predicted total loss from a system by:

— calculating the operating pressure in each section of the system

— calculating the surface area of the ductwork in each corresponding pressure section

— calculating the allowable loss at the operating pressure for each section of the system (see above for indicative leakage figures).

Variable pressures in systems

Designers can achieve significant cost savings by matching operating pressures throughout the system to constructional standards and appropriate air leakage testing. The practice of specifying construction standards for whole duct systems based on fan discharge pressures may incur unnecessary costs on a project.

For example, some large systems could well be classified for leakage limits as follows:

— *plant room risers*: Class C

— *main floor distribution*: Class B

— *low-pressure outlets*: Class A.

Further information on air leakage is given in section 2.5.4.

Fan power energy requirements

Fan energy requirements are commonly specified in terms of specific fan power (SFP) which is defined in Building Regulations Approved Document L (NBS, 2013a) as 'the sum of the design total circuit watts including all losses through switchgear and controls such as inverters, of all fans that supply air and exhaust it back to outdoors (i.e. the sum of supply-and-extract fans) divided by the design ventilation rate through the building'.

Energy-efficiency requirements invariably specify maximum SFP values of typically of 2.0 W/litre·s^{-1} or less. Actual maximum SFP values should always be checked against the relevant current regulations such as Part L of the Building Regulations (NBS, 2013a).

The formula for calculating fan power is:

$$P_{\mathrm{ef}} = \frac{\Delta p_{\mathrm{t}}\, q_{\mathrm{v}}}{\eta_{\mathrm{o}}} \qquad (2.2)$$

where P_{ef} is the fan power (W), Δp_{t} is the difference in total pressure around the air circuit (Pa), q_{v} is the volume flow (m^3·s^{-1}) and η_{o} is the overall efficiency (%).

The selection of a fan type is primarily determined by the application and, where a choice is available, the most efficient should be chosen. Fans should be sized as close to the actual demand as possible in order to keep capital and running costs to a minimum. Motors should not be significantly oversized, as efficiency and power factor will reduce. Dependent on the fan type selected, the motor may be located within or external to the duct. Motors within the duct can increase the air temperature.

In general, centrifugal fans are more efficient, more controllable and quieter. Backward-curved centrifugal fans

Table 2.15 Recommended air leakage margins for design figures

Margin	Value of margin for stated class of system / %		
	Low pressure	Medium pressure	High pressure
System total pressure loss margin:	+10	+5	+5
(*a*) allowance for margin on volume flow rate	+10	+5	+5
(*b*) allowance for uncertainty in calculation	+10	+10	+10
(*c*) combined system total pressure loss margin (sum of (*a*) and (*b*))	+20	+15	+15

have high efficiency (up to 80 per cent) with aerofoil backward curved fans providing even higher efficiency. Maximum efficiency for axial flow fans is about 75 per cent. With all fans the efficiency varies with flow rate, so the chosen fan needs to have an operating point close to the point of peak efficiency. This is covered in more detail in section 2.6.

Fan characteristics should be matched to the chosen method of control of volume. This can be achieved by various means, such as variable speed motors to optimise fan performance at part load. Inlet guide vanes, disc throttles and dampers are not generally recommended for energy efficiency due to the 'throttling' effect.

In theory, fans can operate at better than 80 per cent efficiency but in practice less efficient units tend to be specified to save money or provide a safety margin. The loss of efficiency (termed 'fan gains') is dissipated as heat. This can result in an air temperature rise of up to 2 K, which can make the difference between a comfortable building and one that is too warm. Heat will also be dissipated into the ductwork from fan motors located in the duct.

Significant energy savings can be achieved by reducing unnecessary pressure drops in the system by careful sizing, routing and detailing of ductwork. In particular, pinch points in index runs require higher pressure drops than much of the rest of the system.

Variable flow control of air systems, which can be used on most distribution systems, can give considerable savings in fan energy. Variable flow control VAV systems have potentially greater air distribution savings over other central plant systems, provided that pressures are well controlled and air-handling plant and drives are intrinsically efficient.

Variable speed drives also allow rapid matching of fan duties during commissioning and will provide significant savings compared with manual regulation dampers. Typical energy savings are 20 per cent at 90 per cent flow and 40 per cent at 80 per cent flow, dependent upon characteristics. Damper control increases system resistance and therefore energy savings are reduced.

Energy can be reduced in ventilation systems by:

— avoiding unnecessary bends
— using bends instead of mitred elbows
— having a 'shoe' on the branch fittings for tees
— avoiding reduced duct size (i.e. maintain cross-sectional area)
— minimising duct length
— minimising the length of flexible ducting
— good inlet and outlet conditions either side of fan (see fan inlet and outlet below)
— using equipment with low pressure drops (i.e. filters, attenuators, heat exchangers).

Poor inlet and outlet conditions can cause poor fan performance, and hence inefficient operation, often referred to as 'installation effects'. These can alter the aerodynamic characteristics of the fan so that its full potential is not realised. This can be the result of practical difficulties installing the ductwork and associated equipment, which may not be in exact accordance with the original design routing. Measures to reduce installation effects at the fan inlet and outlet include the following.

(*a*) Fan inlet:

— Ensure that air enters axial fans without spin by improved inlet design or a by installing a splitter.
— Include turning vanes where there is a duct bend close to a fan inlet.
— Include a transition piece where the duct size reduces.
— Ensure flexible connections are correctly fitted without offset or slack.
— Where fans are installed in plenum chambers, ensure the fan inlet is a minimum of one diameter from the plenum wall with no obstructions.

(*b*) Fan outlet:

— Ensure a minimum of two diameters of straight duct.
— Where bends are close to the outlet, ensure that radius bends with splitters are used.
— Axial and propeller fans should preferably be fitted with guide vanes to provide energy recovery. (Where guide vanes are not fitted, air swirl will significantly increase system resistance, i.e. pressure drop. This can be corrected by a carefully designed cross-piece.)

Fan connections are considered in detail in section 2.6.1.

Environmental issues

For a typical air conditioned and mechanically ventilated building, fan energy can consume up to 8 per cent of the electrical consumption and therefore every effort must be made to ensure that the ductwork installation is energy efficient.

Cleaning of ductwork must be taken into account in the design and installation stages by ensuring adequate and safe provision is made for access. Clear guidance is given in BS EN 15780: 2011: *Ventilation for buildings. Ductwork. Cleanliness of ventilation systems* (BSI, 2011b).

Filter removal and replacement must be considered by ensuring sufficient space and means of access is provided. Noise in ductwork can be contentious, particularly where the system or components (e.g. intake, exhaust, AHU etc.) produce a noise nuisance to the building occupants, neighbours or passers-by. Noise is generated where eddies are formed as flow separates from a surface. The generated noise level is particularly sensitive to the velocity. See section 2.5.2.3 and section 2.6 for further details.

The visual effect of ductwork can be an environmental issue because of its physical size and location. Whilst ductwork may be hidden in risers, ceiling voids and below the floor, there will be occasions where it is exposed and possibly made an architectural feature. The design, including the shape, location and visual appearance will need to be addressed to ensure sympathy with the visual environment. Where ducting is exposed, the installation

standards may require additional attention, particularly to jointing and sealing.

Fire issues

The ventilation system will have fire safety requirements, mainly at compartment boundaries.

Where a standard ventilation duct passes through a supporting construction (wall or floor) designed as a fire compartment boundary, that penetration is required to be protected. This is achieved by using a fire damper specifically tested using an installation method to suit the particular wall (masonry, blockwork, dry wall partition, etc.) or floor that is being used. The classification of the fire damper should meet that of the supporting construction being penetrated by the duct. Fire dampers selected to protect escape routes and areas of sleeping risk are required to act in response to a smoke alarm signal, not just their integral fusible links. They are also required to have an 'ES' classification. To achieve this fire dampers have to have been tested to BS EN 1366-2: 2015: *Fire resistance tests for service installations. Fire dampers* (BSI, 2015a) and classified to BS EN 13501-3: 2005 + A1: 2009: *Fire classification of construction products and building elements. Classification using data from fire resistance tests on products and elements used in building services installations: fire resisting ducts and fire dampers* (BSI, 2005b). ES-classified fire dampers are generally known as fire and smoke dampers.

Fire dampers in other areas should have a minimum 'E' classification (BS EN 1366-2 (BSI, 2015a) and BS EN 13501-3 (BSI, 2005b)) and may close simply under the action of a fusible link.

In the case where all fans are to be turned off in the event of fire, dampers tested to BS 476-20: 1987/BS 476-22: 1987 (BSI, 1987a/b) may be allowed. Note, however, that fire dampers tested to these standards cannot be classified ES, so they must never be used to protect escape routes.

In all cases fire dampers shall be installed following the methods provided by the fire damper manufacturer in line with their testing. Care shall be taken to make sure that there is room to do this and that there is adequate access to the damper for maintenance and cleaning, inside and out.

Further information on fire dampers is available in and *Fire Dampers (European Standards)* ('the ASFP Grey Book') (ASFP, 2010) and DW/145: *Guide to Good Practice for the Installation of Fire and Smoke Dampers* (BESA, 2010).

Where fire-resisting ductwork is used, care must be made that this is installed in the supporting construction using the method of installation recommended by the manufacturer.

Where fire-resisting ductwork is used to protect fire compartments, the junction where it passes through a supporting construction (wall or floor) designed as a fire compartment boundary, the method of sealing the penetration must be made using the method of installation recommended by the manufacturer. This should be proven by using a fire-resisting duct specifically tested using an installation method to suit the particular wall (masonry, blockwork, dry wall partition etc.) or floor that is being used. The classification of the fire-resisting duct shall meet that of the supporting construction being penetrated by it.

Additional restrictions may be specified for the duct in terms of leakage or insulation.

To demonstrate performance, fire-resisting ducts should been tested to BS EN 1366-1: 2014: *Fire resistance tests for service installations. Ventilation* (BSI, 2014a) and classified to BS EN 13501-3: 2005 + A1: 2009 (BSI, 2005b) or tested as a minimum to BS 476-24: 1987: *Fire tests on building materials and structures. Method for determination of the fire resistance of non-loadbearing element of construction* (BSI, 1987c).

Further protection may be made by the use of fire dampers at the end of fire-resisting duct runs.

Further information on fire-resisting ductwork is available in *Fire Rated and Smoke Outlet Ductwork* ('the ASFP Blue Book') (ASFP, 2000).

Where fire doors are used for ventilation, held open by magnetic catches that release on the receipt of a smoke alarm, it must be checked that the equipment meets the required standards and that all closers are correctly tested and set up. All fire doors, frames and associated ironmongery should be installed using the methods defined by the manufacturer. It is recommended that approved installers are used. It should not be assumed that double-leaf doors have the same fire resistance as single-leaf doors and that the inclusion of glazing has been tested; this should be checked.

Further information of fire doors is available from the British Woodworking Federation (BWF) and the Guild of Architectural Ironmongers (GAI).

Guidance to the building regulations with regard to fire safety is given in Part B of the Building Regulations (NBS, 2013g), supported by BS 9999: 2008: *Code of Practice for fire safety* in *the design, management and use of buildings* (BSI. 2008a). The latter document generally replaces the BS 5588 series. This is supported by CIBSE Guide E: *Fire engineering* (CIBSE, 2010).

Consideration should also be made of the RRFSO (TSO, 2005). This states what is required for a building user to certify their own fire safety. This is generally done by risk assessment, but requires full records of design, selection and maintenance. Supporting this is Part J of the Building Regulations (NBS, 2013f), which requires that all information related to fire safety should be passed on the client/building user. This is represented by, but not limited to, information such as required maintenance schedules, as-built drawings etc. A building regulation is a legal requirement.

Note: It is now required that any fire-resisting products used are subject to third-party certification and are CE marked.

Smoke control

Smoke control is a much broader subject, but it must be noticed that, in the same way as normal ventilation ducts, fire compartments should not be compromised.

Smoke control design requires specialist advice using fire-engineered solutions for the most part. Reference should be made to Approved Document B with supporting documentation being provided from other sources. CIBSE

Guide E: *Fire engineering* (CIBSE, 2010) gives further guidance. A range of other guides are also available from the BRE, ASFP and the Smoke Control Association (SCA).

— BRE Report BR 186: *Design Principles for Smoke Ventilation in Enclosed Shopping Centres* (BRE, 1990).

— BRE Report BR 368: *Design Methodologies for Smoke and Heat Exhaust Ventilation within Atria* (BRE, 1999a).

— BRE Report BR 375: *Natural Ventilation in Atria for Environment and Smoke Control: An Introductory Guide* (BRE, 1999b).

— BRE Project Report 213179: *Smoke Ventilation of Common Access Areas of Flats and Maisonettes (BD2410): Final Factual Report* (BRE, 2005).

— *Fire Rated and Smoke Outlet Ductwork* ('The Blue Book') (ASFP, 2000), European version.

— *Guidance on Smoke Control to Common Escape Routes in Apartment Buildings (Flats and Maisonettes)* (HEVAC, 2012).

— *Design of Smoke Ventilation Systems for Loading Bays and Coach Parks* (HEVAC, 2010).

Any and all equipment used should be checked to confirm compliance with the latest European Standards.

Note: It is now required that any smoke control products used are subject to third-party certification and are CE marked.

Weight of ductwork

The weight of ductwork, including insulation where applied, is normally insignificant in relation to the structural support capability of the structure. In some types of buildings the weight of the ductwork may be important (e.g. lightweight retail, storage and factory structures). Examples of the types of problems are insufficient support centres from which to hang the ductwork and lightweight purlins that are unable to support the weight of the installed ductwork. Sufficient structural support for fans must be provided. Information on the weight of ductwork materials is given in 'Weight of ductwork' in section 2.3.5.2.

Testing, commissioning, cleaning and maintenance

It is essential for duct systems to be commissioned, kept clean and regularly maintained. These issues are considered in relation to HVAC systems in general in section 2.7.1.

Controlling costs

Lower first costs can be achieved by:

— using the minimum number of fittings possible; fittings can be expensive and the resulting pressure loss is far greater than for straight duct sections

— ensuring ductwork is sealed to minimise air leakage; this allows reduction in both equipment and ductwork size

— using round ductwork where space and initial costs allow because it offers the lowest duct friction loss for a given perimeter or given velocity

— when using rectangular ductwork, maintaining the aspect ratio as close as possible to 1:1 to minimise duct friction losses and initial cost; this can also avoid problems with 'difficult' elbows.

2.3.5.3 Design criteria

Introduction

The primary function of a ductwork system is to convey air between specific points. In fulfilling this function, the duct assembly must perform satisfactorily within fundamental performance characteristics. One of the most important performance characteristics is energy efficiency. This aspect is particularly relevant because changes to Part L of the Building Regulations (NBS, 2013a) imposed new performance constraints on air-moving systems and equipment. Early in the process, designers need to ensure that their design can meet the overall performance requirements of Part L. The energy-efficiency standards of Part L should not be regarded as an absolute target. In many situations, an improved level of performance may be beneficial in terms of whole-life cost and/or as a means of providing a trade-off opportunity to offset against another aspect of the design where achieving the required standard of energy efficiency is more difficult or more costly.

Elements of the assembly include an envelope (e.g. sheet metal or other material), reinforcement, seams, joints, support hangers and, possibly, insulation. Performance limits must be established for:

— dimensional stability

— containment of air

— vibration

— noise generation and containment

— exposure to damage, weather, temperature extremes

— support

— emergency conditions, e.g. fire

— heat gain or loss to the airstream

— adherence to duct walls of dirt and contaminants.

Due consideration must be given to the effects of differential pressure across the duct wall, airflow friction pressure losses, dynamic losses and air velocity leakage, as well as the inherent strength characteristics of the duct components. Ductwork installations can account for a significant proportion of the cost of mechanical services. Ducts should be sized and constructed in accordance with recognised sources of data and standards of construction.

Duct air velocities

The velocity of air flowing through a duct can be critical, particularly where it is necessary to limit noise levels. The duct air velocity is not a major factor in the constructional specification of ductwork.

Recommended velocities for particular applications, using the BESA system classifications, are given in Tables 2.16 and 2.17. These figures are a general guide and assume reasonable distances between the fittings (e.g. four times the duct hydraulic diameter). Higher velocities may be

used if additional attenuation is employed. Maximum velocities, as stated in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) are given in Table 2.14.

Table 2.18 gives recommended maximum air velocities for rectangular and circular ducts in risers and ceiling spaces. Table 2.19 gives recommended velocities for supply and return air openings.

Legislation

No legislation has been produced that relates specifically to ductwork. The general requirements of the Health and Safety at Work etc. Act (HMSO, 1974) and the Construction (Design and Management) Regulations 2015 (TSO, 2015) will apply during all the stages of design, installation, commissioning, operation, maintenance and finally demolition and disposal. Part L of the Building Regulations (NBS, 2013a) includes limitations on specific fan power. These are described in 'Fan power energy requirements' in section 2.3.5.2. Part B of the Building Regulations (NBS, 2013g) gives full details on fire-safety issues with regard to ductwork and fire dampers. Building Regulation 38 requires that all information on all aspects of fire protection, installation, positioning, maintenance etc. be passed on to the building owner. The latter is the law.

Health and safety

Health considerations will be addressed if a good inspection, maintenance and cleaning regime is applied. Further information on cleaning is provided in section 2.7.2.3.

Three aspects of safety concerning ductwork need to be addressed:

— *During design*: that there are safe and secure means of access to the ductwork and associated plant and equipment (e.g. filter housings) for inspection, maintenance and cleaning.

— *During installation*: by ensuring that the ductwork can be installed safely and securely.

— *During building operation*: that maintenance and fire protection are maintained.

Fibrous materials were often used as duct linings to provide sound absorption. However, they are not now generally used because:

— they can contribute to mould growth

— fibrous materials degrade with time

— fibres can erode from the surface and be carried in the air

— fibrous materials are difficult to clean.

Suitable alternative sound-absorbing proprietary materials such as acoustic foam are now used and have the advantage of not requiring facings or edge treatment.

2.3.5.4 Airflow in ducts

General

Air in ducts follows natural laws of motion. While the detailed prediction of flow behaviour is very difficult, good design should ensure that the air follows the line of the duct with uniform velocities and that excessive turbulence is avoided. Ductwork fittings cause major pressure losses and good design is essential, particularly where higher velocities are used. Bad design in relation to airflow can lead to vibration of flat duct surfaces, increases in duct pressure losses, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of

Table 2.16 Recommended maximum duct velocities for low-pressure ductwork systems where noise generation is the controlling factor

Typical applications	Typical noise rating (NR)*	Velocity / m·s^{-1}		
		Main ducts	Branch	Run-outs
Domestic buildings (bedrooms)	25	3.0	2.5	<2.0
Theatres, concert halls	20–25	4.0	2.5	<2.0
Auditoria, lecture halls, cinemas	25–30	4.0	3.5	<2.0
Bedrooms (non-domestic buildings)	20–30	5.0	4.5	2.5
Private offices, libraries	30–35	6.0	5.5	3.0
General offices, restaurants, banks	35–40	7.5	6.0	3.5
Department stores, supermarkets, shops, cafeterias	40–45	9.0	7.0	4.5
Industrial buildings	45–55	10.0	8.0	5.0

* See CIBSE Guide A (2015a), Table 1.16

Table 2.17 Recommended maximum duct velocities for medium and high-pressure systems

Volume flow in duct /m^3·s^{-1}	Velocity / m·s^{-1}	
	Medium-pressure systems	High-pressure systems
<0. 1	8	9
0.1–0.5	9	11
0.5–1.5	11	15
>1.5	15	20

Table 2.18 Guide to maximum duct velocities in risers and ceilings

Duct location	Duct type	Maximum air velocity / m·s^{-1} for stated room type		
		Critical	Normal	Non-critical
Riser or above plasterboard ceiling	Rectangular	5	7.5	10
	Circular	7	10	15
Above suspended ceiling	Rectangular	3	5	6
	Circular	5	7	10

Table 2.19 Maximum velocity for supply and return air openings (grilles and terminals)

Supply or return air	Permitted air velocity / m·s^{-1}		
	Critical	Normal	Uncritical
Supply	1.5	2.5	3
Return	2	3	4

installed plant items such as fans and dehumidifying coils. It is much cheaper to get the design right than to try and correct abnormal flow situations on-site.

Behaviour of air flowing through a duct

In normal circumstances the flow of air in ducts is turbulent with the flow generally in the direction of the duct axis. Eddies and secondary motions will result in energy dissipation due to internal fluid friction. Streamlines will not be parallel to the duct centre-line. In unobstructed straight ducts, eddies give rise to only relatively small transverse components of the duct velocity and the flow velocities are symmetrical about the duct axis.

Disturbance to the flow arising from obstructions, duct fittings or other components has two major effects:

— the eddies can be significantly larger in size and their velocities much higher

— the flow velocities across the duct become asymmetrical, i.e. much higher velocities can occur in part of the duct section, whilst in other parts even reverse flow may occur.

From the point of view of duct design the important aspects of the effects of disturbance to airflow are:

— increased pressure loss due to creation of eddies

— increased pressure loss as high-velocity air mixes with low-velocity air

— noise generated by the interaction on eddies with the inner surfaces of the ducts.

More information on the flow characteristics through duct components and fittings is given in section 2.6.

Heat gains or losses

In a duct system, the air temperature change can be significant, e.g. when passing through an untreated space. This has the effect of reducing the heating or cooling capacity of the air and increasing the energy input to the system. The heat transmission to and from the surrounding space can be reduced by insulation of the ducts. The following notes give guidance on the estimation of temperature changes in ducted air due to heat gains or losses.

The heat gain or loss rate through the walls of a run of air ducts is given by:

$$\Phi = U A_s (t_{ad} - t_{as}) \qquad (2.3)$$

where Φ is the heat exchange (W), U is the overall thermal transmittance ($W \cdot m^{-2} \cdot K^{-1}$), A_s is the surface area of the duct run (m^2), t_{as} is the ambient temperature outside the duct (°C) and t_{ad} is the temperature of the air inside the duct (°C).

The temperature of the air inside the duct is given by:

$$t_{ad} = {}^1/_2 (t_{ad1} + t_{ad2}) \qquad (2.4)$$

where t_{ad1} is the air temperature in the upstream end of the duct run (°C) and t_{ad2} is the air temperature in the downstream end of the duct run (°C).

The duct surface area is given by:

$$A_s = P \times l \qquad (2.5)$$

where A_s is the duct surface area (m^2), P is the perimeter of the duct cross section (m) and l is the length of the duct run (m).

The heat gain or heat loss rate given by equation 2.3 is equal to the heat gain or loss rate from the air in the duct, which is given by:

$$\Phi = c A \circ c_p \Delta t_{ad} \times 10^3 \qquad (2.6)$$

where c is the velocity of the air in the duct ($m \cdot s^{-1}$), A is the cross-sectional area of the duct (m^2), ρ is the density of air in the duct ($kg \cdot m^{-3}$), c_p is the specific heat capacity of air in the duct at constant pressure ($kJ \cdot kg^{-1} \cdot K^{-1}$) and Δt_{ad} is the temperature difference between the ends of the duct run (K).

Δt_{ad} is given by:

$$\Delta t_{ad} = t_{ad1} - t_{ad2} \qquad (2.7)$$

Equating equations 2.2 and 2.5 and rearranging gives:

$$\Delta t_{ad} = \frac{U P (t_{ad} - t_{as}) l}{c A \circ c_p 10^3} \qquad (2.8)$$

or:

$$\Delta t_{ad} = \frac{4 U (t_{ad} - t_{as}) l}{c \circ c_p d_h 10^3} \qquad (2.9)$$

where d_h is the hydraulic mean diameter of the duct (m).

The hydraulic mean diameter is given by:

$$d_h = 4A / P \qquad (2.10)$$

For air at 20 °C, $\rho = 1.2$ $kg \cdot m^{-3}$ and $c_p = 1.02$ $kJ \cdot kg^{-1} \cdot K^{-1}$. Hence, by substituting these values and combining the numerical factors:

$$\Delta t_{ad} = \frac{U (t_{ad} - t_{as}) l}{306 c d_h} \qquad (2.11)$$

Ignoring the thermal resistance of the duct material, the U-value of the insulated duct is given by:

$$U = \frac{1}{(1/h_{si} + l_n/\lambda_n + 1/h_{so})} \quad (2.12)$$

where h_{si} is the heat transfer coefficient of the inside surface of the duct ($W \cdot m^{-2} \cdot K^{-1}$), l_n is the insulation thickness (m), λ_n is the thermal conductivity of the insulation ($W \cdot m^{-1} \cdot K^{-1}$) and h_{so} is the heat transfer coefficient of the outside surface of the duct ($W \cdot m^{-2} \cdot K^{-1}$).

The value of h_{si} is a function of the Reynolds number and an approximate value is given by:

$$h_{si} = 3.5\,(c^{0.8} / d_h^{0.25}) \quad (2.13)$$

For most typical applications, h_{si} may be taken as 37.5 $W \cdot m^2 \cdot K^{-1}$. The value of h_{so} also depends on the conditions surrounding the duct. A typical value for unvented building voids is 10 $W \cdot m^{-2} \cdot K^{-1}$, but this can be influenced by reflective facing materials on the insulation and by draughts. Estimated values of U for insulated ducts with these values of h_{si} and h_{so} are given in Table 2.20.

The temperature change in an insulated duct can be estimated from equation previous 2.11 and Table 2.12. For insulation with thermal conductivity of 0.045 $W \cdot m^{-1} \cdot K^{-1}$ values of $(\Delta t_{ad}/l\,(t_{ad} - t_{as}))$ are given in Figure 2.24. The approximate values for an uninsulated duct are also shown in Figure 2.24, for typical still locations, but these temperature changes could be underestimated by about 20 per cent if the duct is in draughty conditions.

Example 2.1

For a 600 mm × 500 mm duct with 50 mm of thermal insulation (λ_n = 0.045 $W \cdot m^{-1} \cdot K^{-1}$), an air velocity inside the duct of 9.5 $m \cdot s^{-1}$ and an air temperature t_{ad} = 10 °C, passing through surroundings at t_{as} = 30 °C, the change in air temperature per metre run is calculated as follows.

Cross sectional area of duct:

$$A_s = 0.6 \times 0.5 = 0.3\ m^2$$

Perimeter of duct:

$$P = 2\,(0.6 + 0.5) = 2.2\ m$$

Hydraulic diameter of duct:

$$d_h = (4 \times 0.3)/2.2 = 0.55\ m$$

Hence:

$$d_h\,c = 0.55 \times 9.5 = 5.23\ m^2 \cdot s$$

From Figure 2.24:

$$\Delta t_{ad}/l\,(t_{ad} - t_{as}) = 0.0005\ m^{-1}$$

Hence the change in air temperature per metre of duct run is:

$$\Delta t_{ad} = 0.0005 \times 20 = 0.01\ K \cdot m^{-1}$$

For an uninsulated duct, from Table 2.20:

$$\Delta t_{ad}/l\,(t_{ad} - t_{as}) = 0.004\ m^{-1}$$

Therefore:

$$\Delta t_{ad} = 0.004 \times 20 = 0.08\ K \cdot m^{-1}$$

Since this method assumes that Δt_{ad} is small, some error will be introduced if the length of ductwork is considered large, and the smaller the value of $(d_h \times c)$, the larger the error. A maximum length of 10 m is recommended. It may be noted from Figure 2.24 that as the value of $(d_h \times c)$ falls below 1.5, the rate of temperature drop in the ducts with 50 mm or less insulation increases considerably. For small ducts and low air velocities, the insulation thickness should be at least 50 mm. BS 5422: 2009: *Method for specifying thermal insulating materials for pipes, tanks, vessels, ductwork and equipment operating within the temperature range –40 °C to +700 °C* (BSI, 2009b) gives guidance on the assessment of the economic thickness of duct insulation. However, in the absence of such assessment, BS 5422: 2009 recommends insulation thicknesses for ducts carrying chilled and warm air as shown in Tables 2.21 and 2.22 respectively. For detailed information on the thermal insulation of ductwork, see BS 5422: 2009 and BS 5970: 2012: *Thermal insulation of pipework, ductwork and other industrial installations in the temperature range –100 °C to +870 °C. Code of practice* (BSI, 2012b).

2.3.5.5 Condensation and vapour barriers

Condensation of water vapour within air occurs whenever the temperature falls below the ambient dew-point. This can occur on the outside of the cold duct when the temperature of the duct air causes the duct itself to have a temperature below the dew-point of the surrounding air. Even when the ductwork is insulated, this can occur due to diffusion through the insulation of the more humid air external to the duct. In turn this can lead to corrosion of the ductwork as well as diminishing the thermal resistance of the insulation, leading to more condensation.

Vapour sealing will be required where the temperature of the air within the duct is at any time low enough to promote condensation on the exterior surface of the duct and cause moisture penetration through the thermal insulation. In this case the most important requirement is to limit penetration of the seal. The vapour barrier must be carefully installed to ensure the seal is continuous with no routes for penetration of humidity.

BS 5970: 2012 (BSI, 2012b) warns of the risk of condensation within the layer of insulation, which is primarily used to avoid condensation on its outside surfaces. With a suitable choice of insulation material and thickness, the surface temperature of the ductwork can be raised sufficiently above the ambient dew-point temperature to avoid surface condensation on the duct.

The extent of any vapour sealing of ductwork thermal insulation and the support method to be used should be clearly specified in advance by the designer.

Table 2.20 Estimated *U*-value for insulated ducts

Thermal conductivity of insulation / $W \cdot m^{-1} \cdot K^{-1}$	*U*-value (/$W \cdot m^{-2} \cdot K^{-1}$) for given thickness of insulation/mm

Minimum air temp. inside duct/°C	Minimum thickness of insulating material (mm) for stated thermal conductivity λ (/W·m^{-1}·K^{-1}) and external surface emissivity ε								
	$\lambda = 0.04$			$\lambda = 0.045$			$\lambda = 0.05$		
	$\varepsilon = 0.05$	$\varepsilon = 0.44$	$\varepsilon = 0.9$	$\varepsilon = 0.05$	$\varepsilon = 0.44$	$\varepsilon = 0.9$	$\varepsilon = 0.05$	$\varepsilon = 0.44$	$\varepsilon = 0.9$
15	29	15	10	32	17	11	36	18	12
10	52	26	17	58	29	19	64	33	21
5	75	38	24	83	42	27	92	47	30
0	96	49	31	108	56	35	120	61	39

Notes: (*a*) assumes ambient conditions of 25 °C still air, 80% relative humidity, dew-point temperature 21.3 °C; (*b*) thicknesses calculated in accordance with BS EN ISO 12241: 1998: *Thermal insulation for building equipment and industrial installations* (BSI, 1998) based on 0.6 m vertical flat surface of rectangular duct but are also adequate for horizontal surfaces; (*c*) Thermal conductivity values of insulating materials quoted at mean temperature of 10 °C.

Table 2.22 Indicative thickness of insulation for ductwork carrying warm air to control heat loss (based on BS 5422: 2009: (BSI, 2009b))

Surface emissivity	Thermal conductivity of insulation (mm) for stated thermal conductivity λ (W/·m·K)							Maximum permissible heat loss / W·m^{-2}
	$\lambda = 0.020$	$\lambda = 0.025$	$\lambda = 0.030$	$\lambda = 0.035$	$\lambda = 0.040$	$\lambda = 0.045$	$\lambda = 0.050$	
Low ($\varepsilon = 0.05$)	17	21	25	29	33	38	42	16.34
Medium ($\varepsilon = 0.44$)	21	26	31	36	41	46	51	16.34
High ($\varepsilon = 0.90$)	22	27	33	38	44	49	54	16.34

Notes: (a) heat loss relates to specified thickness and temperature; *(b)* insulation thickness in this table has been calculated according to BS EN ISO 12241: 1998 using standardised assumptions: horizontal duct at 35 °C, with 600 mm vertical sidewall in still air at 15 °C, emissivity of outer surface of insulated system as specified.

The thickness of insulation to prevent surface condensation can be determined from the following approximate equations governing solid state heat transfer:

For rectangular ducts:

$$l_n = \frac{(t_{ds} - t_{ad})\lambda}{(t_{as} - t_{ds})h_{so}} \qquad (2.14)$$

where l_n is the insulation thickness (m), t_{ds} is the ambient dew-point temperature of the air outside the duct (°C), t_{ad} is the temperature of the air inside the duct (°C), λ is the thermal conductivity of the insulation (W·m^{-1}·K^{-1}), t_{as} is the ambient temperature outside the duct (°C) and h_{so} is the heat transfer coefficient of the outside surface of the duct (W·m^{-2}·K^{-1}).

Example 2.2

Calculate the thickness of glass wool ($\lambda = 0.045$ W·m^{-1}·K^{-1}) to prevent surface condensation on a circular duct of diameter 0.8 m, carrying cooled air at 12 °C, exposed in a ceiling void at 35 °C with relative humidity of 85%.

From a psychrometric chart, for a dry bulb temperature of 35 °C and 85% RH:

$$t_{ds} = 32.1\ °C$$

Taking h_{so} as 10 W·m^{-2}·K^{-1}, using equation 2.14, the required thickness is:

$$l_n = \frac{(32.1 - 12) \times 0.045}{(35 - 32.1) \times 10} = 0.030\ \text{m} = 30\ \text{mm}$$

Table 2.21 recommends an insulation thickness of 50 mm. Hence the glass wool thickness required for vapour resistance is less than that recommended for thermal insulation and surface condensation should not arise under these operating conditions.

Vapour barriers

In normal circumstances the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the insulation thickness for vapour resistance may be larger than that for heat resistance. When cold ducts pass through areas of high dew-point, carefully selected vapour barriers should be applied externally to the

insulation. Well-installed vapour barriers with sealed joints will minimise vapour penetration and combat the risk of internal condensation in the insulation. It is good practice to provide 'nominal' vapour barriers to cold ducts or to use thermal insulation with a low value of permeability, even when the insulation thickness for vapour resistance is less than that which is recommended for thermal resistance. Although polystyrene foam provides a high resistance to vapour transfer, other thermal insulation materials, for example rock wool, have minimal vapour resistance (see Hayden and Parsloe (1996), Table 3.49).

There are three main types of vapour barrier:

— *rigid barriers*: such as reinforced plastics and sheet metal, which are erected by mechanical means with sealed joints and suitable protection to resist impact damage

— *membrane barriers*: such as metal foils, plastic films and coated papers, which are easier to install and are in many cases available as backing material with heat-resisting insulation but are more easily damaged

— *coating barriers*: which are usually available as paints, hot melts, pastes or powders with chemical hardeners.

Vapour barriers need to be effective and continuous. The slightest leak will permit water vapour to diffuse throughout the insulation. It is therefore imperative that cracks in vapour barriers due to poor workmanship or thermal forces are avoided. This is not normally a significant problem because Δt is often small.

A common problem is that accidental damage to barriers caused by maintenance workers is subsequently not rectified.

2.3.5.6 Duct and plenum design

Air terminal devices will only perform as intended if the approach velocity is even. If the duct connections and/or volume flow regulators created eddies at the terminal, the following problems may arise:

— unpredictable throw, spread and drop

— breakdown of Coanda effect

— high noise levels

— balancing is difficult or impossible.

Design procedures for duct and plenum connections to various types of air terminal are given elsewhere (HEVAC, 2000); also see section 2.6.8.

If the ceiling is to be used as an exhaust plenum, it is important to create a uniform negative pressure throughout the whole ceiling void to ensure even exhaust throughout all terminals. This is particularly important where exhaust is by means of air-handling luminaires, the performance of which varies with airflow rate. Ceiling voids should be made as large as possible and, if

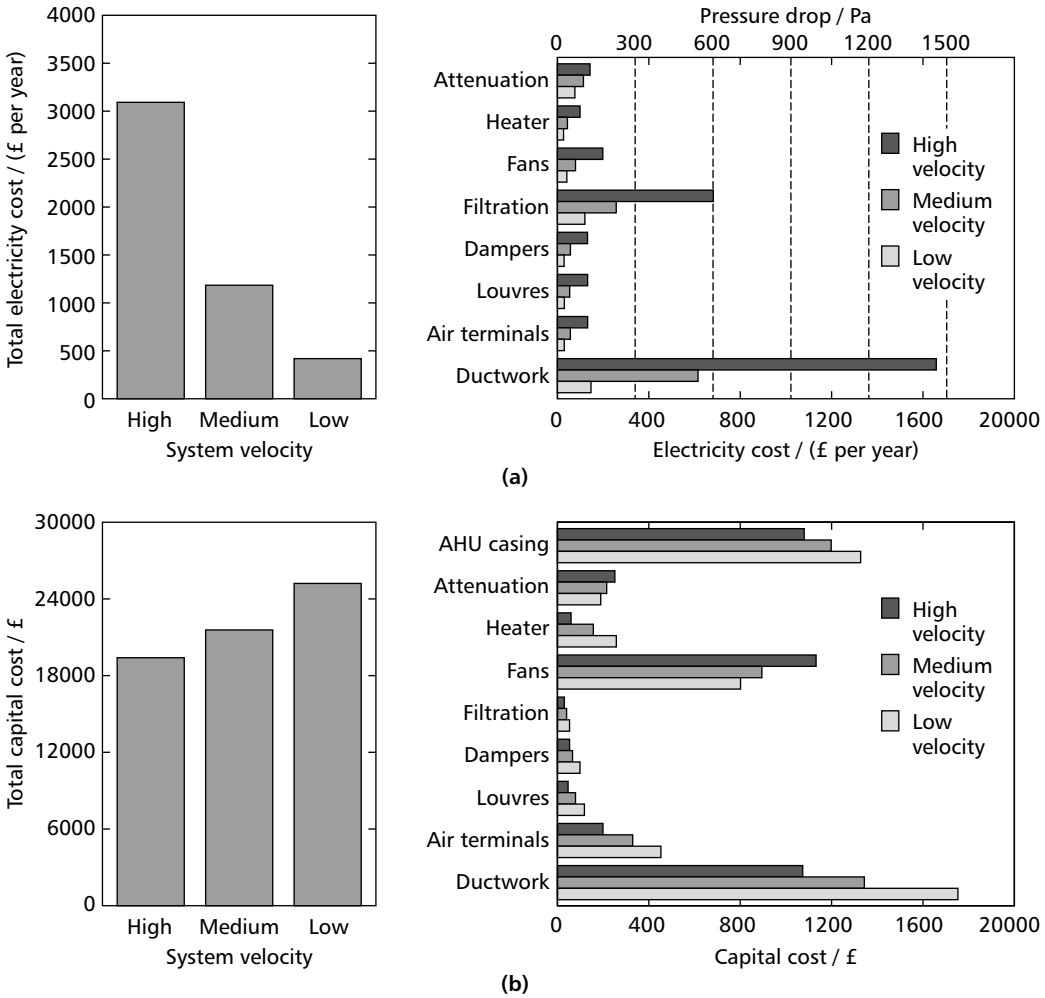

Figure 2.25 Comparison of high, medium and low-velocity systems (Action Energy, 1997); (a) electricity costs (b) capital costs

obstructed by luminaires, ductwork etc., exhaust stub ducts should be provided to ensure even exhaust over the full ceiling area.

2.3.5.7 Ductwork and system velocities

Optimising duct design is essential for achieving energy efficiency. For optimum energy efficiency ductwork should have as large a cross-sectional area as possible to produce low-velocity systems and reduce system pressure drops. Figure 2.25 which is based on Jackman (1990) and Good Practice Guide GPG 257 (Action Energy, 1997) illustrates the running and capital costs for systems having different design air velocities. These figures show how the running costs are reduced for low-velocity systems and how some components become more expensive while others become cheaper. The benefits of the energy-efficient (i.e. low-velocity) system include a reduction in electricity costs of approximately 70 per cent, while the additional capital cost is recovered in under five years.

The basis of the comparison is as follows:

— all systems supplying 2 $m^3 \cdot s^{-1}$ of air

— all systems supplied by a centrifugal fan operating at an efficiency of 70 per cent

— pulley and motor efficiencies of 90 per cent and 80 per cent respectively

— electricity cost: 10 pence per kW·h

— annual run time: 3000 hours

— noise levels less than 40 dBA.

In a low-velocity system, the AHU face velocity would typically be less than 2 $m \cdot s^{-1}$ with the main duct velocity less than 3 $m \cdot s^{-1}$. In a medium-velocity system these figures would become 2–3 $m \cdot s^{-1}$ and 5 $m \cdot s^{-1}$ respectively. In a high-velocity system the AHU velocity would typically be greater than 3 $m \cdot s^{-1}$ with the main duct velocity at 8 $m \cdot s^{-1}$.

Air leakage from ductwork should be minimised to prevent the wastage of fan power. Ductwork should be insulated accordingly and runs through unoccupied spaces should be minimised. Testing of ductwork air tightness should be undertaken (see DW/143: *Guide to Good Practice: Ductwork Air Leakage Testing* (BESA, 2013b)).

Good duct design should achieve airflow that is as uniform as possible throughout the ductwork run to reduce the pressure drop. To achieve this:

— changes to the direction of the flow should be minimised

— where possible 2–3 diameters of ductwork should be allowed either side of components before changing direction

— radius bends should be used in preference to right-angled bends

— Y-junctions should be used in preference to T-junctions

— turning vanes should be used wherever appropriate

— for rectangular ductwork, the aspect ratio should be as close to unity as possible.

Ductwork noise is considered in more detail in sections 2.5.2.3 and 2.6.7 and CIBSE Guide B4 (CIBSE, 2016c).

Noise

Noise should be prevented from getting through to the occupied spaces. Design features in support of this objective, which largely correspond to those required for energy efficiency, include the following:

— a low air velocity in the ductwork

— the use of round ducts

— the use of bends with large internal radii

— smooth transitions and changes in flow direction

— the use of low-noise control vanes

— low air leakage.

2.3.6 Ventilation control systems

2.3.6.1 General

Control systems are essential to maintain air quality, thermal comfort and energy efficiency. Increasingly, a wide variety of controls are becoming available that are appropriate for both mechanical and natural ventilation systems. Controls incorporate a variety of sensors and actuators that enable optimum operating conditions to be maintained.

In designing a control system the following should be taken into account.

— Ensure fairness and consistency of control by avoiding occupants being unduly affected by controls from which they do not benefit.

— Provide rapid acting controls that give feedback to occupants to demonstrate response.

— Make sensible decisions with regards to the choice of manual versus automatic control (manual overrides should be provided where practical); any automatic change in state should happen gradually to avoid feelings of discomfort.

— Remove unnecessary complexity by providing controls that are simple and well labelled.

Further guidance on these issues can be found in Bordass *et al.* (1995, 1999).

2.3.6.2 Sensors

Typical sensors for automatic control may include:

— CO_2 sensors for occupant generated pollutant

— gas sensors to monitor specific gasses that may be present in a space

— humidity sensors

— passive infra red (PIR) sensors to detect the presence of occupants

— temperature sensors to control thermal comfort and natural cooling

— solar gain sensors for feed forward control to increase ventilation when gains are high.

In addition, sensors for natural ventilation include:

— wind-speed sensors to throttle back vent openings at high wind speeds

— rain sensors to indicate potential driving rain problems

— wind direction sensors to optimise vent opening

2.3.6.3 Sensor location

The positioning of sensors to obtain representative readings is very important. Important considerations are outlined below.

CO_2 and gas sensors

These should be placed to provide a representative value of room space conditions. In a well-mixed mechanically ventilated space sensors may be placed at the extract where they can provide direct feedback to the supply air. It is important not to locate the sensor directly in the breathing zone where a distorted reading can be obtained. Typically a CO_2 sensor might be set at about 1000 ppm. Inevitably some flexibility in operating range must be acceptable such that, for example, this threshold is maintained on average but can be allowed to drift, for example, to 1400 or 1500 ppm. The outdoor concentration needs to be checked and allowance made by setting the threshold proportionately higher if the outdoor concentration is above approximately 400 ppm. Typically 400 ppm is the concentration in open country but it could exceed 500 ppm in city centres.

Temperature sensors

Internal temperature sensors should not be too close to windows as incoming fresh air may not have mixed with the room air and the sensed condition may not therefore be representative. Again, for mechanical ventilation control, exhaust air temperature should be included in the control loop. External temperature sensors should not be placed on sunny walls that can absorb solar radiation and elevate the sensor reading throughout the 24-hour cycle.

In view of the vertical temperature gradients associated with displacement ventilation systems (see section 2.8.2), the room air temperature sensor is best placed at about head height in a location free from significant draughts.

Humidity sensors

Humidity sensors and associated controls are typically located in 'wet' zones to control humidity levels and prevent humid air from reaching other parts of a building. They are also used to control humidity levels in air-conditioned buildings where they are linked to humidifiers and dehumidifiers as necessary. This is covered in detail in CIBSE Guide B3 (2016a).

Actuators

Automatically controlled openings could be modulated, open/shut, have intermediate fixed positions or open in sequence where a number of vents serve a common zone. Operation should be a function of prevailing weather conditions as well as the required ventilation rate since these will influence the driving forces. Wind speed override may be required to prevent excessive ventilation under windy conditions.

Manual control is the most common form of control. It provides occupants with increased personal control over the environment in their workspace, a factor often associated with increased occupant satisfaction. Control (Willis *et al.*, 1995) should be:

— territorial, positioned locally and, ideally, affect a single person

— intuitive

— accessible.

2.3.6.4 Control of volume airflow rate

Volume airflow rate control may be achieved by the following means:

— *Damper*: normally of the butterfly or multi-leaf type and capable of controlling the volume. The main distribution dampers are located to fine balance airflows through legs of the ductwork (assuming that the ductwork has been sized on static regain principles). Typically these dampers are required to provide a pressure drop across the damper of between 50 and 100 Pa. If the pressure drop is higher, there will be a tendency to generate excessive noise, which will require the introduction of a downstream silencer. Normally these dampers are supplied as separate components for direct installation in the ductwork and not as part of an air terminal device. With multiple air terminal devices on a duct leg dampers can also be supplied as integral accessories on the rear of the air terminal device to provide a final terminal balance; typically in this application the dampers provide 10 to 40 Pa pressure drop. Due to the energy inefficiency of damper control, dampers should no longer be used as a primary method of fan duty control. In both applications, final adjustment is carried out manually on-site.

— *Pressure regulating valve*: an assembly consisting of one or two rows of shaped blades, the size of which changes when volume adjustment is required. Because of the particular blade shape, the device gives volume adjustment up to pressure drops of about 600 Pa without generating excessive noise, however a downstream silencer may still be required for a low-noise environment. The majority of dampers are set on-site, but they can be controlled from a static pressure-sensing element. Such units are generally supplied as a separate component for direct installation in the ductwork and not as part of a terminal unit.

— *Mechanical volume controller (air terminal unit)*: a unit that is self-actuating and capable of automatically maintaining a constant pre-set volume flow rate through it independent of upstream duct pressure. The minimum pressure drop across the air terminal unit depending on size varies from 100 to 50 Pa and typically up to a maximum of about 500 Pa. As the supply air pressure increases, most devices of this

type tend to close the airway progressively by means of a butterfly, single or multi-blade damper in the airway. As such an air terminal unit achieves volume reduction by reducing the airway, there is a tendency to generate noise, particularly when working at high air pressures. For this reason, the air terminal unit is generally supplied either with additional acoustic cladding and a separate secondary silencer or the air terminal unit has these features integrated into a single factory-supplied unit. It is factory pre-set to pass a specific volume and, when installed, will automatically give a pre-balanced air distribution system up to and including the air terminal unit. It can be adjusted on-site if required. With the addition of a sensing system and an actuator, this type of air terminal unit can be used for variable volume applications where the flow supplied at the dictates of the sensing system is again independent of upstream duct pressure.

2.3.6.5 Control of temperature

This may be achieved by the following means:

— *Blending*: two separate airstreams, one warm and one cool, are supplied to a zone and mixed in a terminal unit to produce a supply air temperature that offsets the zone cooling or heating loads.

— *Reheat*: controlled reheat of a pre-conditioned, low temperature air supply by means of hot water, steam or electric coils, may be used to give a resultant supply air temperature that will satisfy the zone requirement.

2.3.6.6 Control options for natural ventilation openings

Control options for natural ventilation openings should be specified with the needs of the occupants in mind. Control mechanisms for natural ventilation opening include the following.

Window/damper actuators

A number of different actuator types are available for window control. These are electrically driven and include chain, helical cable, piston and rack and pinion type actuators. Because of their linear action, the last two types suffer some disadvantage because they protrude into the space. The actuator will have to cope with the weight of the window and with any wind forces. The use of vertically pivoted windows minimises the effect of the weight of the window but they are less efficient as ventilators. If dampers are used, conventional control mechanisms (pneumatic or electric actuators) can be considered. More details are provided in CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005).

Sensors

Any automatic control system must be regulated in response to signals from appropriate sensors. Equipment to be specified includes the following:

— *Temperature sensors*: room temperature sensors may be sufficient to indicate excessive ventilation rates because of the influence of ventilation on room temperature. However this approach will need to be integrated with heating system controls to avoid the two systems fighting each other. Other control parameters may be required as well as temperature.

— *Wind sensors*: wind speed sensors (anemometers) can be used to reduce window opening as wind speeds increase in order to maintain a nominally constant ventilation rate. They may also be used in conjunction with rain sensors to give an indication of potential ingress of driving rain. Wind direction sensors can be used to shut exhaust vents on the windward side of a building and simultaneously open leeward vents in order to avoid back-draughts.

— *Solar sensors*: solar sensors (pyranometers) can be used to indicate periods of high solar gain. The sensor must integrate the gain over a certain period to avoid hunting during periods of patchy cloud.

— *Rain sensors*: windows and vents may need to be closed during periods of rainfall to prevent ingress of water. Typical sensors include the 'tipping bucket', which collects rainfall and tips over at a certain level. Each tipping action generates a pulse, the frequency of which can be used to determine the intensity of the rainfall. An alternative approach is to use a device whereby the capacitance changes as the area of moisture on its surface increases. The sensor is heated to dry off the surface when the rain stops.

— *Air-quality sensors*: several approaches to measuring air quality have been used. These usually rely on taking a particular pollutant as indicator for the overall air quality. CO_2 and humidity sensors have been most commonly used; the former in commercial buildings and the latter in residential buildings where condensation is a bigger problem.

— *Occupancy sensors*: infrared sensors that detect movement have been used to identify the presence of occupants and adjust ventilation rates (and lighting etc.) accordingly. Further details on the application of these sensors can be found elsewhere (Oughton and Wilson, 2015).

Air conditioned buildings will have quite complex control mechanisms to ensure optimum operation. When various areas to be air conditioned have differing heat gain patterns with respect to time, these can be met from a central plant in which either the temperature or volume (or both) of the air supplied to each area is varied to meet the particular requirements of the area. Such temperature or volume control may be carried out in ductwork serving a number of rooms or zones, or may be carried out in the terminal units feeding individual rooms. Control strategies include the following.

2.3.6.7 Control options for mixed-mode ventilation

In the case of a mixed-mode system, it is also important to remember that the control characteristics of windows differ from the 'designed' characteristic of HVAC dampers and coils. The control authority of a window is low and non-linear or proportional, hence the use of sophisticated control algorithms will not bring greater accuracy. Given the pulsing effect of the wind or natural ventilation,

continuously correcting automatic controls should be avoided and the control's response slowed.

The reactions of the occupants to the control systems must also be allowed for in terms of:

— the provision of intuitive user interfaces and control strategies

— adverse reactions to systems that appear to operate in a capricious manner noticeable by changing noise levels or creating a draught

— giving occupants the ability to override automatic controls manually and the impact on system performance

— providing a rapid response to a requested control action.

Elements of the following control sub-strategies may be included:

— *Normal working day control*: where mechanical cooling is switched on when a predetermined temperature is exceeded.

— *Seasonal control*: where, for example, the building is sealed in peak winter and summer conditions under mechanical operation but runs freely during spring and autumn.

— *Top-up/peak lopping control*: where mechanical cooling is switched on only at times of peak load.

— *Pre/post-occupancy space conditioning*: where selected areas prone to overheating may be cooled outside of working hours to ensure that the space temperature is the minimum acceptable at the start of the working day.

— *Overnight cooling*: where the building thermal mass is utilised either through natural or mechanical means, see section 2.4.2.4.

— *Moisture control*: where exposed direct cooling such as chilled ceilings or chilled beams are used.

— *Ventilation control*: where carbon dioxide (CO_2) sensors are used as a surrogate indicator of occupancy levels to switch on mechanical ventilation when the level exceeds a pre-set value and occupants have not elected to open windows.

2.3.6.8 Control of displacement ventilation systems

The main forms of control are as follows.

— *Constant supply air temperature, constant airflow rate*: in which the supply air temperature is maintained at a constant design value selected to be at least 1 K below the required zone mean air temperature. Variations in heat gain will affect the temperature gradient within the space so that, provided the maximum heat gain does not create a temperature gradient in excess of comfort limits, acceptable conditions will be maintained.

— *Constant supply air temperature, variable airflow rate*: the supply airflow rate may be adjusted to accommodate higher variations in heat load and maintain a substantially constant temperature gradient within the occupied zone. This adjustment can be automatically controlled to maintain a constant difference between the room air temperature and supply air temperature.

— *Variable supply air temperature*: this form of control is not as effective in displacement ventilation systems as it is in mixed-flow systems because the supply air temperature required to maintain an acceptable mean room air temperature is not so directly related to internal heat gains.

Using a control system to maintain substantially constant thermal conditions within a room requires a temperature sensor located in a position that provides a reading that is representative of the occupied zone. In view of the vertical temperature gradients associated with displacement flow, the room air temperature sensor is best placed at about head height in a location free from significant draughts.

2.3.6.9 Energy-efficient control of mechanical ventilation systems

Increased system efficiency, i.e. reduced specific fan power, can be achieved by the following measures.

— Select efficient fans (see section 2.6.1).

— Select appropriate attenuation, filtration and heat-recovery devices to reduce system pressure drops (see sections 2.3.3 and 2.3.4).

— Choose appropriate ductwork and system velocities to reduce system pressure drops (see section 2.3.5.3).

— Vary the volume of air through the system, e.g. through the use of two-speed or variable-speed fans (as covered, for example, by Part L of the Building Regulations (NBS, 2013a) for fans rated above 1100 W. This can be achieved through variable speed drives or inlet guide vanes. (The latter technique is not recommended due to its relative inefficiency.) Further information on variable speed fans is available in GIR 41: *Variable Flow Control* (Action Energy, 1996).

— Ensure local extraction by the appropriate location of plant in order to minimise duct runs and hence fan power.

— Use intelligent zoning to avoid the system operating to suit the needs of one small area.

— Switch off systems when they are not in use or not required. Systems may run for longer than intended for a various reasons, e.g. controls may have been overridden and not reset afterwards; automatic controls (e.g. frost thermostats or hidden hardware or software interlocks) may have switched on systems unnecessarily as a consequence of poor setting, calibration or programming. Suitable fault detection should be incorporated, e.g. by reporting the running hours of devices and systems during periods when they are programmed to be off.

— Appropriate coverage of a building by mechanical ventilation, i.e. using natural systems where applicable (mixed-mode approach) (see section 2.3.2.4).

— Control fan operation according to occupancy in both variable and constant volume systems.

— Log hours of operation of systems to identify if systems are operating unintentionally, particularly outside the occupied period. Anticipatory systems (e.g. for optimum start or night cooling) are prone to such behaviour.

— Take care to avoid parasitic loads that may increase energy consumption. Examples include heat-recovery systems that break down unnoticed (or continue to operate when cooling is required); 'free-cooling' control systems that introduce the wrong proportions of outside air; and unnecessary heating of air intended for night cooling. Ideally, the performance of such systems should be automatically monitored against the design intentions. Alternatively, systems can be designed deliberately to allow such technical problems to become noticed.

— The supply of air to a space can be controlled by a number of manual or automatic means. The most popular options are:

  — *CO_2 sensing*: useful in buildings where there are wide variations in the ventilation requirement, e.g. bingo halls, cinemas, theatres and meeting rooms

  — *temperature sensing*: useful where it may be advantageous to increase the flow of air when conditions are favourable to take advantage of free cooling

  — *humidity sensing*: fresh air rates can be increased when internal humidity levels are too high, an option used for example in areas where moisture is produced, e.g. kitchens and bathrooms

  — *occupancy sensing*: this enables systems to be switched off when rooms are not occupied.

2.3.6.10 Fire damper control systems

There is a variety of additional systems that give control to fire dampers, either as simple systems to close them on alarm or more sophisticated systems that allow smoke and heat exhaust or area pressurisation. These need to be considered as part of the design process and the latter systems need a very clear cause-and-effect schedule to make sure they achieve what they have been designed to do.

2.4 System design

2.4.1 Introduction

This section is not intended to provide step-by-step design guidance but to summarise the key issues and performance targets that need to be addressed during design. The guidance contained in this section should be read in conjunction with CIBSE Guides A (2015a) and F (2012). For details of refrigeration methods, see CIBSE Guide B3 (2016a).

System design starts with decision making, taking into account the needs of the occupier and any planning requirements. Energy and environmental impact also play an important part of the decision-making process. A typical selection approach is presented in Figure 2.26. From this the designer will make a choice between a natural or mechanical system and identify zones that may be suitable for mixed-mode ventilation.

2.4.2 Designing for natural ventilation

In the case of natural ventilation important factors relating to the driving forces and the configuration of openings must be considered. Full guidance is given in CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005).

A key issue to consider is the need to take into account all operational regimes—winter and summer, as well as night ventilation and passive cooling if required. Ventilation strategy should be considered on the basis of the whole building rather than just room by room, although each individual room case needs close attention to ensure the efficiency of the proposed design. Circulation areas such as stairwells or corridors can be used as plenums or supply ducts, although care must be taken to avoid these routes acting as 'short circuits'. Compliance is also needed with fire and smoke regulations as outlined in section 2.5.3.

Consideration must be given to where the fresh air will be brought from (see section 2.6.5), for example it may be beneficial to draw the air from one side of the building to:

— avoid noise and traffic fumes from a busy road

— maximise benefit from wind velocities.

Guidelines for minimising the ingress of external pollution are given in Kukadia and Hall (2011).

The magnitude and pattern of natural air movement through a building depends on the strength and direction of the natural driving forces and the resistance of the flow path as described in section 2.3.2.2.

Fresh air requirements are based on occupant needs (see section 2.2.3) and/or pollutant loads (see section 2.2.2). Airflow rates for cooling will normally be based on a summertime temperature prediction using some form of thermal analysis and also on thermal gains such as from processes and equipment use (see section 2.2.4).

2.4.2.1 The BREEAM requirements for natural ventilation

In addition to the guidelines on natural ventilation, given in section 2.3.2.2, BREEAM (2014) also gives guidance aimed at achieving an excellent environmental rating. A range of supporting guidance documents are being released and the BREEAM website should be consulted. BREEAM is an internationally recognised rating scheme covering the environmental performance of buildings, which sets performance criteria for installed ventilation systems. In the case of the natural ventilation of office-type buildings, the criteria state that: natural ventilation strategy performance must be demonstrated via *either* of the following.

(*a*) The openable window area in each occupied space is equivalent to 5 per cent of the gross internal floor area of that room/floor plate. For room/floor plates 7–15 m in depth, the openable window area is on

opposite sides and evenly distributed across the area to promote adequate cross-ventilation.

(*b*) The design demonstrates (by calculation, using ventilation design tool types recommended by CIBSE AM10: *Natural ventilation in non-domestic buildings*) that the natural ventilation strategy provides adequate cross flow of air to maintain required thermal comfort conditions and ventilation rates.

For a strategy that does not rely on openable windows, or that has occupied spaces with a plan depth greater than 15 m, the design must demonstrate (by calculation in accordance with requirement (*b*) above) that the ventilation strategy can provide adequate cross flow of air to maintain the required thermal comfort conditions and ventilation rates.

2.4.2.2 The design process

The design of a natural ventilation system should take account of the following steps.

— Assess the potential for natural ventilation (see Figure 2.26). Factors include:

  — availability of fresh air

  — minimising problems associated with outdoor noise

  — suitability of building.

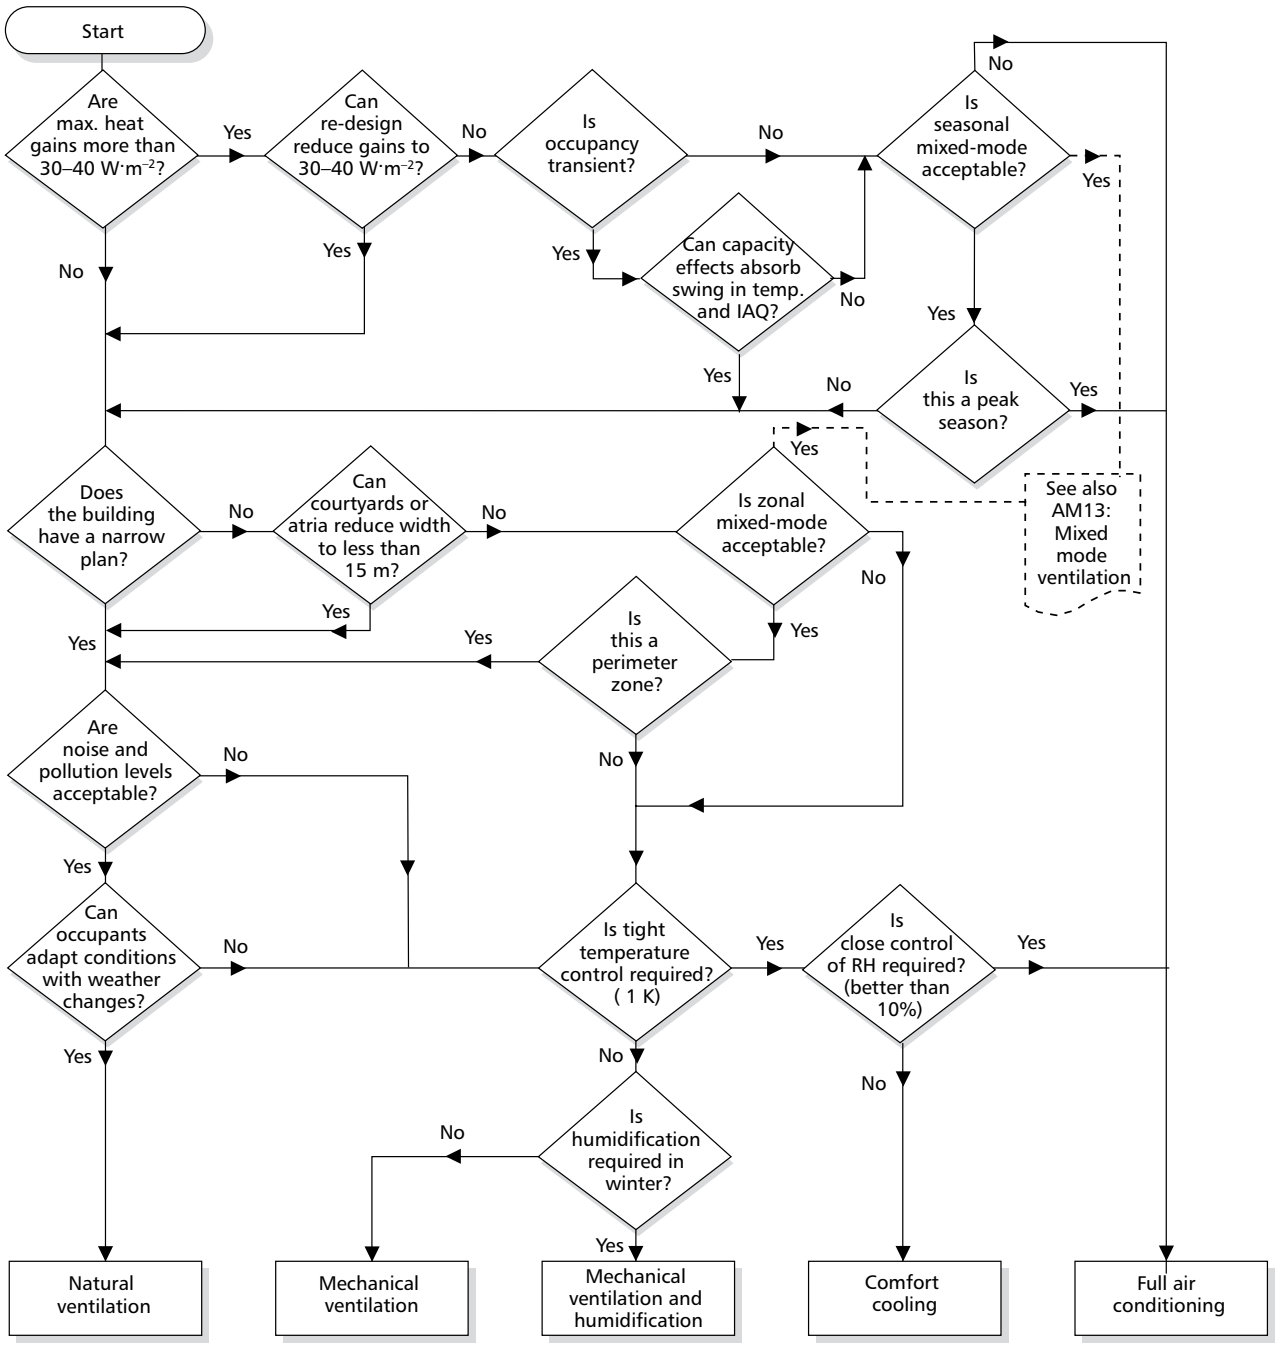

Figure 2.26 Decision-making process (from CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005))

— Determine ventilation rates required for fresh air (see section 2.2.3).

— Determine the requirements for cooling needs (see section 2.2.4).

— Based on local weather data consider the optimum driving forces (wind, stack or combined) for the building.

— From fresh air and cooling need calculate the size and location of openings. Initial estimates can be determined from the calculation equations given in CIBSE Guide A (2015a) and CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005). More detailed analysis using multi-zone, computational fluid dynamics (CFD) modelling or wind tunnel and flume scale modelling may be required for complex buildings (see section 2.4.6).

— Plan the use of windows, vents, passive stacks and wind towers.

— Plan interaction building form, e.g integration with thermal mass (see section 2.4.2.4).

— Identify a control strategy (see section 2.3.6).

— Plan flexibility for future needs including mixed-mode ventilation and mechanical cooling.

2.4.2.3 Meeting thermal comfort and cooling needs

If the internal heat gain rises above approximately 40 W/m^2, natural ventilation on its own may be inadequate and a strategy involving mechanical assistance may be required (BMI, 1999). Table 2.23 illustrates how the design of the building fabric might be adapted to meet this target (BMI, 1999). However, this table is indicative of a scale only and will vary depending on the characteristics of the particular building and on the freedom or otherwise allowed to the designer to maintain thermal comfort within acceptable limits using these design features. If natural ventilation is to be used for comfort cooling, control of heat gains into the occupied space is a prerequisite. Thus measures must be taken to reduce solar and internal heat gains during warm periods in order to maximise periods of thermal comfort. Advantage needs to be taken of adaptive thermal comfort criteria to enable a temperature spread to be applied.

The ability to open windows to provide increased air movement can provide a beneficial cooling effect in summer (see chapter 1 of CIBSE Guide A (2015a)). However, the high ventilation flow rates associated with summer conditions can cause nuisance draughts that may disturb papers etc. This can be reduced by specifying that the openable part of the window to be above desk height.

The minimisation of draughts is a particular issue for natural ventilation systems in winter. The potential problem can be reduced in a number of ways such as:

— providing multiple trickle ventilators (or similar)

— using specially provided ventilation openings positioned so that the air is warmed before reaching the occupied space (e.g. behind a radiator or in a floor void with a suitable convector heater)

— using a separate natural ventilation system that can pre-heat the air such as a combined weather louvre, control insulated damper, heating coil and internal grille system.

Table 2.23 Relationship between design features and heat gains

Design features	Total heat gains*/W·m^{-2} floor area			
	10	20	30	40
	Minimum room height/m			
	2.5	2.7	2.9	3.1
Controllable window opening (to 10 mm)	Essential	Essential	Essential	Essential
Trickle vents for winter	Essential	Essential	Essential	Essential
Control of indoor air quality	May be required	May be required	Essential	Essential
Design for daylight to reduce gains	May be required	Essential	Essential	Essential
Daylight control of electric lighting	May be required	May be required	Essential	Essential
100% shading from direct sun	May be required	Essential	Essential	Essential
Cooling by daytime ventilation only	Essential	Essential	Problem	Problem
Cooling by day and night ventilation	Not necessary	May be required	Essential	Essential
Exposed thermal mass	Not necessary	Not necessary	Essential	Essential

* i.e. people + lights + office equipment + solar gain

It should be recognised that not all parts of a building need to be treated in exactly the same way. Different natural ventilation strategies may be applied to different parts of a building as appropriate.

2.4.2.4 Interaction with building form and fabric

The interaction between building form and ventilation strategy is important. Natural ventilation relies on the building envelope (rather than any mechanical system) to provide the primary environmental control (air quality and thermal comfort). The building form will need to facilitate the airflow strategy. Particular consideration should be given to the following.

— *Building spacing and orientation and their impact on building shading and wind effects*: increasingly this is being analysed by wind tunnel and numerical methods (sections 2.4.6.6 and 2.4.7.8). Some guidance is given in Kukadia and Hall (2011).

— *Planning the width/floor-to-ceiling height ratio to achieve effective ventilation*: as air flows across the zone a sufficiently high 'stratification height' is required to lift heat and contaminants above the downstream occupied space (see CIBSE AM10: *Natural ventilation in non-domestic buildings*).

— *Achieving good solar control by sensible choice of glazing ratios and by shading provision*: buildings with their main façades facing north and south are much easier to protect from excessive solar gain in summer (see CIBSE AM10: *Natural ventilation in non-domestic buildings*). Note that a balance must be achieved in allowing appropriate natural lighting levels.

— *Openings in the external façades to provide airflow paths*: classical single-zone and multi-zone airflow models as well as CFD techniques can assist in optimising opening configurations. These models are discussed in more detail in (section 2.4.6.5 and in CIBSE AM10: *Natural ventilation in non-domestic buildings*). Manufacturers also have a range of programs available to allow review of selection of external, transfer and exhaust units.

— *Use of exposed thermal mass to aid passive and night cooling*: thermal modelling techniques are available to assist design and check with energy performance requirements.

— *Airtightness*: to minimise energy losses and cold draughts in winter and to assist the controllability of natural ventilation.

2.4.2.5 Empirical guidelines for sizing openings and calculating natural ventilation rates

Detailed guidance on calculating driving forces, the size of openings and natural ventilation rates is presented in CIBSE Guide A, chapter 4 (2015a) and CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005).

Some empirical equations for the conditions are available to assist in obtaining approximate guidance on opening sizes. These are taken from BS 5925: 1991: *Code of practice for ventilation principles and designing for natural ventilation* (BSI, 1991). The assumption that ventilation openings can be represented by orifice flow equations (see section 2.4.6) enables the estimation of ventilation rates using standard formulae for simple building layouts. These layouts and associated formulae are shown in Table 2.24 for a simple building with airflow through opposite sides and in Table 2.25 for a situation with openings in one wall only. Both wind-induced and temperature-induced ventilation are given.

The values of area (A) used in the formulae should be taken as the minimum cross-sectional area perpendicular to the direction of the airflow passing through the opening.

The formulae given in Table 2.24 illustrate a number of general characteristics of natural ventilation, as follows.

— The effective area of a number of openings combined in parallel, across which the same pressure difference is applied, can be obtained by simple addition.

— The effective area of a number of openings combined in series (across which the same pressure difference is applied) can be obtained by adding the inverse squares of the individual areas and taking the inverse of the square root of the total (see Table 2.24(b)).

— When wind is the dominating mechanism the ventilation rate is proportional to wind speed and to the square root of the difference in pressure coefficient. Thus, although ΔC_d may range between 0.1 and 1.0, this will result in a ratio of only about 1 to 3 in the predicted ventilation rates for the same wind speed.

— When stack effect is the dominating mechanism the ventilation rate is proportional to the square root of both temperature difference and height between upper and lower openings. When wind and stack effect are of the same order of magnitude, their interaction is complicated. However, for the simple case illustrated, the actual rate, to a first approximation, may be taken as equal to the larger of the rates for the two alternative approaches, considered separately. This is shown in Table 2.24(c).

Measurements (Braham *et al.*, 2001) have shown that, with normally sized windows, the magnitude of the resulting single-sided ventilation, while smaller than cross-ventilation with similar areas of opening under comparable conditions, can be large enough to contribute to natural cooling. Table 2.25 provides formulae that enable ventilation rates to be calculated for wind and stack effect. It is suggested that calculations be carried out using both formulae and the larger value taken. The formula for wind-induced infiltration represents a minimum, which will be enhanced up to threefold for certain wind directions and windows with openings that tend to deflect inwards the impinging wind.

Ducted or under-floor pathways

In order to improve air distribution into deeper spaces, it is possible to use ducted or under-floor ventilation pathways. This can provide ventilation to internal spaces or a perimeter zone local to a pollution source (e.g. a busy road). Because of the low driving pressures with natural ventilation (<10 Pa), it is important to design the supply duct for very low pressure drops. Problems could occur if incoming air is cooled to below the condensation temperature since this will result in condensation in the duct, thus leading to microbiological contamination.

More advanced calculation techniques are available for detailed design and evaluation. These are described in more detail in section 2.4.6 and include:

— zonal models

— CFD

— combined thermal and ventilation models.

A simple design tool and guidance is included in CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005).

2.4.2.6 Other design considerations

Measurement techniques for evaluating natural ventilation systems

For complex buildings it may be necessary to commission laboratory or other measurement studies to understand flow behaviour. Measurement methods are covered in more detail in section 2.4.7.

Minimising problems associated with outside noise

Noise from outside sources can present a major problem to natural ventilation designs. Solutions include sound insulation, acoustic vents and the location of openings away from sound sources. These methods are described in more detail in section 2.5.2.

Table 2.24 Standard formulae for estimating airflow rates for simple building layouts (openings on both sides) (reproduced from CIBSE Guide A)

Conditions	Schematic	Equations
(*a*) Wind only		$Q_w = C_d A_w v_r (\Delta C_p)^{0.5}$ $\frac{1}{A_w^2} = \frac{1}{(A_1 + A_2)^2} + \frac{1}{(A_3 + A_4)^2}$
(*b*) Temperature difference only		$Q_b = C_d A_b \left(\frac{2 \Delta\theta h_a g}{\bar{\theta} + 273} \right)^{0.5}$ $\frac{1}{A_b^2} = \frac{1}{(A_1 + A_3)^2} + \frac{1}{(A_2 + A_4)^2}$
(*c*) Wind and temperature difference together		$Q_t = Q_b$ for $(v_r / \sqrt{\Delta t}) < 0.26 (A_b/A_w) (h_a / \Delta C_p)^{0.5}$ $Q_t = Q_w$ for $(v_r / \sqrt{\Delta t}) > 0.26 (A_b/A_w) (h_a / \Delta C_p)^{0.5}$

Table 2.25 Standard formulae for estimating airflow rates for simple building layouts (openings on one side only) (reproduced from CIBSE Guide A)

Conditions	Schematic	Equations
(*a*) Wind only		$Q = 0.025 A V_r$
(*b*) Temperature difference only: two openings		$Q = C_d (A_1 + A_2) \left(\frac{\varepsilon \sqrt{2}}{(1 + \varepsilon)(1 + \varepsilon^2)^{0.5}} \right) \left(\frac{\Delta\theta\ h_a g}{\bar{\theta} + 273} \right)^{0.5}$ where $\varepsilon = (A_1 / A_2)$
(*c*) Temperature difference only: one openings		$Q = C_d (A/3) \left(\frac{\Delta\theta\ h_a g}{\bar{\theta} + 273} \right)^{0.5}$ If opening light is present: $Q = C_d (A f_\phi / 3) \left(\frac{\Delta\theta\ h_a g}{\bar{\theta} + 273} \right)^{0.5}$ where f_ϕ is given by Figure 4.15 in CIBSE Guide A (2015a)

External noise should not normally present a significant problem unless opening windows face busy main roads or are within 100 m of a railway line. A partially open window typically has a weighted sound reduction index of 10–15 dB compared with 35–40 dB for thermally insulating double glazing (BSI, 2014b). Measures to improve acoustic performance include:

— the use of acoustic baffles
— siting the opening windows on a quiet side of a building
— the use of acoustic ventilators (as opposed to windows)
— placing buffer zones (e.g. a circulation space) adjacent to the noise source.

As well as the ingress of external noise, consideration also needs to be given to internal acoustic design issues including:

— conflict between partitioning for acoustic privacy and provision of air paths
— that exposed thermal mass increases the number of hard surfaces (see section 2.4.2.4).

Solutions include perforated sound-absorbing tiles and acoustic baffles. Acoustics is dealt with in detail in section 2.5.2.

Climate variability

In both the long and short term, local climate will vary. It is therefore important that the ventilation design takes this into account. In particular, wind and temperature will vary on an hourly basis thus there could be as many as 8760 combinations of driving force in a year. Although rationalisation is possible by taking into account prevailing winds and typical temperature ranges, extreme conditions also need to be considered. Simple calculation methods are useful for performing multiple calculations but they may not have the accuracy of more time-consuming complex methods. Weather sequences must also take into account climate trends.

Flexibility

Flexibility should be provided to cope with changing occupant requirements over the life of the building. Systems can be designed to be capable of relatively simple upgrading (and downgrading) so that extra cooling systems can be added when and where required. Contingency planning is required at the design stage to provide:

— space for any subsequent installation of additional equipment
— sufficient floor-to-soffit height to enable additional servicing to be routed through floor or ceiling voids
— breakout floor zones that could form future service risers.

Multiple occupied spaces

Problems may arise if a single opening is required to provide ventilation for a group of occupants. This can be minimised if the window unit has high- and low-level openings for independent control by occupants internally and at the perimeter respectively. This may require actuators on the high-level openings operated by a remote controller (that could also be used as part of an automatically controlled night-cooling regime).

Intuitive manual control will not necessarily lead to windows or ventilators being opened at the optimum time of day. The instinctive reaction is to open windows to increase ventilation as indoor temperatures increase later in the day, whereas higher ventilation rates may be more beneficial earlier in the day, when ambient temperatures are lower.

Night cooling

If night cooling is under manual control, windows will either be closed or left open for all the unoccupied hours resulting in either:

— inadequate pre-cooling, with overheating the following afternoon, or
— overcooling, with cold discomfort problems the next day (or a need for heating).

These problems can be avoided by some form of automatic control of window or ventilator opening or by provision of a separate mechanical night ventilation system (see section 2.3.6 on controls).

Security

If a ventilation strategy relies on opening windows (especially if they are left open overnight for night ventilation), particular thought needs to be given to the security implications. Movement of ventilation openings at night and entry of birds through openings can cause problems with movement detection security systems. Stacks and wind-tower configurations, combined with controlled mechanical vents, provide a more satisfactory means for providing night ventilation because they can offer weather and intruder protection and can be kept under a constant control regime

Rain

The large ventilation openings that may be needed to deliver the required airflow should be designed to avoid rain entering the building, taking account of the effects of driving wind, splashing etc.. Particular thought needs to be given to ventilators left unattended during night ventilation.

Fire safety

The ventilation strategy must comply with fire and smoke regulations. More details are presented in section 2.5.3. Solutions include zoning and the use of intumescent vents. See BS 9999: 2008: *Code of practice for fire safety in the design, management and use of buildings* (BSI, 2008a), Part B of the Building Regulations (NBS, 2013g) and RRFSO (TSO, 2005).

2.4.3 Mechanical ventilation design

2.4.3.1 Introduction

Decisions relating to mechanical ventilation must take into account many aspects including:

— system size (fresh air and recirculation capacities)
— system type (displacement and mixing)
— requirements of individual zones
— room air distribution system design
— location of exhaust terminals
— installation configuration (incorporation of ductwork)
— filtration design
— integration with heating and cooling plant.

These design aspects are summarised in this section.

2.4.3.2 System size

Ultimately the system must be sized to meet the fresh air requirements for the intended number of occupants (see section 2.2.3). Also it must be sized (and designed) to ensure that process pollution or pollution from any other sources is maintained at a safe concentration. In a building without mechanical cooling the ventilation system must provide sufficient fresh air ventilation for cooling purposes (see section 2.2.4). Where space heating and cooling is provided by the ventilation system the additional recirculation air also needs to be determined

2.4.3.3 System type

An early decision needs to be made about the type of mechanical system. This includes choosing between displacement and mixing ventilation (section 2.2.8) as well as the choice of heating and cooling system.

2.4.3.4 Requirements of each zone

Individual zones will need to be separately sized to meet requirements. Plans for adaptation are also necessary to cope with any subsequent redesign of the building layout

2.4.3.5 Room air distribution system design

Room air diffusion: criteria for design

Air diffusion is the main interface between the system and the occupants. If the air diffusion is not well designed the system will fail, no matter how accurately building loads have been modelled and how carefully the plant and equipment have been selected.

The effectiveness of all ventilation and air-conditioning systems depends on the method by which supply air is introduced to, and vitiated air removed from, the space. The parameters that influence the quality of the air at any point in the room are:

— air supply velocity
— temperature differential between the room and supply air
— quality of the supply air
— position of the air supply terminals
— room shape and geometry, including projections
— position, size, and shape of all sources and sinks for heat and contaminants
— temperature of any heat sources and sinks
— rates of evolution and sorption of contaminants
— other factors influencing air movement, such as movement of the occupants and machinery, and air infiltration.

As discussed later, if terminal devices are poorly selected or positioned this can result in draughts, stagnation, poor air quality, inappropriate mixing, large temperature gradients and unwanted noise. The terminal type and layout may be affected by architectural or structural considerations, but conversely particular room air diffusion requirements should form part of the integrated/co-ordinated building design and/or structure (e.g. floor supply).

The occupants' perception of the effectiveness of the system will normally be determined by:

— the velocity of air adjacent to any uncovered or lightly covered skin (e.g. neck and ankles)
— temperature of airstream in relation to that of still air adjacent to other parts of the body
— the level of activity taking place
— the occupants' clothing
— the quality of air in the breathing zone
— the individual's susceptibility and acclimatisation
— the appearance and positioning of any ventilation devices or openings
— the noise emitted.

The above are discussed in detail in section 1.4 of CIBSE Guide A (2015a).

BS EN ISO 7730: 2005 (BSI, 2005a) recommends that, during cooling, the mean air velocity should be less than 0.25 $m \cdot s^{-1}$ for moderate thermal environments with light, mainly sedentary, activity and that, in winter, it should be less than 0.15 $m \cdot s^{-1}$. No minimum velocity is suggested, although stagnant zones could result in temperature gradients between the ankle and the neck greater than the 3 K recommended. It is likely that sufficient air movement will be generated by other means.

The occupied zone can be defined as a region, the outer limits of which are described by an envelope 1.8 m from the floor and 0.15 m from the walls. However, in the case of low-level supply terminals, the occupied zone is any region where the occupants are likely to linger for significant periods. In the case of desk terminals, this definition does not apply. For desk terminals, mixing occurs over the desk surface and for seatback terminals, mixing occurs in the regions above and between the seats.

An assessment of predicted percentage dissatisfied (PPD) (BSI, 2005a) for a wide range of activity levels, clothing,

body temperatures and velocities shows that, even at low activity levels, velocities as high as 1.0 m·s^{-1} can be acceptable in offsetting high temperatures. This technique has been applied to the concept of spot cooling in some industrial applications (Hwang *et al.*, 1984) whereby heat stress in the workers is avoided by keeping the local conditions below an agreed value of wet-bulb globe temperature.

Air terminal phenomena

Many studies of jets and their effect on room air movement have been undertaken. A detailed account and review is presented by Awbi (2003). Figure 2.27 shows the predicted airflow patterns for various types and positions of air terminal device (ASHRAE, 2009).

It should be noted that these patterns are based on stylised terminals. For predictions of air movement appropriate to specific air terminals the manufacturers' data must be consulted. For non-standard situations it may be necessary to model room air movement using a mock up. In many cases it will be necessary to allow for on-site adjustment of airflow pattern, either during commissioning or operation by the occupant (e.g. desk-mounted terminals).

Air diffusion terminology

BS EN 12792 (BSI, 2003) gives definitions and standard terminology used in connection with air movement. Some of the more important parameters are listed below.

Throw

A free jet having a given momentum on discharge will establish velocity profiles known as isovels, the shape of which depends on the geometry of the terminal, the temperature of the jet and any other disturbing influences. The velocity decays with increasing distance from the terminal. Throw is defined as the distance from the terminal (measured perpendicular or parallel to the face of the air terminal device depending on the predominant direction of flow) to the 0.5 m·s^{-1} isovel.

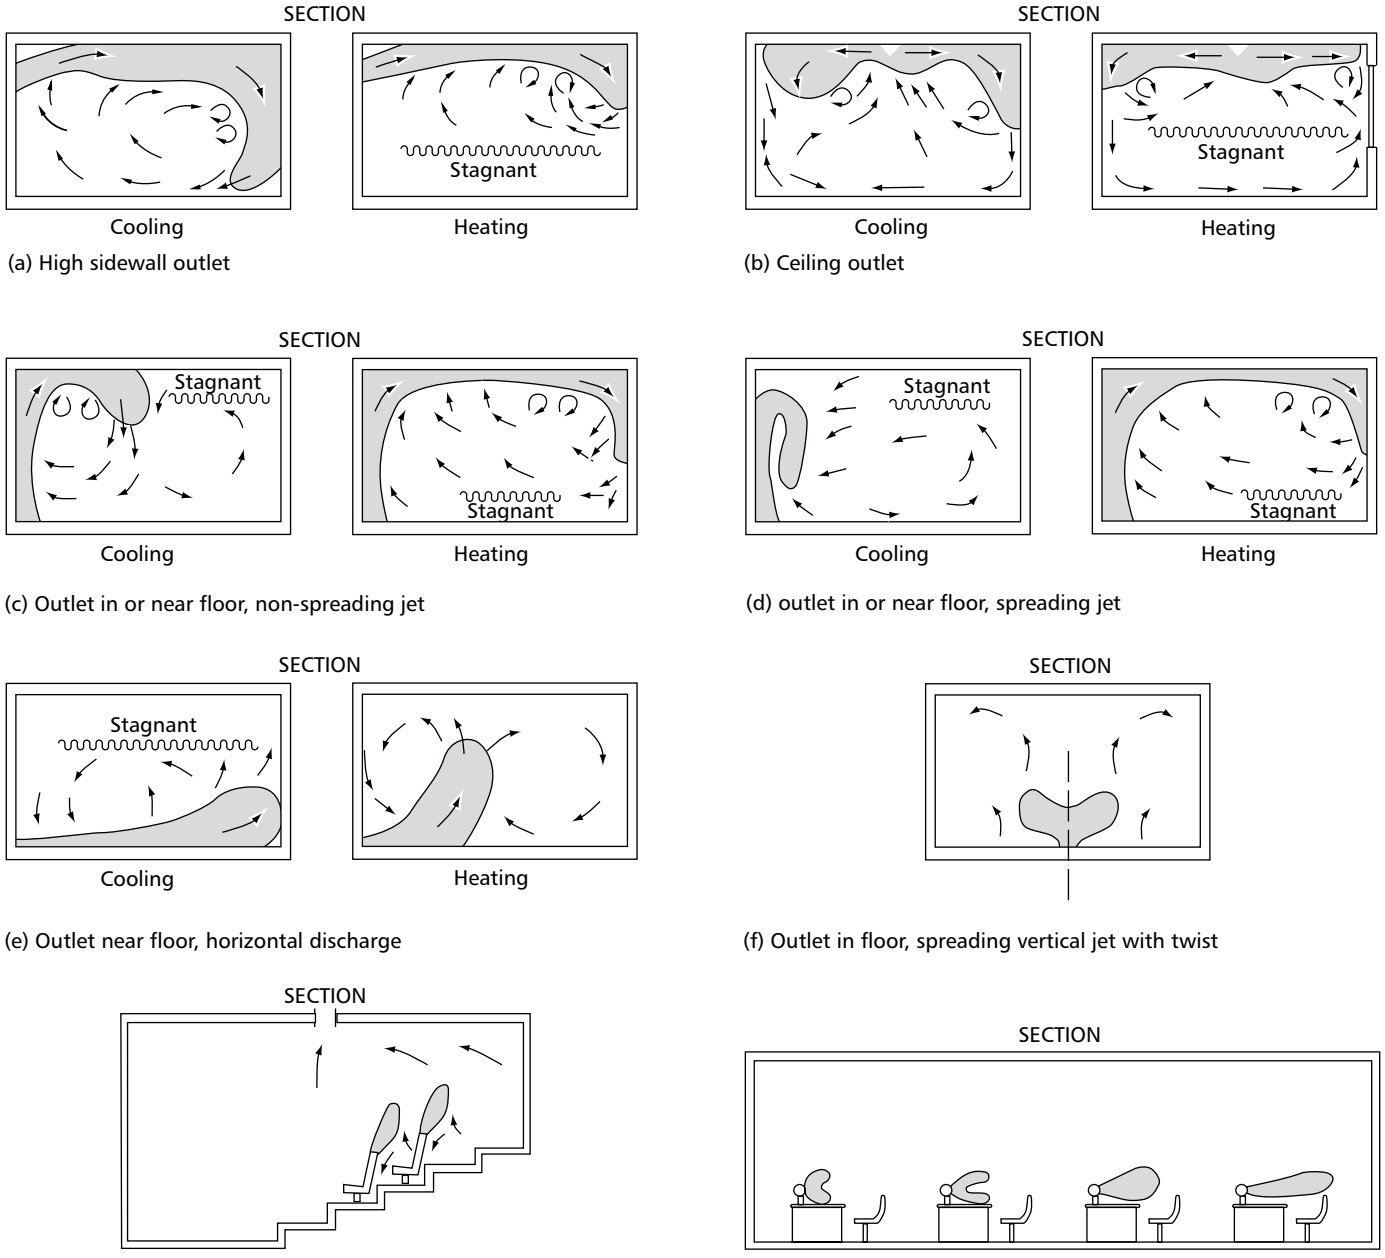

Figure 2.27 Predicted airflow patterns (adapted from ASHRAE, 2009)

Normally lower velocities are required for air entering the occupied zone, typically 0.25 m·s^{-1} for cooling, 0.15 m·s^{-1} for heating. Reference should be made to manufacturers' literature for throw data and recommended mounting distances from solid surfaces and neighbouring terminals.

The maximum throw for an air terminal device depends upon the characteristics of the device, the mounting height and the influence of neighbouring devices.

Spread

The spread of a horizontal jet is defined as the width of the 0.5 m·s^{-1} isovel. Note that most manufacturers give the width of the 0.25 m·s^{-1} isovel, which is generally of more use to the designer.

Drop

The drop is defined as the vertical distance from the centre-line of the terminal to the bottom edge of the 0.25 m·s^{-1} isovel.

Entrainment, mixing and boundaries

Frictional forces cause a momentum transfer to take place between the jet and adjacent room air, which draws the room air in the same direction as the jet. The jet expands with distance from the terminal as it entrains adjacent room air. Hence kinetic energy is expended in creating turbulence, which transfers thermal energy and assists the dilution of contaminants. This process of diffusion may be enhanced by the introduction of a rapidly expanding jet and still further by imparting a swirling motion to the jet.

A jet that is constrained by the walls of a room, such as a full width slot, will entrain less room air and expand more slowly than a free conical jet (Awbi, 2003).

Effect of temperature differential

Figure 2.27 above shows that a jet that is not influenced by the proximity of a solid surface follows a path that is a function both of velocity and temperature. A warm jet tends to rise until it attaches itself to a horizontal surface, whilst a cold jet falls. Care must be taken to ensure that this does not lead to unacceptable temperature gradients in the occupied zone during heating and excessive air velocities during cooling. The terminal must be mounted such that the 0.25 m·s^{-1} isovel does not enter the occupied zone.

The difference in temperature between the supply and return air may be greater than that between the supply air and the occupied zone, particularly with a low-level supply designed to encourage high-level stratification. This temperature difference is related to sensible heat gain and supply air mass flow, as follows:

$$q_s = m\, C_{ph}\, \Delta T \qquad (2.15)$$

where q_s is the total sensible heat gain (kW), m is the mass flow rate of supply air (kg·s^{-1}), C_{ph} is the specific heat of the air and water vapour mixture (kJ·kg^{-1}·K^{-1}) and ΔT is the room air to supply air temperature differential (K).

Therefore the mass flow rate, and hence the cost of air handling, will depend upon the temperature difference chosen by the designer. This decision will also be influenced by the evaporator temperature and the level of control of humidity. For example, a displacement system with low-level input can supply air at 18 °C with a temperature difference of about 10 K. This can be achieved with high evaporator temperatures and correspondingly low compressor power. However, high-level humidity control will suffer unless the supply air is overcooled and reheated, normally an undesirable combination at peak load. Alternatively, a permanent bypass around the cooling coil can be provided and, if motorised dampers are incorporated at the coil face and in the bypass, part load control supply temperature can be achieved by damper modulation.

For comfort applications, air change rates are unlikely to exceed 10 ACH, corresponding to a cooling temperature differential of 8–12 K. A free horizontal jet from a rectangular grille is likely to create down draughts if providing more than 8 ACH with a cooling temperature differential greater than 8 K.

A maximum cooling differential of 10 K can be applied when either:

— the presence of the Coanda effect (see below) is assured, or

— for a free jet, mixing of supply air with room air outside the occupied zone can be assured without promoting discomfort.

Table 2.26 gives general guidance on the maximum air change rates that can be achieved using various air terminal devices supplying air with a cooling temperature differential of 10 K.

If sufficient mixing between terminal and occupants cannot be guaranteed (e.g. with low-level supply) then the minimum supply temperature of 18 °C applies, with a temperature differential in the occupied zone of 4–5 K. However, the cooling temperature differential is ultimately determined by the maximum exhaust air temperature (Sodec, 1984) (see Table 2.27).

The larger temperature differential indicated for high ceilings is possible due to the smaller influence of ceiling temperature on the mean radiant temperature experienced by the occupants.

Downward discharge is generally only satisfactory for very high air change rates, and hence small temperature differentials, or where room convection is not significant (see below). An exception is the specific case of split air-conditioning systems, where temperature differences can be as high as 20 K. Particular care is therefore needed in their specification, see CIBSE Guide B, Chapter 3 on air conditioning.

High-level supply jets must overcome the buoyancy forces in the room air generated by heat emitters, solar gain, occupants etc., whereas low-level input cultivates these forces to assist the supply jet. For this reason, low-level supply is most satisfactory for applications with high room gains and high ceilings. For low ceilings the radiant heating effect of the ceiling itself may be significant. This may also be a problem where the ceiling void is used as an exhaust air plenum, carrying air heated by air-handling luminaires.

Table 2.26 Typical maximum air change rates for air terminal devices

Device	Air change rate / h^{-1}
Side-wall grilles	8
Linear grilles	10
Slot and linear diffusers	15
Rectangular diffusers	15
Perforated diffusers	15
Circular diffusers	20
Swirl diffusers	20-30

Table 2.27 Typical cooling temperature differentials for various applications

Application	Maximum temp. differential / K
High ceiling (large heat gains/ low-level input)	12
Low ceiling (air handling luminaires/low-level input)	10
Low ceiling (downward discharge)	5

Free descending jets are not recommended for normal use, since the low velocity approaching the occupied zone would cause instability. This could result in localised high velocities due to deflection by convective forces elsewhere in the room (see Figure 2.28). An exception is the case of laminar downflow cleanrooms (BS EN ISO 14644 (BSI, 1999–2013)) where an even velocity across the full area of 0.4 $m \cdot s^{-1}$ should be maintained from ceiling to floor. However, even in these circumstances, sources of extremely buoyant upflow should be avoided.

Coanda effect

When a jet is discharged from a terminal device adjacent and parallel to an unobstructed flat surface, the jet entrains air from one side only resulting in deflection of the axis of the jet towards the surface. This phenomenon, known as the Coanda effect, is due to frictional losses between the jet and the surface.

The effect diminishes with distance from the terminals as increasing volumes of air are entrained from the room-side of the jet, resulting in a reduction of jet velocity. However, the Coanda effect is maintained despite temperature differences between the jet and the room air. It is a critical factor influencing the selection and positioning of supply air terminals, particularly for rooms with low ceilings, which have little space above the occupied zone in which mixing can occur.

If the Coanda effect is not present the maximum throw for any terminal is reduced by approximately 33 per cent. The main factors that influence whether or not the Coanda effect will occur are:

— the distance between terminal and surface

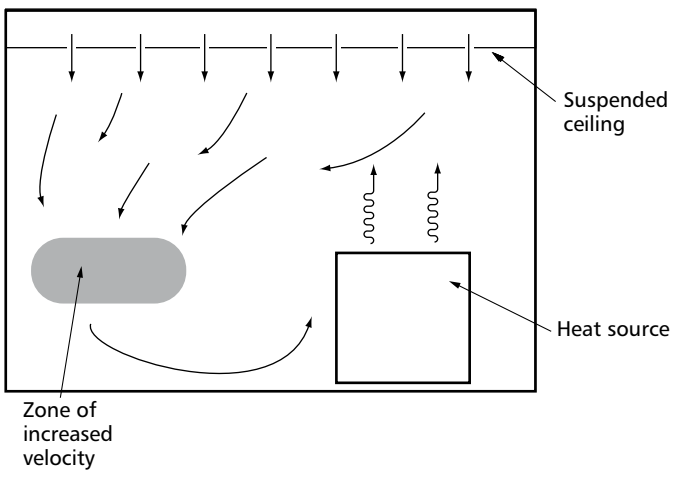

Figure 2.28 Effect of room convection currents

— the width of jet exposed to surface

— the velocity of the jet

— the presence of projections and other disturbing influences.

The importance of these influences for side-wall terminals with various aspect ratios, velocities and temperature differences is discussed elsewhere (Awbi, 2003). The most important factor is temperature difference, i.e. buoyancy effects. For the usual range of temperature differences for cooling of 8–12 K, the opening should be within 300 mm of the surface to guarantee attraction. For systems designed to make use of the Coanda effect, provision should be made for on-site adjustment of the jet.

When a jet adheres to a surface, dust particles will be deposited on the surface leading to staining, hence supply air cleanliness is of paramount importance. Cleanliness of the exhaust air is difficult to control and some staining of surfaces near to exhaust openings is inevitable.

Techniques exist (Awbi, 2003) for predicting the influence of projections, such as downstand beams and surface-mounted luminaires, on a jet flowing across an otherwise smooth surface. An obstruction may cause the jet to separate completely from the surface, hence destroying the Coanda effect, or it may separate and join some distance downstream of the obstruction.

The critical distances at which these phenomena are likely to occur depend on the depth and shape of the obstruction and size of the supply opening. The influence of supply air to room air temperature differential is small but depends upon the extent to which mixing has occurred before the jet meets the obstruction.

Figure 2.29 shows the effect of a horizontal surface on a jet rising close to the vertical surface. The Coanda effect is maintained after the change in direction provided that the velocity is adequate, particularly in the case of cooling jets, and that the temperature differential between supply and room air is not too large. Guidance for selecting optimum supply velocities and temperature is given elsewhere (Awbi, 2003).

Interaction between jets

Figure 2.30(a) shows possible room air velocity patterns for two jets directed towards each other along a 3 m high ceiling. The individual velocities of the two airstreams must not be greater than 0.25 $m \cdot s^{-1}$ at the boundary otherwise discomfort may occur due to excessive down-draughts.

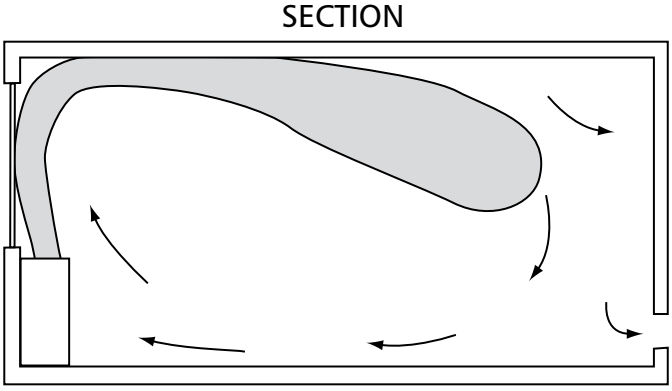

Figure 2.29 Effect of horizontal surface on a jet

The envelopes of two converging jets may also interfere with each other, combining to form a single, wide jet with a maximum velocity at the new axis between the two jets (see Figure 2.30(b)). A similar phenomenon occurs with two jets moving in tandem (see Figure 2.30(c)). The downstream jet entrains and accelerates the decaying upstream jet and forms a wider jet with an axis further from the neighbouring surface. The cumulative effect of a series of single-way jets can result in a deep jet that intrudes into the occupied zone resulting in unacceptably high room velocities.

Figure 2.31 shows examples of possible layouts for ceiling diffusers. The main problems likely to be encountered are those described above. Down-draughts may be encountered in areas marked 'X' and this problem may be eliminated by avoiding terminals with excessive throw, particularly in large spaces where stagnation between terminals is unlikely to occur. The layout shown in Figure 2.30(c) may cause convergence problems with long rooms.

For side-wall applications, the spacing of diffusers should be in accordance with manufacturers' recommendations. However, in the absence of such recommendations, Table 2.28 may be used in conjunction with throw and deflection data to determine the diffuser spacing. For a terminal mounted close to a wall, spacing should be halved to give the minimum distance from the centreline to the wall. Table 2.29 (Sodec, 1984) indicates typical turndown limits for various types of fixed air terminal device.

2.4.3.6 Location of exhaust terminals

The positioning of the opening has little influence on the airflow pattern in the space because the zone of localised high velocities associated with exhaust openings is very close to the opening.

Exhaust terminals may be sited to advantage:

— in a stagnant zone where supply jet influence is limited

— close to a source of unwanted heat and/or contamination, e.g. above a luminaire

— close to an excessively cold surface to increase its surface temperature and thereby reduce radiant losses and cold draughts

— at a point of local low pressure, e.g. the centre of a ceiling diffuser.

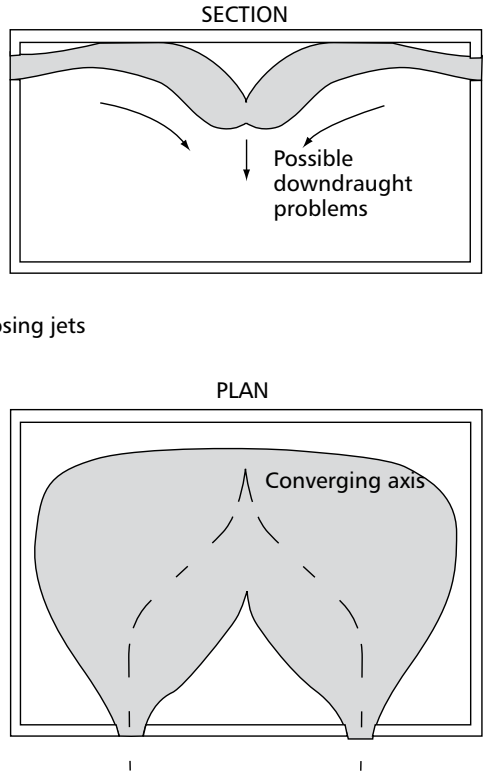

Figure 2.30 Room air velocity patterns; interaction between jets

Positions that should be avoided are:

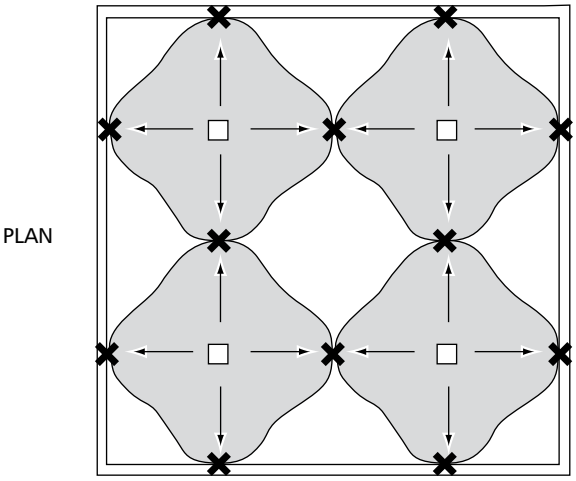
— within the zone of influence of a supply air terminal since this allows conditioned air to pass directly to exhaust without first having exchanged heat with its surroundings; this results in very low ventilation efficiency

— close to a door or aperture that is frequently opened since this leads to the exhaust handling air from outside the conditioned space

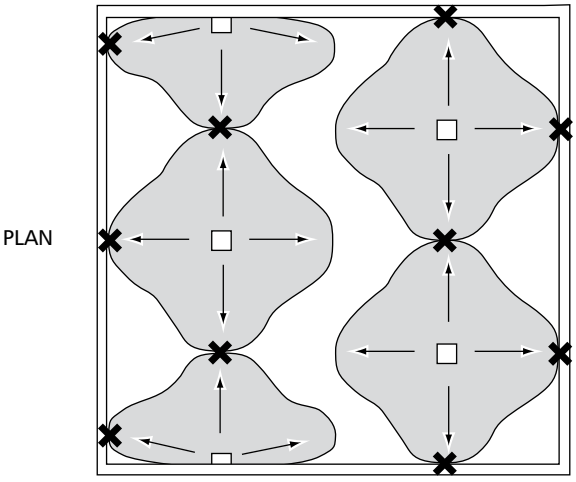
— in a position that causes contaminated room air to be drawn through the occupants' breathing zone.

2.4.3.7 Installation configuration: incorporation of ductwork

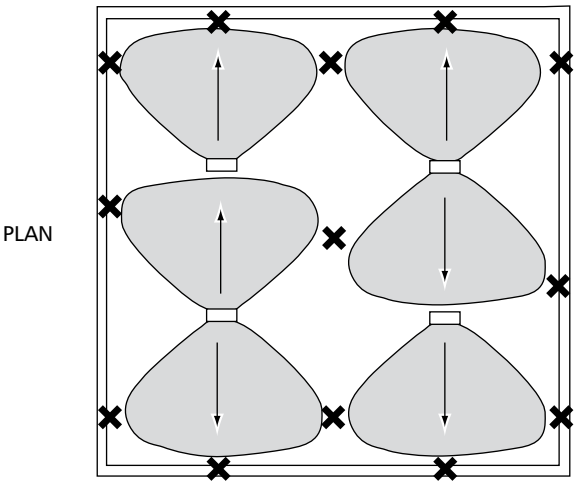
Considerations of layout are discussed in section 2.3.5.2. Ductwork is covered more generally in sections 2.3.5, 2.4.5 and 2.6.7.



(a) Four-way ceiling diffusers, symmetrical layout



(b) Four-way ceiling diffusers, off-set layout



(c) One-and two-way ceiling diffusers, contra-flow layout

Figure 2.31 Supply terminal layouts for open plan spaces

Further information on spatial allowance for ductwork is available from Design and Maintenance Guide 08: *Space requirements for plant access, operation and maintenance* (DEO, 1996), BSRIA TN 10/92: *Spatial Allowances for Building Services Distribution Systems* (1992) and BS 8313: 1997: *Code of practice for accommodation of building services in ducts* (BSI, 1997).

Table 2.28 Data for determining spacing of ceiling diffusers

Deflection / deg.	Spacing / m	
0	0.20 L_x	0.33 L_y
22.5	0.25 L_x	0.50 L_y
45	0.30 L_x	1.0 L_y

Note: L_x = throw (m) where axial velocity has decayed to 0.25 m·s^{-1}; L_y = throw (m) where axial velocity has decayed to 0.5 m·s^{-1}

Table 2.29 Turndown limits for types of fixed air terminal device (Sodec, 1984)

Type of outlet	Maximum turndown/%
Ceiling mounted:	
— not using Coanda effect	50
— using Coanda effect	40
Floor mounted outlets:	
— perforated plate and fixed bar grille	60
— free jet outlets	50
— outlets with swirl	40
Desk outlets:	
— linear type	50
— ball type	50
— outlets with swirl	40

2.4.4 Mixed-mode ventilation design

2.4.4.1 Introduction

Mixed-mode ventilation will incorporate both natural and mechanical design requirements and therefore it is important to refer to the previous two sections. In the case of the mixed-mode approach, however, dominance often falls on natural ventilation with the mechanical systems being as simplified as possible. In the design of a mixed-mode system the issues described in this section also need to be considered.

2.4.4.2 General design issues

The range of circumstances encompassed by the term 'mixed-mode' system is extremely broad. It encompasses, for example, a building that is almost entirely naturally ventilated except for areas of high heat or moisture production served by mechanical systems, to one that is entirely served by air conditioning with the intention that this might in the future be converted to natural ventilation. Hence the guidance provided here must be considered in the light of the specific strategy, or its derivative, as determined in section 2.3.2.4. Furthermore, this section cannot be treated in isolation but read in conjunction with sections 2.4.2, 2.4.3 and CIBSE Guide B3 (CIBSE, 2016a), which consider the principles of the individual operating modes.

Building fabric

Mixed-mode is a term describing servicing systems that combine natural ventilation with any combination of mechanical ventilation, cooling or humidification in a strategic manner. In common with buildings that are solely naturally ventilated, this approach requires that benefit be obtained from the building fabric.

The presence of mechanical systems means that a balance needs to be drawn, using value engineering principles, between investment in the relatively long-lived fabric and expenditure on the shorter-lived (and easier to modify/replace) building services, components of which can subsequently be added when and where necessary.

Although the building services in a mixed-mode system should usually cost less than in a fully mechanically serviced building, some additional investment may be needed to improve their efficiency, responsiveness, control and adaptability. The initial cost of the mechanical services and the openable windows or vents combined can be greater than that for a sealed building.

Obviously, the greatest economies are made if the improvements to the fabric allow the building services system to be completely eliminated from part or all of the building. For example, reducing fabric and internal heat gains may allow mechanical cooling to be avoided. A highly insulated and airtight fabric with low-powered mechanical ventilation (and heat recovery) may allow both mechanical refrigeration and perimeter heating to be avoided. The effective use of external night-time temperature differentials can permit any excess heat built up during the day to be removed at night, using natural and/or mechanical ventilation, thereby reducing or eliminating the need for mechanical cooling during the daytime (see 'Night cooling' in section 2.4.2.6) and see CIBSE Guide B, Chapter 3 on air conditioning.

In the particular case of zoned systems, a consideration may be to introduce 'localised' fabric enhancements to reduce heat gain, e.g. additional treatment of the roof fabric to ameliorate solar heat gains or additional solar shading of selected windows. A further option might be to introduce 'assisted passive' measures before employing full mechanical systems. This might take the form of a fan in selected natural ventilation 'stacks' for use under peak conditions or on days when inadequate external forces are available or possibly simple desk fans.

Combining natural and mechanical systems effectively

Within complementary systems, the balance between the operation of the natural and mechanical system elements needs to be optimised. This requires a 'trade off' between the extent of passive and active features, for example the number and location of the openable windows will depend upon the extent of mechanical ventilation. The processes by which this balance can be achieved are given in CIBSE AM13: *Mixed mode ventilation* (2000a).

In the case of zoned systems, it requires an understanding of the problem areas that will require mechanical assistance. These might include:

— zones facing inferior environmental conditions, such as top floors, corner rooms, internal areas, areas local to non-openable façades, or areas where partitioning inhibits bulk air movements

— toilet areas

— areas where heat- or odour-producing equipment is located such as areas containing photocopiers or drinks machines, tea rooms or cleaners' cupboards

— restaurants or kitchens

— areas with dense occupation or high equipment heat loads that may require comfort cooling or close-control air conditioning such as meeting rooms, electronic data processing rooms, dealer rooms etc.

— atria.

Flexibility

Flexibility is of particular concern with contingency systems where future change is taken into account. This requires the provision of a building fabric with a stated indoor environment control performance and a defined strategy for subsequent adaptation through the addition and omission of either centralised or localised supplementary mechanical systems. The extent to which systems are initially installed, or allowance made for them, will depend upon the context but the decision must be taken in the light of the ease and speed of subsequent installation and the likely extent of upgrades, sub-tenancies, or critical areas.

Plant rooms

It may be possible to include space for plant rooms that can be put to alternate use until it is required for ventilation or cooling purposes, for example as storage or car parking. External flat roof and undercroft locations may also be suitable. Plant room locations should preferably allow mechanical plant containers to be installed. A further option is prefabricated plant rooms that can be obtained on hire and 'plugged in' with minimum site disruption. These can subsequently be disconnected for reuse elsewhere when a tenancy terminates.

Distribution routes

The availability of space for routing services to and around individual rooms often determines the overall level of flexibility. The recommended heights of exposed ceiling soffit slabs to facilitate natural ventilation can often provide adequate space for a future suspended ceiling void or bulkhead, capable of accommodating a wide range of HVAC systems. A suspended floor may also allow direct expansion, chilled water and condensate pipes to be routed to any potential 'hotspot'. With appropriate initial sizing the floor void also has the potential to become a floor supply plenum, from which rooms or larger areas can be supplied with air.

It is important to ensure continuity of the routes between the various parts of the system. A clear route without constrictions is needed from the spaces designated for main plant, via the risers, to the tertiary run-outs. Care should be taken to avoid inadequate space for connection between risers and the floors they are to serve.

Room must be given for the installation of fire dampers at compartment boundaries. This should also allow for access for maintenance. See notes on fire safety in 'Fire issues' in section 2.3.5.2 if fire doors are to be used as part of the route.

Choice of HVAC system

The choice of HVAC system will depend upon the client's functional requirements (see section 2.2.1). In the case of

zoned or contingency systems the choice between freestanding or centralised systems is dependent upon:

— the size and distribution of the zones to be treated

— planning restrictions on the use of the façade

— the availability of space for logical horizontal and vertical distribution routes.

2.4.4.3 Energy-efficient operation of mixed-mode systems

The principles for achieving energy-efficient operation in mixed-mode systems are a combination of those applied to buildings operating in either natural or mechanical ventilation modes. Prioritisation of these principles depends upon the extent to which mechanical systems for ventilation, cooling or humidification have been installed.

Additionally, consideration needs to be given to the following points.

— Mechanical systems should be used only when and where required. The specific fan power increases with air change rate. Furthermore, as the air change rate increases, the occupants are more likely to notice the difference between when the system is operating and when it is not. This may reinforce the tendency for it to be left running unnecessarily. The use of zoned mixed-mode systems helps to overcome the need for whole systems having to operate in order to service small demands.

— Natural and mechanical systems should not conflict in their operation, e.g. mechanical systems competing with air coming in through the windows, or simultaneous humidification and dehumidification. Such situations can be reduced through making users aware of the rationale behind the operation of the system and having suitable trigger points for changeover operation. The state and performance of the system should be monitored and system conflicts reported.

— Systems should not default to a non-optimal state, e.g. switched on when they could be switched off or, at least, operating at reduced output. This risk can be minimised by avoiding over-complex design.

2.4.4.4 Control

The control strategy for mixed-mode systems is context dependent, but aims overall for energy-efficient operation, maximum staff satisfaction and ease of building management. This is achieved through:

— maximisation of the natural operating mode

— integration of natural and mechanical systems to avoid system conflicts, wasteful operation and discomfort

— simple and effective control for occupants that is non-presumptive

— simple and effective controls for the building management that are easy to commission and operate on occupation of the building.

The general principles of a good control strategy are given in section 2.3.6.

2.4.4.5 Performance assessment

Some aspects of mixed-mode design may be difficult to resolve or to optimise using normal calculation methods and rules of thumb. More detailed simulation may be desirable in:

— appraising options

— developing new concepts and testing their robustness under all foreseeable conditions

— demonstrating the capabilities of an option to clients

— refining a chosen approach.

Appendix 2.A6 considers the techniques of dynamic thermal simulation and air movement analysis. In applying them specifically to mixed-mode systems the designer must consider:

— the full variety of potential (often overlapping) operational modes and control variables

— the trigger points for each control strategy element

— the potential actions of occupants

— uncertainty concerning the actual operation of the building compared with the intent and the consequent robustness of the solution

— possible differences between parts of the building and areas of particularly demanding localised conditions that place particular demands on the ventilation system

— possible adverse interactions between adjacent zones in different operating modes

— possible adverse effects of facilities designed for one mode and operating in another, e.g. facilities designed for summertime ventilation and cooling may not work well in cold weather, possibly leading to draughts or excessive heat losses.

The selection of appropriate weather data and treatment of heavyweight buildings within thermal models is discussed in Appendix 2.A6.

2.4.5 Ductwork principles of design

2.4.5.1 General

General background information on this topic is provided in section 2.3.5.2. Design is concerned with duct layout, sizing minimising pressure loss and fire safety. For further fire safety information see section 2.5.3.3.

2.4.5.2 Duct layout

In most installations, the constraints imposed by the building or other structures (e.g. single or multiple plant rooms, split systems based on tenancy arrangements etc.), and the siting of fans, plant items and terminals, can lead to the adoption of an overall duct layout that is not ideal. Room must be given for the installation of fire dampers at compartment boundaries. This should also allow for access for maintenance

Considerations of duct layout design are discussed in detail section 3.5.2.

2.4.5.3 Spatial requirements

Provision of sufficient space for ductwork is essential and must be addressed at an early stage in the design process of the building.

Laying out the space required for ductwork is, to an extent, an amalgam of experience, skill and three-dimensional visualisation. Adequate space must be provided for installation and maintenance of the ductwork and associated equipment such as fire dampers at compartment boundaries. The designer should ensure that ductwork is co-ordinated with the other engineering services to be accommodated in the same space, particularly in false ceiling voids and riser spaces where there may be several distribution systems vying for restricted space. Developments in building information modelling (BIM) (ASHRAE, 2013) should be considered for this type of task.

Branches from vertical risers to serve horizontal distribution routes should be considered with care, as this is likely to be the most congested area of the service core. If the service core is enclosed on three sides (e.g. by a lift shaft and an external wall) the horizontal distribution from the core will be extremely difficult, with little space for installation and maintenance.

The area served by a single riser will dictate the size of the horizontal branch duct. The depth selected for a branch duct will have a significant influence on the false ceiling or raised floor depth. It will also affect the overall floor-to-floor heights and hence have significant influence on building costs.

The depth of the horizontal element is a function of the number of vertical risers, generally:

— maximum number of vertical risers equates to minimum horizontal element depth

— minimum number of vertical risers equates to maximum horizontal element depth.

Adequate space must be allowed around ducts for fitting of insulation, hangers and supports during installation and for access during subsequent maintenance. Access will also be dependent on the clearance from adjacent objects such as structural items and the type of jointing method.

Suitable allowances are given in Appendix 2.A2, which also shows examples of common problems associated with ductwork access.

Ductwork clearances can be reduced with care, providing jointing, insulation and maintenance of any vapour barrier is achieved. Consideration should also be given to how the ductwork will be tested and how it will eventually be replaced.

Adequate space shall be allowed at compartment boundaries for the installation of fire dampers using a tested installation method. The fire damper installation method to be used should be clearly defined as part of the ductwork/supporting construction design, so that it meets the fire classification of the boundary.

Further information on spatial allowance for ductwork is available from Design and Maintenance Guide 08: *Space requirements for plant access, operation and maintenance* (DEO, 1996), BSRIA TN 10/92: *Spatial Allowances for Building Services Distribution Systems* (1992) and BS 8313: 1997: *Code of practice for accommodation of building services in ducts* (BSI, 1997).

2.4.5.4 Interaction with structure and building form

Because ductwork is likely to be the most space-intensive service provided, it is important that the ductwork design is fully co-ordinated with the design of the building structure to minimise the number of bends and other fittings, each of which will increase the resistance to airflow. This is particularly important for new installations where requirements apply to maximum fan power levels. The structural design may have reached beyond an outline design and shape by the time that ductwork design commences.

Provided they are allowed for early in the design, it is usually possible to accommodate vertical ducts of any desired size without great difficulty from both structural and planning viewpoints. Horizontal ducts present more problems; if they are located between floors, headroom will be restricted and there will be limits on the floor area that a horizontal duct can serve. Early checks should be carried out to ensure that the vertical main ducts enable horizontal distribution without compromising the performance of the installation or the available headroom and that structural members allow branch ducts to leave the main ducts.

Distribution of the engineering services within a building are likely to follow a pattern associated with the main building circulation route that represents the main functional pattern of the building. This may not be the most efficient route for the ductwork. The large space requirements for ductwork mean that it can be desirable to locate plant close to the areas they serve.

This should include space to fit fire dampers that are suitable to any supporting construction used. The requirements of Part B of the Building Regulations (NBS, 2013g) should be followed. Details of fire damper installation methods are given in DW/145: *Guide to Good Practice for the Installation of Fire and Smoke Dampers* (BESA, 2010) and *Fire Dampers (European Standards)* ('the ASFP Grey Book') (ASFP, 2010).

Sufficient space needs to be provided for ease of fitting the ductwork. Providing access for maintenance is also important since it will be expensive to install retrospectively, whether ducts are horizontal or vertical. Space should also be allowed for additions and alterations.

Co-ordination of the engineering services should ensure that the area for removal of access panels and covers and entry into the ductwork is free of services and readily accessible without obstructions.

2.4.5.5 Duct sizing

Background

Duct sizing and pressure loss calculations are normally carried out as a combined exercise to quantify the ductwork dimensions and provide data for specifying the fan duty. The duct sizing process and pressure loss calculations require the specification of system requirements, including:

— system type, i.e. low, medium, high pressure or industrial

— volume flow rates in all parts of the ductwork

— positions of fans, other plant items, supply-and-extract terminals

— special operating requirements, e.g. minimum conveying velocities in extract systems

— ductwork type, i.e. circular, rectangular, flat oval

— layout of the duct runs, including fittings, dampers and plant items

— duct material.

The purpose of duct sizing is (*i*) to determine the cross-sectional dimensions of the various parts of the duct system, and (*ii*) to ensure a balanced system that delivers design conditions. Furthermore the system, fans and other plant items should be:

— economical in installed and operating costs

— compatible with the space limitations imposed by the structure and other services

— sufficiently quiet in operation

— easily regulated after installation to achieve the design airflow at each terminal.

In practice, duct sizing seeks to obtain an economical and practical solution to these objectives by either simplified manual procedures or computer programs. The computer programs can vary in complexity from computerisation of manual procedures to overall design including optimisation, damper settings and noise assessment.

Before commencing duct sizing, a schematic of the air distribution system must be prepared. This should indicate the airflow directions and contain the following information:

— system identification for each section

— air volume flow rates in each section

— the length of all straight sections

— descriptions of fittings, dampers, plant items and terminals.

An example schematic is shown in Figure 2.32.

Approximate sizing

Because ductwork can be large, it will often be necessary to assess the size of individual ductwork in critical locations, particularly where horizontal branches leave the main vertical risers. It is often possible to adjust the size of the vertical space well into the detailed design. Horizontal branches, however, cannot encroach on the necessary headroom.

To make a preliminary estimate of a branch size, calculate the airflow rate required in the area served by multiplying the zone volume by the number of air changes per hour and divide by 3600 to obtain the zone flow rate in $m^3 \cdot s^{-1}$. Two air changes an hour may be appropriate for offices with a separate heating system for fabric losses. Where the air is used for heating, four air changes an hour may be required or six air changes or more for an air-conditioned space. Dividing this flow rate by the velocity given in Tables 2.16 and 2.17 gives the duct cross-sectional area required. For conventional systems, the aspect ratio (long side to short side) of rectangular ducting should not exceed 3:1.

Manual duct sizing method

Simple design methods include:

— velocity method

— constant pressure drop (or equal friction loss) method

— static regain method.

The most common method is based on delivering constant pressure drop per unit length for a duct run, with maximum duct velocities as set out in Tables 2.16 and 2.17 for low-, medium- and high-pressure systems.

These methods are simple procedures that use ductwork data charts to determine duct dimensions. The overall cost effectiveness, ease of system regulation and noise can be taken into account by imposing limits on some of the design parameters. It is recommended that the calculated duct size is rounded to the nearest recommended duct size (see Appendix 2.A1) before the pressure drop calculations are carried out. A brief description of these methods is given below.

Velocity method

This method is based on the selection of duct velocities by the designer using limiting noise generation and/or pressure drop. In a typical system the velocity at the fan connection is chosen and velocities are also chosen for subsequent duct runs with the aim of progressively reducing velocities from the fan to the terminals. Tables 2.16 and 2.17 give some guidance on suitable maximum air velocities. In practice, this is only used on simple layouts or sections of systems, as the procedure depends on experienced but subjective judgements. It is difficult to produce a coherent selection of sizes for a complex layout on this basis. In industrial systems where minimum transport velocities are required this method may be employed more frequently.

Constant pressure drop (equal friction loss) method

The basis for this method is to select a constant pressure loss per unit length for the duct runs and then to size the ducts at this rate using Figure 2.33 below. This method is used for sizing very simple low-pressure supply-and-extract systems, some medium-pressure systems and also for VAV systems. For low-pressure systems, typical values used for the constant pressure loss rate are in the range 0.8–1.2 $Pa \cdot m^{-1}$ with duct velocities not exceeding 10 $m \cdot s^{-1}$. At large volume

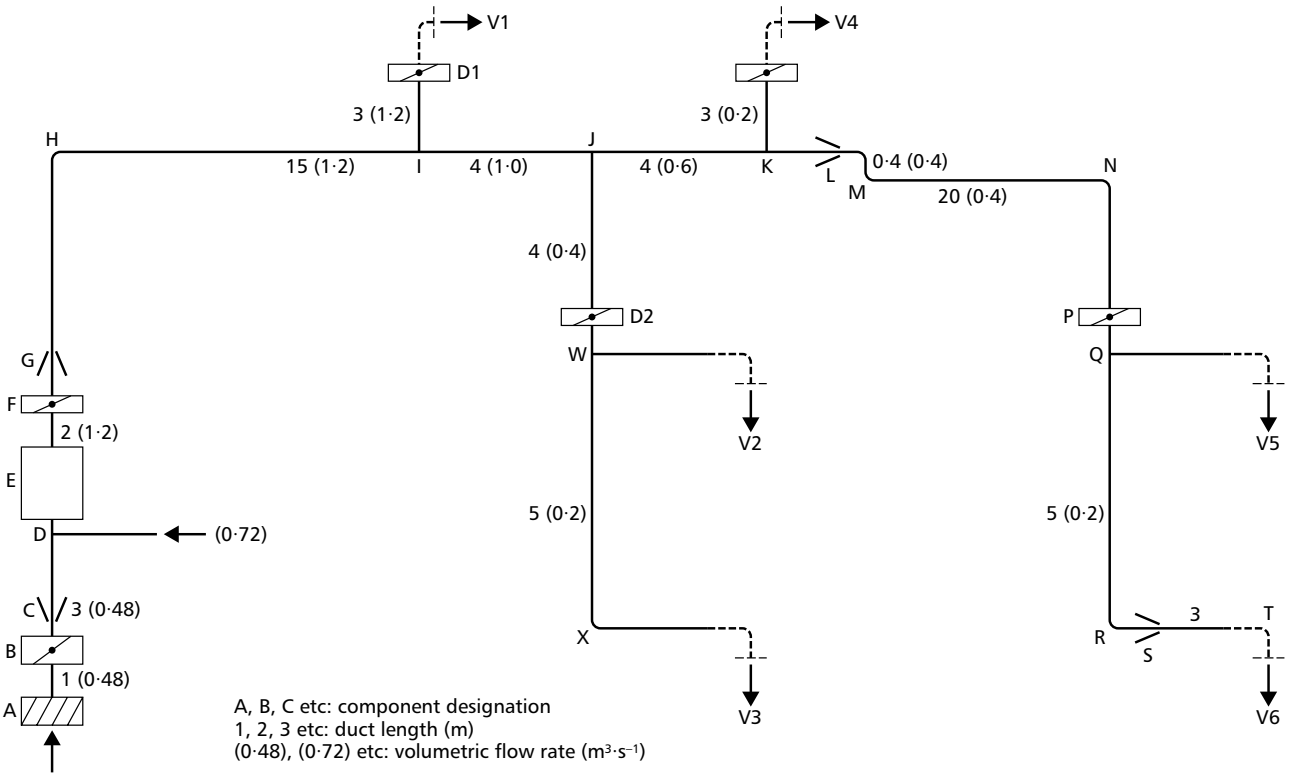


Figure 2.32 Example schematic of ductwork layout, showing lengths (m) and flow rates ($m^3 \cdot s^{-1}$) (see Appendix 2.A5 for calculation procedure)

flow rates in low-pressure systems the 10 $m \cdot s^{-1}$ duct velocity limit should override the constant pressure loss rate chosen, leading to somewhat lower pressure loss rates in the large ducts.

The sizing process involves:

— the selection and use of a vertical constant pressure loss line in Figure 2.33, appropriate to the design requirement

— reading off the circular duct diameter for the actual volume flow rate

— if a rectangular or flat oval duct is required, taking the dimensions from Tables 2.A1.1 or 2.A1.2 (see Appendix 2.A1), as appropriate, for the equivalent circular diameter.

The friction loss method gives a reducing velocity from the fan to the terminals. Adopting different pressure loss rates for the individual branches of a system can be used to produce a more nearly equal resistance to each duct run and so assist balancing the system. This modification can be introduced during the pressure loss calculation.

Initially, all parts of the system should be sized to the same pressure loss rate and the adjustments to individual branch sizes only carried out after the pressure losses in the initial system design have been computed. These adjustments are most quickly and conveniently carried out by computer.

Static regain method

When the velocity in a duct is reduced without excessive losses occurring, the static pressure increases. In high-pressure systems, this increase can be significant and is the basis for the static regain duct-sizing method. The principle is to size ducts between branch take-offs so that the recovery in static pressure after one branch take-off due to reduction in velocity is equal to the static pressure loss due to friction and fittings in the subsequent duct run. The method seeks to equalise the static pressures at the branch take-offs, and where these take-offs serve high-pressure terminals an inherently balanced system can be achieved.

The static regain method is used primarily for those parts of a high-pressure system where the initial duct velocity pressure is sufficient to give static pressure regain without unnecessarily low duct velocities at the end of the run. In practice, only the duct mains serving multiple terminal branches are sized by this method, while the smaller branches to terminals are sized by the equal friction method (see 'Constant pressure drop (equal friction loss) method' above) to minimise their size and cost. High-pressure terminals on the same system normally all have roughly the same pressure loss. If this value is high compared with the branch duct pressure loss, then variations in the latter between different branches arising from the use of the equal friction sizing method will not significantly unbalance the system. The static regain method uses duct static pressure losses rather than total pressure losses in the sizing procedure.

The static regain is due to the drop in velocity pressure. However it must be emphasised that there is still a drop in total pressure Δp_t, due to friction. For the branch shown in Figure 2.34, subscript 'c' denotes 'combined' flow, subscript 'b' denotes 'branch' flow and subscript 's' denotes 'straight' flow.

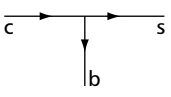

Figure 2.34 Schematic of duct branch

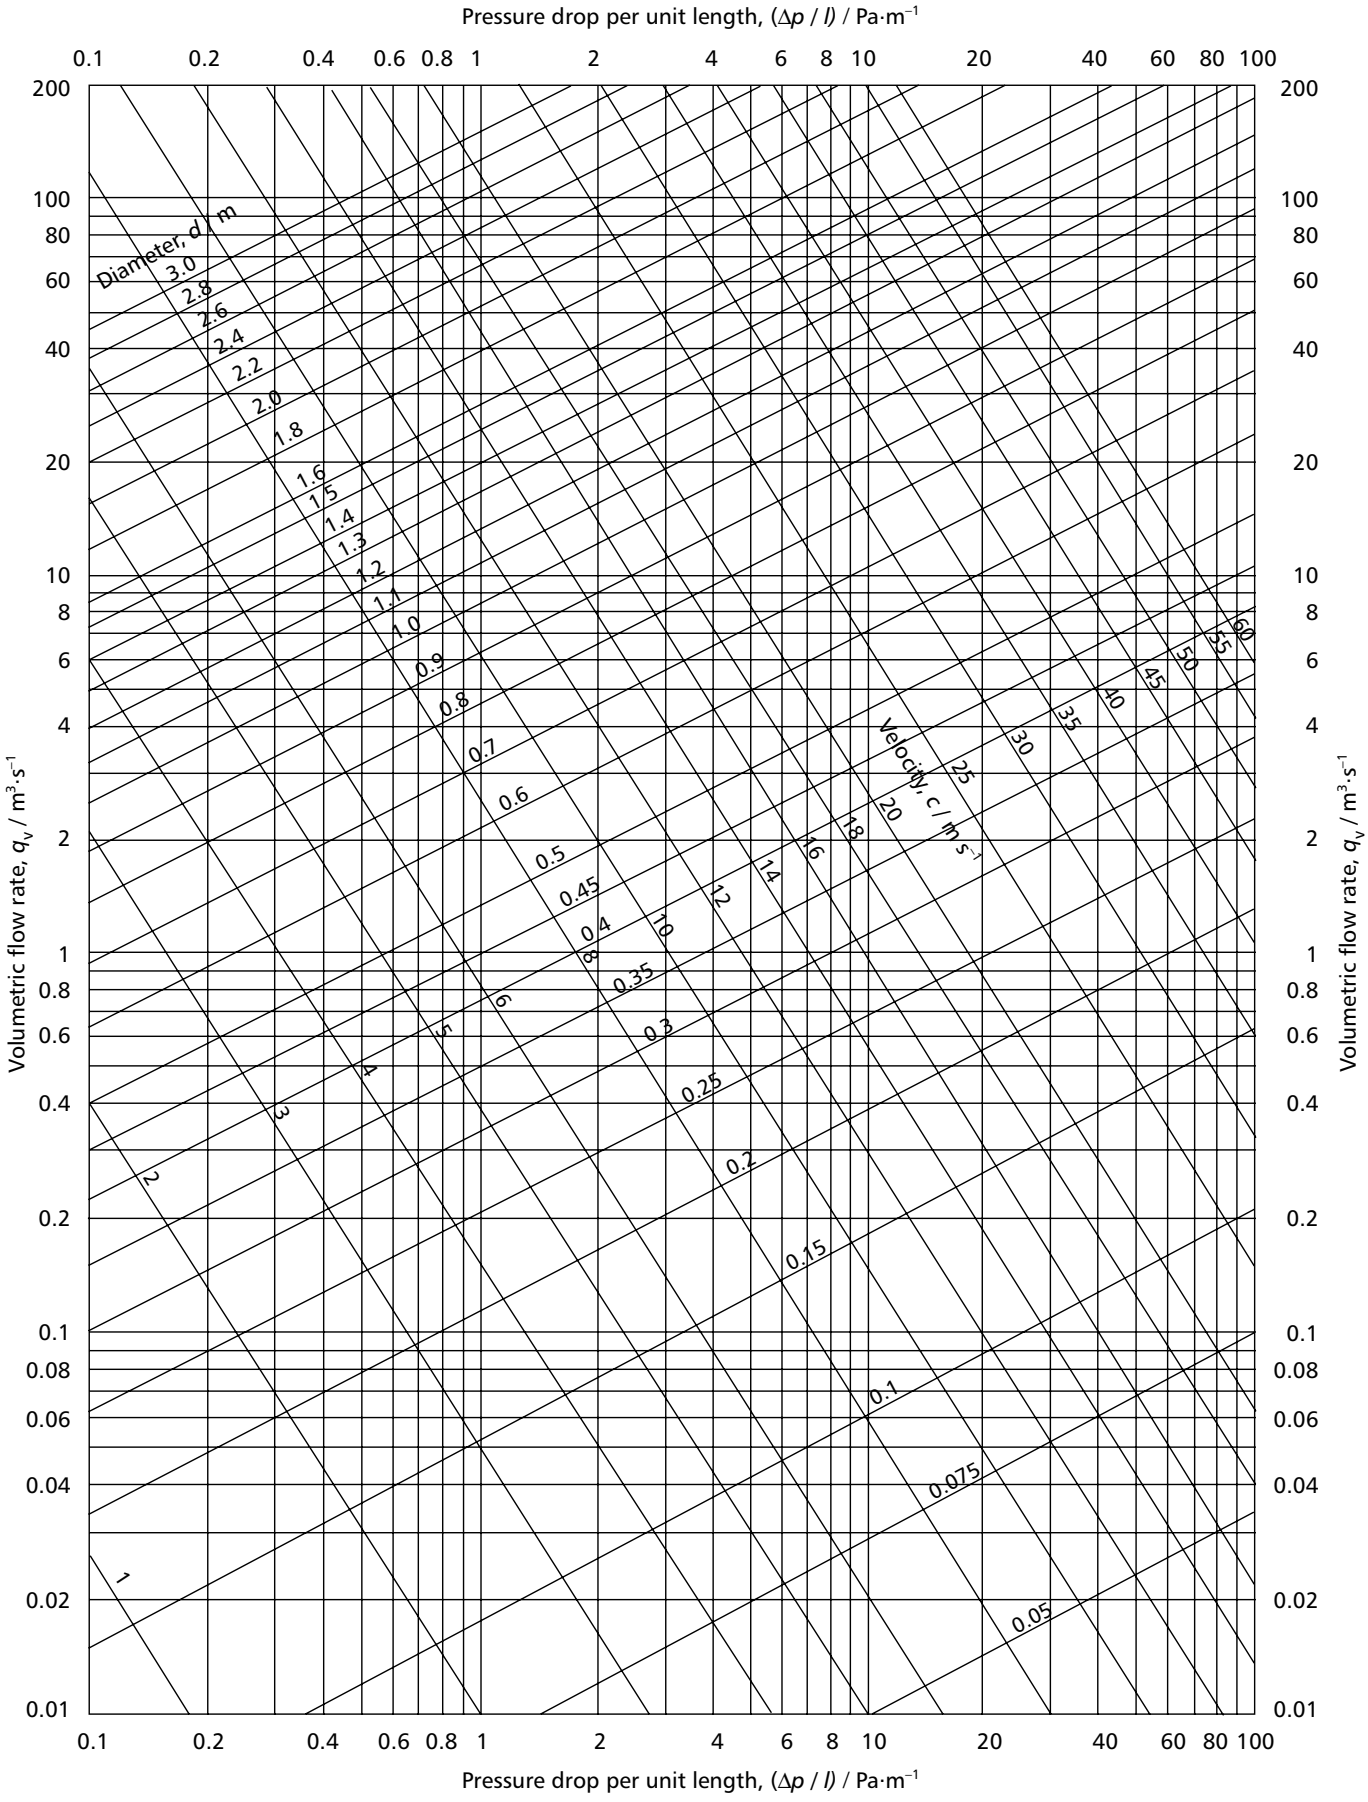

Figure 2.33 Pressure drop for air in galvanised circular ducts (ρ = 1.2 kg·m^{-3}; T = 293 K)

A46676816

Pressure drop across the branch is given by:

$$\Delta p_t = p_{tc} - p_{ts} = {}^{\circ}_{c-s}\,{}^{1}/_{2}\,\rho\, c_c^2 \qquad (2.16)$$

where Δp_t is the loss of total pressure across the branch (Pa), p_{tc} is the total pressure on the upstream side of the branch (Pa), p_{ts} is the total pressure on the downstream side of the branch (Pa), ζ_{c-s} is the pressure loss factor for the branch, ρ is the density of air (kg·m^{-3}) and c_c is the air velocity on the upstream side of the branch (m·s^{-1}).

Static regain is given by:

$$p_s - p_c = {}^{1}/_{2}\,\rho\,(c_c^2 - c_s^2) \qquad (2.17)$$

The air velocities are given by:

$$c_c = q_c / A_c \qquad (2.18)$$

$$c_s = q_s / A_s \qquad (2.19)$$

where q_c and q_s are the flow rates on the upstream and downstream sides of the branch respectively (kg·s^{-1}), A_c and A_s are the cross-sectional areas of the inlet to and outlet (straight flow) from the branch respectively (m^2).

(In general, $A_c = A_s$, but the cross-sectional area could increase between inlet and outlet if required.)

It must be emphasised that the fan must produce a rise in *total pressure* equal to the drop in *total pressure* of the ductwork system. The deliberate use of 'static regain' does not directly influence this, except that the downstream duct sizes are larger than might otherwise have been the case.

The value of air pressure in the duct ('static pressure', p) is only of consequence in duct air leakage calculations, and for ensuring approximately equal pressures behind any air outlets immediately on the duct itself. Sizing ductwork by the static regain method is normally carried out using a computer program.

Choice of duct sizing method

Use of the static regain method on low- and medium-pressure systems is limited, and its worth depends on the equivalent length of the index run; the shorter the index run, the more favourable the case for the static regain method. This is because in a low-pressure system the loss of velocity pressure is small and in a large installation its recovery is not significant in comparison with the friction loss in the system.

The equal friction loss method is easier to use in design and results in smaller duct sizes. Ducts sized using this method can cost up to 8 per cent less than those sized by the static regain method. However, the savings will be at least partly offset by higher commissioning costs, especially where the index run is relatively short but with numerous branches and outlets. This reduction in duct size may not be an option under Part L of the Building Regulations (NBS, 2010a), which limits specific fan power to 2 W/l·s^{-1}.

Similar considerations apply for high-pressure systems but, because of the higher potential loss of velocity pressure and the greater need to equalise static pressures at terminals (to avoid generation of noise at terminal dampers), there will be more occasions when the static regain method is worthwhile. The additional cost of ductwork will probably be less than 1 per cent.

Calculation of system pressure loss

The pressure loss in a ductwork system is made up of the pressure losses at plant items and terminal equipment, the friction loss in the straight ducts plus the losses due to duct fittings.

The losses due to both straight duct and fittings are directly related to the duct sizes, so that the determination of the system pressure loss follows the duct sizing process. The calculation as described, using data given in section 4.10 of CIBSE Guide C (2007), gives the 'total pressure' loss and this can be used to assess the required fan total pressure for the system. The total pressure loss of plant items and fittings is related to the static pressure loss as follows:

$$\Delta p_t = \Delta p + p_{vi} - p_{vo} \qquad (2.20)$$

where Δp_t is the total pressure loss (Pa), Δp is the static pressure loss (Pa), p_{vi} is the inlet velocity pressure (Pa) and p_{vo} is the outlet velocity pressure (Pa).

In the case of plant items and fittings where the inlet and outlet connection areas and flow rates are equal, then $p_{vi} = p_{vo}$ and the total and static pressures are identical. The advantage of using total pressure losses is that the friction and fitting losses are such that the total pressure always decreases in the direction of airflow so that the losses can simply be added. The total pressure loss of the terminals must be included in the overall total system pressure loss.

The calculation of pressure loss is essential in identifying the fan total pressure, as well as for balancing the system. It is very important to note that the total pressure loss along each duct run will always be the same. A system will always naturally balance itself so that the total losses in each run are the same. The duct sizing procedures outlined above will not normally deliver a balanced system, that is, the total pressure loss along each duct run will not normally be equal following the design process. Thus, it is crucial that the pressure loss along each run is equalised in order to deliver the design conditions, and this is normally achieved by adding dampers to balance the system.

The required fan total pressure for the system is then equal to the total pressure loss along one of the runs (which is, of course, the same as the total pressure loss along all the other runs) but it is prudent to allow a margin on the calculated total pressure loss to take account of:

— differences between the design concept and the actual installation

— the effect of system leakage on the fan duty.

Suitable air leakage margins are given in Table 2.15.

The second step is to compute the index run total pressure loss. This calculation should (for a supply system) typically include pressure losses at the following items:

— *entry*: intake opening, louvres, bird screens

— *suction duct*: straight duct sections, duct fittings, control and fire dampers, mixing chambers

— *plant*: filters (dirty condition), heaters, cooling coils, humidifiers, eliminators, attenuators

— *fan*: inlet vanes, inlet duct connection, outlet duct connection, flexible connections

— *supply duct*: straight duct sections, attenuators, duct fittings, balancing and fire dampers, zone plant items, control boxes, flexible ducting, terminals.

Extract systems will probably include many of the same items, but in a different order. Where the connections to equipment are different in size, or where multiple connections occur, the manufacturer's pressure loss data should be checked to ensure that they are the total pressure losses.

The next step in the manual calculation of the total pressure loss in a system is to identify the 'index' duct run. This is the duct run that has the greatest total pressure loss when using the duct sizing method described above: the duct sizing calculations will normally deliver a different total pressure loss for each run and the index run is the largest of these calculated pressure losses. Normally the index run will be that which links the fan and the most distant terminal. However, this is not automatically true because it is possible for shorter runs to have higher pressure losses if they contain plant items, high-pressure loss terminals or a high proportion of duct fittings.

The final step is to balance the system and here it is necessary to put in dampers to equalise the total pressure losses along each duct run, alternatively it may be necessary to consider resizing the duct to take out excess pressure. This ensures that the diameters chosen in the duct sizing process deliver the required design conditions; if dampers are not added the system will self balance and the flow rates in the ducts will depart from those originally chosen.

Ductwork sizing process

Duct sizing is an iterative process following identification of the duct runs. It requires the determining of the airflow requirements in the main ducts and subsidiary branches to assess the size of each. These then need to be checked against the original design parameters. A balance needs to be obtained between the duct sizes required to achieve the design outputs and the space allocated for the ductwork system. Within an overall ductwork installation, there may be different ductwork standards, resulting in a mixture of high-, medium- and low-pressure systems. Proper sealing of ductwork will mean reduced air leakage and therefore reduced ductwork size.

Materials, equipment, fittings and construction methods need to be chosen with respect to whole-life costs, not just the initial or installation cost. It can be beneficial and cost effective to standardise the types and sizes of the ducts and fittings used in the installation.

The areas served by the risers are likely to dictate the size of the horizontal branches. The depth of horizontal ductwork will also have a significant influence on the depth of false ceilings or floors and the overall floor-to-floor height.

The depth of the horizontal element is a function of the number of the vertical risers:

— maximum number of, or space in, vertical risers equates to the minimum horizontal element depth

— minimum number of, or space in, vertical risers equates to the maximum horizontal element depth.

It is essential that ductwork is sized correctly for air velocity, particularly to avoid noise. Where noise is likely to be a problem, providing two smaller ducts in parallel (rather than a single large duct) will reduce the air velocity and hence the noise. However, energy can be wasted by reducing the duct size since this will result in increased fan power. A worked example of the duct sizing process is provided in Appendix 2.A5.

Computer-based sizing methods

Computer programs have been produced that cover one or more of the following design aspects:

— duct sizing

— pressure losses in ductwork systems

— total fan pressure

— duct heat losses or gains and terminal temperatures

— acoustic analysis, with attenuation calculations from fan to terminals

— leakage analysis.

Users of computer-based sizing methods are advised to ensure that the reference data and equations used by the computer program are data provided in CIBSE Guide C (2007).

2.4.6 Ventilation design calculation techniques

2.4.6.1 Summary and introduction

Reliable calculations are essential for good design. Ventilation and airflow calculation methods are increasingly needed to evaluate the performance of ventilation design. To some extent they are able to replace expensive and time-consuming field tests and provide a comprehensive range of test conditions. Often, calculation methods can lead to an improved understanding of flow behaviour and provide confidence in design. They are especially important for making preliminary evaluations of complex ventilation and airflow strategies.

There are many calculation techniques available to predict ventilation and related airflow parameters in buildings. The main difficulties concern ease of use and providing suitable input data. Many advances have developed in the commercial field, especially in the areas of user-friendly access and embedded databases. As these developments continue, the ease with which calculation techniques may be applied is steadily improving.

In general, the designer is faced with a set of fixed conditions relating to the environment in which the building is located. These include climate, pollutant sources (e.g. from traffic and adjacent buildings etc.) terrain characteristics and the shielding presented by surrounding buildings.

Calculation techniques form part of the process of matching design variables (e.g. building layout, approach to ventilation etc.) with the various design constraints to achieve an optimum ventilation. Reliable results are dependent on a good working knowledge of techniques and data. More detailed calculation guidance is presented in CIBSE Guide A (2015a). CIBSE AM11: *Building performance modelling* (2015c) also provides important guidance on the integration of energy and environmental modelling for buildings.

2.4.6.2 Applications

Typical applications for which numerical methods are needed include:

— estimating air change rate induced by air infiltration and ventilation

— calculating the influence of parameters such as climate and building airtightness on air change rate

— determining the rate and direction of flow through purpose-provided and air infiltration openings

— calculating the rate of airflow between rooms

— calculating the pattern of airflow within individual zones or rooms (ventilation efficiency parameters).

Subsidiary calculations, based on knowledge of airflow and ventilation prediction, include:

— determining the energy impact of ventilation

— predicting pollutant concentration (indoor air quality analysis and pollutant removal effectiveness)

— estimating the transfer of pollutants between zones or between the outside and inside of a building

— calculating room and building pressures for back-draughting or cross-contamination assessment

— the sizing of ventilation openings (to optimise ventilation performance)

— cost and energy performance analysis (e.g. to compare alternative ventilation strategies)

— thermal comfort analysis (temperature and draught risk).

Further methods are necessary to evaluate the strength of natural driving forces. These include:

— wind pressure calculation

— stack pressure calculation.

A summary of calculation methods and applications is presented in Table 2.30.

The rate and pattern of airflow throughout a building is uniquely defined by:

— the distribution and airflow characteristics of all flow paths (openings) that penetrate the building envelope and that link individual rooms; these paths include constructional cracks and gaps, intentionally provided air vents and any open windows or doors

— the pressure difference acting across each opening; this is developed by the combined effect of naturally and mechanically induced driving forces.

Additionally, the pattern of air movement within any individual space is further influenced by the:

— locations of all sources of incoming air

— temperature, velocity and turbulence of incoming air at each source

— location and flow rate of all sources of outgoing air

— distribution of flow obstructions (e.g. partitioning, furnishings and fittings)

— distribution and strength of all thermal sources and sinks

— thermal characteristics of all surfaces.

These extra needs can make the prediction of airflow patterns in enclosed spaces an extremely complex exercise.

In reality, it would be a formidable task to identify the flow characteristics, driving forces, size and location of every opening. Instead it is necessary to introduce a number of simplifying assumptions that allow the main physical concepts of airflow to be represented without compromising results. It is the degree to which the flow mechanics are simplified that identifies the type of model, the detail of data needed and the range of applicability of results. Generic forms of calculation method used for the prediction of ventilation and airflow patterns in buildings include:

— estimation from building airtightness data

Table 2.30 Summary of calculation techniques and applications

Application	Calculation type			
	Empirical/look-up tables	Single-zone models	Multi-zone models	Computational fluid dynamics
Initial design average infiltration rate	*			
Hourly infiltration and whole-building ventilation rate and contaminant concentration		*		
Hourly room airflow rate and contaminant concentration			*	
Airflow and contaminant flow between rooms			*	
Airflow distribution within rooms				*
Room ventilation efficiency				*

— 'simplified' theoretical methods

— network (zonal) models

— computational fluid dynamics (CFD).

2.4.6.3 Estimation from building airtightness data: estimation of average air infiltration rate for basic loading design

The simplest method for estimating air infiltration rate is by inferring it from airtightness data. For small buildings such as dwellings, the wholly empirical rule of thumb has been to divide the air change at 50 Pa (see 'Building airtightness' in section 2.4.7.2) by 20 to obtain the average annual infiltration rate. This however is very sensitive to building size. The method is further developed in section 4.6 of CIBSE Guide A (2015a) to take account of building size through a series of design tables and figures such as that illustrated in Figure 2.35.

Advantages

— It is easy to apply using both measured or design data.

Limitations

— It is only a very approximate solution for preliminary design purposes only. Final losses will usually need to be determined as part of a whole-building thermal analysis.

— This approach largely ignores the driving forces that vary considerably over time, so time varying changes to air change are also ignored. Therefore this is not suitable for short-term use, since the instantaneous rate of ventilation can differ considerably from the 'average' value.

2.4.6.4 Simplified theoretical models

A much improved approach that incorporates the effects of airtightness and natural and mechanical driving forces has been developed (Sherman and Grimsrud, 1980). This adds to airtightness data by including the driving forces of ventilation (both natural and mechanical) as well as local shielding conditions that can affect wind pressure. It can thus be used for calculating hourly air change rates. The method is based on making a basic assessment of the leakage distribution and using simplified wind and stack pressure equations to determine the driving forces. The result is an estimate of total air change rate for the space.

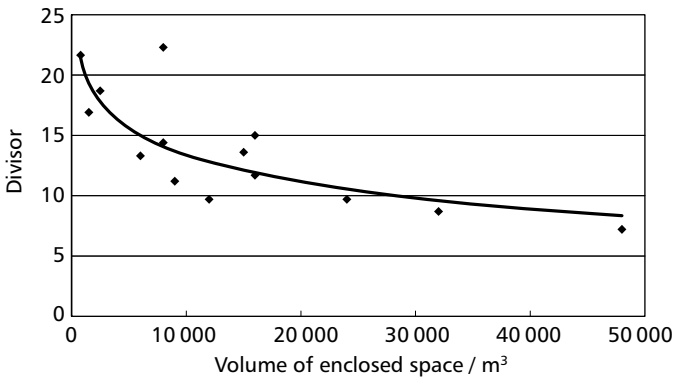

Figure 2.35 Approximate ACH at 50 Pa; divisor to obtain average annual air infiltration rate

Advantages

— It is a fairly simple spreadsheet calculation procedure.

— It can be used for hourly ventilation calculations taking into account airtightness, local shielding and ambient driving forces.

Disadvantages

— The building is treated as a single zone only.

— It calculates an air change rate only; there is no information about inflow and outflow directions through openings.

2.4.6.5 Network (zonal) models

A network model is one in which a building is represented by a series of 'zones' or 'cells' interconnected by flow paths. Each 'zone' typically represents an individual room, while flow paths represent individual or amalgamated flow openings. These models thus provide a more rigorous incorporation of flow theory and can be used to estimate the flow rate and flow direction through defined openings in the building fabric. They can also incorporate air leakage data, specific natural ventilation openings and flow rates induced by mechanical ventilation systems. Wind and stack (buoyancy forces) are taken into account as well as wind shielding.

The pressure due to wind, stack and mechanical driving forces is calculated for each opening in the flow network. The corresponding flow rate through each opening is determined by applying a standard power law or quadratic law flow equation (see CIBSE Guide A (2015a)). The average pressure inside each zone is then iteratively adjusted until a flow balance between incoming and outgoing airflow is achieved. Zonal models can also be used to calculate steady-state contaminant concentrations within zones for given concentration sources.

There are two configurations of these models: single zone and multi zone, discussed below.

Single zone

This treats the building as a single open zone of uniform indoor pressure. Calculation of flow balance is relatively easy and an algorithm listing is given in Appendix 4.A3 of CIBSE Guide A (2015a).

Multi zone

Each room in a space is treated as a separate zone, thus the flow rate into each room can be determined. This involves a much more complex solution procedure since the flow rate into each zone as well as the whole building itself must be balanced. A popular open source algorithm is CONTAM (NIST, 2010) developed at NIST in the US. An alternative program is COMIS (AIVC, 1990).

Advantages

— Network methods are used to calculate the rate of airflow through individual openings. Thus, this technique represents some of the closest of approximations to the true system of ventilation and infiltration airflow.

— By calculating the rate and direction of flow through each flow path, it is possible to evaluate virtually every ventilation-related parameter. Applications include the calculation of:

  — air change rate as a function of climate and building air leakage

  — ventilation and air infiltration rate (mechanical and natural)

  — the rate and direction of airflow through individual openings

  — the pattern of airflow between zones

  — internal room pressures

  — pollutant concentration

  — pollutant flow between zones and between the inside and outside of the building

  — back-draughting and cross-contamination risks.

Limitations

— The driving forces need to be quantified and all openings in the structure of the building need to be accurately accounted for.

— It assumes that air and pollutant in each zone is uniformly mixed.

— As with the preceding methods, this approach does not provide information on pollutant distribution within the individual zones.

— It does not handle wind-driven single-sided flow.

2.4.6.6 Computational fluid dynamics (CFD)

Often, knowledge is needed about the pattern of airflow and the distribution of air temperature and pollutants within an enclosed space. This may be especially important to check the performance of a ventilation system, to verify comfort conditions or to predict thermal transport and smoke and fire spread prediction. In the past, design has been based on scale-model analysis and measurements of airflow patterns in full-size buildings. More recently, the application of CFD mathematical models representing the flow field has become increasingly popular. These are numerical methods that approximate the enclosure by a series of 'control' volumes or elements. Airflow in each element must follow the fundamental laws of physics covering motion, energy transport and conservation of mass.

Specific applications include the simulation and prediction of:

— room airflow

— airflow in large enclosures (atria, shopping malls, airports, exhibition centres etc.), air change efficiency

— pollutant removal effectiveness

— temperature distribution

— air-velocity distribution (for comfort, draughts etc.)

— turbulence distribution

— pressure distribution

— fire and smoke movement

— airflow around buildings (for wind-pressure distribution).

Simulation approach

The space to be simulated is 'discretised' into a set of control volumes or elements. Typically, the enclosure may be divided into 500 000–2 000 000 control volumes or more; therefore each element represents only a fraction of the total enclosure volume. The system of discretisation can be non-uniform so that clusters of elements can be located at areas of greatest interest. Flow, energy propagation and contaminant spread are represented in each of the control volumes by a series of discretised transport equations. In structure, these equations are fundamentally identical but each one represents a different physical parameter. Direct solution techniques are not available, so iteration is applied. Parameters are initially given arbitrary values from which the iteration can commence. These values are then adjusted until each of the transport equations balances. The process of reaching a balance is referred to as 'convergence'. Considerable computational effort is normally necessary, with the result that processing times can be lengthy, sometimes taking many hours.

Key parameters

Key parameters calculated as part of a CFD analysis include:

— *Pressure distribution*: airflow is driven by the pressure distribution, therefore the pressure field is fundamental to the whole flow process. Pressure is maintained by a combination of driven air or forced convection and by buoyancy forces or natural convection. Forced convection is driven by mechanical ventilation or the natural flow of air through openings. Free convection is driven by buoyancy forces created by imbalance in temperature difference.

— *Velocity field*: air movement is a vector having components in both speed and direction. To determine the air velocity distribution, airflow must usually be represented by three transport equations.

— *Temperature field*: the temperature field is sustained by thermal sources and sinks distributed about the enclosure. Sources can include heat emitters, solar gain and surfaces warmed by radiation. Sinks can include chilled ceilings and cold surfaces such as windows or uninsulated walls. Buoyancy forces and free convection currents are generated by the temperature field. Temperature is a scalar quantity acting only on the vertical component of velocity field through a gravitational term.

— *Turbulence*: turbulence is the random fluctuation of the airstream from its mean flow direction. It contributes to the rapid mixing of air and pollutants

in the space and thus has a major impact on the flow field and pollutant distribution. The representation of the turbulence of room air currently presents a challenge to the credibility of CFD techniques. Turbulence must be accurately represented but the representation of turbulence is usually highly empirical. This is because the scale length of turbulence is usually much smaller than the grid size that can practicably be used in a CFD simulation. Modelling turbulence has, therefore, become an important area of research and is an area that is most likely to lead to erroneous results. Modern techniques are increasingly adopting a large eddy simulation (LES). In this method the most significant scale of turbulence is represented by grid size. However considerable computing capacity is needed.

— *Boundary layer flow*: airflow close to surfaces is subjected to boundary layer effects in which the rate of flow is influenced by surface friction. This further adds to the complexity of flow modelling.

Advantages

— It can be used to calculate steady-state and transient airflow patterns within a space.

— It can also be used to calculate associated pollution distribution and ventilation effectiveness parameters.

Disadvantages

— It is often difficult to validate results.

— Complex calculation techniques require meticulous setting up.

— Turbulence can be difficult to represent, thus risking erroneous results.

2.4.7 Ventilation design measurement techniques

2.4.7.1 Introduction

Measurement methods for airflow and related parameters are essential for commissioning, diagnostic analysis, design and research. Many techniques have been developed with each having a specific purpose. The intention of this section is to present a summary of measurement methods, principally for design, and to provide guidance on the selection of techniques according to application. Comprehensive information on measurement techniques is published by Charlesworth (1988) and Roulet (1991). In addition, a simplified discussion is presented in *AIVC Guide to Energy Efficient Ventilation* (Liddament, 1996) on which the following discussion is based. Typical measurement requirements cover:

— building airtightness

— duct airtightness

— ventilation rate

— ventilation effectiveness

— airflow characteristics and air movement

— airflow through terminal units and ducts

— pressure distribution and airflow around buildings.

Figure 2.36 Airtightness testing: (*a*) blower door and (*b*) trailer fan (reproduced courtesy of BSRIA Compliance)

2.4.7.2 Measuring airtightness

The main objectives of an airtightness test are to:

— determine the leakage rate of air through a building component or duct at a specified test pressure

— determine the relationship between air leakage and pressure over a typical operating pressure range.

Building airtightness

In the UK airtightness requirements for building are covered by Part L of the Building Regulations (NBS, 2013a). Testing usually requires a whole-building pressurisation test to determine the air leakage at a reference pressure of 50 Pa. This is the average pressure between the inside and outside of the building. The conduction of the test is covered by a protocol as described in CIBSE TM23: *Testing buildings for air leakage* (2000c). The 50 Pa reference pressure is selected on the basis that results will not be adversely affected by wind and stack pressures under calm conditions but is not sufficiently high for the generated pressure itself to distort leakage openings physically (either by opening or closing them). Despite this there is invariably a difference in results between pressurising and depressurising a building as a consequence of the behaviour of leaks.

Measurements are made using a 'blower door' (Figure 2.36(a)) or, in the case of very large buildings, a 'trailer fan' (Figure 2.36(b)) to create incremental pressure differences between the inside and outside of a building in the ±100 Pa pressure range. For each pressure increment, the corresponding airflow rate through the fan is measured. The relationship between induced pressure and flow rate is then plotted. From this, the air leakage rate at 50 Pa is determined by interpolation as well as the pressure flow characteristics. The flow characteristics are commonly described by the power law equation as described in CIBSE Guide A (2015a).

By carrying out multiple pressure tests between zones, the airtightness of individual rooms and leakage across party walls can be determined.

Duct airtightness

In the UK it is recommended as good practice that all significant installations (e.g. those with a fan capacity greater than 1 $m^3 \cdot s^{-1}$) should be tested in accordance with DW/143: *Guide to Good Practice: Ductwork Air Leakage Testing* (BESA, 2013b). Duct testing is also a requirement of Part L of the Building Regulations (NBS, 2013a) in England (and related requirements for Scotland, Wales and Northern Ireland).

2.4.7.3 Leak detection

Simple leak detection methods are necessary to track design faults and poor workmanship. Suitable methods are outlined below.

Smoke methods

Leaks may be detected by fan pressurising a building or an individual room within a building and observing the movement of smoke emitted from a smoke stick or puffer. This approach is very effective and easy to undertake. The smoke source is gently moved in the vicinity of potential sources of leaks during the course of the test. Sometimes leak locating and sealing may be undertaken while conducting a routine pressurisation test. Ideally, the building or room should be pressurised at positive pressure so that the flow of smoke, from inside to outside, can be clearly identified.

Thermography

Leaks may also be located by thermography. Testing may be undertaken from either the inside or outside of the building. For indoor testing, the building or room is depressurised to permit the ingress of cold outdoor air. An interior thermographic scan will indicate the location of fabric leaks.

Alternatively, scanning can be undertaken externally, in which case the building is pressurised and the sources of exfiltrating hot air are located. This may be undertaken on a cold night when it is possible to locate air leaks and location of excessive fabric heat loss arising from inadequate or poorly installed insulation.

Limitations

— Leak detection does not quantify the infiltration loss but only identifies the source of leaks.

— Infrared thermography is costly and experience is needed to interpret results.

2.4.7.4 Measuring ventilation rate

The tracer gas technique

Fresh air ventilation rate is commonly determined using the 'tracer gas' technique. This tends to be a specialist task rather than routine and therefore requires specialist contractors. A tracer gas is ideally an inert gas that is non-toxic, measurable at low concentrations and not normally present in the atmosphere. In the past, nitrous oxide and sulphur hexafluoride were commonly used. However, neither of these would probably now be acceptable where occupants are present. Also SF_6 is a substantial greenhouse gas and its general use has largely been banned. The remaining choice is carbon dioxide, which is generated by people (metabolic CO_2—see section 2.2.2.4) or is otherwise readily available and is perfectly safe at transient concentrations up to 5000 ppm.

To make a measurement, tracer gas is emitted into the space to be tested and is well mixed using mixing fans. These fans are then switched off and concentration behaviour under normal room conditions is observed. Various emission configurations are possible including:

— Concentration decay: the tracer gas injection is switched off and the decay in concentration over time is monitored. For a uniform ventilation rate, the decay is logarithmic with respect to time and the air change rate is proportional to the log gradient.

— Constant concentration: gas is injected at a sufficient rate to maintain a constant concentration.

The ventilation rate is proportional to the gas injection rate. This test requires sensitive feedback controls and actuators, thus adding to complexity.

— Constant emission: the tracer gas is discharged at a constant rate. Air change rate can be determined from the corresponding time varying room concentration. Eventually a steady state may be reached, at which point this test corresponds to a constant concentration test. At all times the concentration of tracer gas must be carefully monitored to ensure that the safe concentration of tracer gas is not exceeded.

In all cases, tracer gas blends with incoming air that is not treated with tracer gas. This could be fresh outdoor air or it could be infiltrating air from adjacent rooms. To determine the fresh air ventilation rate into a space the following options must be considered.

— The entire enclosure must be tested as a single entity.

— The constant concentration method is used in which all adjacent rooms are held at the same concentration as the test room. The injection rate in the test room will therefore be proportional to the unseeded outdoor air.

Airflow between rooms can be determined by using multiple tracers.

'Passive' tracer gas techniques

A variation on the tracer gas technique is the 'passive' tracer gas method. This technique is used to estimate the average air change rate into a building over an extended period of time. It is a method that was pioneered by Dietz and Cote (1982). It is based on the use of volatile perfluorocarbon tracers (PFTs), which may be detected in the air in minute concentrations within the parts per trillion range. The tracer gas is gradually emitted over a period of time within the test space. An exposed sample tube is used to adsorb the gas over the same time period. Air change rate is calculated from the amount of gas emitted and collected by the emission and sample tubes respectively. Analysis of the sample tubes is undertaken in a laboratory using gas chromatograph and electron capture detection. Recent developments are described by Upton and Kukadia (2011).

The concentration of tracer is so small that it is regarded as having no toxic impact. It may therefore be used in occupied dwellings, offices or other buildings. Test periods can vary from a few hours to several months. By using more than one test gas, it is also possible to use this method to analyse airflow between zones. This method is inexpensive and unobtrusive. It may easily be applied to occupied spaces and may be conducted by relatively unskilled operators.

There are various limitations to this approach, including the following.

— This method is only accurate if air change remains reasonably constant over the measurement time.

— This approach provides insufficient weighting to peaks in air change, such as those associated with airing, door opening or transient high infiltration driving forces, i.e. transient changes in conditions are not 'seen'.

Arguably, if the objective of the measurement is to estimate the average pollutant dose received by occupants in a space resulting from a constant emitting pollutant source (e.g. furnishings and fittings), this method provides a reliable result. However, it can ignore the benefit of ventilation for transient pollutant emissions (e.g. airing for washing and cooking) and underestimate ventilation-related thermal losses (especially through open windows).

2.4.7.5 Measuring ventilation effectiveness

Ventilation effectiveness is a measure of how well air is mixed in a space (see section 2.2.8). This can be measured using the tracer gas technique. Gas is discharged in the occupied zone and the concentration is measured at key points including the extract grille and occupant workstations. Key characteristics are as follows.

— A similar concentration in the occupied zone and extract grille indicates perfect mixing.

— A lower concentration in the extract grille than the occupied space indicates short circuiting, i.e. the supply air reaches the extract grille before mixing in the space.

— A higher concentration in the extract grille than at individual occupant workstations indicates successful displacement ventilation. The lower the workstation concentration, relative to the extract grille concentration, the better the displacement flow.

2.4.7.6 Airflow distribution in a space

Monitoring of airflow in a space may be necessary to evaluate a system of identify faults. Primarily this is a research and development tool. It may also be used in conjunction with CFD analysis (see section 2.4.6.6).

Applications include the:

— measurement of flow velocity and air turbulence throughout a space

— evaluation of diffuser performance

— response to thermal parameters and flow obstruction to airflow patterns.

Methods are based on qualitative visualisation approaches and quantitative anemometric techniques as outlined below.

Visualisation techniques

A qualitative assessment of airflow pattern and turbulence can be made by applying a number of visualisation techniques. These are based on developing a two-dimensional sheet of bright light, which is directed across a section of room. Smoke or small bubbles are used to highlight the flow pattern. These may be photographed or recorded using a video camera.

Limitations

— Qualitative methods are fairly easy to perform but provide only visual information.

Anemometry (hot wire)

Anemometry is used to give quantitative evaluation of spatial air velocity and turbulence distribution. Anemometers must be very sensitive and are usually based on 'hot wire' techniques. A resistance wire (the anemometer element) is heated while the current through the wire is monitored. Air speed fluctuations rapidly change the temperature and, therefore, the resistance of the wire. The resultant current change provides a measure of instantaneous air speed (turbulence). Hot wire anemometers are used in 'test' chamber studies where 'traverses' are made across sections of the chamber to build up a complete pattern of airflow information.

Limitations

— Quantitative (anemometric) techniques are complex and time consuming and therefore tend to be restricted to research or product (diffuser) development applications.

— Measurements give snapshot results only. In reality, the pattern of airflow will vary depending on the location of obstructions and the balance between forced and free convection forces.

— Small changes to conditions can vastly influence airflow pattern.

Flow distribution: flume models

Flume models provide a method by which air movement, pollutant transport and temperature distribution can be predicted using scale models inserted in a water flume. They have been used to assist in the design of a variety of buildings and to predict the transient pattern of airflow. Specific applications include:

— predicting the role and pattern of airflow and pollutant transport through defined openings

— predicting flow patterns through a building

— predicting flow and pollutant distribution in individual rooms.

A 1:20 to 1:100 scale model of the building is constructed using transparent Perspex. This model is necessarily simplified but the essential features controlling the ventilation process, including envelope openings and openings between individual rooms, are retained. This model is completely immersed in a glass-sided water channel such that the pattern of flow can be observed using a video camera. Buoyancy-induced flow (density stratification) is represented by sources of dense salt solution to which a tracer dye is added. The model and video camera are inverted so that the salt solution appears to rise. Cooling is similarly simulated using a less dense alcohol water mixture. Quantitative measurements of flow velocities are made by measuring samples of salt solution taken from within the model. Automated image processing of the video film allows the measurement of dye intensities to give the instantaneous temperature distribution throughout the building, while flow velocities can be measured by particle tracking. Mixing and diffusion processes may also be quantified.

Limitations

— Flume models require considerable laboratory space, thus restricting this approach to the laboratory.

— Primarily this method provides an aid to assessing the impact of stack-induced airflow. The wind regime is more difficult to predict, since it is not usually possible to incorporate surrounding obstructions.

— It is not really practicable to represent infiltration or other openings resulting from construction technique or poor site practice.

2.4.7.7 Airflow through terminal units and ducts

Flow measurements through individual ventilation openings are needed to ensure that the airflow rate and flow direction conform to design requirements. They are also needed to balance ventilation systems as part of servicing or commissioning. Examples include:

— monitoring the flow through passive ventilation stacks

— monitoring the performance of mechanical ventilation systems

— measuring naturally or mechanically driven airflow through air inlets and outlets.

Basic anemometry systems are straightforward to use but might not be as accurate as more complex methods.

Techniques are based on standard airflow measuring instrumentation and include those listed below.

Orifice plates and nozzles

These are calibrated devices that are fitted in series with ductwork and have a known relationship between airflow rate and pressure drop relationship. The flow rate is determined by measuring the pressure drop across the device. Long, straight lengths of duct are needed both upstream and downstream of the system while the constriction imposed by the orifice or nozzle can impede flow.

Pitot-static traverses

Air velocity at a specific location is commonly measured using a pitot-static tube. Duct airflow can be measured by inserting the tube into a prepared opening and measuring the air speed at several depths across the cross-section of the tube. The total flow rate is determined by integrating the results.

Several types of anemometer are used to measure the flow rate through ducts and openings; these include vane anemometers and hot wire anemometers. The vane anemometer is the most likely device for use in servicing and commissioning since it is robust and is satisfactory for measuring relatively high airflow velocities. Hot wire anemometers are delicate, precision devices for measuring very low flow rates and turbulent fluctuations (see 'Anemometry (hot wire)' in section 2.4.7.6).

Figure 2.37 Flow hood (reproduced courtesy of BSRIA Compliance)

Flow hoods

Anemometers can disrupt or impede the flow of air through an opening, thus introducing error, especially if the flow rate is low. One device specifically designed to overcome this problem and to monitor the direction and rate of airflow through an opening is the flow hood. Developed in conjunction with the Netherlands Organisation for Applied Scientific Research (TNO) (Phaff, 1988), it is an active device containing its own calibrated fan, which is operable over a flow range of between 0 and 225 $m^3 \cdot h^{-1}$. The funnel opening of the flow hood is placed over the opening through which the flow rate is to be measured, forming an airtight seal. The internal fan speed is adjusted until there is zero pressure difference across the opening. The resultant flow rate through the device is equivalent to the undisturbed flow rate through the opening. The impact of the measurement system on the rate of flow is therefore substantially minimised. An example of a flow hood is shown in Figure 2.37.

Tracer gas injection

Sometimes, tracer gas injection is used to measure airflow rate. Tracer gas is injected into the duct at a constant known rate. The flow rate of air through the duct is proportional to the tracer concentration measured in the duct.

2.4.7.8 Pressure distribution and airflow around buildings

The wind pressure distribution is needed to calculate the flow rate through building envelope openings. Accurate design requires knowledge relating to a particular building shape and location. The following method may be used.

Wind tunnel testing provides detailed information on spatial pressure distribution. It can also be used to assess airflow patterns around buildings and air intake contaminant ingress risks.

A scale model of the building and immediate surroundings is produced that can fit within the working section of a boundary layer wind tunnel. Pressure taps connected via plastic tubing are placed on each face of the model so that the pressure distribution can be determined. The model needs to be placed on a turntable so that pressure can be analysed for the complete spectrum of wind direction. Wind speed is determined with respect to a specific datum height, normally corresponding to the height of the building. Upwind roughness is normally developed using an array of cubic blocks. Smoke combined with photography is often used to provide visualisation of the flow regime.

An 'environmental or boundary layer' wind tunnel that can accurately represent the lower levels of the Earth's turbulent boundary layer and accommodate reasonably sized scale models of the building and surrounding environs is necessary. These are restricted to laboratory applications on scale models. A typical minimum scale for analysis of wind pressure distribution is 1:50. Models must also incorporate an accurate representation of the surrounding environment.

CFD is also used to assess wind pressures on buildings with several commercial models being available. In all instances care needs to be taken to ensure proper validation in order to obtain accurate results. Typical problems relate to the choice of turbulence model and selection of the correct grid size and layout.

2.5 Other design considerations

2.5.1 Introduction

In developing ventilation strategies there are other important design considerations that need to be addressed. These are covered in this section and include:

— noise

— fire and smoke protection

— air leakage.

Energy and carbon performance considerations are discussed in 2.1.4.

2.5.2 Noise

Both natural and mechanical systems can present noise problems. General guidance on acceptable noise levels can be found in CIBSE Guide A (2015a). The following provides information on noise sources and abatement. More detailed information is covered in CIBSE Guide B4 (2016c).

2.5.2.1 Outdoor noise

Local noise sources can be continuous, such traffic, industrial processing and low-flying aircraft; other sources might be regular, such as playgrounds or entertainment

and sports venues; while other sources might be random, such as construction sites and road maintenance or noise from adjacent buildings. In each case, noise levels should be assessed and incorporated in the ventilation design. External noise can be a particular problem in the case of natural ventilation when windows face busy main roads or are within 100 m of a railway line. A partially open window typically has a weighted sound reduction index of 10–15 dB compared with 35–40 dB for thermally insulating double glazing (BSI, 2014b). Measures to improve acoustic performance include:

— the use of acoustic baffles

— siting the opening windows on a quiet side of a building

— the use of acoustic ventilators (as opposed to windows)

— placing buffer zones (e.g. a circulation space) adjacent to the noise source.

Outside noise is of particular concern in schools. *Acoustic Design of Schools* (EFA, 2004) contains detailed design guidance on minimising noise impact).

2.5.2.2 Indoor noise sources

As well as the ingress of external noise, and noise generated from mechanical systems, consideration also needs to be given to internal acoustic design issues including:

— conflict between partitioning for acoustic privacy and provision of air paths

— that exposed thermal mass increases the number of hard surfaces (see section 2.4.2.4).

Indoor noise can be generated by:

— occupants

— equipment

— mechanical ventilation systems.

2.5.2.3 Noise from ductwork and HVAC plant

Noise generation increases rapidly with increases in velocity at grilles, bends and other fittings where the flow separates from the walls, leaving turbulent eddies in its wake. The noise generated at grilles and terminals is of particular importance. High-velocity systems require noise

Table 2.31 Noise-reduction methods for various noise sources and transmission paths

Path	Description	Noise-reduction measures
(*a*)	Direct sound radiated from sound source to ear	Direct sound can be controlled only by selecting quiet equipment.
	Reflected sound from walls, ceiling, and walls	Reflected sound is controlled by adding sound absorption to room and to location of equipment.
(*b*)	Air- and structure-borne sound radiated from casings and through walls of ducts and plenums is transmitted through walls and ceiling into room	Design ducts and fittings for low turbulence; locate high velocity ducts in non-critical areas; isolate ducts and sound plenums from structure with neoprene or spring hangers.
(*c*)	Airborne sound radiated through supply and return air ducts to diffusers in room and then to listener by path (*a*)	Select fans for minimum sound power; use ducts lined with sound absorbing material; use duct silencers or sound plenums in supply and return air ducts.
(*d*)	Noise is transmitted through plant/equipment room walls and floors to adjacent rooms	Locate equipment rooms away from critical areas; use masonry blocks or concrete for equipment room walls and floor.
(*e*)	Building structure transmits vibration to adjacent walls and ceilings from which it is radiated as noise into room by path (*a*)	Mount all machines on properly designed vibration isolators; design equipment room for mechanical dynamic loads; balance rotating and reciprocating equipment.
(*f*)	Vibration transmission along pipe and duct walls	Isolate pipe and ducts from structure with neoprene or spring hangers; install flexible connectors between pipes, ducts, and vibrating machines.
(*g*)	Noise radiated to outside enters room windows	Locate equipment away from critical areas; use barriers and covers to interrupt noise paths; select quiet equipment.
(*h*)	Inside noise follows path (*a*)	Select quiet equipment.
(*i*)	Noise transmitted to diffuser in a room into ducts and out through an air diffuser in another room	Design and install duct attenuation to match transmission loss of wall between rooms.
(*j*)	Sound transmission through, over and around room partitions	Extend partition to ceiling slab and tightly seal all around; seal all pipe, conduit, and duct penetrations.

Noise source	Transmission paths
Circulating fans; grilles; diffusers; registers; unitary equipment in room	(*a*)
Induction coil and fan-powered mixing units	(*a*), (*b*)
Unitary equipment located outside of room served; remotely located air handling equipment, such as fans and blowers, dampers, duct fittings and air washers	(*b*), (*c*)
Compressors and pumps	(*d*), (*e*), (*f*)
Cooling towers; air-cooled condensers	(*d*), (*e*), (*f*), (*g*)
Exhaust fans; window air conditioners	(*g*), (*h*)
Sound transmission between rooms	(*i*), (*j*)

control by using sound-absorbent units between the duct system and the room outlets and inlets.

Noise in ductwork can be contentious, particularly where the system or components (e.g. intake, exhaust, AHU etc.) produce a noise nuisance to the building occupants, neighbours or passers-by. Noise is generated where eddies are formed as flow separates from a surface.

The generated noise level is particularly sensitive to the velocity (see CIBSE Guide B4 (2016c)).

The velocity of air flowing through a duct can be critical, particularly where it is necessary to limit noise levels. Recommended velocities for particular applications, using the BESA system classifications to control noise, are given in Table 2.16.

Table 2.31 lists noise-transmission paths for a variety of sound sources and suggests appropriate methods of noise reduction (SMACNA, 2006).

2.5.3 Fire and smoke protection

2.5.3.1 General

Building Regulations in the UK require that buildings be subdivided, with fire-resisting construction depending on size and use, to inhibit the spread of fire within the building. Advice on the degree of compartmentation and fire-resisting periods are given in Part B of the Building Regulations (NBS, 2013g).

In addition, Part J of the Building Regulations (NBS, 2013f) has specific legal requirements:

> **38.—(1) This regulation** applies where building work—
> (a) consists of or includes the erection or extension of a relevant building; or
> (b) is carried out in connection with a relevant change of use of a building,
> and Part B of Schedule 1 imposes a requirement in relation to the work.
> (2) The person carrying out the work shall give fire safety information to the responsible person not later than the date of completion of the work, or the date of occupation of the building or extension, whichever is the earlier.
> (3) In this regulation—
> (a)"fire safety information" means information relating to the design and construction of the building or extension, and the services, fittings and equipment provided in or in connection with the building or extension which will assist the responsible person to operate and maintain the building or extension with reasonable safety;
> (b)a "relevant building" is a building to which the Regulatory Reform (Fire Safety) Order 2005 [RRFSO, 2005] applies, or will apply after the completion of building work;
> (c)a "relevant change of use" is a material change of use where, after the change of use takes place, the Regulatory Reform (Fire Safety) Order 2005 will apply, or continue to apply, to the building; and
> (d)"responsible person" has the meaning given by article 3 of the Regulatory Reform (Fire Safety) Order 2005.

The RRFSO (TSO, 2005) makes each building user, via a responsible person, liable for all fire safety within a building. However, in passing over the information, liability is not devolved from a designer, installer or manufacturer and remains in place.

See also CIBSE Guide E: *Fire engineering* (2010) for general guidance on fire protection.

Information on fire-resisting and smoke-control ductwork is given in the *Fire Rated and Smoke Outlet Ductwork* ('the ASFP Blue Book') (ASFP, 2000). Fire-resisting ductwork is tested to BS EN 1363-1: 2012: *Fire resistance tests. General requirements* (BSI, 2012c) and classified to BS EN 13501-3: 2005 + A1: 2009: *Fire classification of construction products and building elements. Classification using data from fire resistance tests on products and elements used in building service installations: fire resisting ducts and fire dampers* (BSI, 2005b). Fire-resisting ductwork may also be tested under BS 476-24: 1987: *Fire tests on building materials and structures. Method for determination of the fire resistance of ventilation ducts* (BSI, 1987c) but this does not allow classification to BS EN 13501-3 (BSI, 2005b). Smoke control ductwork may be tested under BS EN 1366-8: 2004: *Fire resistance tests for service installations. Smoke extract ducts* (BSI, 2004) and BS EN 1366-9: 2008: *Fire resistance tests for service installations. Single compartment smoke extraction ducts* (BSI, 2008b) for single and multiple compartment applications respectively, for classification to BS EN 13501-4: 2007 + A1: 2009 (BSI, 2007c). CE marking is now mandatory.

Information on fire dampers is given in *Fire Dampers (European Standards)* ('the ASFP Grey Book') (ASFP, 2010) and DW/145: *Guide to Good Practice for the Installation of Fire and Smoke Dampers* (BESA, 2010). Fire dampers are tested to BS EN 1366-2: 2015: *Fire resistance tests for service installations. Fire dampers* (BSI, 2015a) and classified to BS EN 13501-3 + A1: 2009: (BSI, 2005b). There is a product standard and this is BS EN 15650: 2010: *Ventilation for buildings. Fire dampers* (BSI, 2010b). CE marking is now mandatory.

In some cases fire dampers may be tested to BS 476-20: 1987/BS 476-22: 1987 (BSI, 1987a/b) should all the fans be turned off in the event of a fire alarm. This does not allow classification to BS EN 13501-3: 2005 + A1: 2009 (BSI, 2005b).

Fire dampers protecting escape routes and in most cases areas with sleeping risk must have an ES classification to BS EN 13501-3 + A1: 2009 (BSI, 2005b) and this is not possible for a fire damper tested to BS 476-20: 1987/BS 476-22: 1987 (BSI, 1987a/b) alone.

In all cases fire-resisting products should be installed as tested, otherwise fire-resistance performance is not guaranteed. This does mean separate fire test reports for different wall and floor constructions. Some assessment may be available, but this is rare for dampers tested to BS EN 1366-2: 2015: *Fire resistance tests for service installations* (BSI, 2015a).

The following notes summarise the main fire precautions issues relating to the design and installation of ductwork systems. Advice on fire-protection systems is laid down in Approved Document B and supplemented in BS 9999: 2008: *Code of practice for fire safety in the design, management and use of buildings* (BSI, 2008a).

Fire and smoke containment and hazards are factors that influence the design and installation of ductwork systems.

A design that is required to perform a particular action as part of a fire strategy is likely to combine electrical,

mechanical and builders' work components, which would be influenced by the normal day-to-day operation requirements. Some of the more common components are:

— ductwork

— fire dampers

— smoke extract fans.

Ductwork is often required to transmit heat and smoke from the fire zone to the outside. The layout, jointing and potential expansion in the ductwork must be designed to withstand the calculated temperatures while maintaining integrity (to ensure containment of smoke and possibly heat) and insulation (to prevent spread of fire by radiation at high temperatures). The need for fire protection should be based on compartmentation requirements and calculated smoke temperatures. Where the fire-resistant ductwork passes through a wall or floor, a penetration seal must be provided that has been tested and/or assessed with the fire-resisting ductwork to the same fire rating as the compartment wall through which the fire-resisting ductwork passes. Where the fire-resisting ductwork passes through the fire compartment wall or floor, the ductwork itself must be stiffened to prevent deformation of the duct in a fire to:

— maintain the cross-sectional area of the duct

— ensure that the fire-rated penetration seal around the duct is not compromised.

Fire dampers are provided in ductwork for fire containment by preventing flow when a predetermined temperature is reached. The operation is usually activated by a fusible link that releases the damper at 72 °C. Generally they are required where ducts penetrate walls or floors that form fire compartments. The damper assembly should have a fire-resistance rating equal to that of the fire barrier it penetrates. It should be fire tested as detailed above.

Fire dampers would not normally be specified in ductwork used for smoke transport, although they may be required as part of the overall fire strategy in other ductwork. These would become smoke control dampers. Various types of fire damper are available: simple E classified integrity only units and ES classified fire dampers with reduced leakage for fire and smoke control. Details are given in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) and DW/145: *Guide to Good Practice for the Installation of Fire and Smoke Dampers* (BESA, 2010).

Electrically controlled dampers are required in some circumstances to control the flows, depending on the location of the fire and the control system logic as determined by the requirements of the fire strategy. Fire dampers responding to smoke alarms are required to protect escape routes and areas with sleeping risk (BSI, 2008a).

Smoke extract fans must be selected to ensure reliability at the design temperature and length of exposure as predicted by the fire engineering calculations. These should reflect performances as detailed in BS EN 12101-3: 2015: *Smoke and heat control systems. Specification for powered smoke and heat control ventilators (Fans)* (BSI, 2015b).

Natural smoke ventilators should reflect the requirements of BS EN 12101-2: 2003: *Smoke and heat control systems. Specification for natural smoke and heat exhaust ventilators* (BSI, 2003b).

2.5.3.2 Main areas within a building where ductwork should be fire protected

Agreement for these areas should be sought from the building control officer responsible for the building. Reference should also be made to the current Building Regulations.

Smoke extract systems

If the ductwork incorporated in a smoke extract system is wholly contained within the fire compartment, it must be capable of resisting the anticipated temperatures generated through the development of a fire. This may be demonstrated by testing to BS EN 1366-8: 2004 (BSI, 2004) and BS EN 1366-9: 2008 (BSI, 2008b) or BS 476-20: 1987 (BSI, 1987a). BS 476-24: 1987 (BSI, 1987c) also requires that ductwork that is intended as a smoke extract must retain at least 75 per cent of its cross-sectional area within the fire compartment. If the ductwork penetrates a fire-resisting barrier, it must also be capable of providing the same period of fire resistance as the barrier.

Escape routes covering stairways, lobbies and corridors

All escape routes must be designed so that the building occupants can evacuate the building safely in the case of fire. Ductwork that passes through a protected escape route must have a minimum of 30 minutes' fire resistance and be at least equal to the fire compartment through which the ductwork passes, either by the use of fire dampers or fire-resisting ductwork. Any fire dampers used should have an ES classification to BS EN 13501-3: 2005 + A1: 2009 (BSI, 2005b). The performance of the penetrated partition must also be maintained.

Non-domestic kitchen extract systems

Where there is no immediate discharge to atmosphere, i.e. the ductwork passes to atmosphere via another compartment, fire-resistant ductwork must be used. Kitchen extract ductwork presents a particular hazard, as combustible deposits such as grease are likely to accumulate on internal surfaces; therefore, all internal surfaces of the ductwork must be smooth. A fire in an adjacent compartment through which the ductwork passes could lead to ignition of the grease deposits, which may continue through the ductwork system possibly prejudicing the safety of the kitchen occupants. For this reason consideration must be given to the stability, integrity and insulation performance of the kitchen extract duct which should be specially tested to BS EN 1366-9 (BSI, 2008b) or BS 476-24: 1987 (BSI, 1987c) for a kitchen rating.

Particular points to note are as follows:

— Access doors for cleaning must be provided at distances not exceeding 3 m.

— Fire dampers must not be used.

— Use of volume control dampers and turning vanes are not recommended.

Further information on kitchen extract systems is contained in DW/172: *Specification for Kitchen Ventilation Systems* (BESA, 2005).

Enclosed car parks that are mechanically ventilated

Car parks must have separate and independent extract systems, designed to run in two parts, each extracting 50 per cent of the design load. Fans are required to be rated at 300 °C for a typical period of two hours and the ductwork and fixings constructed from materials with a melting point not less than 800 °C. Full details of the requirements are given in Part B of the Building Regulations (NBS, 2013g).

Due to the fire risks associated with car parks, these systems should be treated as smoke extract systems and therefore maintain a minimum of 75 per cent cross-sectional area under fire conditions in accordance with BS EN 1366-8: 2004: *Fire resistance tests for service installations* (BSI, 2004) or BS 476-24: 1987: *Fire tests on building materials and structures* (BSI, 1987c). Fire dampers must not be installed in extract ductwork serving car parks.

Basements

Ductwork from basements must be fire rated except for car parks as above. If basements are compartmented, each separate compartment must have a separate outlet and have access to ventilation without having to gain access (i.e. open a door to another compartment). Basements with natural ventilation should have permanent openings, not less than 2.5 per cent of the floor area and be arranged to provide a through draft with separate fire ducts for each compartment. See Part B of the Building Regulations (NBS, 2013g) for full details.

Pressurisation systems

Pressurisation is a method of restricting the penetration of smoke into certain critical areas of a building by maintaining the air at higher pressures than those in adjacent areas. It applies particularly to protected stairways, lobbies, corridors and fire-fighting shafts serving deep basements, as smoke penetration to these would inhibit escape. As the air supply providing pressurisation must be maintained for the duration of a fire, fire dampers cannot be used in the ductwork to prevent spread of fire. Any ductwork penetrating fire-resisting barriers must be capable of providing the same period of fire resistance.

Good practice in such systems requires the following.

— *Holes in compartment walls and floors*: all builders' work openings through the compartment walls and floors surrounding the pressurised space (e.g. penetrations for building services) must be made good and sealed.

— *Builders' shafts*: if constructed of brick or blockwork, the inside surfaces of shafts used as part of the system should have a smooth rendered finish to ensure low resistance to airflow and provide a good seal against leakage. The shafts must be pressure tested and be proven to have a leakage factor of less than 10 per cent.

— *Correctly sized shafts and ducts*: since most systems use a very basic shaft layout with simple spigot connections to discharge grilles, it is important to size the shafts and ducts for relatively low air velocity to ensure that correct air distribution is achieved at each grille.

— *Ductwork arrangements*: good working practice must be employed in the layout of the ductwork system. The system must be designed for correct operation of the pressurisation system, not simply to fit the building constraints.

— *Position of air intake*: if at roof level, the intake should be positioned so that it is unlikely to be affected by smoke and should be lower than any shaft or duct that may discharge smoke in the event of a fire. Changes to plant layout during construction should not compromise the air intake position.

— *Position of discharge*: for buildings over three stories in height there should be a discharge grille for every three floors.

Hazardous areas

There are other areas within the building where the building control officer could state a requirement for fire-resisting ductwork, for example areas of high fire risk, boiler houses, plant rooms, transformer rooms.

2.5.3.3 Methods of fire protection of ductwork

There are three methods of fire protection related to ductwork systems as given in Approved Document B supported by BS 9999: 2008: *Code of practice for fire safety in the design, management and use of buildings* (BSI, 2008a). These are described in Appendix 2.A4.

Fire resistance and BESA DW/144

It should be noted that ductwork constructed to DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) has no tested fire resistance. General purpose ventilation/air-conditioning ductwork and its ancillary items do not have a fire rating and cannot be either utilised in or converted into a fire-rated ductwork system unless the construction materials of the whole system (including supports and penetration seals) are proven by test and assessment in accordance with BS EN 1366-1: 2014 (BSI, 2014a) or BS 476-24: 1987 (BSI, 1987c).

In the case where galvanised sheet steel ductwork is clad by the application of protective materials, the ductwork construction must be type tested and comply with the protective material manufacturers' recommendations, for example gauge of ductwork, frequency of stiffeners and non-use of low melting point fasteners or rivets. Sealants, gaskets and flexible joints should be as tested at the same time and certified in accordance with BS EN 1366-1: 2014 (BSI, 2014a) or BS 476-24: 1987 (BSI, 1987c) and comply with the manufacturers' recommendations.

Methods of fire protection for galvanised steel ductwork are given in Appendix 2.A4.

Design considerations

Where ducting penetrates a fire wall or barrier, it is usual to install a fire damper that has the same fire rating as the wall itself. An alternative in some circumstances is to use fire-rated ducting provided this does not link two different fire zones. For example, it is not permitted to install fire

dampers in kitchen extract ducting and, once the ducting has left the kitchen area, it will have to be fire rated up to the point of discharge from the building. No openings into the duct will be permitted nor connections to other areas, not even another kitchen.

In instances where ducting links an escape route to an adjacent area, a fusible link fire damper will not be sufficient. There will be the possibility that 'cool' smoke will fail to melt the fusible link and thereby enter the escape route and render it unusable. In these instances an additional mechanism will be required that will close the damper on a signal from the building fire detection system. The dampers may be reopened manually or mechanically. Where the damper is not within easy reach, or where there are a significant number of them, motors will be used. In planning the design, adequate space for the installation and maintenance of these items must be allowed.

It is usual to route ducting along corridors with branches into the treated area, as this has advantages from the point of view of maintenance access, potentially deeper ceiling void, proximity to risers etc. However, where there is a need for a large number of dampers that are released by the fire alarm system, the designer may consider it better to run the ductwork through the treated area in order to reduce the complication and cost of numerous dampers on several branch ducts.

Fire-resisting stability

Where ductwork is required to be fire resisting, it is classified according to stability, integrity and insulation. Stability is the ability of a duct to stay in place for the specified period of time when exposed to a fire. Ductwork supports must match the stability of the ductwork. This can be achieved by oversizing them or by applying a protective covering. In all cases, fire-resisting ducts and any associated supports shall be installed as tested. Integrity is the ability of the duct to prevent the passage of fire either into or out of the duct. Insulation is usually called for if the building control officer believes that a duct carrying hot smoke may become sufficiently hot to compromise an escape route.

Fire-resisting ductwork can be either single or double skin. Double-skin ducting is used to encase insulation where this is required, though the more usual alternative is to add insulation to a fire-resisting duct. It is important that adequate space is allowed if a duct is to be insulated. Site modifications to fire-resisting ducts are much more difficult than to normal ducting, as the duct and fittings are often manufactured off-site and site changes may well compromise the classification. Any alterations being made to existing ductwork should be installed as tested, with special care being given to any strengthening at compartment boundaries. Any holes needed for pitot tube measuring instruments need to be cut at the manufacturing stage as site drilling is not allowed.

2.5.4 Air leakage

2.5.4.1 General

Air leakage in buildings and ductwork has a critical impact on ventilation and energy performance. Part L of the Building Regulations (NBS, 2013a) now imposes air-tightness requirements for buildings in order to reduce unwanted air infiltration and reduce energy consumption. Once airtightness is increased much more emphasis is needed on the development and durability of ventilation systems to ensure that air quality is not compromised.

2.5.4.2 Duct leakage

Leakage from ducted air distribution systems is an important consideration in the design and operation of ventilation and air-conditioning systems. A ductwork system having air leakage within defined limits will ensure that the design characteristics of the system can be maintained. It will also ensure that energy and operational costs are not greater than necessary.

Leakage from sheet metal air ducts occurs at the seams and joints and is therefore proportional to the total surface area of the ductwork in the system. The level of leakage is similarly related to the air pressure in the duct system and, whilst there is no precise formula for calculating the level of air loss, it is generally accepted that leakage will increase in proportion to pressure to the power of 0.65.

The effect of air leakage from high-pressure ductwork is critical in terms of system performance, energy consumption and the risk of high frequency noise associated with leakage. These problems are less critical with medium-pressure systems, but should be considered. Low-pressure ducts present the lowest risk in terms of the effect of leakage on the effective operation of the system.

It is important that ductwork should be made as airtight as possible. Conventional sheet metal ductwork is formed by seaming sheets and jointing sections; these seams and joints, penetrations made by damper spindles, control sensors, test holes, access doors etc., all give rise to air leakage. The designer should accept that some leakage will occur in conventional ductwork and make an assessment of the acceptable level in a given system. In some cases it may not be important, for example for a general extract system where the ducting is all in the space being served. In others it may be very important, for example where obnoxious or hazardous contamination is being handled. In the latter case, a completely airtight system may be necessary, where fully welded ducting with air-tight enclosures at all penetrations could be the basis of a special specification, outside the scope of DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a).

For most ventilating and air-conditioning applications, compliance with the construction and sealing requirements of DW/144 (BESA, 2013a) will ensure acceptably low leakage rates. For sheet metal ductwork, the specification requires sealant to be applied to all longitudinal seams (except spirally wound, machine-made seams) and cross-joints; for plastic and resin bonded glass fibre ductwork, similar sealing requirements are specified. The sheet metal specification also gives details of an air leakage test procedure. Recommended acceptable leakage rates in $l \cdot s^{-1}/m^2$ of surface area are given in Table 2.32.

Appendix 2.A3 shows these limits for a range of duct static pressure differentials. These rates are in accordance with the comparable classes in BS EN 12237: 2003: *Ventilation for buildings. Ductwork. Strength and leakage of circular sheet metal ducts* (BSI, 2003a) and BS EN 1507: 2006: *Ventilation*

for buildings. Sheet metal air ducts with rectangular section. Requirements for strength and leakage (BSI, 2006a) but these European Standards do not cover the full range of high-pressure ductwork.

Whilst leakage occurs at seams, joints and penetrations, the purpose of giving acceptable leakage rates in terms of surface area of ductwork is to require that the airtightness is of a consistent standard for air leakage test systems. It does not follow that the total leakage of a system that meets specified leakage requirements will always be a set percentage of the total flow rate; the percentage leakage from short runs can be substantially less than that from long runs. The design therefore plays a very important part in the likely total leakage loss from ductwork systems, since long runs not only provide more crackage and penetration, but also require higher working pressures to operate. Where limitation of air leakage is important, the designer should first ensure that the duct runs are as short as possible, that the operating pressure is as low as possible, that the number of seams, joints and penetrations is kept to a minimum and that there is adequate room around the ducts for site-made joints to be effectively sealed.

Items of equipment and plant installed in ductwork systems can also leak, and particular attention should be paid to the sealing of these items. Where leakage testing is required, the designer should ensure that suppliers of these items can demonstrate that their equipment meets the required airtightness standards. The designer should make adequate allowance in the fan selection for some air leakage so that the completed installation can meet its intended purpose without subsequent adjustments to the fan(s) and motor(s). Table 2.15 gives some recommendations for margins that should be included for complete installations (i.e. ductwork and equipment).

System leakage loss

There is no direct relationship between the volume of air conveyed and the surface area of the ductwork system. It is therefore difficult to express air leakage as a percentage of total air volume. Operating pressure will vary throughout the system and, since leakage is related to pressure, the calculations are complex. However, it is generally accepted that, in typical good-quality systems, the leakage from each class of duct under operating conditions will be in the region of:

— low pressure (Class A): 6 per cent

— medium pressure (Class B): 3 per cent

— high pressure (Class C): 2 per cent.

Table 2.32 Ductwork air leakage limits

Ductwork pressure class	Air leakage limits / $l \cdot s^{-1}$ per m^2 of duct surface area
Low pressure (Class A)	$0.027 \times p^{0.65}$
Medium pressure (Class B)	$0.009 \times p^{0.65}$
High pressure (Class C)	$0.003 \times p^{0.65}$
High pressure (Class D)	$0.001 \times p^{0.65}$

Note: p = differential pressure / Pa

Designer's calculations

The designer can calculate with reasonable accuracy the predicted total loss from a system by:

(*a*) calculating the operating pressure in each section of the system

(*b*) calculating the surface area of the ductwork in each corresponding pressure section

(*c*) calculating the allowable loss at the operating pressure for each section of the system (see above for indicative leakage figures).

This is illustrated in the duct sizing example shown in Appendix 2.A5.

Variable pressures in systems

Designers can achieve significant cost savings by matching operating pressures throughout the system to constructional standards and appropriate air leakage testing. The practice of specifying construction standards for whole duct systems based on fan discharge pressures may incur unnecessary costs on a project.

For example, some large systems could well be classified for leakage limits as follows:

— plant room risers: Class C

— main floor distribution: Class B

— low-pressure outlets: Class A.

2.5.4.3 Duct air leakage testing

General

It is normal practice for leak testing to be a requirement for all or part of high-pressure ductwork installations, but it is not a regular practice for medium- or low-pressure ductwork installations. It is recommended as good practice that all ductwork installations of significant size (e.g. with a fan capacity greater than 1 $m^3 \cdot s^{-1}$) should be leak tested in accordance with DW/143: *Guide to Good Practice: Ductwork Air Leakage Testing* (BESA, 2013b). It should be noted that air leakage testing of low- and medium-pressure ductwork is not obligatory under DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a); this will therefore be an individual contractual matter. However, in the case of low- and medium-pressure ductwork, the relevant country's Building Regulations should be checked for additional requirements.

Factors that should be taken into account in deciding whether leak testing of all or part of a ductwork installation is necessary are:

— whether adequate supervision of the installation can be provided and whether a final detailed examination of the system is feasible

— whether some sections need to be checked, because access will be impracticable after the installation is complete

— safety hazards that may arise from leakage of contaminated air

— whether special circumstances make necessary more stringent control of leakage than is given in the existing specification

— the cost to the client of the leakage testing and the delays caused to the completion of the installation.

The need for leak testing and the extent to which it is carried out should be assessed and, if judged to be necessary, this requirement and its extent should be included in the designer's ductwork specification.

Where it is decided that leak testing is required as part of the commissioning process, the ductwork designer should specify which sections of the ductwork system should be tested and the test pressures and leakage criteria for those sections. DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) describes an appropriate leak testing procedure and gives test pressures and leakage criteria appropriate to high-, medium- and low-pressure ductwork. These leakage rates are given in Appendix 2.A3.

To ensure that the ductwork is sufficiently airtight for the needs of the design, it is recommended that:

— ductwork is sealed in accordance with the design and construction specification

— a visual check is made during erection, with particular attention to site-made joints

— where leakage testing is required, the ductwork is tested in sections as the work proceeds, and the measured air leakage rate for each section checked against the leakage criterion (the sections so chosen should be sufficiently large that the maximum permitted leakage from the sections can be accurately measured with the test equipment)

— joints between test sections that need to be remade can be visually checked

— non-ductwork items (such as attenuators, coils, fire dampers) should be visually inspected, as the leakage from these is not covered by the relevant BESA specification.

Ductwork constructed and installed in accordance with DW/144 (BESA, 2013a) should provide a level of air leakage that is appropriate to the operating static air pressure in the system. However, the environment in which systems are installed is not always conducive to achieving a predictable level of air leakage; it is therefore accepted that designers may require the systems to be tested in part or in total.

It should be recognised that the testing of duct systems adds a significant cost to the installation and incurs some extra time within the programme.

Duct pressure

Ductwork constructed to DW/144 (BESA, 2013a) will be manufactured to a structural standard that is compatible with the system operating pressure, i.e. Classes A, B, C and D.

Specifying air leakage testing

As previously stated, it is recommended as good practice (and now required by UK Part L legislation) that all significant installations (e.g. with a fan capacity greater than 1 $m^3 \cdot s^{-1}$) should be tested in accordance with DW/143: *Guide to Good Practice: Ductwork Air Leakage Testing* (BESA, 2013b).

Respecting both the cost and programme implications associated with testing ducts for leakage, the designer may, for example, indicate that a particular system is tested as follows:

— high-pressure ducts: all ductwork to be tested.

— medium-pressure ducts: 10 per cent of the ductwork to be selected at random and tested

— low-pressure: ductwork does not need to be tested.

In the case where a random test is selected for medium-pressure ducts, the following clause from DW/144 (BESA, 2013a) is suggested for inclusion by the designer:

> **The designer** shall select at random a maximum of 10 per cent of the duct system to be tested for air leakage. The duct shall be tested at the pressure recommended in Table 22 of DW/144 for the classification for the section of the ductwork that is to be tested.
>
> **The tests** shall be carried out as the work proceeds and prior to the application of thermal insulation. In the event of test failure of the randomly selected section, the system designer shall have the right to select two further sections at random for testing. Where successive failures are identified there shall be a right to require the contractor to apply remedial attention to the complete ductwork system.
>
> **The ductwork** contractor shall provide documented evidence of the calculations used to arrive at the allowable loss for the section to be tested and the client, or his agent, shall witness and sign the results of the test.

Special cases

There may be situations where special consideration needs to be given to containing air losses, for example a long run of ductwork may incur a disproportionate level of air loss. In such cases the designer can specify an improved standard of airtightness, for example 80 per cent of allowable loss for Class B ducts. The designer should not specify a Class C test at Class C pressure for a Class B duct. For more information refer to section A6 of DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a).

Testing of plant items

Items of in-line plant will not normally be included in an air leakage test. The ductwork installation contractor may include such items in the test if the equipment has a certificate of conformity for the pressure class and air leakage classification for the system under test.

2.5.4.4 Building and component leakage

Introduction

Airtightness requirements for building are covered by Building Regulations. Testing usually requires a whole-building pressurisation test to determine the air leakage at a reference pressure of 50 Pa. This is the average pressure between the inside and outside of the building. The conduction of the test is covered by a protocol as described

in CIBSE TM23: *Testing buildings for air leakage* (2000c) and by the Air Tightness Testing and Measurement Association (ATTMA, 2010). The 50 Pa reference pressure is selected on the basis that results will not be adversely affected by wind and stack pressures under calm conditions but it is not sufficiently high for the generated pressure itself to distort leakage openings physically (either by opening or closing them). Despite this, there is invariably a difference in results between pressurising and depressurising a building as a consequence of the behaviour of leaks.

Whole-building leakage testing by fan pressurisation

Measurements are made using a 'blower door' (see Figure 2.36(a)) or, in the case of very large buildings, a 'trailer fan' (Figure 2.36(b)) to create incremental pressure differences between the inside and outside of a building in the ±100 Pa pressure range. For each pressure increment, the corresponding airflow rate through the fan is measured. The relationship between induced pressure and flow rate is then plotted. From this the air leakage rate at 50 Pa is determined by interpolation as well as the pressure flow characteristics. The flow characteristics are commonly described by the power law equation, as described in CIBSE Guide A (2015a).

By carrying out multiple pressure tests between zones, the airtightness of individual rooms and leakage across party walls can be determined.

Whole-building leakage testing using building HVAC system

Testing has sometimes been conducted using the building's own HVAC system. In this case the building is pressurised using the building supply fans. Return air and extract fans are switched off and all dampers are closed.

Component airtightness testing

The air leakage of individual components may also be measured by pressurisation. Sometimes this is undertaken by the manufacturer to check compliance for rain penetration. In this case the component is installed in a test rig such that the pressure difference can be created across the component and the leakage versus airflow rate measured. Components can also be tested in situ by constructing a pressure chamber across the component.

2.6 Equipment

2.6.1 Fans

2.6.1.1 General

Fans consume a large proportion of the total energy in mechanically ventilated buildings. A high priority should therefore be given to achieving energy-efficient fan operation. To achieve this there is a wide selection of fan types, each of which is designed to perform specific functions. Fan selection is critical for ensuring the correct performance of mechanical ventilation systems. Consideration must be given to optimum fan flow volume rates and the minimisation of pressure drops as outlined in section 2.3.2.3 and in CIBSE Guide F (2012). Fan types and characteristics are considered in this section.

2.6.1.2 Fan types and components

Table 2.33 provides a summary of fan types.

The following definitions should be used in relation to fans.

— *Casing*: those stationary parts of the fan that guide air to and from the impeller.

— *Guide vanes*: a set of stationary vanes, usually radial, on the inlet or discharge side of the impeller, covering the swept annulus of the impeller blades (or wings). Their purpose is to improve the recovery of the energy contained in the helical whirl of the airstream and thus raise the performance and efficiency of the fan. Inlet guide vanes are intended to pre-rotate the air entering the impeller and therefore alter the performance of the fan.

— *Impeller*: that part of a fan that, by its rotation, imparts movement to the air.

Important fan types

(*a*) Axial-flow fans

Axial-flow fans comprise an impeller with a number of blades, usually of aerofoil cross section, operating in a cylindrical casing. The fineness of the tip clearance between impeller blades and casing has a marked effect on the pressure development of the fan and, in turn, its output and efficiency. The blades may also have 'twist', i.e. the pitch angle increases from tip to root to equalise the work done along the blade length. As the pitch angle is increased, flow rate and impeller power demand increase. The tendency for flow separation from the blade surface (stall condition) also increases, limiting the maximum operating pressure. The hub is used to support the blades, generally incorporates a means of adjusting the blade angle and acts as a fairing for the motor. Large hubs and short blades characterise a high pressure-to-volume ratio and vice versa. Refinements include guide vanes to correct whirl at inlet or discharge and fairings and expanders to recover a greater proportion of the velocity head in the blade swept annulus.

Axial-flow fans are of high efficiency and have limiting power characteristics, but as the highest pressure single-stage axial-flow fans develop only about one fifth of the pressure produced by a forward-curved (multi-vane) fan, they are best suited for high-volume/pressure ratios. However, axial-flow fans may be staged or placed in series and when fitted with guide vanes the aggregate pressure developed is proportional to the number of stages for a given volume. A two-stage fan can be contra-rotating, and without the use of guide vanes the pressure developed may be up to 2.75 times greater than that of a single stage.

(*b*) Centrifugal fans

Centrifugal fans comprise an impeller that may (depending on type and application) rotate in a diffusing casing that has an expanding radial dimension (referred to as a volute or scroll casing). The air flows into the impeller axially, turns through a right angle within it and is discharged radially by centrifugal force. The scroll acts as a collector

Table 2.33 Summary of fan types

Fan type	Efficiency / %		Advantages	Disadvantages	Applications
	Static	Total			
1. Axial-flow (without guide vanes) 	50–65	50–75	Very compact, straight-through flow. Suitable for installing in any position in run of ducting.	High tip speed. Relatively high noise level comparable with type 5. Low-pressure development.	All low-pressure atmospheric air applications.
2. Axial-flow (with guide vanes) 	65–75	65–85	Straight-through flow. Suitable for vertical axis.	Same as type 1 but to lesser extent.	As for type 1, and large ventilation schemes such as tunnel ventilation.
3. Forward-curved or multivane centrifugal 	45–60	45–70	Operates with low peripheral speed. Quiet and compact.	Severely rising power characteristic requires large motor margin.	All low- and medium-pressure atmospheric air and ventilation plants.
4. Straight or paddle-bladed centrifugal 	45–55	45–70 60 (non-shrouded)	Strong, simple impeller. Least likely to clog. Easily cleaned and repaired.	Low efficiency. Rising power characteristic.	Material transport systems and any application where dust burden is high.
5. Backwards-curved or backwards-inclined blade centrifugal 	65–75	65–85	Good efficiency. Non-overloading power characteristic.	High tip speed. Relatively high noise level compared with type 3.	Medium- and high-pressure applications such as high-velocity ventilation schemes.
6. Aerofoil-bladed centrifugal 	80–85	80–90	Highest efficiency of all fan types. Non-overloading fan characteristic	Same as type 5.	Same as type 5 but higher efficiency justifies use for higher power applications.
7. Propeller 	<40	<40	Low first cost and ease of installation.	Low efficiency and very low pressure development.	Mainly non-ducted low-pressure atmospheric air applications. Pressure development can be increased by diaphragm mounting.
8. Mixed-flow 	45–70	45–70	Straight-through flow. Suitable for installing in any position in run of ducting. Can be used for higher pressure duties than type 2. Lower blade speeds than types 1 or 2, hence lower noise.	Stator vanes are generally highly loaded due to higher pressure ratios. Maximum casing diameter is greater than either inlet or outlet diameters.	Large ventilation schemes where the higher pressures developed and lower noise levels give an advantage over type 2.
9. Cross-flow or tangential-flow 	—	40–50	Straight across flow. Long, narrow discharge.	Low efficiency. Very low pressure development.	Fan coil units. Room conditioners. Domestic heaters.

that permits vortex flow to the casing outlet and converts some of the high velocity pressure at the blade tips into static pressure. There are several variations of the basic form (see below) and the impellers may be arranged as single-inlet types or double-inlet, double-width types (DIDW), essentially two single inlet impellers running back to back in parallel.

— *Forward-curved or multi-vane*: the impeller has a relatively large number of short, forward-curved blades. The air is impelled forward in the direction of rotation at a speed greater than the impeller tip speed. For a given duty, this type of fan is the smallest and least noisy of the centrifugal types. It operates with the lowest tip speed and is often referred to as a low-speed fan. As the velocity of the air does not decrease within the blade passages, the efficiency is not high (although it is generally equivalent to other types at low operating pressures) and the motor can easily be overloaded if the system resistance is overestimated (i.e. the fan power increases as system resistance is decreased). This type can only be used within a scroll housing.

— *Straight-radial or paddle-blade*: the impeller has a few (typically six) straight blades, which may be fixed by the roots to a spider or may have a back-plate and shroud-plate. This is the simplest, and least efficient of fan types but is well suited to applications where airborne material is present, as the blades are unlikely to clog. The impeller is of high mechanical strength and is cheap to refurbish. Renewable blades or wear plates are often fitted.

— *Backwards-curved blade*: the air leaves the impeller at a speed less than the impeller tip speed and the rotational speed for a given duty is relatively high. The impeller has from 10 to 16 blades of curved or straight form, inclined away from the direction of rotation. Because the blades are deep, good expansion within the blade passages takes place and this, coupled with a relatively low air speed leaving the impeller, ensures high efficiency and a non-limiting power characteristic. This fan type may be operated without a scroll diffuser and has become popular for AHU applications as a 'plug' fan, where its compact axial dimensions are beneficial.

— *Aerofoil blade*: a refinement of the backwards-curved fan in which the impeller blades are of aerofoil contour with a venturi throat inlet and fine running clearance between inlet and impeller. The casing is compact and the volumetric output is high. It has the highest static efficiency but is a relatively high-speed fan due to the low-pressure development.

(*c*) Propeller fans

Propeller fans comprise an impeller of two or more blades of constant thickness, usually of sheet steel, fixed to a centre boss and are designed for orifice or diaphragm mounting. They have high volumetric capacity at free delivery but very low-pressure development. However, this may be increased by fitting the fan in a diaphragm, which in turn may be installed in a circular or rectangular duct of area greater than the blade-swept area. The conventional efficiency of propeller fans is low, but in their typical application of moving air across a partition, their specific fan power may be acceptable.

(*d*) Cross-flow or tangential fans

These resemble a forward-curved centrifugal type impeller but with greatly increased blade length and the conventional inlets blocked off. The impeller runs in a half casing with conventional discharge but no inlet. Air is scooped inwards through the blade passages on the free side, but at the opposite side of the impeller, due to the influence of the casing, the air obeys the normal centrifugal force and flows out of the impeller and through the fan discharge.

The principle of operation relies on the setting up of a long cylindrical vortex stabilised within the impeller, which, being much smaller in diameter than the impeller, rotates at high angular velocity. This in turn drives the main airstream past the blades of the fan with higher velocity than the peripheral speed of the blades themselves. In effect the air flows 'across' the impeller, almost at right angles to the axis. Because this fan is so different from other types, direct comparisons are not valid. A serious disadvantage of this type is that it cannot be operated at shaft speeds widely different from that for which it has been designed. Consequently it obeys the fan laws only within narrow limits of speed change. It operates with a high discharge velocity and an expander is desirable when connected to ductwork, especially as the efficiency (which is rather less than that for the multi-vane fan) peaks at near-free delivery conditions. The discharge opening is characteristically narrow so the fan is not easily applicable to ducting but is well suited to fan coil units and electric space heaters.

(*e*) Mixed-flow in-line fans

Mixed-flow fans comprise an impeller with a number of blades, often of aerofoil section, similar to the axial flow fan. The hub is of conical shape such that the passage of air through the impeller has both axial and radial components, hence the term 'mixed flow'. Mixed-flow fans are of high efficiency and can be designed for higher pressure duties than axial flow fans. To remove the swirl generated by the passage of air through the impeller, stator guide vanes are fitted downstream. These vanes are generally highly loaded due to the high-pressure ratios. If the inlet and outlet flanges are to be of the same diameter, a change in casing profile is necessary in the region of the guide vanes. Separation of airflow can occur if the conditions for which the fan was designed are not maintained in practice.

(*f*) Bifurcated fans

Bifurcated fans handle atmospheres normally detrimental to the life of the fan motor, including saturated and dust-laden atmospheres, heated air, hot gases and corrosive fumes. They are normally direct drive with the motor isolated from the system airstream. These fans are generally of the axial flow type, but similar 'motor out of airstream' concepts are well established for centrifugal types.

2.6.1.3 Fan performance

Definition of terms

Fan performance is expressed in terms of fan size, air delivery, pressure, speed and power input at a given air density. Efficiency will be implied or specifically expressed. The size of a fan depends on the individual manufacturer's coding but is generally expressed as, or is a function of,

either the inlet diameter or the impeller diameter. Other terms are defined in BS EN ISO 5801: 2008: *Industrial fans. Performance testing using standardized airways* (BSI, 2008c) and BS EN ISO 13349: 2010: *Fans. Vocabulary and definitions of categories* (BSI, 2010c).

— *Standard air*: for the purposes of rating fan performance, reference air is taken as having a density of 1.200 kg·m^{-3}; this value corresponds to atmospheric air at a temperature of 293.15 K, a pressure of 101.325 kPa, relative humidity of 40 per cent and a gas constant (R_w) of 288 J/kg·K (section 12.1 of BS EN ISO 5801: 2008 (BSI, 2008c)).

— *Fan inlet area* (A_1): the surface plane bounded by the upstream extremity of the air-moving device. *Note*: fan inlet area is, by convention, taken as the gross area in the inlet plane inside the casing.

— *Fan outlet area* (A_2): the surface plane bounded by the downstream extremity of the air-moving device. *Note*: fan outlet area is, by convention, taken as the gross area in the outlet plane inside the casing

— *Fan pressure* (p_f): the difference between the stagnation pressure at the fan outlet (p_{sg2}) and the stagnation pressure at the fan inlet (p_{sg1}) given by the equation:

$$p_f = p_{sg2} - p_{sg1} \tag{2.21}$$

Note: when the Mach number is less than 0.15, it is possible to use the relationship:

$$p_f = p_{tf} = p_{t2} - p_{t1} \tag{2.22}$$

where p_{tf} is the fan total pressure.

Note: it is possible to refer the fan pressure to the installation category A, B, C or D (see below).

— *Stagnation pressure at a point* (p_{sg}): pressure that would be measured at a point in a flowing gas if it were brought to rest via an isentropic process.

Note: *Ma* is the Mach number at this point; for Mach numbers less than 0.122 obtained for standard air with duct velocities less than 40 m·s^{-1}, the stagnation pressure is virtually the same as the total pressure.

— *Dynamic pressure at the fan outlet* (p_{d2}): conventional dynamic pressure at the fan outlet calculated from the mass flow rate (q_m), the average gas density at the outlet and the fan outlet area:

$$p_{d2} = \rho_2 \frac{v_{m2}^2}{2} = \frac{1}{2\rho_2}\left(\frac{q_m}{A_2}\right)^2 \tag{2.23}$$

— *Fan static pressure* (p_{sf}): this is defined as the fan pressure minus the fan dynamic pressure corrected by the Mach factor (f_{M2}) as given by the following equation:

$$p_{sf} = p_{sg2} - p_{d2} f_{M2} - p_{sg1} = p_2 - p_{sg1} \tag{2.24}$$

Note: it is possible to refer the fan static pressure to the installation category A, B, C or D (see below).

— *Inlet volume flow rate*: the methods of flow measurement in this International Standard lead to a determination of the mass flow rate (q_m). In the absence of leakage, q_m is constant throughout the airway system. The inlet volume flow rate can be expressed as the volume flow rate under inlet stagnation conditions, i.e:

$$q_{Vsg1} = \frac{q_m}{\rho_{sg1}} \tag{2.25}$$

where:

$$\rho_{sg1} = \frac{p_{sg1}}{R_w \Theta_{sg1}} \tag{2.26}$$

where Θ is absolute temperature.

— *Fan air power* (P_u): the product of the inlet volume flow rate (q_{Vsg1}), the compressibility coefficient (k_p) and the fan pressure (p_f) given by the following equation:

$$P_u = q_m W_m = q_{Vsg1} p_f k_p \tag{2.27}$$

where W_m is fan (static) work per unit mass.

Note: it is possible to refer the fan air power to the installation category A, B, C or D (see below); fan air power is expressed in watts when q_m is in kg·s^{-1} and W_m is in J·kg^{-1}; fan air power is expressed in watts when q_{Vsg1} is in m^3·s^{-1} and p_f is in Pa.

— *Fan static air power* (P_{us}): the product of the inlet volume flow rate (q_{Vsg1}), the compressibility coefficient (k_{ps}) and the fan static pressure (p_{sf}); k_{ps} is calculated using $r = p_2/p_{sg1}$:

$$P_{us} = q_m W_m = q_{Vsg1} k_{ps} p_s \tag{2.28}$$

Note: it is possible to refer the fan static air power to the installation category A, B, C or D (see below); the fan static air power is expressed in watts when q_m is in kg·s^{-1} and W_m is in J·kg^{-1}.

— *Impeller power* (P_r): the mechanical power supplied to the fan impeller, expressed in watts.

— *Fan shaft power* (P_a): the mechanical power supplied to the fan shaft, expressed in watts.

— *Motor output power* (P_o): the shaft power output of the motor or other prime mover, expressed in watts.

— *Motor input power* (P_e): the electrical power supplied at the terminals of an electric motor drive, expressed in watts.

— *Fan impeller efficiency* (η_r): this is defined as fan air power (P_u) divided by the impeller power (P_r) as follows:

$$\eta_r = \frac{P_u}{P_r} \tag{2.29}$$

Note: it is possible to refer the fan impeller efficiency to the installation category A, B, C or D (see below); fan impeller efficiency may be expressed either as a proportion of unity or as a percentage.

— *Fan impeller static efficiency* (η_{sr}): this is defined as the fan static power divided by the impeller power, given by the equation:

$$\eta_{sr} = \frac{P_{us}}{P_r} \quad (2.30)$$

Note: it is possible to refer the fan impeller static efficiency to the installation category A, B, C or D (see below); fan impeller static efficiency may be expressed as a proportion of unity or as a percentage.

— *Fan shaft efficiency* (η_a): this is defined as the fan air power divided by the fan shaft power given by the equation:

$$\eta_a = \frac{P_u}{P_a} \quad (2.31)$$

Note: fan shaft power includes bearing losses, while fan impeller power does not; it is possible to refer the fan shaft efficiency to the installation category A, B, C or D (see below); fan shaft efficiency may be expressed as a proportion of unity or as a percentage.

— *Fan motor shaft efficiency* (η_o): this is defined as the fan air power P_u divided by the motor output power P_o as given by the equation:

$$\eta_o = \frac{P_u}{P_o} \quad (2.32)$$

Note: it is possible to refer the fan motor shaft efficiency to the installation category A, B, C or D (see below); fan motor shaft efficiency may be expressed as a proportion of unity or as a percentage.

2.6.1.4 Fan installation category

According to BS EN ISO 5801: 2008: *Industrial fans. Performance testing using standardized airways* (BSI, 2008c), fans should be tested using a method that is to some extent representative of their intended installation type. The standard contains extensive definitions of the various test ductwork arrangements, and the difference in performance levels achieved can be considerable, and should be included in any assessment of fan suitability.

The four categories of installation are as follows:

— *category A:* free inlet, free outlet

— *category B:* free inlet, ducted outlet

— *category C:* ducted inlet, free outlet

— *category D:* ducted inlet, ducted outlet.

In the above classification, the terms should be taken to have the following meanings. Free inlet or outlet signifies that the air enters or leaves the fan directly from or into the unobstructed free atmosphere. Ducted inlet or outlet signifies that the air enters or leaves the fan through a duct directly connected to the fan inlet or outlet respectively.

2.6.1.5 Fan efficiency

The various definitions of impeller efficiency given in the section on terminology (section 2.6.1.3), demonstrate that it is always important to identify the precise scope of the term being considered. This has become a pertinent issue, as the need to identity, quantify and verify products in terms of their energy efficiency has become very important. The Ecodesign of Energy-using Products (EuP) Directive 2005/32/EC (EC, 2005) was recast as the ErP (Ecodesign of Energy-related Products) Directive 2009/125/EC (EC, 2009), expanding its scope from products that require energy to perform their primary function to include products that influence energy use. The European government has sought to apply energy-labelling schemes (Energy Labelling Directive 92/75/EEC (EC, 1992)) to a wider variety of products, and fans are now included in this exercise.

Because of the wide variety of fan types and their specific operating characteristics, there has been a great deal of work necessary to establish fan product groups and then to determine appropriate efficiency measures and levels for each type. The approach that has been adopted is to consider each fan type when operating at its peak efficiency point. (On a fan performance curve, there is one operating point that corresponds to the intended design conditions — for all other duty points the fan efficiency levels are not optimised.)

There are also issues of physical scale to be considered, as impeller details such as blade thickness and running clearances do necessarily scale with the principal dimensions of the impeller. This generally means that larger impellers are more efficient.

The result of this exercise has been to establish a range of fan/motor efficiency grades (FMEG) appropriate to each fan type, which are related to the fan input power (BSI, 2015c). The grades are applicable to fans with input powers in the range 0.125 kW to 500 kW. The minimum efficiency target when plotted against fan input power is constructed such that two curves are defined for the ranges 0.125–10 kW and >10–500 kW. Depending on the fan type and the appropriate installation category, efficiency grades may be based on static or total pressures. The FMEG came into effect in the EU from 2013.

An example efficiency curve set is illustrated in Figure 2.38.

The work has led to the publication of BS EN ISO 12759: 2015: *Fans. Efficiency classification for fans* (BSI, 2015c), which specifies:

> 'requirements for classification of fan efficiency for all fan types driven by motors with an electrical input power range from 0.125 kW to 500 kW. It is applicable to (bare shaft and driven) fans, as well as fans integrated into products. Fans integrated into products can be measured as stand-alone fans.'

2.6.1.6 The fan laws

For a given system in which *the total pressure loss is proportional to the square of the volume flow*, the performance of a given fan at any changed speed is obtained by applying the following three rules (the air density is considered unchanged throughout).

— *Rule 1*: The inlet volume varies directly as the fan speed.

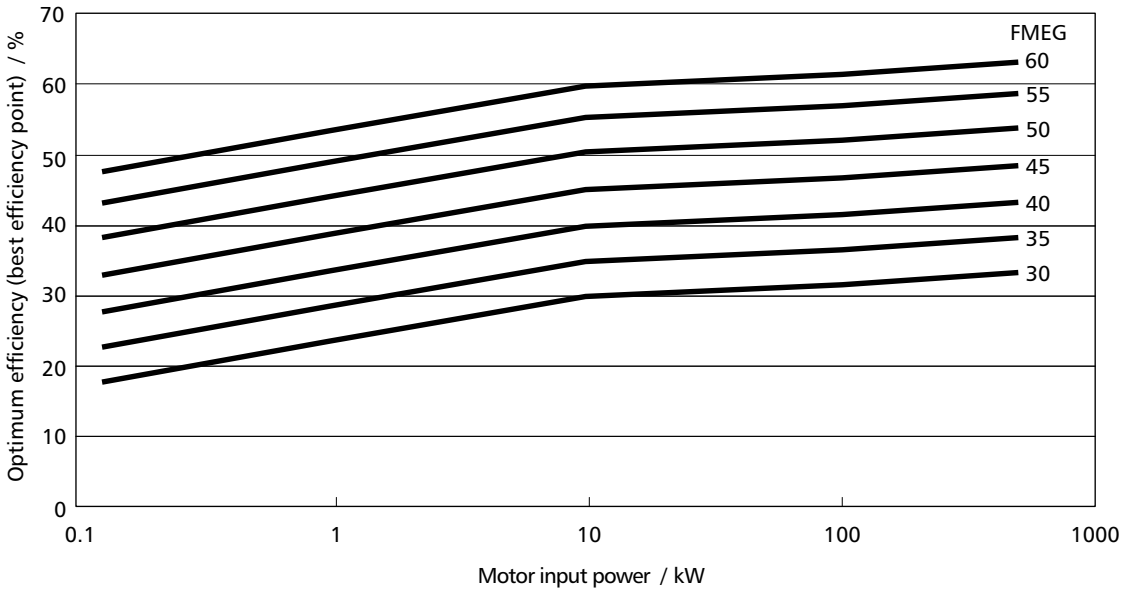

Figure 2.38 Efficiency curves for different fan/motor efficiency grades

— *Rule 2:* The fan total pressure and the fan static pressure vary as the square of the fan speed.

— *Rule 3*: The air power (total or static) and impeller power vary as the cube of the fan speed.

It should be noted that the pressure loss characteristics of several common system element types (e.g. filters, heat exchangers) do not conform to this pattern. Where such elements represent a significant proportion of the overall system resistance, use of these calculations can lead to inaccurate results.

For changes in density the following rule is applied.

— *Rule 4*: The fan total pressure, the fan static pressure and the fan power all vary directly as the mass per unit volume of the air, which in turn varies directly as the barometric pressure and inversely as the absolute temperature.

For geometrically similar airways and fans operating at constant speed and efficiency the performance is obtained by applying the following three rules (the air density is considered unchanged throughout).

— *Rule 5*: The inlet flow rate varies as the cube of the fan size.

— *Rule 6*: The fan total pressure and the fan static pressure vary as the square of the fan size.

— *Rule 7*: The air power (total or static) and impeller power vary as the fifth power of the fan size.

2.6.2 Air control units

2.6.2.1 General

Fans consume a large proportion of the total energy in mechanically ventilated buildings. A high priority should therefore be given to achieving energy-efficient fan operation. Fan volumes and pressure drops should be minimised by good design. Benchmarks for fan volumes and pressure drops are provided in CIBSE Guide F (2012).

The two approaches used to regulate the amount of energy used by fans (within the EU), have their basis in the Energy Performance in Buildings Directive (2002/91/EC) (EC, 2002) and the EuP Directive 2009/125/EC (EC, 2009).

The specific fan power (SFP) is a measure of ventilation system performance that unifies the various elements of system design and has been widely adopted in regulations. It integrates the effects of active components such as fans and AHUs, and the passive (in airflow terms) elements such as filters and ducting.

The calculation methods and uses of SFP in ventilation system design and validation are extensively covered in European standards, for example BS EN 13779: 2007: *Ventilation for non-residential buildings. Performance requirements for ventilation and room-conditioning systems* (BSI, 2007a).

In its simplest form, the SFP is the result of dividing the total input power to the ventilation system (i.e. including the loads due to controls and ancillary items) by the delivered air volume flow rate and may be considered at the unit, zone or building level.

Consideration should be given to over-sizing parts of the system to reduce pressure drops, for example by increasing the AHU cross-sectional area, as components such as heat recovery devices, filters and cooling coils are likely to be responsible for the majority of the losses.

Equipment and ductwork dimensional selections may be optimised for both whole-life cost and minimum energy use, with the resulting designs differing principally in terms of capital costs. Selection should favour the more efficient fan types and try to ensure that the fans will be operating at peak efficiency.

In ventilation systems for spaces where occupancy levels or type of use varies, efficient means of volume flow rate control should be incorporated to meet varying levels of demand. This may be at the dictates of temperature, pressure or air-quality sensors. Flow control may be achieved by a number of means including:

— on/off, multi-speed or variable speed operation

— varying the blade pitch (during operation) for axial fans

— inlet guide vanes.

These types of demand-controlled ventilation can have a very significant effect on the energy required to operate the system — in terms of both fan power and the heating and/or cooling loads. There are additional benefits in terms of reduction in system noise levels, maintenance requirements and improvements in overall system longevity.

Control is particularly needed when various areas to be air conditioned have differing heat gain patterns with respect to time; these can be met from a central plant in which either the temperature or volume (or both) of the air supplied to each area is varied to meet the particular requirements of the area. Such temperature or volume control may be carried out in ductwork serving a number of rooms or zones, or it may be carried out in the terminal units feeding individual rooms.

2.6.2.2 Volume flow control

Fan speed control

Of the methods mentioned, fan speed control is the most widely adopted, and today's ventilation systems have the advantage of the availability of very effective motor control technologies.

Two control families tend to dominate fan applications. First, speed control by variable frequency device (inverter) applied to essentially standard three-phase AC induction motors (suitably rated and constructed). These devices allow a speed control range of approximately 30 to 100 per cent (over-speed operation is also possible where sufficient motor capacity is available) and offer a variety of interface options for building management system (BMS) and other control system integration.

The second and, more recently, popular speed control type is referred to as 'EC' technology in reference to the electronic commutation applied to a high efficiency permanent magnet DC motor. Power supply conversion is generally provided on the motor itself, allowing direct connection to the AC mains supply. Again, a range of interface options is available.

AC induction motor designs have reached good levels of efficiency, particularly in larger sizes, and European legislation (IEC, 2014) for minimum motor efficiency levels extends down to approximately 80 per cent at 0.75 kW. The best EC-type motors are capable of reaching these efficiency levels in motors with output ratings down to approximately 200 W.

It is important for the system designer to understand that control elements (both electrical and mechanical types) have an inherent power conversion efficiency that is less than unity and that their use may also have a detrimental effect on the base motor efficiency.

These effects need to be assessed and compared with the potential energy savings with full knowledge of the modes of system operation.

Mechanical volume controller

This is a device that is self-actuating and capable of automatically maintaining a constant pre-set volume through it, provided that the pressure drop across it is above a minimum of about 120 Pa and below a maximum of about 250 Pa. As the supply air pressure increases, most devices of this type tend to close progressively by means of a flexible curtain or solid damper — a multi-orifice plate fixed across the complete airway of the unit. As such a unit achieves volume reduction by reducing the airway, there is a tendency to generate noise, particularly when working at high air pressures. For this reason, the volume controller is generally supplied in an acoustically treated terminal unit. It is factory pre-set to pass a specific volume and, when installed, will automatically give a pre-balanced air distribution system up to and including the terminal unit. It can be adjusted on-site, if desired.

Pressure regulating valve

This is an assembly consisting of one or two rows of shaped blades, the size of which changes when volume adjustment is required. Because of the particular blade shape, the device gives volume adjustment up to pressure drops of about 630 Pa without generating excessive noise.

The majority of dampers are set on-site, but they can be controlled from a static pressure-sensing element. Such units are generally supplied as a separate component for direct installation in the ductwork and not as part of a terminal unit.

Damper control

A damper is normally of the butterfly or multi-leaf type and capable of controlling the volume, providing the pressure drop across the damper does not exceed about 40 Pa. If the pressure drop is higher, there will be a tendency to generate excessive noise. Normally the damper is supplied as a separate component for direct installation in the ductwork and not as part of a terminal unit. Final adjustment is carried out manually on-site.

Dampers, while essential for airflow balancing in branched systems, waste fan energy and should not generally be used for primary air volume control. See GIR 41: *Variable Flow Control* (Action Energy, 1996) for further information on volume control.

2.6.2.3 Control of temperature

The control of temperature may be achieved by:

— *blending*: two separate airstreams, one warm and one cool, are supplied to a zone and mixed in a terminal unit to produce a supply air temperature that offsets the zone cooling or heating loads

— *reheat*: controlled reheat of a pre-conditioned, low temperature air supply by means of hot water, steam or electric coils, may be used to give a resultant supply air temperature that will satisfy the zone requirement.

2.6.3 Mixing boxes

A mixing box is a plenum in which recirculated and fresh air are mixed before entering an AHU. It may be part of the ductwork installation, a builder's work chamber or a standard module attached to packaged plant.

Mixing boxes must be designed to provide sufficient mixing so that freezing outside air does not stratify below warm recirculation air on entering the filters. If in doubt, a frost coil at the air intake should be provided. Motorised dampers should be located and set to promote mixing of the airstreams. Parallel blade dampers may assist mixing. Air blenders/baffles can also be used. To improve the range ability of a motorised control damper, the face velocity should be increased to 5–6 $m \cdot s^{-1}$ by adjusting the duct size or by blanking off an appropriate area of the duct at the damper. Damper quality is critical; play in linkages and pivots should be minimal and leakage on shut-off should be less than 0.02.

The use of high velocities and the other methods mentioned to promote improved mixing does have consequences in terms of system operating power and of noise generation.

2.6.4 Air terminal devices: diffusers and terminals

2.6.4.1 Introduction

An air terminal device is needed to ensure the correct discharge of air from a ventilation system into the ventilated space. Air can be supplied to the space in a number of ways (HEVAC, 2015), the principal division being between diffusers and perpendicular jets. Airflow patterns for both types are strongly dependent upon the presence or absence of the Coanda effect (see 'Coanda effect' in section 2.4.3.5). Table 2.34 summarises the types of air terminal devices and provides information on typical face velocities (based on any local control devices being fully open) and noise levels.

The location of terminal devices is also an important consideration. A floor-based supply is usually selected if raised floors are in place as might be common for IT systems. Floor-based systems allow the ceiling mass to be exposed. They may however restrict the furniture layout unless any under-floor units or distribution grilles are designed for easy relocation. Access for maintenance is, in theory, easy. Displacement system diffusers are normally floor based or floor mounted. Alternatively, diffusers may be ceiling based. This allows greater flexibility of furniture layout and also allows heat to be more efficiently extracted from light fittings. Supply terminals may also be incorporated into wall (high or low level), desktop, seat back or under seats. Further guidance can be obtained from HEVAC (2015). Conventional mixing systems are typically ceiling based.

Diffusers may be radial, part-radial or linear and normally utilise the Coanda effect and or/swirl to reduce the risk of excessive room air movement. A perpendicular jet is formed by discharging air through grilles, louvres, nozzles or any opening that allows perpendicular flow. Direction and spread adjustment can be provided using blades and/or swivel adjustment.

2.6.4.2 Terminal and diffuser types

Types vary according to need, and it is important to select the correct component. Common types are described in more detail below (REHVA, 2003; Jackman, 1990).

Pure displacement terminals

Pure displacement terminals aim to get air into the room with a minimum of eddies, room air mixing and temperature pick-up before it reaches the occupants. Hence there is a very small temperature difference between the supply air and that of the occupied zone.

Induction-type diffusers

Induction-type diffusers are intended to promote various levels of eddy mixing of the room air at the diffuser face. This allows lower supply air temperatures and hence marginally greater displacement cooling capacity. They have a larger approach temperature, generally require some mechanical cooling and impart a higher turbulent intensity with potential discomfort. Induction type diffusers for displacement ventilation require a substantial diffuser open area to obtain low velocities. Without this the discharge, velocity will be too high to support displacement ventilation (see section 2.2.8.2).

Swirl-type diffusers

Swirl type diffusers introduce air into a space with a swirling rotational discharge. This results in a rapid induction of room air into the primary air stream causing a quicker reduction of primary air velocity and temperature differential than in the case of conventional square or circular diffusers.

2.6.5 Ventilation air intake and discharge points

Outdoor air is drawn into a mechanical ventilation system through an air intake and discharged into the atmosphere from the ventilation system through a discharge terminal.

Each intake and discharge point should be protected from the weather by louvres, cowls or similar devices. Any space behind or under louvres or cowls should be 'tanked' and drained if there is a possibility of penetration by, and accumulation of, rain or snow that could stagnate and give rise to unpleasant odours within the building. Bird screens and insert mesh should be used to prevent entry by birds or other large objects. Intake points should be situated to minimise pollution from potential sources (existing and planned) including:

— traffic
— boiler flues and exhausts from standby generators (or combined heat and power engines)
— cooling towers and other heat rejection plant
— vents from plumbing, oil storage tanks etc.
— ventilation exhausts from fume cupboards, kitchens, toilets, car parks, print rooms
— stagnant water (e.g. on flat roofs)

— roosting ledges for birds (droppings can be a source of biological contamination)

— gardens or areas of vegetation (sources of fungal spores or pollen)

— areas where leaves or other litter might accumulate

— radon gas.

Because traffic is generally a ground-level pollutant, there is normally a reduction in pollutant concentration with height, so that concentrations are lower at roof level. Vehicle loading bays can be subject to traffic pollution.

Whilst wet cooling towers give rise to the greatest health concern because of the potential risk of legionella, other heat rejection equipment can also affect system performance by elevating the temperature of the intake air and increasing the cooling demand on the system.

Locating system discharge and intake points close together facilitates the use of some heat-recovery strategies. However, it will also increase the risk of 'short circuiting'. Even extract systems from 'normal' occupied areas will contain pollutants generated by internal sources. These may not represent a health hazard but may still result in an odour nuisance if recirculated. The more remote the intake from the discharge point, the less the risk of short circuiting. Locating the intake and discharge on different façades can also help to reduce the risk. However, wind forces on the two fan systems (which will be balanced for openings on the same façade) may affect fan performance and cause flow instabilities, particularly where fan pressures are low. The influence of wind pressures can be reduced by:

— positioning openings within a zone of minimal pressure fluctuation

— providing balanced openings that face in two or more opposite directions or an omni-directional roof-mounted cowl.

Table 2.34 Types of air terminal device

Type	Application	Location	Core velocity / $m \cdot s^{-1}$		Description and remarks
			Quiet	Commercially quiet	
1. Perforated or stamped lattice	Supply, extract, transfer	Ceiling, side wall, floor	Up to 3	Up to 6	Simple form of grille with small free area. Alternatively can be used as supply diffuser with high air entrainment allowing large quantities to be diffused. For low-level 'laminar flow' panels to give displacement ventilation, a velocity of 0.25 $m \cdot s^{-1}$ is used.
2. Aerofoil blades (one row adjustable)	Supply, extract	Ceiling, side wall, desk top	4	8	Frequently used grille with large free area. Directional control in one plane only for supply applications.
3. Aerofoil blades (two rows adjustable)	Supply	Side wall	4	8	As type 2 but with directional control in two planes.
4. Fixed blade	Supply, extract		4	8	Robust grille with limited free area. Some directional control possible using profiled blades.
5. Non-vision	Extract, transfer	Side wall	3	8	Low free area. Designed to prevent through vision.
6. 'Egg crate'	Extract	Ceiling, side wall	4	8	Generally largest free area grille available.
7. Fixed geometry diffusers	Supply, extract	Ceiling, floor, desk top	4	8	Radial discharge diffusers offer good air entrainment allowing diffusion of large air quantities. Square or rectangular diffusers can provide 1-, 2- or 3-way diffusion. Angled blades can be used to apply twisting motion to supply air.
8. Adjustable diffusers	Supply	Ceiling	4	6	As type 7 but offers horizontal or vertical discharge. Can be thermostatically controlled.
9. Slot and discharge, linear diffusers	Supply, extract	Ceiling, side wall, desk top, under window	4	8	Offers vertical or horizontal single or multiple slots. Care must be taken with design of plenum box. Desk top units may incorporate induction of room air.
10. Air handling luminaires	Supply, extract	Ceiling	4	8	As type 9 but single slot only. Normally used in conjunction with extract through luminaire.
11. Ventilated ceiling nozzle	Supply, extract		—	—	Void above ceiling is pressurised to introduce air at low velocity through many single holes or through porous panels. Air entrainment is restricted and natural air currents may affect room air distribution.
12. Nozzles, drum and punkah louvres	Supply	Ceiling, side wall, under window, seat back	—	—	Adjustable type can be rotating drum or swivelling ball, with or without jet for long throws and personal air supply or 'spot' cooling. Fixed multiple nozzles are used for high-induction applications. Velocities depend on throw, noise and induction requirements.

Measures that should be considered to minimise re-entry from contaminated sources include (ASHRAE, 2009):

— grouping exhaust to increase plume rise due to the greater momentum of the combined exhaust

— placing inlets on the roof where wind pressures will not vary greatly with direction to ensure greater stability

— avoiding locating exhaust outlets within enclosures or architectural screens that may hold contaminants within areas of flow recirculation

— discharging exhausts vertically

— locating wall exhausts on the upper third of a façade and intakes on the lower third to take advantage of normal wind separation on a building façade (although consideration should be given to flow recirculation that can occur on a leeward façade)

— avoiding locating inlets and exhausts near edges of walls or roofs due to pressure fluctuations.

Toxic and hazardous exhaust must not be discharged in a manner that will result in environmental pollution. The local authority environmental health officer should be consulted to ensure that the proposed discharges will be acceptable. European Directive 80/779/EEC (EC, 1980) gives mandatory air-quality standards for smoke and sulphur dioxide (see also section 2.2.2). A vertical discharge stack, capable of imparting a high efflux velocity to the exhaust, may be required. If so, provision must be made for handling rainwater and avoiding corrosion. Industrial processes resulting in polluting emissions to air, water or land come under the requirements of the Environmental Protection Act (HMSO, 1990). CIBSE Guide A (2015a) provides guideline values for pollutants. Reference should also be made to CIBSE TM21: *Minimising pollution at air intakes* (1999) for more detailed guidance on pollution sources and assessment methods.

2.6.6 Process exhaust hoods

2.6.6.1 General

Exhaust hoods are required to collect stale or contaminated air from processes for safe discharge into the atmosphere. In the case of chemical or biological contamination, cleaning and filtration of the exhaust will be necessary.

Typical examples of extract hood are illustrated in Table 2.35 below. For each hood the table also gives the equations for air volume flow rates through overhead canopies for both cold and hot processes (Stewart, 1985). Appropriate control velocities and convective heat transfer rates are given in Tables 2.36 and 2.37 respectively.

Table 2.38 shows the effects of adjacent surfaces on the basic form of hoods and canopies. However, specific processes may require other hood arrangements not shown in either Table 2.35 or 2.38. A publication by the American Conference of Government Industrial Hygienists (ACGIH, 2013) provides a wide range of empirically based design data sheets for many common industrial processes, which should always be consulted before proceeding with the design of a local exhaust system.

The size, aspect ratio, position and number of openings used depend upon:

— the size and nature of the source (opening must overhang source if possible)

— the dynamics and rate of evolution of contaminant

— the access needs and position of the operator

— the prevailing room air currents (side baffles should be provided if possible).

2.6.6.2 Overhead canopies

Overhead canopies are only appropriate for hot processes that cannot be kept covered and must not be used if the operator is likely to lean over the process or if strong cross draughts are likely to occur. Baffle plates can be incorporated into larger hoods to ensure an even velocity across the opening, whilst very large hoods should be sectioned, each section having its own off-take.

2.6.6.3 Lateral exhaust

For processes in which the emission momentum is small or tends to carry the pollutant horizontally away from the source, horizontal slots or hoods at the edge of a work surface or tank may be used. Slots may be arranged one above the other (see Figure 2.39) or facing each other along

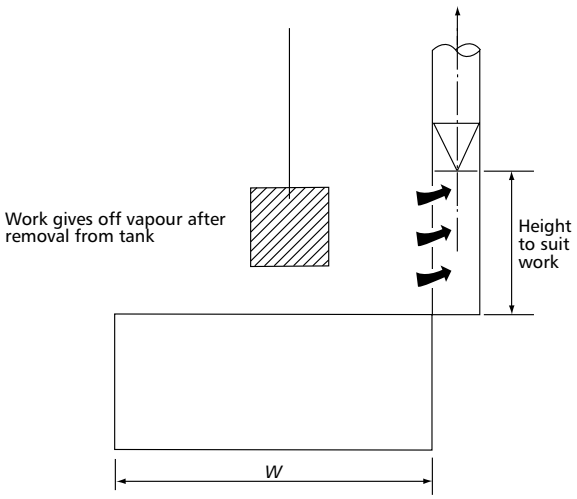

Figure 2.39 Open surface tank with drying facility, single side exhaust

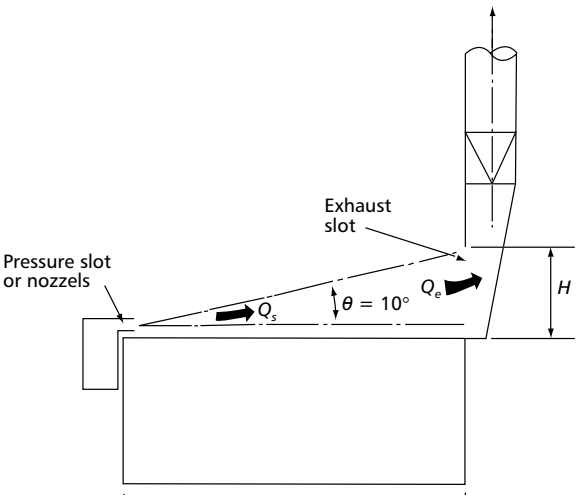

Figure 2.40 Push-pull hood

Table 2.35 Air volume flow equations for hoods and canopies

Type of opening	Equation	Notes
Canopy 	Cold source: $Q = 1.4\,P\,D\,v$	If $D > 0.3\,B$, use equation for hot source. Canopy should overhang tank by $0.4\,D$ on each side.
	Hot source, exposed horizontal surface: $Q = 0.038\,A_s\sqrt[3]{h\,D} + 0.5\,(A - A_s)$	Q is progressively underestimated as D increases above 1 m. Canopy should overhang tank by $0.4\,D$ on each side
	Hot source, exposed sides and top: $Q = 0.038\,A_s\sqrt[3]{\left(h\,A_t\,D\right)/A_s} + 0.5\,(A - A_s)$	Q is progressively underestimated as D increases above 1 m. Canopy should overhang tank by $0.4\,D$ on each side
Plain slot 	$Q = L\,v\left(4\,X\sqrt{X/W} + W\right)$	Aspect ratio R should be not less than 10
Flanged slot 	$Q = 0.75\,L\,v\left(4\,X\sqrt{X/W} + W\right)$	Aspect ratio R should be not less than 10. If $\times > 0.75\,W$, use equation for plain slot
Plain opening 	$Q = v\left(10\sqrt{R\,X^2 + A}\right)$	Aspect ratio R should not exceed 5; equation may be used for $R > 5$ but with loss of accuracy
Flanged opening 	$Q = 0.75\,v\left(10\sqrt{R\,X^2 + A}\right)$	Aspect ratio R should not exceed 5; equation may be used for $R > 5$ but with loss of accuracy If $\times > 0.75\,W$, use equation for plain opening

Symbols:

A = area of hood/opening (m^2)
A_s = horizontal surface area of source (m^2)
A_t = total exposed heated surface area of source (m^2)
B = breadth of source (m)
D = height above source (m)
L = length of hood/opening (m)
P = perimeter of source (m)
Q = volume flow rate ($m^3 \cdot s^{-1}$)
R = aspect ratio (L/W)
W = width of hood/opening (m)
X = distance from source (m)
h = rate of convective heat transfer ($W \cdot m^{-2}$)
v = control velocity ($m \cdot s^{-1}$)

opposite long edges, depending upon the vertical distance of the source above the rim of the tank. If the most remote part of the source is less than 0.5 m from the slot, a single exhaust slot along the longer edge is adequate, otherwise two slots, on opposite sides of the source, are required.

2.6.6.4 Jet-assisted hoods

Jet-assisted hoods are non-enclosing hoods combined with compact, linear or radial jets. They are used to separate contaminated zones from relatively clean zones in working spaces. They prevent contaminated air from moving into clean zones by creating positive static pressures, typically in the form of an air curtain.

2.6.6.5 Push-pull hoods

For sources larger than 1 m across, a push-pull hood arrangement should be used (see Figure 2.40) in which a slot or row of nozzles is used to blow air across the source. Design data for the hood illustrated in Figure 2.40 are given below.

Exhaust air quantity:

$$Q_e = (0.5 \text{ to } 0.75) \times A \quad (2.33)$$

where Q_e is the exhaust airflow rate ($m^3 \cdot s^{-1}$) and A is the area of open surface (m^2).

The value of the numerical factor depends on the temperature of the liquid, presence of cross-draughts, agitation of liquid etc.

Supply air quantity:

$$Q_s = \frac{Q_e}{w \times E} \quad (2.34)$$

where Q_s is the supply airflow rate ($m^3 \cdot s^{-1}$), w is the throw length (m) and E is the entrainment factor (see Table 2.39).

Height of exhaust opening:

$$H = 0.18\, w \quad (2.35)$$

where H is the height (m) of the exhaust opening.

Width of supply opening:

size for a supply velocity of 5–10 $m \cdot s^{-1}$.

The input air volume is usually about 10 per cent of the exhaust volume and the input air should be tempered to avoid frost damage. The source must not be placed in the input air path since this could result in deflection of the contaminant into the workspace. If necessary, baffles or screens should be used to deflect cross draughts.

2.6.6.6 Equipment selection principles and integration

Industrial extract equipment may be selected to:

— conform with emissions standards; industrial processes resulting in polluting emissions to air, water or land come under the requirements of the Environmental Protection Act 1990 (HMSO, 1990)

— prevent re-entrainment where they may become a health or safety hazard in the workplace

— reclaim usable materials

— permit cleaned air to be re-circulated

— prevent physical damage to adjacent properties

— protect neighbours from contaminants.

Circular ductwork is normally preferred, as it offers a more uniform air velocity to resist the settling of material and can withstand the higher pressures normally found in exhaust systems. Design velocities can be higher than the minimum transport velocity but should never be significantly lower. Fans (or other air-moving devices) and duct materials and construction should be suitable for the temperatures, abrasion and corrosion likely to be encountered. Fans should normally be located downstream of the air cleaner to reduce possible abrasions and create a negative pressure in the air cleaner so leakage will be inward. However, in some instances the fan may be located upstream from the cleaner to help remove dust.

Exhaust stacks must be designed and located to prevent the re-entrainment of discharged air into supply system inlets (see section 2.6.5). Toxic and hazardous exhaust must not be discharged in a manner that will result in environmental pollution and the local authority environmental health officer should be consulted to ensure that the proposed discharges will be acceptable.

2.6.7 Duct equipment

2.6.7.1 General

Ducting is generally available in rectangular, circular and flat oval sections, although other sections may be made for special situations. The majority of rectangular ductwork is made to order and available in any reasonable dimensions. Ductwork with less than 0.0225 m^2 cross-sectional area (e.g. 150 mm × 150 mm) will generally be more economic if made from circular section.

The designer should consider the full range of sections available and combine them to suit the specific location. Recommended sizes for rectangular, circular and flat oval ductwork are given in Appendix 2.A1.

2.6.7.2 Types of duct

Rectangular ducting

Rectangular ducting is most common for low-pressure systems because:

— it is readily adapted to fit into the space available

— it can be readily joined to such component items as heating and cooling coils and filters

— branch connections are made more easily.

For overall economy and performance, the aspect ratio should be close to 1:1 since high aspect ratios increase the pressure loss, the heat gains/losses and the overall costs.

Table 2.36 Control velocities for hoods

Condition	Example	Control velocity / m·s^{-1}
Released with practically no velocity into quiet air	Evaporation from tanks, degreasing etc.	0.25–0.5
Released at low velocity into moderately still air	Spray booths, intermittent container filling, low speed conveyor transfers, welding, plating	0.5–1.0
Active generation into zone of rapid air motion	Spray painting in shallow booths, conveyor loading	1.0–2.5
Released at high initial velocity into zone of very rapid air motion	Grinding, abrasive blasting	2.5–10

Note: the higher values apply if (*a*) small hoods handling low volumes are used, (*b*) hoods are subject to draughts, (*c*) the airborne contaminant is hazardous, or (*d*) hoods are in frequent use.

Table 2.37 Convective heat transfer rates for horizontal surfaces

Surface temperature / °C	Rate of heat transfer / W·m^{-2}
100	580
200	1700
300	3060
400	4600
500	6600

Table 2.38 Effect of side walls and adjacent surfaces

Type of opening	Baffle	Effect
Canopy, cold source	Side walls	Reduces effective perimeter, hence flow rate Q is reduced
Canopy, hot source	Side walls	Reduces cross draughts but minimal effect on flow rate Q
Plain slot	Long side on flat surface	$Q = L\,v\left(X\sqrt{2X/W} + W\right)$
Plain opening	Long surface on flat surface	For $R \le 2$: $Q = v\left(5\sqrt{(2/R)}\,X^2 + A\right)$ For $2 < R \le 5$: $Q = v\left(5\sqrt{(R/2)}\,X^2 + A\right)$
Flanged slot or opening	Long side (not flanged) on flat surface	For $X > 0.75$, calculate flow rate Q for plain arrangement and multiply by 0.75 W

Symbols:

A = area of hood/opening (m^2)
L = length of hood/opening (m)
Q = volume flow rate (m^3·s^{-1})
R = aspect ratio (= L/W)
v = control velocity (m·s^{-1})
W = width of hood/opening (m)
X = distance form source (m)

However, ducts with a 1:1 aspect ratio require a deep service area and are therefore rarely used in ceiling zones due to space limitations.

Rectangular ducting should not be the first choice for high-pressure systems, as it requires strengthening of the flat sides and needs to be sealed to make it suitable for this application.

Circular ducting

Machine-formed, spirally wound ducting and a standard range of pressed and fabricated fittings makes circular ducting more economical, particularly in low-pressure systems having a relatively small proportion of fittings. It is likely to be easier to install, particularly for the main runs of ductwork.

Table 2.39 Entrainment factors for push-pull hoods

Throw length / m	Entrainment factor
0–2.5	6.6
2.5–5.0	4.6
5.0–7.5	3.3
>7.5	2.3

Circular ducting is preferable for high-pressure systems and for systems operating at high negative pressures, due to its high inherent stiffness. Additional stiffening rings may be necessary at high negative pressure.

Pressed and fabricated fittings can be made of metal or plastic and fitted with push fit gasketed connectors for simple fitting and good airtightness.

Flat oval ducting

Flat oval ducting provides an alternative to circular ducting principally where there is a limitation on one of the dimensions in the space available for the duct run (e.g. depth of ceiling space). It combines the advantages of circular and rectangular ductwork because it can fit in spaces where there is insufficient room for circular ducting and can be joined using the techniques for circular duct assembly. Flat oval ducting has considerably less flat surface that is susceptible to vibration and requires less reinforcement than the corresponding size of rectangular duct. Flat oval duct is suitable for both positive and negative pressure applications within the limits defined in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a).

Other sections

Other sections may be used, such as triangular sections to pass through roof trusses. Such sections present difficulties in the provision of fittings and connections to standard plant items and are likely to be more expensive than traditional sections.

2.6.7.3 Bend and duct fitting components

Background

In normal circumstances, the flow of air in ducts is turbulent, with the flow generally in the direction of the duct axis. Eddies and secondary motions will result in energy dissipation due to internal fluid friction. Streamlines will not be parallel to the duct centre-line. In unobstructed straight ducts, eddies give rise to only relatively small

transverse components of the duct velocity and the flow velocities are symmetrical about the duct axis.

Disturbance to the flow arising from obstructions, duct fittings or other components has two major effect.

— The eddies can be significantly larger in size and their velocities much higher.

— The flow velocities across the duct become asymmetrical, i.e. much higher velocities can occur in part of the duct section, whilst in other parts even reverse flow may occur.

From the point of view of duct design, the important aspects of the effects of disturbance to airflow are:

— increased pressure loss due to creation of eddies

— increased pressure loss as high-velocity air mixes with low-velocity air

— noise generated by the interaction on eddies with the inner surfaces of the ducts.

Bends

Figure 2.41 illustrates common bend types; their influence on the airflow is described below. Bends may be characterised as 'hard' or 'soft' according to whether the change of direction is in the plane of the longer or shorter side of the cross section, respectively (see Figure 2.42).

Radiused bends

The air will flow to the outer surface causing high velocities at discharge on the outside with much lower velocities on the inside. In addition, the centrifugal effect will cause a higher static pressure at the outer surface, leading to some transverse flow towards the inner surface, and hence producing a spiral motion at the outlet. If the bend is too tight (i.e. $r/w < 1$), flow will readily separate from the inside surface with subsequent eddying and increased pressure loss. In practice, radiused bends should have an r/w value of 1.5; for low pressure-loss situations r/w should be increased to 2. They should have a downstream straight duct of at least five equivalent diameters to allow the flow to stabilise again. As a general rule, the formation of an offset in a duct layout is better achieved using two angled bends ($<90°$) rather than two right-angled bends.

(*Note*: in this Guide, r is taken as the mean radius of the bend to the centre-line of the duct; DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) relates r to the throat radius of the duct.)

Splitter bends

These are tight radiused bends that use internal splitters to improve the airflow (see Figure 2.43). Standard settings for splitters are given in Table 2.40, which is taken from BESA (2013a). The flow in the air passages is as described for the radiused bend, but because multiple streams emerge at discharge, the outlet velocity profile will be more uniform than for a plain radiused bend. Hence the minimum straight length of downstream duct may be reduced to about four equivalent lengths.

Mitred elbows (with turning vanes)

Rectangular duct bends with either dimension greater than 200 mm should have properly designed turning vanes. The angle of the turning vane should be the same as that of the bend. Information on the structural requirements of turning vanes is given in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a). The advantage of this type of bend is that it should not significantly distort the velocity profile, so that other duct fittings or components can be placed closer to the outlet, provided the inlet conditions to the bend are uniform. If the flow is not uniform at the inlet, this non-uniformity may persist downstream of the bend.

Optimum design of turning vanes, with careful positioning, should provide a bend with less resistance to airflow than a good design of radiused bend, but this may not be achieved in practice. This is because the inside and outside corners of the bend are usually not rounded, and internal and side fixings provide some obstructions. The pressure losses may then be a little higher than those in a good design of radiused bend, particularly in the case of small duct sizes. Eddies will be formed where air separates from the outside surface of a turning vane causing this type of bend to generate more noise than radiused and splitter bends.

Research by the American Sheet Metal and Air Conditioning Contractors' Association (SMACNA, 2006) on a 600 mm square elbow with blades of 114 mm radius shows the optimum spacing to be 82 mm. When the length of the blades is greater than 900 mm, it is preferable to use double thickness turning vanes to add stiffness, but there is a penalty due to increased pressure drop.

Mitred elbows (without vanes or splitters)

This type of bend is not recommended for bends with angles $>30°$ because the flow becomes both distorted and very turbulent. The flow leaves the bend with higher velocities on the outside surface, and separation occurs at the inside sharp edge, leading to severe eddying. The one advantage of this eddying is that it will lead to mixing of temperature-stratified air but the pressure loss will be high, with large pressure losses resulting (see section 4.11.2.4 of CIBSE Guide C (2007)). For low-velocity systems, mitred elbows can produce useful sound attenuation due to a reflection effect. Other fittings should not be placed close to the elbow.

Branches

There are many designs of branches and junctions in use. The important features are that the flow should be divided (or combined) with the minimum interference and disturbance, and that changes in duct sizes should not be made at the branch but at a short distance downstream (or upstream).

Examples of good and economic branch design are shown in Figure 2.44. A good branch design cannot be effective if the flow entering the branch is not uniform across the section. For some of the BESA recommended tee designs, no experimental data are available for the pressure loss, but the designer should consider their use. Chapter 4 of CIBSE Guide C (2007) provides useful information. Note that the addition of a small shoe on the branch tee can reduce pressure loss in both the branch flow and the straight flow.

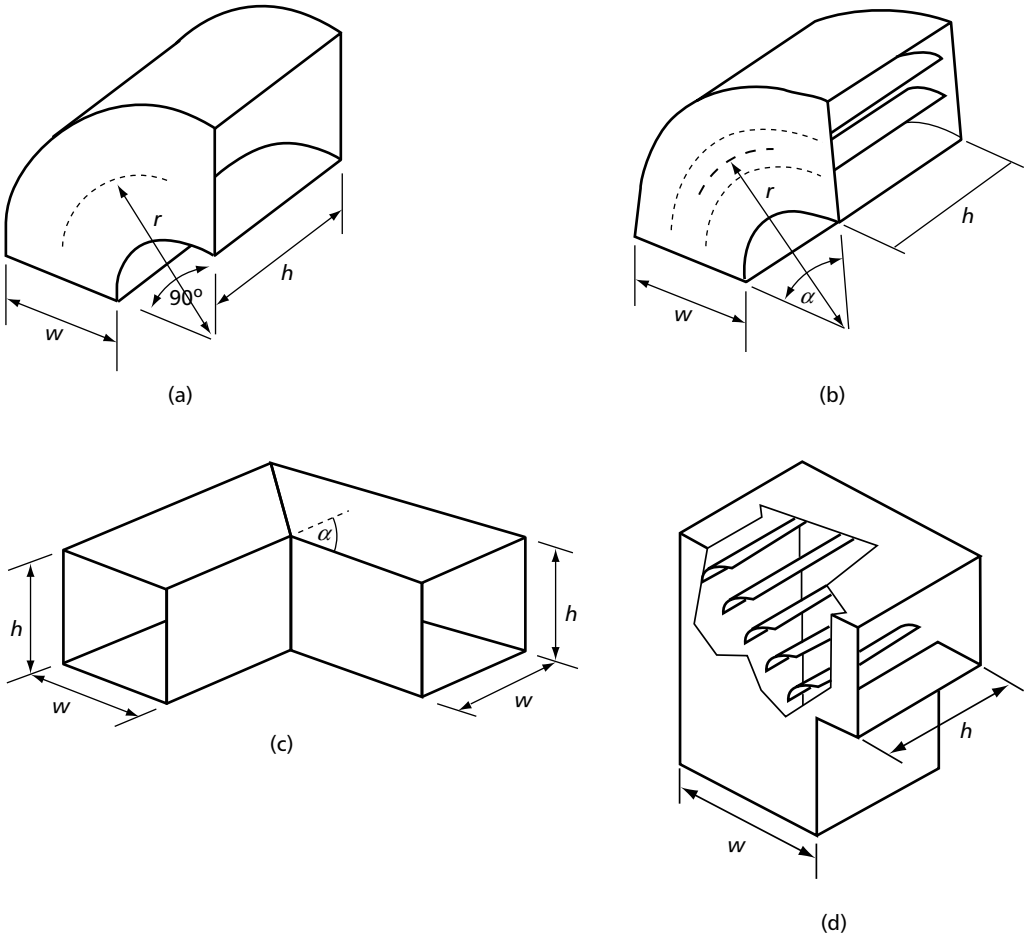

Figure 2.41 Common types of bends: (a) 90° radius bend without vanes, rectangular, (b) short radius bend with vanes (any angle), rectangular, (c) mitred elbow without vanes (any angle), (d) 90° mitred elbow with vanes

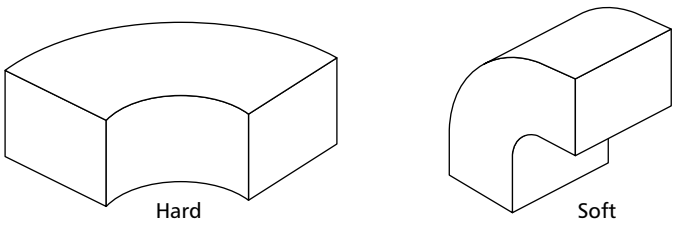

Figure 2.42 'Hard' and 'soft' bends

DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) suggests appropriate shoe dimensions for various sizes of duct.

Change of section

Expansion

A tapered expansion of a duct causes an appreciable pressure loss due to the tendency of the flow to break away from the sides and form eddies. The greater the total included angle of divergence, the greater the pressure loss, especially for large changes in area.

The cheapest form of taper for rectangular ductwork is to maintain the same plane for three sides and incline the fourth side only (see Figure 2.45). In any diverging section, when the plane of any side changes by more than 22.5°, DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) recommends the inclusion of splitter vanes, which should bisect the angle between any side and the duct centre-line (see Figure 2.46). However, it is not clear by how much the friction pressure drop is reduced by the introduction of such vanes. Certainly the inclusion of splitters would not seem worthwhile when the change in section (A_2/A_1) >4. Further information can be found in CIBSE Guide C, chapter 4 (2001).

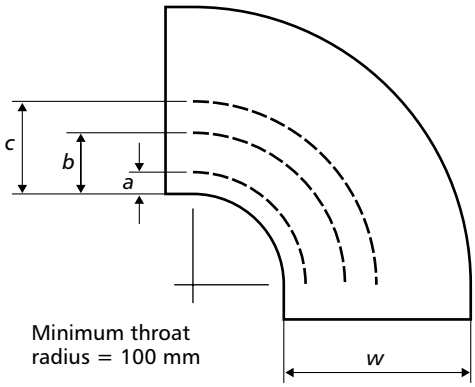

Figure 2.43 Short radius bend with splitters; position of splitters (reproduced from DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) by permission of BESA)

Table 2.40 Short radius bends with splitters; position of splitters (BESA, 2013a)

Dimension w / mm	Number of splitters	Splitter position		
		A	B	C
400–800	1	$w/3$	—	—
800–1600	2	$w/4$	$w/2$	—
1600–2000	3	$w/8$	$w/3$	$w/2$

Note: splitters not required for bend angles less than 45°

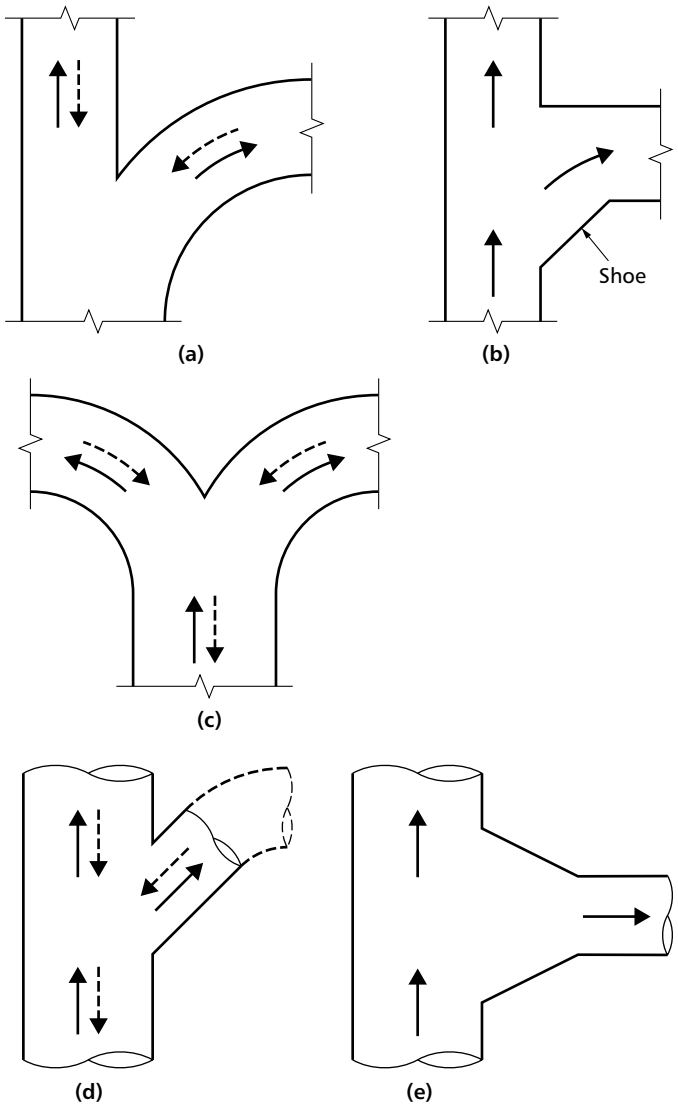

Figure 2.44 Examples of good duct design; (a) 90° swept branch, rectangular, (b) 90° branch tee with shoe, rectangular, (c) 90° radiused twin bend, rectangular, (d) 45° branch tee, circular, (e) 90° conical branch tee, circular

Contraction

Relatively little pressure drop is caused by a contraction. The designer should not feel constrained in choosing the taper angle for a contraction. No splitter vanes are needed for a contraction.

Other fittings

As a general rule, fittings should avoid abrupt changes in direction and sharp edges that cause the flow to separate and form eddies, which in turn increase pressure loss and noise generation. A fitting such as a damper can create vortices, which will result in a greater pressure drop than normal in a subsequent downstream fitting. Separation between the fittings by a minimum length of 5 equivalent diameters is recommended.

In the case of bends in rectangular ductwork, the combination of two bends in close proximity can give a lower pressure drop than two that are far apart. Further information can be found in CIBSE Guide C, chapter 4 (2007). This is not the case for two segmented circular ducts in close proximity, but the effect of close coupling is not significant.

2.6.7.4 Duct support and fixing components

General

Supports are an essential part of the ductwork system and their supply and installation are normally the responsibility of the ductwork contractor. The choice between available methods of fixing will depend on the type of building structure and on any limitations imposed by the structural design. Unless the designer has specified the requirements in detail, the load to be carried will be understood to be limited to the ductwork and its associated thermal and/or acoustic insulation. However, where the duct is large enough to allow human access for cleaning, the duct and its supports should be sufficiently strong to withstand the additional load and the type and location of access components should allow the person carrying out the cleaning to enter and exit the duct. The range of supports available includes an increasing range of proprietary types.

With a proprietary device, unless the designer has specified the requirements in detail, it will be the responsibility of the ductwork installer to ensure that it meets the requirements, with a sufficient margin of overload, and that it is installed in accordance with the manufacturers' recommendations.

Fixing to building structure

The fixing to the building structure should be of a strength and durability compatible with those of the ductwork support attached to it. A fixing to concrete or brickwork must be made in such a way that it cannot loosen or pull out through normal stressing or through normal changes in the building structure.

Horizontal ductwork

The hanger is normally mild steel plain rod or studding or flat strap, pre-treated by hot-dip galvanising, sherardising, electro-deposited zinc plating or other acceptable anticorrosion treatment. Other materials, such as multi-stranded wire, may also be acceptable. Provided the integrity of the ductwork is maintained, hangers may be attached to the corners of either the flanges or stiffeners, as an alternative to the use of a bottom bearer. Details of the construction of supports are given in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a).

Where horizontal ductwork passes through a compartment boundary such as a wall, fire dampers should be used to maintain fire integrity

Vertical ducts

The design of supports for vertical ducts is dictated by site conditions and they are often located to coincide with the individual floor slabs. The designer must specify the particular requirements if the spacing exceeds four m. Vertical ducts should be supported from the stiffening angle or the angle frame or by separate supporting angles fixed to the duct.

Where vertical ductwork passes through a compartment boundary such as a floor, fire dampers should be used to maintain fire integrity.

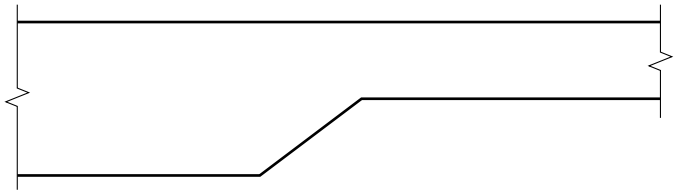

Figure 2.45 Change of section for a rectangular duct; one side only inclined

The support bearer, which, depending on duct/structural opening size, could be either channel or angle section, may be utilised in any of the following arrangements:

— Fixed directly to duct skin with sealed fixings (flat face only of either rectangular or flat oval ductwork).

— Supporting the underside of a flat bar clip in halves (circular or flat oval ductwork).

— Supporting the underside of either the stiffening frame or the flanged joint of any duct section.

— Supporting either a stiffening frame or a flanged joint below using drop rods/studs.

Insulated ducts with vapour sealing

Vapour sealing may be required where the temperature of the air within the duct can fall low enough to promote condensation on the exterior surface of the duct. This can cause moisture penetration through the thermal insulation.

In this case, the most important requirement is to limit penetration of the seal by the support. The extent of any vapour sealing of ductwork thermal insulation, and the method to be used, must be clearly specified in advance by the designer.

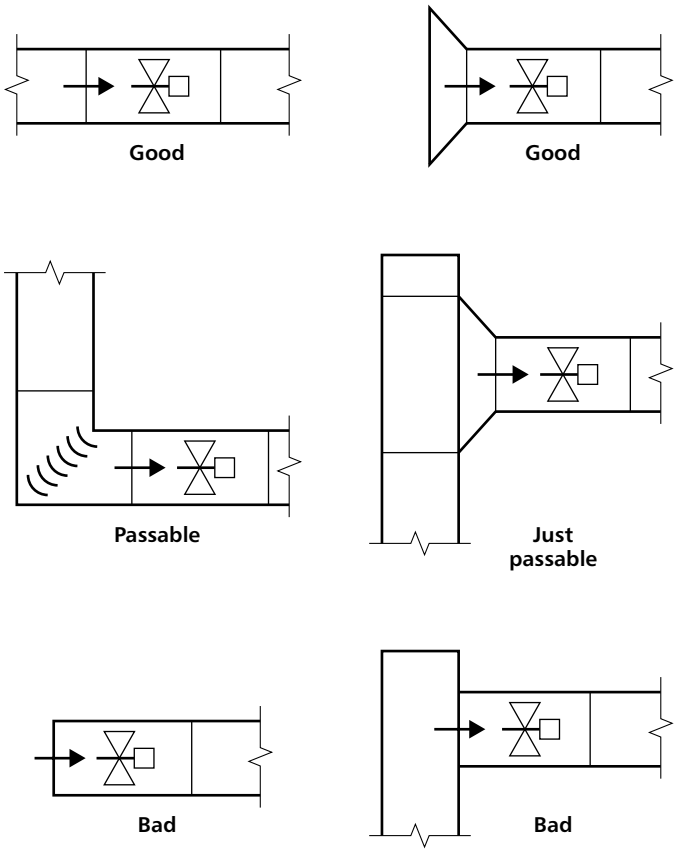

Figure 2.47 Outlet connections to centrifugal fans

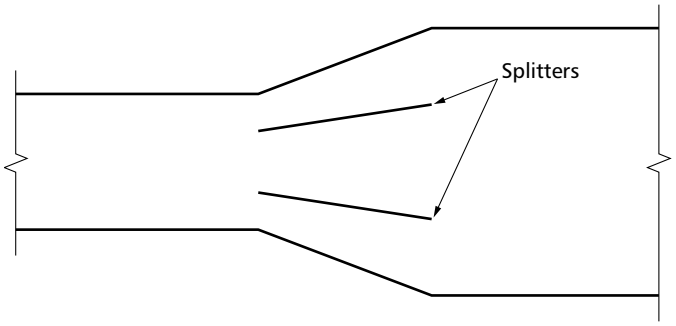

Figure 2.46 Change of section for a rectangular duct with splitters

Heat transfer

It is not normally necessary to make special arrangements for the limitation of heat transfer via the duct supports. However, there may be special cases where the temperature difference justifies a heat barrier to conserve heat or to prevent condensation. Such requirements must be specified by the designer.

Fire-resisting ductwork

Ductwork supports illustrated in DW/144: *Specification for Sheet Metal Ductwork* (BESA, 2013a) cannot be used on fire-rated ductwork systems. Oversizing can be an acceptable method of achieving fire rating of supports.

Fire-resisting ductwork may be required to meet the requirements of either European or British standards. Further comprehensive information may be found in the *Fire Rated and Smoke Outlet Ductwork* ('the ASFP Blue Book') (ASFP, 2000). Additional information may also be found there for smoke control ductwork.

2.6.8 Ductwork connections

2.6.8.1 Fan connections

The fan performance figures given by manufacturers in their catalogue data are based on tests carried out under ideal conditions, which include long uniform ducts on the fan inlet/outlet. These standard test conditions are unlikely to occur in practice. An objective of good ductwork design should therefore be to ensure that, as far as practicable, the fan performance will not be de-rated by the system. Ensuring that the fan inlet flow conditions comprise uniform axial flow velocities with low levels of turbulence can help to achieve this.

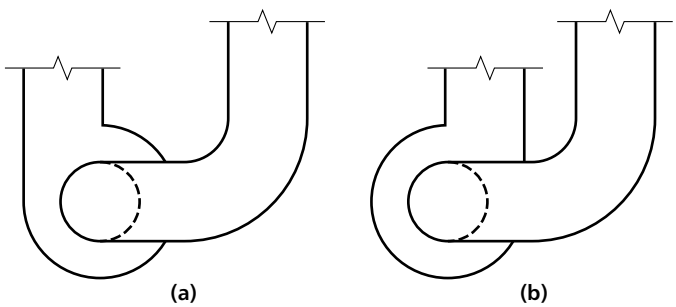

Figure 2.48 Centrifugal fan, swirl to impeller rotation: (a) swirl in same direction as impeller, (b) swirl in contrary direction to impeller

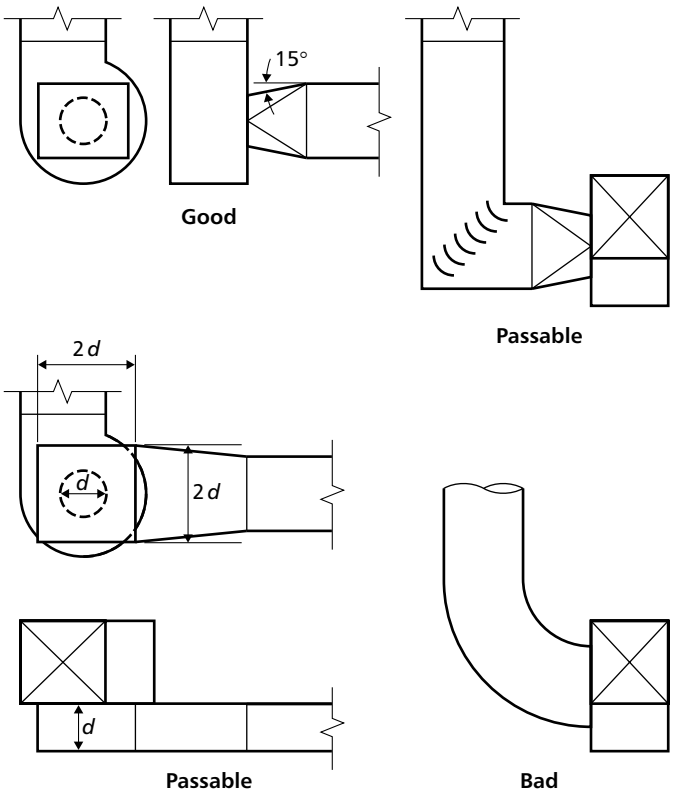

Figure 2.49 Centrifugal fans; inlet connections

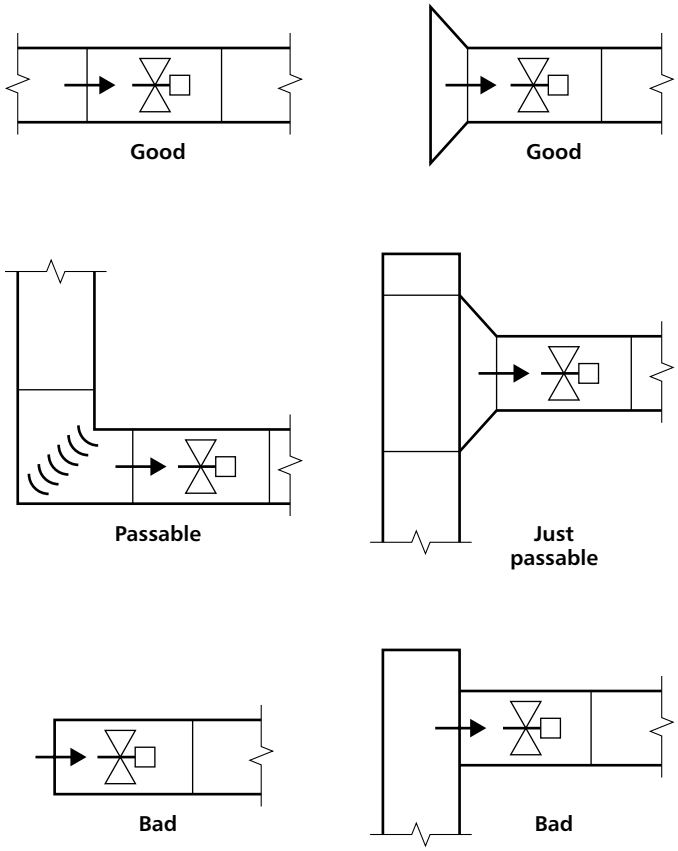

Figure 2.50 Axial fans; inlet connections

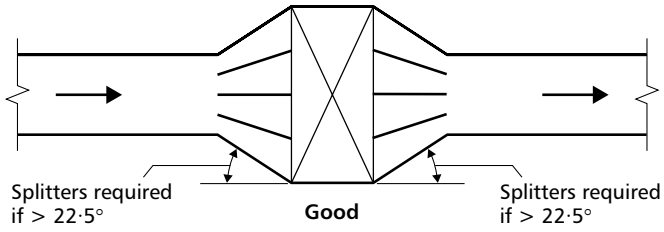

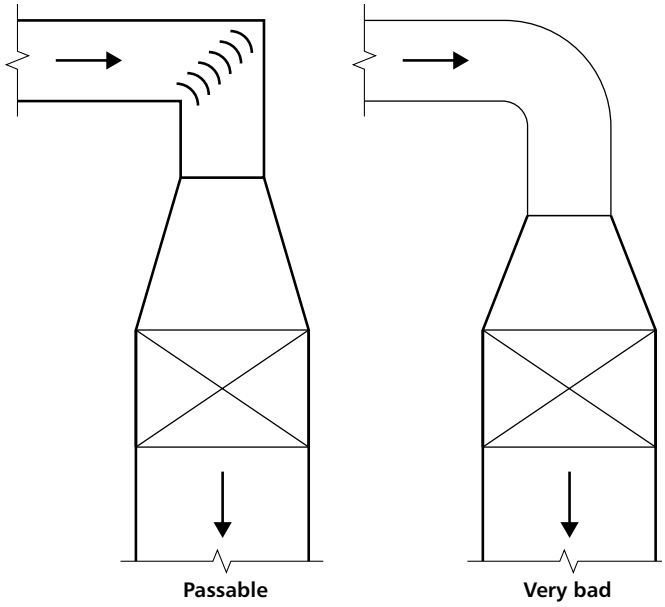

Figure 2.51 Plant connections

Where the outlet duct is larger than the fan discharge connections, there should be a gradual transition as illustrated in Figure 2.47 with a following section of straight duct having a length equivalent to three duct diameters. Figure 2.48 also gives examples of good and bad centrifugal fan outlet connections, which apply equally to axial flow fans.

The design of the fan inlet connection must be carefully considered to avoid swirl in the airstream. When the air spins in the same direction as the impeller, the performance and power consumption of the fan are reduced. When the air spins in the opposite direction to the impeller, the power consumption and noise will increase with hardly any pressure increase. Airstream swirl is usually induced by large variations across the fan inlet eye caused by the air passing round a tight bend immediately before the eye. The two forms of connection to centrifugal fans likely to cause swirl are shown in Figure 2.47.

For any condition in which a centrifugal fan is located within a free inlet the clear distance between the suction opening and the nearest wall should not be less than the diameter of the inlet. If two fans with free inlets are positioned within the same chamber their adjacent suction openings should be at least 1.5 diameters apart. Examples of good and bad practice in duct inlet connections to centrifugal fans are shown in Figure 2.48 and to axial fans in Figure 2.50.

2.6.8.2 Plant connections

Airflow across air treatment components such as filters, heat exchangers and humidifiers will be influenced by the pattern of the approaching airstream and, if unsatisfactory conditions are created, the performance of the components

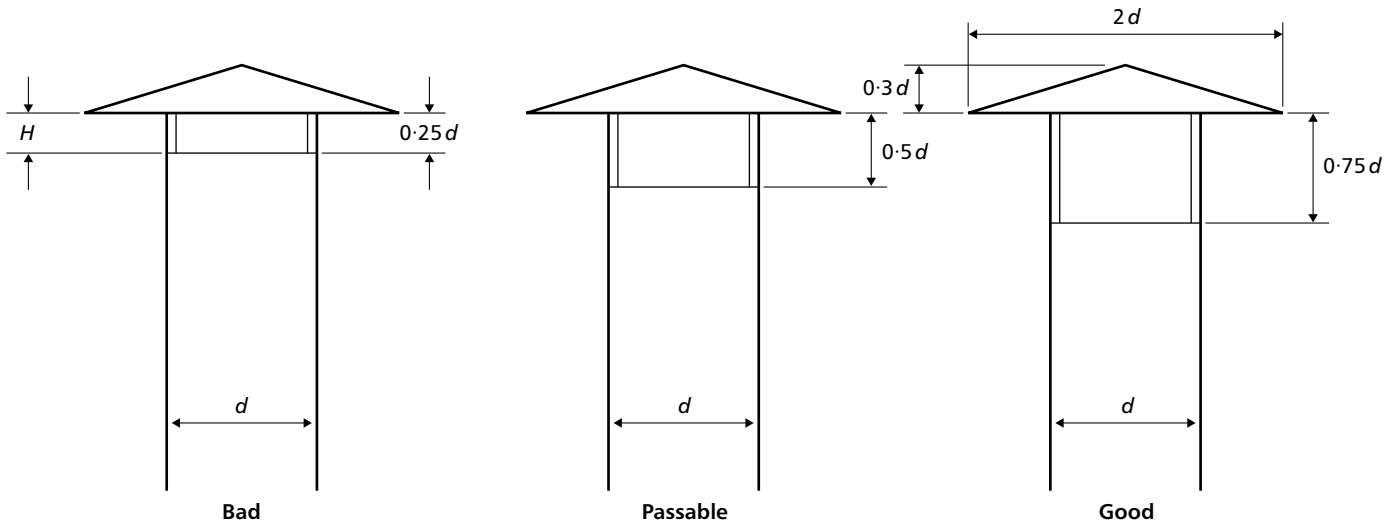

Figure 2.52 Discharge cowls; good and bad design

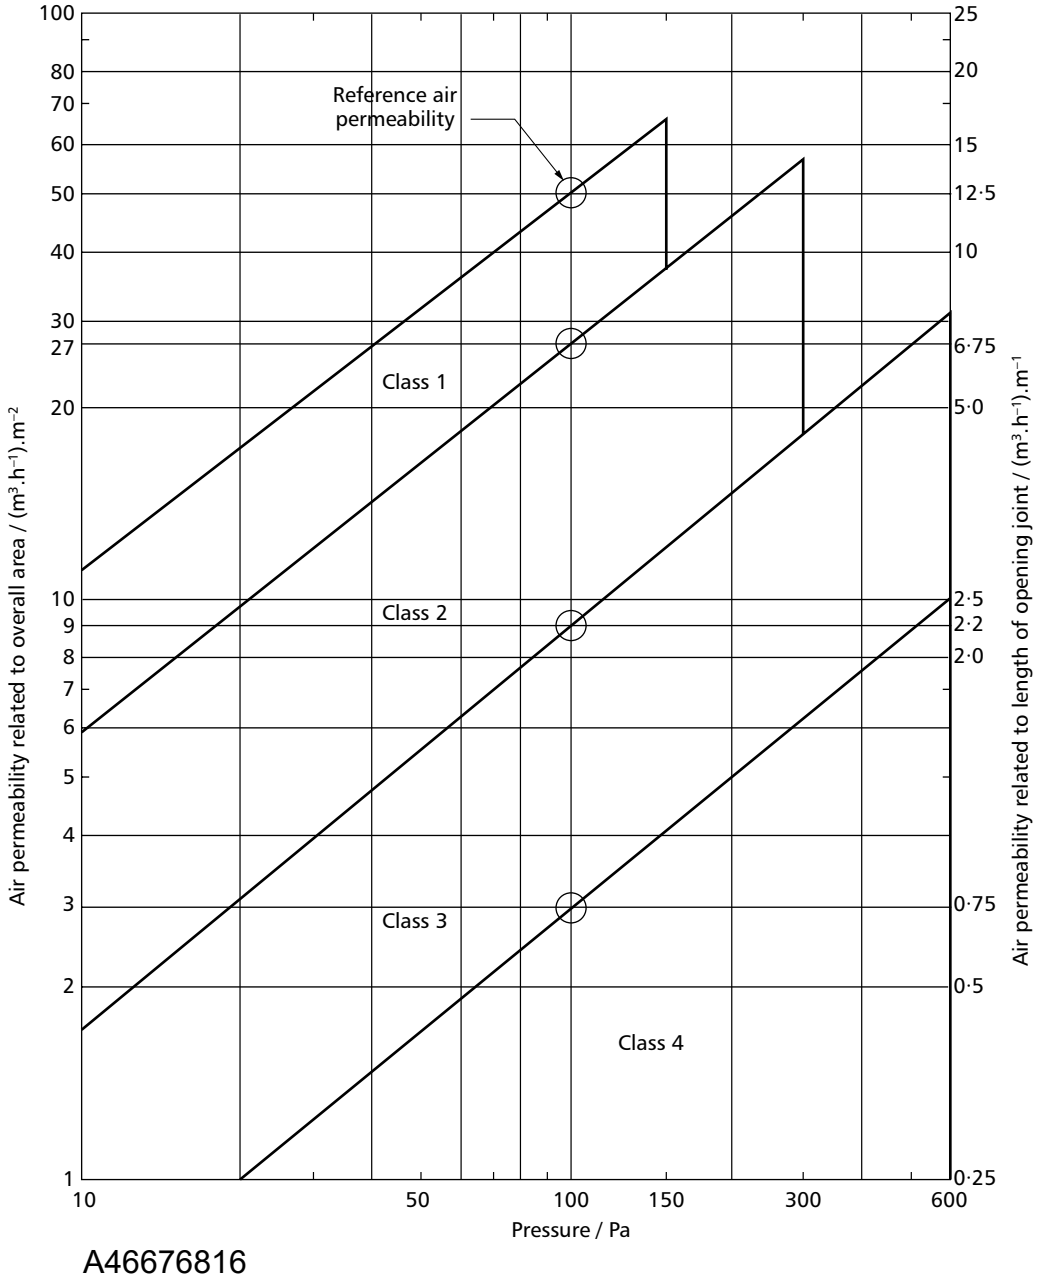

Figure 2.53 Classification of doors and windows by air permeability (reproduced from BS EN 12207: 2000: *Windows and Doors. Air permeability. Classification* (BSI, 2000) by permission of the British Standards Institution)

will be reduced. Examples of good and bad practice are shown in Figures 2.51 and 2.52 below.

2.6.8.3 External louvres and cowl connections

Recommendations on the clearance that should be provided between a cowl and an external vertical duct opening are illustrated in Figure 2.52 (see also sections 4.11.2.31–4.11.2.35 of CIBSE Guide C (2007)). Where adequate clearance cannot be provided, fitting an inverted cone deflector under the cowl can reduce the resistance.

2.6.9 Natural ventilation equipment

2.6.9.1 Openable window design

BS EN 12207: 2000: *Windows and doors. Air permeability. Classification* (BSI, 2000) classifies window and door performance according to their permeability (see Table 2.41 below). Reference air permeabilities are recorded for each class of window related to the permeability of both the overall area and of the opening joint. These are defined at a test pressure of 100 Pa. BS EN 12207: 2000 (BSI, 2000) describes how limits can be defined for other test pressures and how windows are subsequently classified according to the relationship between the two permeability assessments.

Figure 2.53 shows the upper limits of each class, which are derived from the reference air permeabilities at 100 Pa related to the area and length of opening joint, see Table 2.41.

General information on window design and selection is available from other CIBSE/SLL publications such as SLL LG10: *Daylighting — A guide for designers* (SLL, 2015) and CIBSE AM10: *Natural ventilation in non-domestic buildings* (2005). There are a number of important criteria, which are outlined in the following sections.

Ventilation capacity

The ventilation capacity is the amount of air that will flow through a given window area of different designs. It depends on the ratio of the effective open area to the façade area of the window unit. Ventilation capacity will be maximised by increasing the vertical separation and magnitude of those open areas. This will in turn depend on the way the window opens (i.e. side, top/bottom, centre pivot, sliding etc.), and the distribution of the open area over the vertical height of the window. Figure 2.54 shows the open areas for a horizontal centre pivot window compared with a side-hung window. A typical pressure gradient caused by inside–outside temperature differences is also shown. The centre pivot window has a much higher ventilation capacity because the open area is concentrated at regions of high pressure difference. In contrast, much of the open area of side-hung windows is in a region of small pressure difference.

Adjustability

Good control at small openings is particularly important for winter comfort. The flow characteristic is influenced by the mode of opening the window and factors such as the shape and thickness of the window frame. Figure 2.55 illustrates that the effective open area of a window may not increase very rapidly until the opening angle is quite large.

Table 2.41 Reference air permeabilities at 100 Pa and maximum test pressures related to overall area and length of opening joint

Class	Reference air permeability at 100 Pa and maximum test pressure			
	Related to overall area		Related to length of opening joint	
	Permeability / $(m^3 \cdot h^{-1}) \cdot m^{-2}$	Max. test pressure / Pa	Permeability / $(m^3 \cdot h^{-1}) \cdot m^{-1}$	Maximum test pressure / Pa
0*	—	—	—	—
1	50	150	12.50	150
2	27	300	6.75	300
3	9	600	2.25	600
4	3	600	0.75	600

* Not tested

Impact on comfort

The position of the room air inlet will have an effect on comfort factors such as draughts. Air entering the space at the occupied level can improve comfort in summer, when the air movement will provide a cooling benefit. In winter when the entering air is much colder, the same opening may result in discomfort from draughts. Consequently, separate winter openings may be preferred (either separate high-level windows or trickle ventilators). To avoid high summer ventilation rates (causing papers to be disturbed), the height of that part of the window where air enters the space should be above desk level.

Thermal contact

In strategies utilising night cooling and thermal capacity, the ventilation air needs to be able to make good thermal contact with the fabric in order to effect good heat transfer.

Security

The implications of open windows, particularly in night ventilation mode, need to be considered. Some window designs can be lockable in a part-open position, which allows adequate night ventilation rates but minimises the risk of intruders gaining access to the building.

Integration with solar control strategies (particularly blinds)

The blind and window opening may interact in a number of ways including:

— the movement of the window may be restricted by an independent internal (or external) blind; this is mainly a problem for pivoting windows

— with pivoting windows and mid-pane blinds, there is the impact on shading performance when the angle of the blind louvres to the incident radiation changes as the window is opened

— the effect of the blind in providing a resistance to airflow; the blind elements (unless they are mid-pane) will provide an obstruction to the free area of

the opening (this is independent of window type, see Pitts and Georgiadis (1994)).

Window specification

Information on the performance characteristics of various window types (see Figure 2.56) is given below. The effect of these different characteristics should be assessed with reference to the criteria listed above.

— *Horizontal pivot windows*: these have a high ventilation capacity because large open areas are created at a separation equivalent to the window height. With single-sided ventilation, air will enter at the lower level and exit via the top of the window. An opening of 22° is usually considered the norm for 'fully open'; for example for a typical 1200 mm wide by 1600 mm high window this results in an effective open area of 0.66 m^2. They are easily adjustable to provide control of the ventilation rate. Maximising the height of the top of the window in the room will help exhaust warmer air at ceiling level when operating in single-sided ventilation mode. Glazing at high level will also promote good levels of natural light deep into the space. When operating in wind-driven cross-ventilation mode, air will enter at the top and bottom of the window. The air entering through the top gap will be directed upward and this can improve thermal contact with exposed ceilings for effective night ventilation. Solar radiation striking the opaque surfaces of the wall or the ground adjacent to the façade can generate rising convection currents. These can be deflected into the room if the outward projection of the window extends beyond the window reveal.

— *Vertical pivot windows*: because the opening is distributed uniformly over their height, these windows have a lower ventilation capacity. For the same 22° opening, the effective open area is reduced by 40 per cent relative to the horizontal pivot. Vertical pivot windows can act as a form of 'wind scoop' for wind directions parallel to the face of the building. Because they have a large vertical opening, they are more likely to allow rain into the building. Carefully designed weather stripping is required for both horizontal and vertical centre pivot windows to achieve a good performance in winter.

— *Top/bottom hung windows*: as ventilators, these are less effective still, since all the opening area is concentrated at one end of the window height. The effective open area is about 35 per cent of the horizontal pivot type. Depending on where the opening is, the summer ventilation will either provide cooling to the occupant and poor thermal contact with the ceiling, or vice versa. Top hung windows can act as scoops for warm air rising up the outside of the building (e.g. from convection currents generated by solar gain on building surfaces).

— *Side-hung windows*: these are similar in performance terms to vertical pivot windows. Because of the greater distance from window edge to pivot (and hence greater turning moment), they are more susceptible to being blown by gusts of wind. Inward opening windows can cause clashes with furniture positions. The combination of top-hung winter ventilators and side-hung summer windows (with effective weather stripping) provides good all-round performance. The top hung winter ventilator can also provide a secure opening for summer ventilation that, in combination with the side-hung opening, will enhance stack effect.

— *Sliding windows (including sash)*: depending on whether they are vertical sliding (sash) or horizontal sliding windows, these will have similar ventilation characteristics to the horizontal and vertical pivot window respectively. Sliding windows can provide good control over summer ventilation. Sash windows allow the stack effect to be controlled through adjustment of the opening size at both the top and bottom of the window. However, ensuring a good seal in the closed position requires particular attention. This is important in terms of reducing draughts and energy losses in winter. Recent designs have significantly improved the performance of sliding windows in this respect. The design of sash windows needs to be such as to facilitate easy opening of the upper sash.

— *Tilting top vents*: these provide smaller opening areas than the other systems, because the opening portion

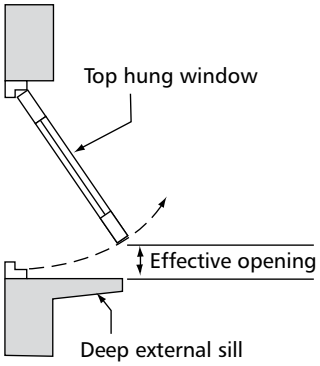

Figure 2.55 Effect of a sill on the relative open area of a window

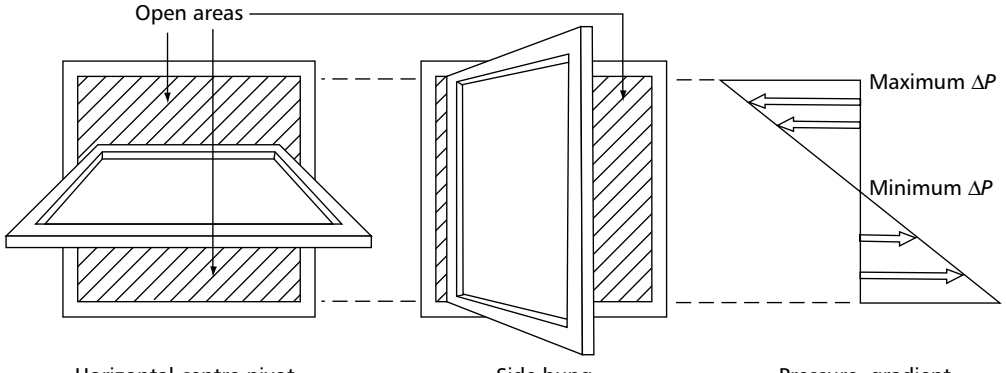

Figure 2.54 Ventilation capacity of different window configurations

occupies only a proportion of the window height. However they can provide good draught-free ventilation, especially in cross-ventilation mode. If the vent is bottom hung and opening inwards (the 'hopper' window), the natural flow pattern may encourage good thermal contact with the ceiling. However, care must be taken to protect the opening from driving rain.

— *Tilt and turn windows*: these are a combination unit offering bottom- and side-hung options (although the side-hung mode is mainly intended for cleaning purposes). A study of several buildings by Willis *et al.* (1995) suggests that the tilt setting provides too much ventilation in winter and insufficient ventilation in summer. The turn mode can cause clashes with furniture.

Whereas windows perform many functions, sections 2.6.9.2 to 2.6.9.8 describe openings in the façade whose sole purpose is to provide ventilation. Note that any such devices should offer a very low resistance to airflow, as the driving forces for natural ventilation may only be in the region of 10 Pa. Further guidance on product development and natural ventilation design tools is available from BRE (1999c).

2.6.9.2 Air bricks and trickle ventilators

Air bricks incorporate no provision for control of infiltration rate. Automatic ventilators, which provide nominally constant infiltration under variable wind velocities, should be considered as an alternative. The concept of 'build tight, ventilate right' is increasingly recognised as the basis of good design for ventilation. This relies upon an airtight fabric and the provision of a means of controlled background ventilation. In a naturally ventilated building this is often provided by trickle ventilators with higher rates of ventilation provided by other means such as the window or specific controlled damper devices.

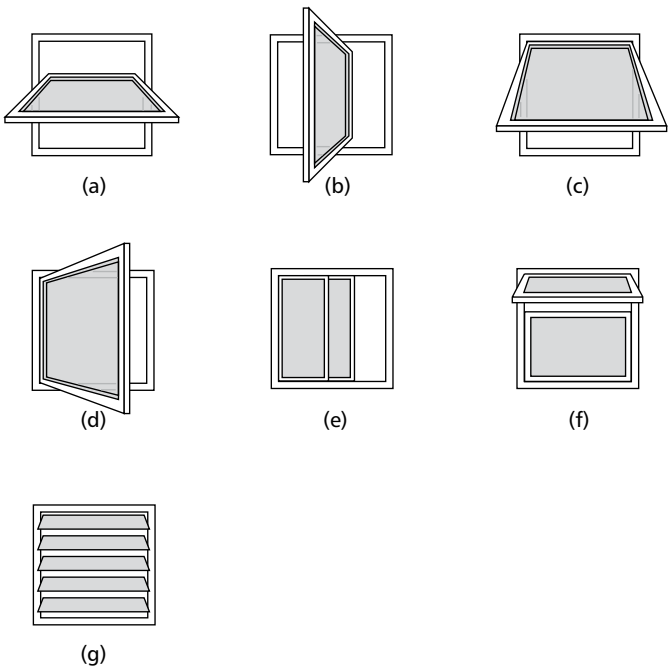

Figure 2.56 Window types: (a) horizontal pivot, (b) vertical pivot, (c) top/bottom hung, (d) side hung, (e) sliding, (f) tilting top vent, (g) louvre

Trickle ventilators are usually designed to provide the required minimum fresh air rate, particularly in winter. For England and Wales, Part F of the Building Regulations (NBS, 2010b) should be consulted for further details of the requirements, and the *Technical Handbook* (Scottish Government, 2015) for requirements in Scotland.

Draughts, especially those occurring at ankle height, can be avoided by directing the incoming air upwards, or positioning the ventilators at high level, e.g. > 1.75 m above the floor. This allows incoming air to mix with the warmer room air before reaching floor level. Alternatively, air can enter through wall ventilators positioned behind heaters. The form of the ventilator should promote rapid mixing with the room air to minimise cold draughts. General guidance on the use of trickle ventilators has been published by BRE (1998).

Added to this is the daily 'reservoir' effect of the trickle vents that purge the room overnight and provide a room full of fresh air ready for the following day's occupants. The larger the room volume, as with the higher ceilings in naturally ventilated rooms, the longer this reservoir effect will last during the occupied period. As trickle vents are intended to promote background ventilation only, their main application is for fresh air supply in the winter months. Twenty-four-hour use of trickle ventilation can provide a reservoir of fresh air that may be sufficient to maintain air quality throughout the day. With higher pollutant loads, rapid ventilation by opening windows for short periods or by mechanical ventilation might be required. For this reason, trickle ventilators are usually used in conjunction with other types of ventilation opening.

Trickle vents can be in the window frame, part of the glazed unit or independent of the window (usually above it). Various refinements on the basic trickle ventilator are available. Acoustic trickle ventilators are available that reduce noise, but they bring a penalty of increased pressure drop.

Control options available include the following.

— *Basic (uncontrolled)*: consisting of a series of holes or slots that are covered to give protection from the weather. No control is possible, hence positioning and appropriate selection are very important.

— *Standard controllable (including 'hit and miss')*: closure may be possible through the use of a manually operated slide that covers the openings. Occupants need to understand the operation of such devices.

— *Humidity controlled*: mostly used in kitchens and bathrooms within dwellings, as the scope for use in offices is limited with moisture not being the dominant pollutant.

— *Pressure controlled*: generally used in offices; inside/outside pressure difference is one possible control strategy.

— *Pollutant (e.g. CO_2 , CO, smoke controlled)*: used in schools, theatres, shopping malls etc. and sometimes in dwellings. Practical use for offices is limited as, except for CO_2 (where considerable drift has been reported), these are not normally the dominant pollutants.

The ventilation performance of trickle ventilators is traditionally specified in terms of 'free air space' or 'open

area'. Acoustic effectiveness is considered in the light of the 'effective area' or 'equivalent area'. This is considered in detail in BRE guidance (BRE, 1998).

Effective area is also considered to be a more realistic measure of airflow performance. It is defined as the area of a single sharp-edged hole (in a thin plate) that passes the same volume airflow rate and at the same applied pressure difference as the vent being tested. It requires to be measured on an airflow test rig. Most trickle ventilators with the same equivalent area will have similar airflow performance, even though their free areas might differ. Consideration of effective area is now required in Part F of the Building Regulations (NBS, 2013b).

2.6.9.3 Louvres

These are usually constructed of either glass or aluminium blades. Security bars can be fitted inside the louvres and this enhances their potential application in the night ventilation mode. Versions incorporating acoustic attenuation are also available. Whilst providing good control over summer ventilation, adjustable louvres usually present the greatest crack length for a given opening. However, conventional hinged louvres are usually difficult to seal when closed, making it difficult to limit infiltration losses.

2.6.9.4 Roof ventilators

In combination with low-level openings in the fabric, roof ventilators can be used to take advantage of summer stack effect, particularly for tall spaces. However, they must be specified to have low crack leakage or wind-induced draughts will cause discomfort in winter.

For maximum effect the outlet should be on the ridge of a pitched roof and the cap should project sufficiently above the ridge to minimise the influence of turbulence arising from wind blowing up the slope of the roof. Natural ventilation openings should try to avoid being installed on the slope of a roof and avoid being located in high-pressure areas of the building environment, where down-draughts are likely to occur.

2.6.9.5 Fixed lights

Crack leakage from roof lights should not be relied upon to provide ventilation even though minor leakage may arise along the crack length of the perimeter.

2.6.9.6 Dampers

Dampers are usually used for applications where automatic control is required. In the context of natural ventilation, this is usually for air inlets, both side-wall mounted above and below false floor level and at main exhaust points (e.g. roof vents). Again, the key performance criterion is the ability of the damper to provide an airtight seal when closed to minimise energy losses. If effective control is required then a significant proportion of the available pressure differential must occur across the damper in order to provide control authority.

2.6.9.7 Dampered openings with louvres

There are dampered openings available that are fixed to the outside building façade and protected from water ingress by a suitable weather-protective louvre. Such systems take advantage of either the stack or mixed-mode principle and manufacturers have developed decorative internal cover grilles if the opening is within the occupied space and even allowed for low-pressure hot water (LPHW) coils to be used in conjunction with these to temper the incoming air for winter conditions and prevent cold slugs of air entering directly into the room.

2.6.9.8 Acoustic dampers with silencers

Internally where the air passes through the building exchanging from room to room or room to atrium, an acoustic damper (Figure 2.57) may be required as a control point for the design of the system. This may require additional silencers to perform to the relevant space-required noise standards but the dampers with acoustic properties should be reviewed for their initial performance.

2.6.9.9 Shafts and ducts

Many ventilation strategies rely on shafts to take air vertically through a building. Similarly, ducts (including floor voids) are used to provide horizontal distribution. The criteria for sizing these airways are very different to those used in sizing conventional mechanical ventilation systems in order to keep pressure drops within the range available from natural driving forces. This means that adequate space must be allowed to incorporate these larger ducts or shafts. A second crucial issue is the requirement to keep the inlet ducts clean to minimise air-quality problems. This will typically require inlet screens and access for cleaning.

By definition, shaft outlets are at high level and therefore are in a region of higher wind speed. This means that the magnitude of the wind pressure acting on the shaft is likely to be large. Wind effects will probably dominate the pressure distribution through the system except at very low wind speeds. It is therefore vital that outlets are designed to create wind pressures that reinforce the intended flow direction. Usually this means creating a negative pressure coefficient at the top of the shaft, the exception being the wind scoop.

Orme *et al.* (1994) provide information on the above roof pressure coefficients. For isolated buildings with no local flow interference, the minimum height of the stack above roof level to avoid back-draughts is given by:

$$h = a\,[0.5 + 0.16\,(\theta - 23)] \tag{2.36}$$

where h is the height above roof level (m), a is the horizontal distance between the outlet and the highest point of the roof (m) and θ is the pitch of the roof (degrees).

For roof pitches of less than 23°, the height of the outlet must be at least 0.5 m above the roof level. These simplified relationships represent a minimum stack height; greater heights may well provide higher suction pressures. This can be beneficial since it is possible to generate a suction greater than that generated on an opening on the leeward vertical face of the building.

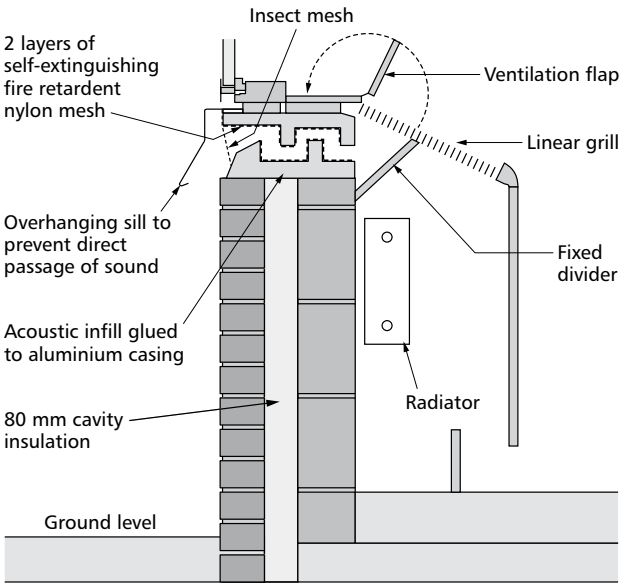

Figure 2.57 Ventilation opening with acoustic protection, based on an illustration from BB93 (EFA, 2004)

More information on pressure coefficients over roofs is given in BS EN 1991-1-4: 2005 + A1: 2010: *Eurocode 1. Actions on structures. General actions. Wind actions* (BSI, 2005c). For complex roof profiles or where surrounding buildings or other obstructions disturb the wind, model testing would be advisable.

As well as the position of the roof outlet, the geometry of the outlet will also affect the pressure coefficient. The outlet should prevent rain entering the stack and can provide flow acceleration local to the outlet to further reduce static pressures.

2.6.9.10 Transfer grilles

Transfer grilles may be required as a minimum to allow air movement across a building if cellular accommodation has been provided. The resistance of these transfer grilles must be included in the design calculation when sizing the façade unit sizes.

2.6.9.11 Wind towers

Wind towers are variously referred to as windcatchers and wind scoops. These are derived from ancient Middle East 'badgir' systems in which a rectangular cross-section chimney is divided by diagonal quadrants into four ducts. Each is exposed to its own opening at the top of the chimney and to a diffuser at its base (see Figure 2.58). Depending on wind direction, positive pressure drives air through the wind-facing quadrants while suction pressure extracts air through the remaining quadrants. In desert regions this took advantage of high-level wind while minimising the risk of sand being driven into the building, as would occur through low-level openings. These devices are multi-directional and function irrespective of wind direction, as any of the four faces can allow supply air to be introduced and to pressurise the room below, with the opposite louvre face achieving a negative pressure and acting as an exhaust louvre. Various manufacturers have developed modern versions of this system. Specific manufacturers' details should be reviewed to check performance criteria are met with this method.

In climates where the balance of driving force varies between wind and temperature, the flow patterns become complex and these devices can perform both as wind towers and chimney stacks according to the net driving force (see section 2.4.6). In terms of mathematical analysis, the opening heights, dimensions and orientation can be treated in exactly the same way as any other natural opening as described in chapter 4 of CIBSE Guide A (2015a) and section 2.4.6. Modern designs focus on reducing the aerodynamic resistance and pressure drops across components. In critical cases, performance data should be independently evaluated by laboratory testing. Flow resistance usually restricts the depth of penetration to two stories. As with chimneys and atria, they can be used to assist in deep-plan natural ventilation.

External roof-mounted terminals have been developed to take advantage of the wind-tower principle and allow a constant airflow relating to wind-driven forces. These terminals take the form of an exposed, roof-mounted, four-sided louvre screen with appropriate weathering properties and suitable roof section. The internal section of the louvre is split into four separate sections across the corners of the terminal to allow wind to penetrate at least one side of the face of the terminal positively and allow air to enter the building and pressurise the room below positively. This creates a negative pressure on the opposite side of the terminal, allowing exhaust warmer air to be evacuated and replaced with the fresh air supplied. These terminals are multi-directional.

2.6.9.12 'Passive' stacks

Stack ventilation can be enhanced by using passive stacks (see Figure 2.59). These are vertical ducts that are typically 100–150 mm in diameter. The lower end terminates in the ventilated space at or close to ceiling level. The upper end penetrates the roof and is ideally located in the wind-

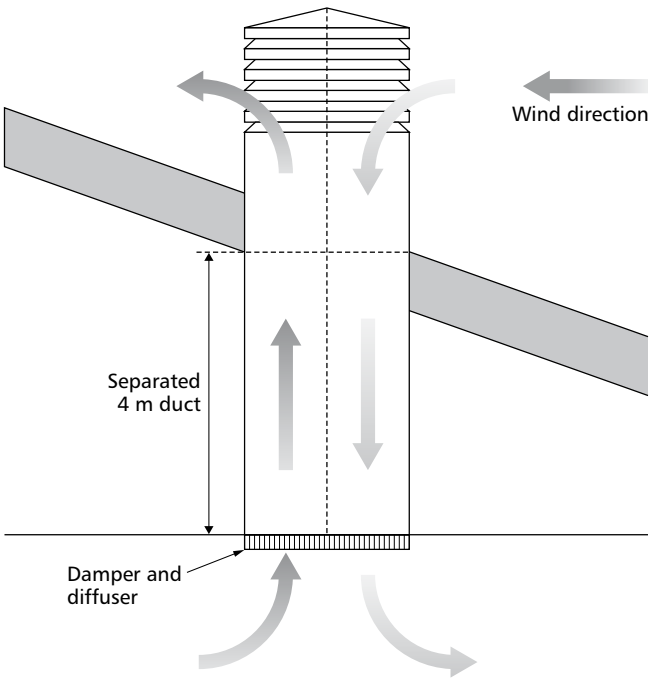

Figure 2.58 A roof mounted wind tower, reproduced from AM10: *Natural ventilation in non-domestic buildings* (CIBSE, 2005)

generated suction region so that ventilation can be driven by both wind and stack-driving forces. Make-up air is provided by trickle ventilators. The essential requirement is for the air in the chimney to be warmer than the ambient air. In dwellings, stacks are placed in 'wet' rooms and 'dry' air is drawn from the living and bedrooms.

Standard passive stack ventilation (PSV) systems have a simple inlet grille to the duct. Humidity-sensitive vents are available that can provide increased flows when humidity is high. Acoustic treatment may be required to reduce ingress of external noise. Fire dampers are required where ducts pass through a fire-separating floor.

For guidance on sizes and available products, manufacturers will be able to advise on the maximum and minimum duct sizes to handle the required airflow through the stack or chimney. Manufactures can calculate driving forces and select suitable equipment to achieve the desired results and prove this system will be able to cope with the required specification.

It is possible to enhance the stack pressures by means of absorbing solar gain (the so-called 'solar chimney') introduced via glazed elements. Location of the solar stack on the sunny side of the building in order to capture the solar radiation will generally result in cooler air being drawn in from the opposite shaded side. Solar performance requires careful thermal analysis because it relies on a rapid rate of heat transfer from the solar heated components to the raising ventilation airstream.

Care should be taken to ensure that there is a net heat gain into the chimney during cooler weather, i.e. the solar gain must be greater than the conduction loss. In cold weather, the conduction heat loss will result in low surface temperature for the glass that may be sufficient to generate down-draughts inhibiting the reverse of the general upward flow through the chimney. The wind-driving pressures can be enhanced by careful design of the roof profile and/or the chimney outlet configuration.

As a means of providing adequate ventilation on very hot and still days, consideration should be given to installing extract fans in the stack to pull air through the building. However, the fan should not provide a significant resistance to flow when the chimney is operating in natural draught mode and noise should be carefully considered (see section 2.3.2.4).

The analysis on stack ventilation often makes the presumption that the air in the stack is at building temperature and outside air is at a lower temperature. A steady reverse-flow pattern, with outdoor airflow down the stack, is possible if the stack was to assume the outdoor rather than indoor temperature. This can occur, for example, if the building has been allowed to cool during unoccupied periods (e.g. weekends or over night). Reverse flow should be avoided in cold weather but it can be used to advantage at night in the warmer seasons where free cooling may be available due to the night-time drop in temperature. This allows air to be drawn into the building at lower than occupant comfort temperatures thus allowing the building to cool significantly prior to the next day's expected elevated temperatures. More technical information on reverse flow in stacks is published by Li (2002).

2.7 Commissioning, operation and maintenance

2.7.1 Testing and commissioning

2.7.1.1 Introduction

All ventilation systems and associated ductwork systems should be tested and commissioned, and those of significant size (e.g. with a fan capacity above 1 $m^3 \cdot s^{-1}$) should also be leak tested. The needs of on-site regulation should be planned and provided for in the design stage, otherwise balancing the system within acceptable limits may not be possible. The designer must accept the implications of the commissioning procedures to which the air distribution system will be subjected. Inadequate commissioning will

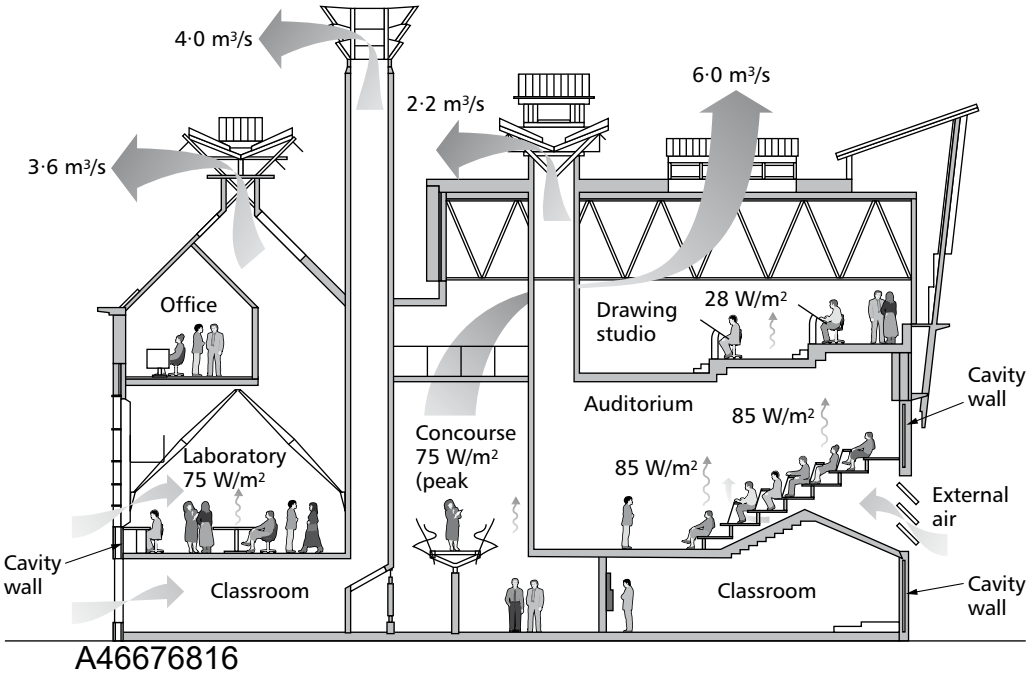

Figure 2.59 An example of a design using a passive stack system to enhance natural ventilation; Queens Building, de Montfort University (reproduced courtesy of Short Ford Architects)

result in poor environmental performance, energy wastage, draughts and noise. The designer's objectives must be to design an air distribution system where arrangements of ductwork and the selection and disposition of the components, particularly the means of air regulation, will promote a balanced and stable airflow. In the UK commissioning is explicitly included in the Building Regulations.

The measuring, regulating and apportioning of airflow in a distribution system are a means to an end. The objective is to ensure that the performance of the commissioned installation is adequate to maintain the specified environmental conditions of the space with optimum efficiency.

Procedures for commissioning air-handling systems are given in CIBSE Commissioning Code A: *Air distribution systems* (2006b) and BSRIA AG 3/89.3: *Commissioning Air Systems* (2001). Table 2.42 shows a summary of the flow-measuring techniques recommended by BSRIA for various ducts and terminals.

Before system regulation starts, the building needs to be complete, with windows and doors open or shut according to their normal state. The air distribution system needs to be complete, with leakage testing satisfactorily concluded. A reasonable standard of system cleanliness should be achieved before system start up.

Each system should be considered on its own merits and a detailed commissioning method statement produced and agreed prior to commissioning. It is important that the designer provides full information on all relevant aspects of the design, particularly VAV systems, in sufficient detail for the commissioning specialist to produce a comprehensive method statement. The commissioning specialist should review the recommendations of the equipment suppliers with regard to the inclusion of their equipment in the commissioning process for the air distribution system.

Successful commissioning and building operation depends on the following design considerations.

— Avoid long duct runs, since these can create balancing difficulties in commissioning.
— The use of variable speed fans allows rapid matching of fan duties during commissioning.
— Ensure there are sufficient dampers and access panels to reduce commissioning time.
— The setting of the automatic control system should be finalised by the controls specialist in liaison with the commissioning specialist.

2.7.1.2 Legislation

CIBSE Commissioning Code M: *Commissioning management* (2003) provides an overview of the management arrangements for commissioning required to ensure compliance with Parts F (NBS, 2013b) and L (NBS, 2013a) of the Building Regulations. Steps include:

— design for commissioning
— co-ordination of the commissioning process
— installation quality assurance
— pre-commissioning
— preparation
— commissioning
— confirming compliance
— certification
— building log book (CIBSE TM31: *Building log book toolkit* (2006c))
— system handover.

Building Regulation 38 (TSO, 2010) requires the handing over of all design, installation positioning and maintenance information for any and all fire safety items.

2.7.1.3 Design provisions to facilitate commissioning

Introduction

Consideration should be given to access for commissioning, inspection, maintenance and cleaning. Openings need to be safe and have sealed panels/covers designed so that they can be easily removed and refixed. Multiple setscrews are not recommended, and self-piercing screws are not acceptable as a method of fixing. Safety restraints should be connected to access panels located in riser ducts.

A sufficiently large area, free of services and other obstructions, is needed around panels and covers to allow them to be removed.

An access panel is required to be adjacent to items of in-line equipment that require either regular servicing or intermittent access. The openings need to be sized as a minimum to allow hand and/or arm access. The designer should specify the size and location of the panels where larger dimensions are required. In these cases the panels should not exceed 450 mm × 450 mm. It may be more practicable to use removable duct sections or flexible ducts/connections.

An inspection panel should be provided adjacent to items of in-line equipment that need only visual inspection of internal elements from outside the ductwork. Such inspection openings should have a minimum size of 100 mm × 100 mm for rectangular ducts and 100 mm diameter for circular ducts.

It will be the responsibility of the insulation contractor to 'dress' the insulation to the edges of the access openings without impeding the functionality of the panel, cover or door.

Provision of access panels

Access panels should be provided for the inspection and servicing of plant and equipment; Table 2.45 provides guidance. However, the ductwork system designer may choose to demonstrate that adequate provision has been made for access, such as by reference to a ductwork cleaning specialist.

In addition, the following should be noted.

— Fire/smoke dampers: panels should be located to give access to both the blades and the fusible links. On multiple assembly units it may be necessary to provide more than one panel; the need for such access may be determined by the external access

Table 2.42 Flow measurement techniques (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of the BSRIA)

Position	Measurement technique	Instruments
Main duct (total flow at fan)	* Velocity traverse in duct	Pitot tube with micromanometer
	† Wilson flow grid	Micromanometer
Branch ducts	* Velocity traverse in duct	Pitot tube with manometer
Terminal connecting ducts	* Velocity traverse or single point reading in duct	Pitot tube with micromanometer or mini-rotating vane anemometer where velocity < 4 $m \cdot s^{-1}$
Grilles	* Velocity traverse across face	Rotating vane anemometer
	* Hood	Rotating vane anemometer or integral hood assembly
Ceiling diffusers	* Flow hood	Rotating vane anemometer or integral hood assembly
	* Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
	* Static pressure in connecting duct	Diaphragm pressure gauge or pitot tube
	† Average peripheral velocity and area	Mini-rotating vane anemometer or thermal anemometer
Slots and linear diffusers	* Face velocity (for slots of equal width and same louvre setting)	Mini-rotating vane anemometer or thermal anemometer
	* Flow hood	Rotating vane anemometer or integral hood assembly
	† Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
Perforated ceiling	* Velocity in connecting duct to ceiling void	Pitot tube/manometer or mini-rotating vane anemometer
Perforated panel diffuser	* Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
	* Flow hood	Rotating vane anemometer or integral hood assembly
	† Face velocity (no deflection)	Rotating vane anemometer or integral hood assembly
Decorative terminals	* Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
Induction units	* Static pressure in nozzle plenum	Diaphragm pressure gauge
High velocity nozzles	* Jet velocity	Pitot tube/manometer or mini-rotating vane anemometer
	* Static pressure in connecting duct; previous calibration or maker's data	Diaphragm pressure gauge
Fan coil units	* Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
Extract openings (grilles)	* Face velocity	Pitot tube/manometer or electronic hood
Slots, perforated panels, decorative openings	* Velocity in connecting duct	Pitot tube/manometer or mini-rotating vane anemometer
Combined lighting units, adjustable exhaust valves	* Manufacturer's recommended technique	Pitot tube/manometer or mini-rotating vane anemometer
	* Velocity in connecting duct	

Note: * indicates preferred measuring technique for stated location
† indicates second choice (i.e. more difficult to use in practice or subject to a greater possibility of error)

conditions and the internal reach to the blades and their fusible links.

— Heating/cooling coils and in-duct fans/devices: the panel should be located on the air entry side i.e. upstream.

— Filters: panel should be located in the air entry side i.e. upstream (note: dimensions of access may need to be changed to suit filter elements of the front withdrawal type).

— Inspection covers: inspection covers should be provided adjacent to regulating dampers where either the control linkage is mounted internally within the airstream or if a multi-bladed unit is an integral part of the ductwork run. It is not necessary to provide inspection covers adjacent to either single blade regulating dampers or flanged damper units.

— Hand holes: hand holes to permit proper jointing of duct sections should be provided at the manufacturers' discretion but kept to a minimum and made as small as practicable. The hand-hole cover should be sealed and securely fastened.

Cleaning of ductwork must be taken into account in the design and installation stages by ensuring adequate and safe provision is made for access.

Filter removal and replacement must be considered by ensuring sufficient space and means of access is provided.

Good ductwork design

The duct sizing procedure (see section 2.3.5) should take into account the requirements of system balancing. The position and number of regulating dampers included in the design should be sufficient for this purpose.

Table 2.43 Information to be provided in schematic drawings

Items of system	Information to be provided
Fans	Fan total pressure
	Volume flow rates
	Motor current
Plant items	Type and identification numbers from equipment schedules
	Volume flow rates
	Pressure losses
	Dry-bulb temperatures, Wet-bulb temperatures, Humidity — For coils and humidifiers as appropriate
Dampers (including motorised) and fire dampers	Identification numbers from equipment schedules
	Location
	Volume flow rates
Main and branch ducts	Location
	Dimensions
	Volume flow rates
Terminals	Identification numbers from equipment schedules
	Location
	Dimensions
	Volume flow rates and velocities
	Operating pressures
Test holes and access panels	Location
Controllers	Set points

Notes:
(1) Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet.
(2) Where volume flow rates are variable, maximum and minimum values should be provided.

Communication

The designer should pass on the design intent to the commissioning engineer by indicating which parts of the system are high, medium and low pressure, and by providing:

— relevant parts of the specification

— schematic drawings as listed in Table 2.43 (see also Figure 2.60 below, which shows a basic schematic for system regulation including damper positions)

— equipment schedules

— controller and regulator schedule

— fan performance curves

— wiring diagrams for electrical equipment, including interlock details

— manufacturers' operating and maintenance instructions.

The information listed above should also be included in the building's log book.

Provision and siting of volume control dampers

Note: it is important to have a means of recording the positions of volume control dampers that have been set during commissioning; spray paint over the quadrant is effective for smaller sizes of dampers.

Low- and medium-pressure systems

Manually operated balancing dampers are generally needed:

(*a*) in the main duct downstream of the fan

(*b*) in the branch or zone ducts

(*c*) in sub-ducts serving four or more terminals

(*d*) at terminals not covered by (*c*) above.

Dampers integral with terminals should only be used for final trimming of air volumes, or noise and air distribution problems may result. Dampers should not be used for primary duty control

High-pressure systems

Where pressure reduction in a high-pressure system is essential, it is recommended that:

— throttling dampers should not be used in high-pressure and high-velocity sections because of duct leakage and noise problems; if this cannot be avoided then additional attenuators and external sound barrier mats may be needed at the damper and downstream to limit noise break-out

— orifice plates or proprietary pressure-reducing valves should be used as first choice in main branches

— where dampers are required they should be confined to areas of relatively low duct velocities; iris type in circular ducts, streamlined blade construction in rectangular ducts.

Variable volume systems

Rather than using throttling dampers in the main duct, system static pressure control in VAV systems should be effected by:

— variable speed motors on the fan(s) or

— inlet guide vanes with centrifugal fans or

— variable pitch blades on axial-flow fans.

Motorised dampers

Motorised dampers for throttling airflow should be opposed-blade type opening through a full 90°; for mixing purposes they should be parallel-blade type opening only through 60°.

Throttling dampers should be sized to have an authority of 5–8 per cent of the fan total pressure. Mixing dampers should be sized to have a face velocity of 4–10 $m \cdot s^{-1}$. To obtain maximum benefit from outside air cooling, fresh air/

recirculation air dampers must have a good shut off; this means they should:

— be rigid with accurate square connections

— be provided with end and edge seals of flexible material

— not be distorted during fitting.

2.7.1.4 Instrument connections

Instrument connections should be provided at locations determined during the design process.

Openings required for other purposes

It is the designer's responsibility to specify the location and size of any openings required other than those covered in this section. In the case of hinged access doors it is the designer's responsibility to indicate on the drawings the location and size of hinged access doors required, ensuring that there is an area free of services and other obstructions to enable the door to be satisfactorily opened. Unless otherwise specified by the designer, openings should not be larger than 1350 mm high and 500 mm wide. Doors should open against the air pressure. Both the opening in the duct and the access door itself need to be adequately reinforced to prevent distortion. A suitable sealing gasket should be provided, together with sufficient clamping type latches to ensure an airtight seal between the door and the duct.

For safety reasons, the manufacturer should incorporate means to prevent personnel being trapped inside the duct, for example by providing access doors with operating handles both inside and outside the duct.

2.7.1.5 Test holes

General

Except in special circumstances, it is not usual practice to install airflow measuring devices permanently in air ducts. The normal procedure is to make velocity traverses across the duct at appropriate locations using a pitot tube. The small test holes for using a pitot tube are usually made by the commissioning specialist.

Test holes for in-duct measurement are needed on the main duct following the air-handling plant. The basic locations for siting test holes for flow measurement are shown in Figure 2.61 as 'principal measuring points'. If there is insufficient space, an alternative is to provide test holes in principal branches so that the total flow from the fan can be obtained by summation. These points are shown in Figure 2.61 as 'secondary measuring points'.

Test holes for in-duct airflow measurement are required:

— on both sides of the fans and heating and cooling coils (for pressure drop measurement)

— in the main ducts

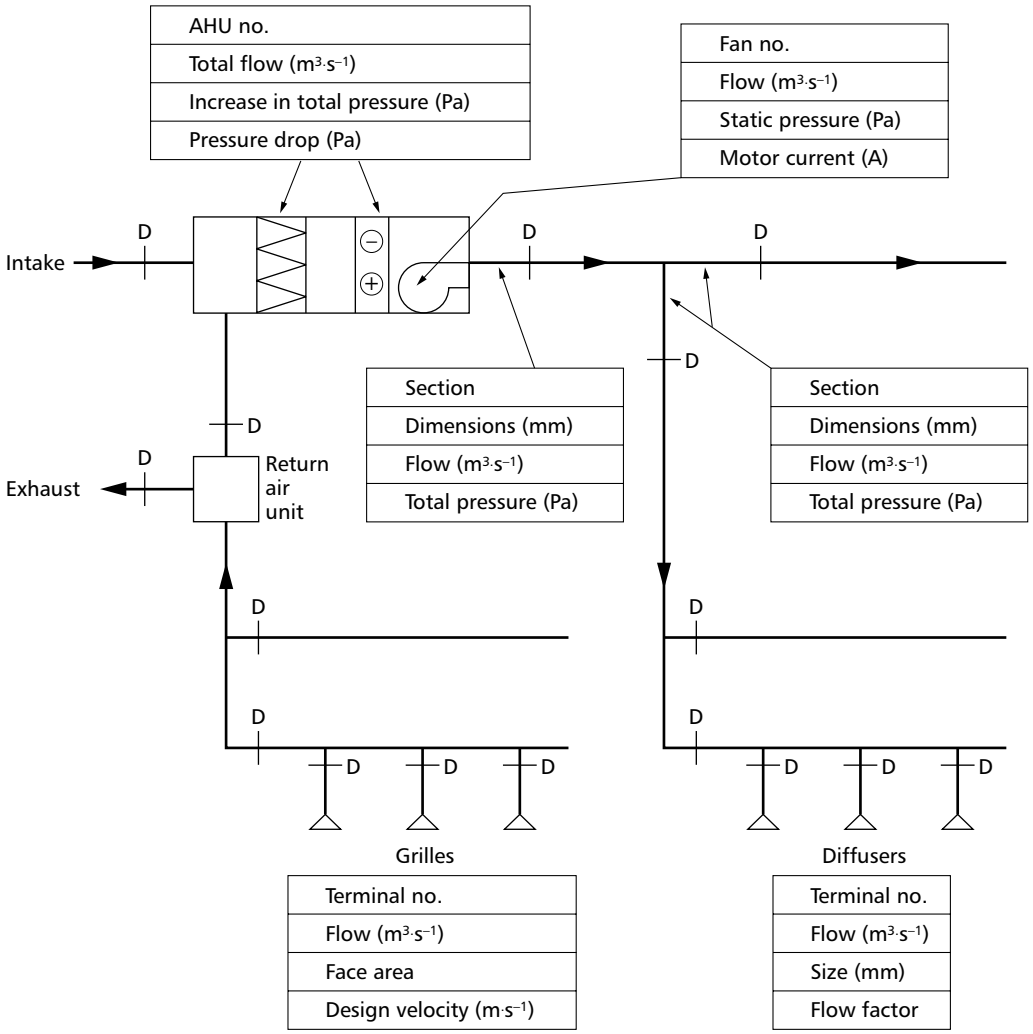

Figure 2.60 Basic schematic for system regulation showing damper positions (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of BSRIA)

— in all branches

— in centrifugal fan drive guards opposite the end of the fan spindle, for speed measurements.

The number and spacing of holes at a particular location are given in BSRIA AG 3/89.3: *Commissioning Air Systems* (2001); these recommendations are summarised in Table 2.44 and Figure 2.62.

The location chosen for the measurement point should be:

— at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends; if this is not possible then well downstream of these sources

— where there is enough space around the duct to insert the pitot tube and take readings

— where the duct has a constant cross-sectional area.

Minimum distances of test holes from sources of turbulence are given in Figure 2.62.

Test hole specification

The main test hole locations are shown in Figure 2.61. Usually the installer will not have drilled the test holes, this being left to the commissioning specialist. However, the designer and the installer should have taken account of the location of test holes to ensure access. It is sometimes appropriate to use re-sealable test holes, included in the ductwork prior to installation.

Figure 2.62 shows the minimum distance of test holes from sources of turbulence. Figure 2.63 gives the dimensions of a standard test hole for a pitot tube for in-duct measurement.

For rectangular ducts, the number of test holes depends on the duct dimensions. For circular ducts, a single test hole is required for ducts less than 150 mm in diameter, and two holes spaced at 90° are required for larger ducts. The appropriate position, number and spacing of test holes are given in BSRIA AG 3/89.3: *Commissioning Air Systems* (2001).

2.7.1.6 Cleanliness of new ductwork and components

The designer should specify the requirements for:

— cleanliness levels for ductwork leaving the factory

— protection during transit

— protection during site storage

— protection of ductwork risers

— inspection and cleaning during installation and before handover.

TR/19: *Guide to Good Practice: Internal Cleanliness of Ventilation Systems* (BESA, 2013c) provides for three grades of pre-commission cleanliness. The designer should determine which is appropriate for the specific installation and state this in the design specification.

In manufacturing ducts, attention should be paid to the grease used in production. The ductwork should leave the factory as clean and dry as possible. Any remaining grease film is a potential base for microbial growth.

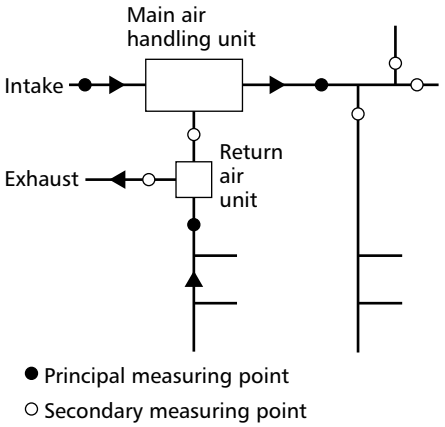

Figure 2.61 Basic test hole positions for flow measurement in duct systems (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of BSRIA)

The whole ductwork installation should be inspected and, where necessary, cleaned before handover. The preferred cleaning method should be specified in the handover documents, including guidelines on access to all points to be cleaned.

During installation the installer should ensure that dust and debris are prevented from entering the ductwork system to ensure that the installation is clean prior to commissioning. The commissioning process should include an inspection of ductwork cleanliness. Where this is not the case, it may be necessary to employ a specialist ductwork cleaning company. The commissioning should not commence until cleanliness has been inspected and certified. The installation should be in a clean state at handover.

Inspection of the ventilation system will usually start with a visual check of the outside air intake, which can be a source of pollution and contamination. A smoke test can quickly determine if outside air is entering the system. Further items to check will be dampers, protective devices against weather, insect and rodents, the hygiene of coils, fans and insulation, the presence of water and condition of condensate drain pans and humidifier reservoirs.

Checking the need for cleaning should be done periodically. Eurovent includes recommendations on indoor air quality (IAQ) (Eurovent, 1999).

2.7.2 Maintenance and cleaning

2.7.2.1 Introduction

Over time, the performance of ventilation systems will deteriorate. The designer should be aware that the air distribution system may become a major odour source. It is possible, with regular cleaning and maintenance, to eliminate nearly all the odour emissions from the system, in both new and renovated buildings.

Components will need regular servicing and replacement to prevent failure. In addition, contaminants such as bacteria, fungal spores, skin scales, dust and moisture could contaminate the ductwork and clog filters. Regular maintenance and cleaning are therefore needed to ensure the correct and efficient operation of the ventilation system.

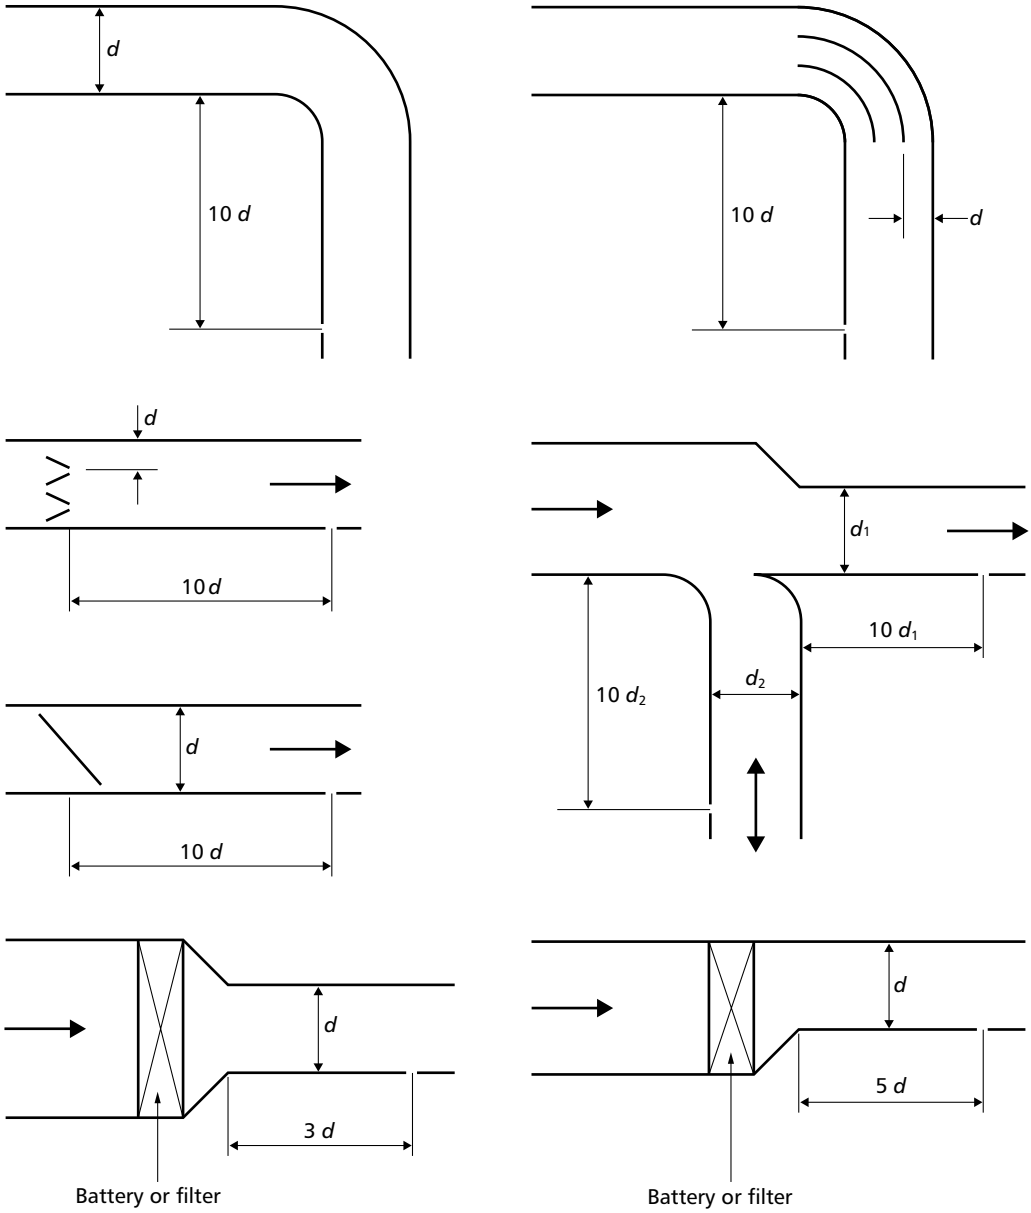

Figure 2.62 Minimum distance of test holes from sources of turbulence (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of BSRIA)

Table 2.44 Test hole positions; special requirements for the measurement of total airflow from the fan (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of BSRIA)

Type of fan	Position of test holes*	
	Upstream	Downstream
Centrifugal	4 *d*	10 *d*
Axial:		
— single stage	4 *d*	Not advised
— single stage with guide vanes	4 *d*	10 *d*
— two-stage, contra-rotating	4 *d*	10 *d*

* *d* = diameter (equivalent diameter for non-circular ducts) of duct following the fan

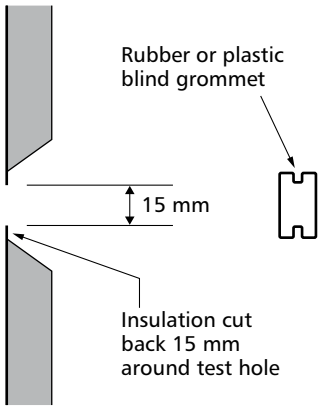

Figure 2.63 Dimensions of standard test holes (reproduced from BSRIA AG 3/89.3: *Commissioning Air Systems* (2001) by permission of BSRIA)

Steps include:

— repeating commissioning exercises

— cleaning

— scheduled replacement of components (filter etc.)

— identifying and rectifying faults.

2.7.2.2 Legislation

The EU Workplace Directive has been implemented in the UK by the Workplace (Health, Safety and Welfare) Regulations (HMSO, 1992). The Health and Safety Commission's Approved Code of Practice and guidance L24 (HSE, 1994) states that: 'Mechanical ventilation

systems (including air-conditioning systems) should be regularly and properly cleaned, tested and maintained to ensure that they are kept cleaned and free from anything which may contaminate the air.' This has applied to all workplaces since January 1996. Additionally, provision for access space for maintenance of the ventilation systems will need to be considered at the design stage. Inspection requirements are also enshrined in the European Energy Performance of Buildings Directive (EPBD) (EU, 2010).

The Regulatory Reform (Fire Safety) Order 2005 (TSO, 2005) requires a responsible person to implement risk assessments on all areas for fire. In addition, they should maintain all fire safety installations and keep records about all such items.) See also Building Regulation 38 (TSO, 2010).

2.7.2.3 Maintenance

Cleaning

Ventilation components and ductwork systems should be clean on completion (see also BS EN 15780: 2011: *Ventilation for buildings. Ductwork. Cleanliness of ventilation systems* (BSI, 2011b)). TR/19: *Guide to Good Practice* (BESA, 2013c) says that where specific verifiable levels of internal cleanliness are required it will be the responsibility of the designer to specify the inclusion of a specialist cleaning contractor.

During use over a number of years, a slow build-up of deposits can occur, particularly at points where the air velocity reduces. More rapid build-up of dirt will result when filters are faulty or damaged, poorly installed or badly maintained.

See 'Testing, commissioning, cleaning and maintenance' in section 2.3.5.2 for information on ductwork cleaning methods.

Special requirements apply to cleaning and maintenance of ductwork in applications such as food preparation (see DW/171: *Standard for Kitchen Ventilation Systems (*HVCA, 2000)), process industries and plant rooms. Detailed maintenance requirements for ductwork are set out in SFG20: *Standard Maintenance Specification for Building Services* (BESA, 2012).

When undertaking maintenance work within ducts, it is essential that sensor probes are withdrawn to protect them from being damaged.

Table 2.45 Requirements for access to duct-mounted components

Component	Location of access opening(s)
Dampers	Both sides
Fire dampers	One side
Heating/cooling coils	Both sides
Circular sound attenuators	One side
Rectangular sound attenuators	Both sides
Filter sections	Both sides
In-duct fans	Both sides
Airflow control device	Both sides

Design for cleaning

To enable cleaning to be carried out safely and efficiently, it is important that the air distribution system is designed and installed so that all internal surfaces and components can be accessed.

A comprehensive standard for access installation is provided by BS EN 12097: 2006: *Ventilation for buildings. Requirements for ductwork components to facilitate maintenance of ductwork systems* (BSI, 2006b).

Components (for example dampers, sensors, airflow measuring devices) should be installed so that they can be cleaned in situ or removed for cleaning. If removal is not possible, service access should be provided according to Table 2.45. Access should be provided that is not obstructed by suspended ceilings, electric cables, lighting, pipes or other ducts.

Abrupt bends, area reductions and sharp objects, such as projecting screws, inside duct joints should be avoided to prevent injury to maintenance and cleaning personnel. Stiffeners and other equipment inside the ductwork should not obstruct the cleaning process. Access doors and covers should be easy to open and be constructed and installed to match the type and location of any thermal, acoustic or fire insulation.

A ductwork component that can be dismounted for cleaning can also be regarded as an access door on condition that its dimensions are in accordance with Table 2.46 or sufficient for the specified and documented cleaning method. Access to duct-mounted components should be provided in accordance with Table 2.45, unless the component is easily removable for cleaning or can be cleaned through the ductwork without obstructions.

The location of and distance between openings depends on the quality of supply-and-extract air and also on the defined or available cleaning method. Unless the cleaning method is known or can be fixed at the design stage, the distance between the openings should not exceed 10 m or not be more than two ≥ 45° bends.

Designers should take specialist advice and stipulate their requirements for the periodic internal cleaning and maintenance of ductwork.

Table 2.46 Openings for ducts; recommended minimum dimensions

Duct type and size	Access opening size	
	A/mm	B/mm
Circular ducts (diam. d/mm):		
— $200 < d \leq 315$	300	100
— $315 < d \leq 500$	400	200
— $500 < d$	500	400
— inspection opening	600	500
Rectangular (side length s/mm):		
— $s < 200$	300	100
— $200 < s \leq 500$	400	200
— $s > 500$	500	400
— inspection opening	600	500

Air quality and health issues

The air quality within a building is influenced by contaminants in the form of particles and gases that are generated within the building envelope and those brought in from outdoors. Contaminant particles may enter the building with the outdoor air. These can include carbon produced by combustion and vehicles, and particles of biological origin. Contaminant gases produced within a building include the volatile organic compounds (VOCs) emitted by some construction materials, fabrics and adhesives, and fumes emitted by photocopiers and laser printers. Gases admitted from outdoors include vehicle exhaust gases. Biological agents such as bacteria, fungal spores and pollen grains can enter the building from outside. Particles generated indoors can include human skin scales, bacteria, viruses and fungi, faecal matter from the house dust mite, textile fibres, building materials and paper dust. Settled deposits in ductwork may cause contamination of air supply by release of chemicals such as odorous VOCs, produced either microbiologically or chemically.

Designers do not normally consider the health effects of microbes in ductwork systems, since their focus is the attainment of specified operating conditions, generally for comfort purposes. It is important to be aware of the potential health issues arising from microbial material in ductwork. There are currently no environmental health criteria setting safe microbial exposure. Possible harmful health effects on the occupants of buildings from microbial growth within the fabric include allergies, infection and toxicosis. Further information about these is provided in CIBSE TM26: *Hygienic maintenance of office ventilation ductwork* (2000b).

Ultraviolet (UV) light can be very effective in deactivating pathogens and other airborne bacteria, viruses and moulds. Where a high-quality air supply is required, such as in health-care facilities and situations where there is a high occupation density, UV lamps can be installed in the ductwork. Medium-pressure lamps, e.g. 3.5 kW and 300 mm in length, run very hot and must be switched off when the fan is not operating. Provision of UV lamps will also have implications for maintenance.

New ductwork construction

According to BS EN 15780: 2011 (BSI, 2011b), in the handover documents the cleanliness quality class, cleanliness criteria and measurement methods should be specified; recommendations for cleaning methods and guidelines for reaching the points to be cleaned should also be given.

The design information should give consideration to the expected cleaning method. Where the system has been designed to be cleaned by wet cleaning methods, warnings regarding conditions and restrictions of use should be given. For example, wet methods are applicable only where ducts are sufficiently moisture-tight, internal surfaces are smooth and slope and drainage arrangements have been provided so that fluid and contaminant can be evacuated.

A sufficient number of access doors should be provided in the ductwork. Special care should be taken regarding obstacles to cleaning, such as dampers, sound attenuators etc., which are mounted in the ducts. In many cases, additional access doors are needed after or before such obstacles, which then can be cleaned carefully. Requirements for location of and distance between access doors are presented in BS EN 12097: 2006: *Ventilation for buildings. Requirements for ductwork components to facilitate maintenance of ductwork systems* (BSI, 2006b) and BS EN 13779: 2007: *Ventilation for non-residential buildings. Performance requirements for ventilation and room-conditioning systems* (BSI, 2007a). Note that it is important that access panels should themselves be reasonably accessible for future maintenance operations.

Cleanliness quality classification

The designer should specify the requirements for the cleanliness quality class to be achieved (see Table 2.47).

The cleanliness quality classification allows the specifier to set measurable maximum acceptable dust accumulation levels, as benchmarks for acceptance.

Annex F of BS EN 15780: 2011: *Ventilation for buildings. Ductwork. Cleanliness of ventilation systems* (BSI, 2011b) provides further guidance on protection, delivery and installation procedures.

Existing ductwork

The normal operation of ductwork systems will introduce dirt both from the external air brought into the system and from re-circulated air containing dust and other particles. The filtration system (where provided) should be designed to remove dirt and dust. However, the level of filtration, the standard of filter medium used and the adequacy of seals and fittings around the filtration equipment can all lead to increased levels of dust and dirt. These in turn can have an effect on plant performance such as reducing the efficiency of the fan and heat transfer equipment. The function of the air movement system and the cleanliness quality class of the building and installation can determine the requirements for cleaning. Certain process applications, for example food and pharmaceuticals, are likely to have considerably higher standards of ductwork cleanliness than those serving a warehouse.

BS EN 15780: 2011: *Ventilation for buildings. Ductwork. Cleanliness of ventilation systems* (BSI, 2011b) provides benchmark measurement levels to define acceptable cleanliness levels for each of the three cleanliness classes and for supply, recirculation and extract.

Dust deposition in ductwork

Dust will generally be deposited mainly over the lower surfaces of air distribution ducts, with the deposition increasing with distance from the AHU. There may be additional deposition where the local flow of air is slowed. This will happen at points where there is a resistance to the flow of air including the filters, heating and cooling coils, corner vanes and changes in the direction of ducting, changes in cross-sectional area and at surface imperfections and jointing cracks between duct sections. Once it is deposited, a physical disturbance or a change in the flow speed would be required to re-entrain significant amounts of the dust into the air.

Table 2.47 Typical applications of cleanliness quality classes (reproduced from Table A1 of BS EN 15780: 2011: *Ventilation for buildings* (BSI, 2011b) by permission of the British Standards Institution)

Quality class	Typical examples
Low	Rooms with only intermittent occupancy, e.g. storage rooms, technical rooms
Medium	Offices, hotels, restaurants, schools, theatres, residential homes, shopping areas, exhibition buildings, sport buildings, general areas in hospitals
High	General working areas in industries, laboratories, treatment areas in hospitals, high-quality offices

Moisture

It is important to take precautions to avoid the generation or ingress of moisture, as the presence of moisture or free water droplets on the surfaces of ducts is well known as a potential cause of microbial contamination. This is normally avoided by the system design and control, but unwanted moisture can arise under some circumstances, for example:

— where the metal duct surface temperature falls below the dew-point of the air flowing through it

— downstream of cooling coils operated below the dew-point (a spray eliminator is usually installed downstream of cooling coils used for dehumidification, but 'normal' cooling coils may also operate unintentionally under these conditions)

— where there is a leak of water from a heating or cooling coil or from water pipework outside the air duct

— as a (temporary) residue from any wet cleaning process

— by ingress of rain water.

See section 2.7.2.5 for cleaning methods.

Fire-resisting products

All fire-resisting products and smoke control items need to be checked regularly and records maintained—see Appendix V and Appendix W of BS 9999: 2008: *Code of practice for fire safety in the design, management and use of buildings* (BSI, 2008a) and the requirements of the RRFSO (TSO, 2005).

2.7.2.4 Inspection for cleaning

Inspection of the ventilation system will usually start with a visual check of the outside air intake, which can be a source of pollution and contamination. A smoke test can quickly determine if outside air is entering the system. Further items to check will be dampers, protective devices against weather, insect and rodents, the hygiene of coils, fans and insulation, the presence of water and condition of condensate drain pans and humidifier reservoirs.

Checking the need for cleaning should be done periodically. Eurovent includes recommendations on indoor air quality (IAQ) (Eurovent, 1999).

Figure 2.64 provides a schematic flowchart for procedures to maintain cleanliness of ventilation systems.

Local exhaust ventilation may be intended to control substances hazardous to health, including biological agents. The Health and Safety Executive (HSE) recommends examination and testing of such systems at least every 14 months and more frequently for certain processes (HSE, 1998).

Ventilation ductwork may be inspected optically using visual inspection instruments (e.g. borescopes) or by remote control inspection vehicles using closed-circuit television (CCTV) to record the internal condition of the ducts. Visual inspection (e.g. video) should be combined with quantitative methods of measuring dirt or microorganisms.

Special attention should be given to the cleanliness of:

— air filters

— sound attenuators

— humidifiers

— components for measurement or control.

The condition of all these items is generally a good indicator of the need for cleaning. It is recommended to start inspection from these components. After cleaning, all these components should be inspected to ensure that no damage has occurred and the cleanliness and functionality are as intended.

The need for cleaning following an inspection of the ductwork will depend on the level of dirt identified at the inspection and the particular requirements of the building, including the specific operations undertaken within the facility. Some buildings will be more sensitive to a build up of dirt and dust in the ductwork and are likely to need a more frequent inspection regime and subsequent cleaning.

Checking the results of cleaning should be combined with checking the functions of the system after cleaning, and readjustments made where required.

In order to maintain ductwork hygiene, both the supply and re-circulated airstreams should be clean (see TR/19: *Guide to Good Practice* (BESA, 2013c)). Access must be available for cleaning to minimise the build up of microbial growth on ductwork, fan blades or coils (see CIBSE TM26: *Hygienic maintenance of office ventilation ductwork* (2000b)); the latter can result in loss of performance. There is also a need for regular inspections. To minimise pressure drops caused by filtration, the airflow entering a filter should be uniform, requiring the filter surface to be as large as possible. A manometer should be installed across each filter bank to ascertain when filters need changing and access doors should be provided for ease of filter replacement.

2.7.2.5 Cleaning methods

There are several methods by which cleaning contractors can remove dust, debris and other surface contaminants:

— vacuum

— steam

— compressed air

— rotary brush.

Cleaning methods are more fully described in TR/19: *Guide to Good Practice* (BESA, 2013c) and BSRIA Technical Note

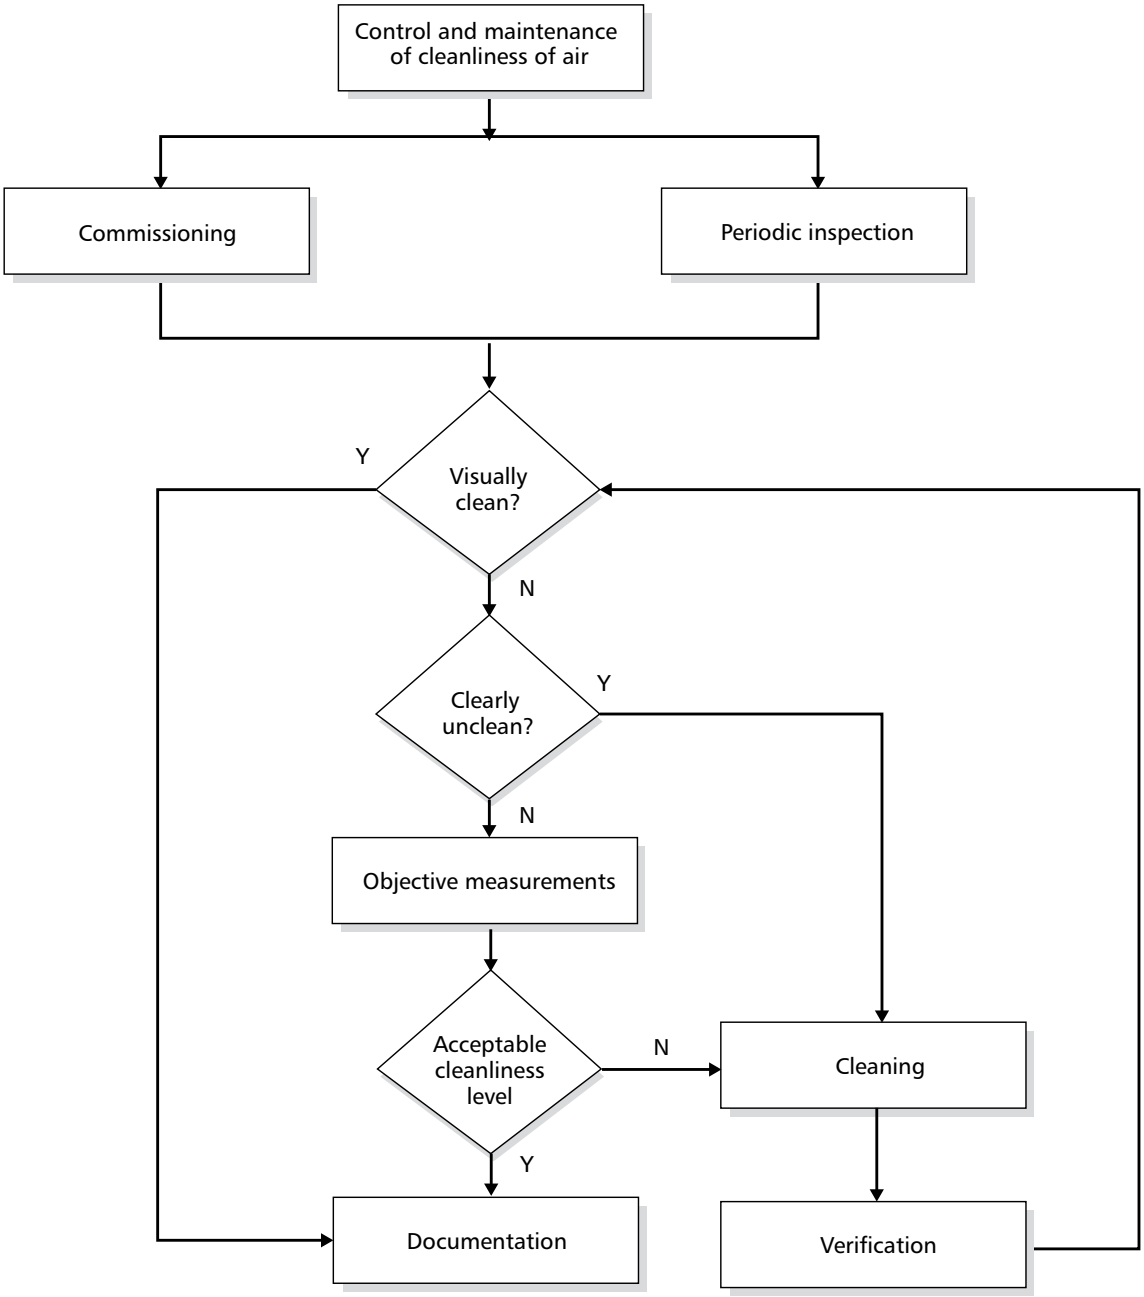

Figure 2.64 Schematic flowchart for procedures to maintain cleanliness of ventilation system (reproduced from BS EN 15780: 2011: *Ventilation for buildings* (BSI, 2011b) by permission of the British Standards Institution)

TN 18/92: *Ventilation System Hygiene: A Review* (1996). Methods will vary according to the air distribution system. On the basis that the contaminants are dry, dry methods of cleaning are adequate for supply air and general extract systems. Wet methods are needed for air ducts in commercial kitchens and similar installations where extract air contains smoke, grease and other impurities.

The cleaning process involves loosening dirt adhering to ductwork surfaces and its subsequent removal. The loosening can be remotely by compressed air or rotary brushing equipment in conjunction with removal by industrial vacuum collector. Dust may alternatively be removed directly by a technician crawling along the ducts using a hand-held vacuum cleaner. When cleaning within ducts it is essential that sensor probes are withdrawn to prevent them from being damaged.

Dust resulting from cleaning, particularly that which may contain biologically active material, should be disposed of safely.

When cleaning is complete, the ductwork system may require rebalancing. Most cleaning contractors leave dampers and other control devices in their 'as found' positions. Based on system performance, the property operator will then need to decide whether rebalancing is required. It is recommended that a commissioning specialist be appointed to undertake this task.

Appendix 2.A2: Space allowances

2.A2.1 Space allowances for ductwork

Figure 2.A2.1 shows the recommended space allowances for rectangular, circular and flat oval ductwork (BSRIA, 1992). Figure 2.A2.2 shows recommended space allowances for vertical risers, both insulated and uninsulated (DEO, 1996). Access to ducts is governed by the space required to install and insulate the ductwork and this is determined by the clearance from firm objects, the jointing method, and whether or not the ducts are to be insulated after installation. See BS 8313[2.A2.3] for details.

Duct clearances can be reduced with care, providing correct jointing, insulation and maintenance of vapour barriers is achieved. Consideration should also be given to how the ductwork will be tested and, eventually, replaced. See also BSRIA Technical Note TN10/92: *Space allowances for building services distribution systems* (BSRIA, 1992).

2.A2.2 Ductwork access: common problems

2.A2.2.1 Fire dampers

Access to fire dampers must not be obstructed by other services. Clear access must be ensured for inspection and testing. Figure 2.A2.3 illustrates two common problems.

2.A2.2.2 Ceiling-mounted terminal units

A typical installation is shown in Figure 2.A2.4. The ceiling grid immediately beneath the terminal unit should be demountable to facilitate access for removal and replacement of filters, fans, motors or the complete unit, if necessary. Access should be provided which is at least equal to the full plan dimensions of the unit (including control and commissioning valves) plus a minimum allowance of 100 mm on all sides.

2.A2.2.3 False ceilings and raised floors

Table 2.A2.1 shows typical floor-to-floor heights and the heights/depths of typical false floors/ceilings (Burberry, 1996). Figure 2.A2.5 illustrates some specific points.

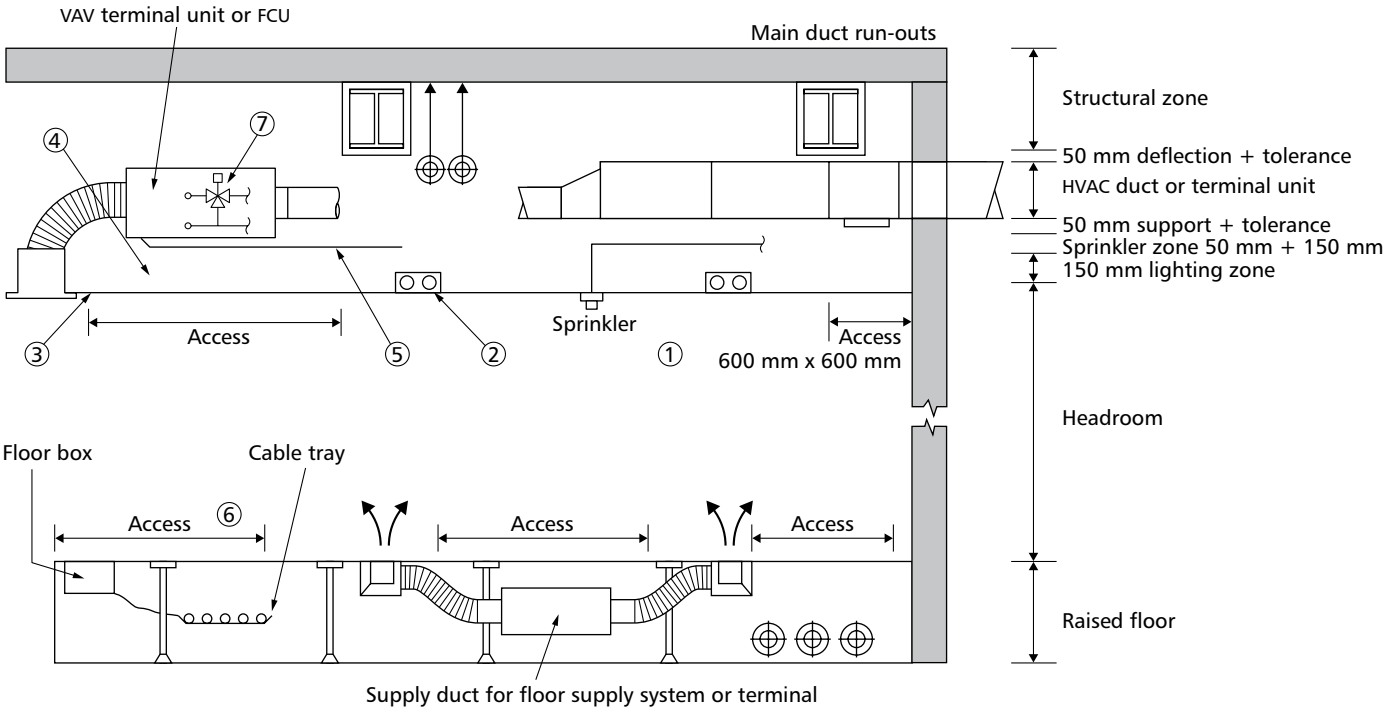
Table 2.A2.1 Typical floor-to-floor heights and heights/depths of typical false floors/ceilings (Burberry, 1996) for offices

Office type	Typical floor-to-floor height / m	Typical false ceiling height / m	Typical false floor depth* / m
Average quality office, refurbished office; average requirements for IT and engineering services	3.6–3.8	0.5–0.6	—
High quality office, minimal perimeter systems; above average requirements for IT and engineering services	3.9–4.2	0.8–1.0	0.4–0.6

* Option to reduce false ceiling height



① Ensure clear access to all fire dampers for inspection and testing
② Clearance of 1·5 times the luminaire depth to facilitate removal of the fitting
③ Demountable ceiling grid to permit access to the ceiling mounted terminal unit and removal
④ Clear access to the terminal unit for removable of the recirculation air filter (FCUs), cleaning of coil and condensate tray
⑤ Additional vertical space to be allowed for condensate drains and their fall (FCUs)
⑥ Access to raised floor shown for the situation where all floor tiles may not be removable
⑦ Provision should be made for permanent access to all commissioning and control valves

Appendix 2.A4: Methods of fire protection

The following information is taken from BESA specification DW/144 (2013), which should be referred to for further information.

2.A4.1 Protection using fire dampers

The fire is isolated in the compartment of origin by the automatic or manual actuation of closures within the system. Fire dampers should, therefore, be sited at the point of penetration of a compartment wall or floor, or at the point of penetration of the enclosure of a protected escape route.

Fire dampers should be framed in such a way as to allow for thermal expansion in the event of fire, and the design must provide for the protection of any packing material included.

Standard types of fire dampers and frames are described in section 22 of DW/144.

2.A4.2 Protection using fire resisting enclosures

Where a building services shaft is provided through which the ventilation ductwork passes, and if the shaft is constructed to the highest standard of fire resistance of the structure which it penetrates, it forms a compartment known as a 'protected shaft'. This allows a complicated multiplicity of services to be transferred together through a shaft transversing a number of compartments and reaching remote parts of the building, without requiring further internal divisions along its length. The provision of fire dampers is then required only at points where the ventilation duct leaves the confines of the protected shaft. However, if there is only one ventilation duct and there are no other services within the protected shaft, between the fire compartment and the outside of the building, no fire dampers will be required.

2.A4.3 Protection using fire resisting ductwork

In this method of fire protection, the ductwork itself forms a protected shaft. The fire resistance may be achieved by the ductwork material itself, or through the application of a protective material. This is provided that the ductwork has been tested and/or assessed to BS 476: Part 24 (1987) with a fire resistance, when tested from either side, that should not be less than the fire resistance required for the elements of construction in the area through which it passes. It should also be noted that the fire resisting ductwork must be supported with suitably sized and designed hangers, which reflect the reduction in tensile strength of steel in a fire condition, i.e.:

— fire resisting ductwork rated at 60 minutes (945 °C): tensile strength is reduced from 430 $N \cdot mm^{-2}$ to 15 $N \cdot mm^{-2}$

— fire resisting ductwork rated at 120 minutes (1049 °C): tensile strength is reduced to 10 $N \cdot mm^{-2}$

— fire resisting ductwork rated at 240 minutes (1153 °C): tensile strength is reduced to 6 $N \cdot mm^{-2}$.

Where the fire resisting ductwork passes through a fire compartment wall or floor, a penetration seal must be provided which has been tested and/or assessed with the ductwork to BS 476: Part 24, to the same fire rating as the compartment wall through which the fire resisting ductwork passes. It should also be noted that where the fire resisting ductwork passes through the fire compartment wall or floor, the ductwork itself must be stiffened to prevent deformation of the duct in a fire to:

— maintain the cross-sectional area of the duct

— ensure that the fire rated penetration seal around the duct is not compromised.

Appendix 2.A5: Example calculations

2.A5.1 Ductwork sizing and pressure drop calculations

Ductwork sizing is so inter-related to pressure drop that the two calculations must be handled together, as will be seen in the following worked example. The ductwork sizing example is in four parts, as follows:

— The first part leads through the ductwork with explanations of the reasons for the first choice of size for each section of ductwork. Some of the sizes could or should be changed later in the light of subsequent calculations. The simple example, see Figure 2.A5.1, is designed to incorporate several different components and illustrate the consequences and choices which can be made. Only the supply ductwork is shown.

— The second part includes the calculations of pressure drop, using data contained in CIBSE Guide C (2007), section 4. A separate but similar calculation would be required for the return ductwork.

— Amendment of some duct sizes in the light of the pressure drop calculations.

— Consideration of the outdoor air supply duct.

2.A5.1.1 System design data

Figure 2.A5.1 illustrates a simple supply system to a suite of six private offices, each requiring 0.2 $m^3 \cdot s^{-1}$ of air. The main ductwork will be in the ceiling void of the corridors. Branches will be in ceiling voids within the offices. Outdoor air will constitute 40% of the total air being treated in the air handling unit (AHU). The main air supply has a winter design temperature of 30 °C.

For initial estimates only, the discharge diffusers will be assumed to give a pressure drop of 20 Pa for a flow of 0.2 $m^3 \cdot s^{-1}$.

It is anticipated that the interior of the building will have a positive pressure of 15 Pa to allow exhaust air to be extracted naturally.

2.A5.1.2 Preliminary sizing and explanation

From CIBSE Guide C[A6.1], Appendix 4.A1, properties of air are as follows:

— at 10 °C: $\rho = 1.24\ kg \cdot m^{-3}$; $\eta = 17.63 \times 10^{-6}\ kg \cdot m^{-1} \cdot s^{-1}$; $c_p = 1.011\ kJ \cdot kg^{-1} \cdot K^{-1}$

— at 30 °C: $\rho = 1.16\ kg \cdot m^{-3}$; $\eta = 18.55 \times 10^{-6}\ kg \cdot m^{-1} \cdot s^{-1}$; $c_p = 1.030\ kJ \cdot kg^{-1} \cdot K^{-1}$.

The minimum size of ductwork is constrained by acoustic considerations which limit air speeds. Otherwise life cycle costing should be the important factor. Thus, the limiting air velocities used as a starting point for duct sizing are as follows:

— *at external louvres*: air velocity, $c = 2.5\ m \cdot s^{-1}$ (from CIBSE Guide C, Table 4.12)

— *in the AHU*: air velocity, $c = 2\ m \cdot s^{-1}$ (face velocity; see Table 2.16)

— *in main duct*: air velocity, $c = 6\ m \cdot s^{-1}$ (Table 2.16)

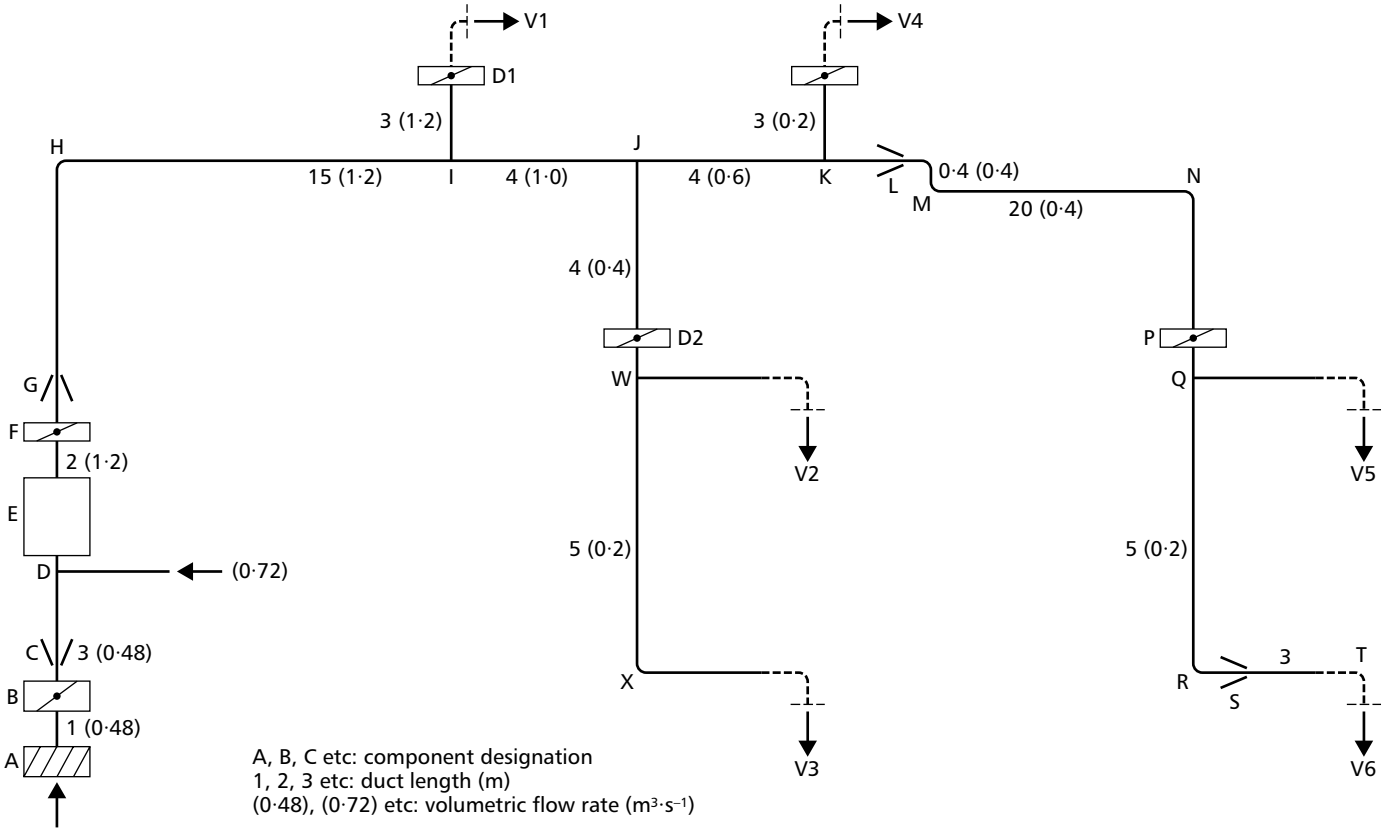

Figure 2.A5.1 Duct layout with lengths (m) and flow rates ($m^3 \cdot s^{-1}$)

— *in branch duct*: air velocity, $c = 5.5$ m·s^{-1} (Table 2.16)

— *in final duct*: air velocity, $c = 3$ m·s^{-1} (Table 2.16)

External louvres and mesh (A)

The pressure drop through louvres can be considerable. CIBSE Guide C, Table 4.35, recommends a maximum velocity of 2.5 m·s^{-1} through the free area in a 'normal' situation. Provisionally assuming a 90% free area, this implies a maximum face velocity of 2.25 m·s^{-1}.

For a total required airflow rate of 1.2 m^3·s^{-1}, 40% of which is outdoor air, the airflow rate at the inlet is:

$$q = 0.4 \times 1.2 = 0.48 \text{ m}^3\cdot\text{s}^{-1}$$

Hence:

$$A_{\min} = q / c = 0.48 / 2.25 = 0.213 \text{ m}^2$$

From Appendix 2.A1, Table 2.A1.1, a rectangular duct measuring 500 mm × 500 mm has a cross-sectional area, $A = 0.25$ m^2.

Substituting back into the previous equation gives velocity, $c = 1.92$ m^3·s^{-1}

(*a*) *External louvres*

CIBSE Guide C, section 4, gives tentative guidance on the friction factor for louvred duct entries. Provisionally assuming louvre ratios, as defined in Guide C, of $(h_i / h) = 0.7$ and $(x / x_1) = 0.9$, and louvres with vertical flat ends (case a), Guide C gives the pressure loss factor, $\zeta = 4.8$.

After selection of an appropriate louvre, the correct figure for pressure drop should be obtained from the manufacturer.

For a typical winter day, outdoor air might have a temperature of 10 °C, hence $\rho = 1.24$ kg·m^{-3}.

(*b*) *Bird mesh*

Provisionally assume a free area of 70%. CIBSE Guide C suggests pressure loss factor, $\zeta = 0.58$.

Outdoor air inlet damper (B)

Provisionally assuming for the moment that it will be an opposed blade damper with 3 blades, CIBSE Guide C suggests pressure loss factors based on the value of parameter x, given by:

$$x = n\,w / [2\,(h + w)]$$

where n is the number of blades, and w and h are the duct width (m) and height (m) respectively. Hence:

$$x = (3 \times 500) / [2 \times (500 + 500)] = 0.75$$

For the damper fully open ($\theta = 0°$), Guide C gives the pressure loss factor $\zeta = 0.52$.

After selection of an appropriate damper, the correct value should be obtained from the manufacturer.

Before continuing with the next item of ductwork, it is necessary to look ahead to the requirements of the air handling unit (E).

This will be handling airflow rate, $q = 1.2$ m^3·s^{-1}. Life cycle costing studies recommend a maximum face velocity of 2 m·s^{-1} for an air handling unit. Hence:

$$A_{\min} = q / c = 1.2 / 2.0 = 0.6 \text{ m}^2$$

For this cross-sectional area, Appendix 2.A1, Table 2.A1.1, suggests a rectangular duct measuring 1000 mm × 600 mm, giving $c = 2.0$ m.s^{-1}.

In anticipation of the tee at D, requiring 1000 mm × 600 mm, an expansion taper is included at C. (Clearly there would be a case both for simplicity and a lowering of face velocity if the louvre size had been chosen as 1000 mm × 600 mm in the first place.)

After the AHU, the air has a temperature of 30 °C, for which $\rho = 1.16$ kg·m^{-3}.

Expansion (C)

BESA specification DW/144 (2013) suggests a maximum taper included angle of $\theta = 45°$.

For expansion from (500 × 500) to (1000 × 600):

$$A_2 / A_1 = (1.0 \times 0.6) / (0.5 \times 0.5) = 2.4$$

For such small expansions the angle of the taper is not very important, so a value of $\theta = 45°$ is chosen.

The determination of ζ is quite complex. For a quick calculation, a speculative value might provisionally be taken from the table, especially as this is not a large expansion. Nevertheless a full calculation is demonstrated here. A typical winter temperature of 10 °C is chosen, but this is not critical.

Based on 500 × 500, $d_h = 500$ mm (from Appendix 2.A1, Table 2.A1.1). At (C), the airflow rate is: $q = 0.48$ m^3·s^{-1}. Hence, velocities before and after the expansion taper are: $c_1 = 1.92$ m·s^{-1} and $c_2 = 0.8$ m·s^{-1}. The Reynolds number is then given by:

$$Re_1 = \rho\, c\, d / \eta = (1.24 \times 1.92 \times 0.5) / 17.63 \times 10^{-6}$$
$$= 0.68 \times 10^5$$

Approximately, taking $A_2 / A_1 = 2$, and $Re = 1 \times 10^5$, Guide C, Table 4.79 gives $\zeta = 0.330$. (More accurately, by graphical interpolation, $\zeta = 0.50$.)

Tee, with shoe on the branch (D)

Note that for all tees, the value of ζ is to be used with the velocity pressure of the combined flow. The velocity for the combined flow is given by:

$$c_c = 1.2 / (1.0 \times 0.6) = 2.0 \text{ m}\cdot\text{s}^{-1}$$

For converging flow, the ratio of straight flow rate to combined flow rate is:

$$q_s / q_c = 0.48 / 1.2 = 0.4$$

From CIBSE Guide C the pressure loss factor for straight flow is: $\zeta_{s-c} = 0.22$.

Assume that the branch, carrying 0.72 $m^3 \cdot s^{-1}$, has a size 300 mm × 400 mm; hence $c = 6$ $m \cdot s^{-1}$. Therefore, ratio of branch flow rate to combined flow rate is:

$$q_b / q_c = 0.72 / 1.2 = 0.6$$

(Note that without a shoe, CIBSE Guide C, section 4.11.4.12, shows that the pressure loss factor for straight flow would have 0.46, i.e. twice that for a tee with a shoe on the branch.)

Air handling unit (AHU) (E)

The air handling unit, including heater battery, filter and fan, may be regarded as a 'black box' which must provide a pressure rise, external to itself, equal to the total pressure drop around the whole air circuit, supply and return.

Control damper, opposed blade, 3 blades (F)

As a first estimate, using CIBSE Guide C, section 4.11.4.18 (see above, section A6.1.2.2), parameter x is given by:

$$x = (3 \times 0.6) / [2 \times (0.6 + 0.6)] = 0.75$$

For the damper fully open ($\theta = 0$), hence $\zeta = 0.52$.

After selection of the damper, the correct value must be obtained from the manufacturer.

Duct (G–H–I)

For a building containing private offices, Table 2.16 gives the maximum permitted velocity in a main duct as 6 $m \cdot s^{-1}$. This also accords with figures derived from life cycle costing.

Again, using the expression $A = q / c$, the required cross-sectional areas of the duct is:

$$A = 1.2 / 6.0 = 0.2 \text{ m}^2$$

Appendix 2.A1, Table 2.A1.1, suggests either 600 mm by 400 mm, or 500 mm by 400 mm ductwork. For this example 500 mm by 400 mm is chosen, and the orientation such as to make the following bend (H), an 'easy' bend, i.e. $w = 400$ mm, $h = 500$ mm.

From the same table, the equivalent diameter is:

$$d_e = 492 \text{ mm}$$

Contraction (G)

For reduction from (1000 × 600) to (400 × 500), the ratio of cross-sectional areas is:

$$A_2 / A_1 = (400 \times 500) / (1000 \times 600) = 0.333$$

The maximum taper recommended in BESA specification DW/144 is an included angle $\theta = 45°$.

CIBSE Guide C, section 4.11.5.2, shows that for contractions the included angle is not important and ζ is small. Note that ζ is to be used with the outlet velocity, c_2. An included angle of 45° is chosen hence, from CIBSE Guide C by interpolation: $\zeta = 0.055$.

The outlet velocity is:

$$c_2 = q / A_2 = 1.2 / (0.4 \times 0.5) = 6.0 \text{ m} \cdot \text{s}^{-1}$$

Bend, with splitter vanes (H)

CIBSE Guide C section 4.11.4.2 applies. For $400 < w < 800$, Table 2.40 (based on BESA specification DW/144) recommends a single splitter vane. The BESA standard radius for bends is r = w, and this radius will be used. Hence:

$$h / w = 500 / 400 = 1.25$$

From CIBSE Guide C, Table 4.112, $\zeta = 0.05$.

Note that this value is considerably less than would have been the case without the vane.

Typical branch (I–D1–V1)

The 'index run', i.e. the pipe run likely to give the highest pressure loss, would appear to be the run from G to R to V6. In reality, it would depend upon the route taken by the return duct from the room supplied at V6.

Thus at the next few tees, it is necessary to consider only the pressure loss factors for straight flow, ζ_{c-s}. Since the pressure drop incurred by tees depends upon the relative size of the branch, it is worth digressing at this point to consider the branches to the final run outs.

In this example, each final branch has the same flow. It is more convenient for the branches to be circular, especially as it is convenient to make the final connection to a diffuser by a flexible duct. However the length of such flexible ducts should be kept to a minimum as their pressure loss is high.

Taking a typical branch, I–D1–V1, assumed now to be within the office space, noise is the most important criterion, therefore velocity $c < 3$ $m \cdot s^{-1}$ (see Appendix 2.A1, Table 2.A1.1). Generally, even lower velocities are used, a velocity $c = 2.5$ $m \cdot s^{-1}$ will be assumed. Hence, the branch duct area is:

$$A = q / c = 0.2 / 2.5 = 0.08 \text{ m}^2$$

For a circular duct, this gives a minimum diameter $d_{min} = 319$ mm. This is so close to a standard size of 315 mm that the difference might be considered trivial. Furthermore this is a branch which provides an air route of minimum length and resistance. It is tempting to have the smaller diameter for this first branch and larger branches for the others, but this might lead to confusion for the installers. As the branch ducts are short it might be thought that the pressure drop will be small. However, the use of a short length of flexible ductwork for the final connection to the diffuser can add a disproportionate pressure drop. For these reasons, $d = 315$ mm is chosen for the branch diameter.

For $d_b = 315$ mm, the branch cross-sectional area is $A_b = 0.0779$ m^2. Hence, the ratio of the cross-sectional area of the branch to that of the main duct flow is:

$$A_b / A_c = 0.0779 / (0.5 \times 0.4) = 0.390$$

The air velocity in the branch is:

$$c_b = q_b / A_b = 0.2 / 0.0779 = 2.57 \text{ m} \cdot \text{s}^{-1}.$$

Tee (with shoe) (I)

For the rectangular main duct (500 × 400): $A_c = 0.2$ m^2, $q_c = 1.2$ m^3·s^{-1}, hence $c_c = 6$ m·s^{-1}

For the circular branch ($d = 315$ mm): $A_b = 0.0779$ m^2, $q_b = 0.2$ m^3·s^{-1}.

Hence:

$$A_b / A_c = 0.0779 / 0.2 = 0.39$$

$$q_b / q_c = 0.2 / 1.2 = 0.166$$

$$q_s / q_c = 1.0 / 1.2 = 0.833$$

(Note that the pressure drop to the branch is less than it would be without the shoe, but is still considerably greater than that for the straight, which is to be expected.)

Branch (J–X)

This is required to carry 0.4 m^3·s^{-1} with a limiting speed of 5.5 m·s^{-1}. This implies a diameter of 304 mm. There would seem little option but to choose circular ductwork the next size up, i.e. 315 mm, though rectangular ductwork 300 mm × 250 mm could be chosen.

Ducts (I–J and J–K)

The straight runs I–J and J–K are short enough not to justify the complication of reductions in size, so, for convenience, the duct dimensions will remain the same as for ductwork run (G–H–I), i.e. 500 mm × 400 mm.

Tee (with shoe) (J)

For the rectangular main duct (500 mm × 400 mm): $A_c = 0.2$ m^2, $q_c = 1.0$ m^3·s^{-1}, hence $c_c = 5$ m·s^{-1}.

For the circular branch ($d = 315$ mm): $A_b = 0.0779$ m^2, $q_b = 0.4$ m^3·s^{-1}.

Hence:

$$A_b / A_c = 0.0779 / 0.2 = 0.39$$

$$q_b / q_c = 0.4 / 1.0 = 0.4$$

$$q_s / q_c = 0.6 / 1.0 = 0.6$$

Tee (without shoe) (K)

For the rectangular main duct (500 mm × 400 mm): $A_c = 0.2$ m^2, $q_c = 0.6$ m^3·s^{-1}, hence $c_c = 3$ m·s^{-1}.

For the circular branch ($d = 315$ mm): $A_b = 0.0779$ m^2, $q_b = 0.2$ m^3·s^{-1}.

Hence:

$$A_b / A_c = 0.0779 / 0.2 = 0.39$$

$$q_s / q_c = 0.4 / 0.6 = 0.667$$

Duct (L–M–Q)

This main branch could tolerate velocities up to 5.5 m·s^{-1}. The ductwork could conveniently be circular.

Hence, for $q = 0.4$ m^3·s^{-1}:

$$A_{min} = q / c = 0.4 / 5.5 = 0.0727 \text{ m}^2$$

$$d_{min} = 304 \text{ mm}$$

A diameter of 315 mm could easily be chosen here, but since this is the index run, it is advisable to minimise pressure losses along this run as this will make subsequent balancing easier. Therefore the next size up is selected: $d = 355$ mm.

Hence:

$$A_c = 0.100 \text{ m}^2$$

Contraction, rectangular to circular (L)

For reduction from rectangular (500 mm × 400 mm) to circular ($d = 355$ mm), with a maximum taper angle of $\theta = 45°$, CIBSE Guide C, section 4.11.5 applies.

$$A_2 / A_1 = 0.1 / 0.2 = 0.5$$

Segmented bends in close proximity (M)

CIBSE Guide C, section 4.11.2.5 applies. Separation of bends, $l = 400$ mm, so $(l / d) = 400 / 355 = 1.1$; $(r / d) = 1$ for each bend. The Reynolds number is given by:

$$Re = \rho c d / \eta = 1.16 \times 4.0 \times 0.355 / (18.55 \times 10^{-6})$$
$$= 0.888 \times 10^5$$

90° segmented bend (N)

By interpolation, from CIBSE Guide, Table 4.119, for $(r / d) = 1$, $R_e = 0.9 \times 105$, $d = 355$ mm:

$$\zeta = 0.305$$

Fire damper (P)

This should have a totally clear area when open, presenting a small resistance. Provisionally, until manufacturer's data are available, assume $\zeta = 0.12$.

Tee (without shoe) (Q)

For the circular main duct ($d_c = 355$ mm): $A_c = 0.10$ m^2, $q_c = 0.4$ m^3·s^{-1}.

For the circular branch ($d_b = 315$ mm): $A_b = 0.0779$ m^2, $q_b = 0.2$ m^3.s^{-1}.

Hence:

$$A_b / A_c = 0.0779 / 0.10 = 0.78$$

$$q_b / q_c = 0.2 / 0.4 = 0.5$$

Duct (Q–R)

Logically, the diameter could be reduced to 315 mm. However, since this is the index run, it is better to minimise

pressure loss, therefore it is better to maintain the duct diameter as 355 mm until after the final bend R.

90° segmented bend (R)

The air velocity is given by:

$$c = q / A = 0.2 / 0.1 = 2.0 \text{ m·s}^{-1}$$

Hence, the Reynolds number is:

$$Re = \rho c d / \eta = 1.16 \times 2.0 \times 0.355 / (18.55 \times 10^{-6})$$
$$= 0.44 \times 10^5$$

Symmetrical contraction (S)

For reduction from $d_1 = 355$ mm to $d_2 = 315$ mm, ratio of cross-sectional areas is:

$$A_2 / A_1 = (315 / 355)^2 = 0.79$$

CIBSE Guide C, section 4.11.2.8 applies. For an included angle $\theta = 45°$, CIBSE Guide C, Table 4.57 gives, by extrapolation: $\zeta = 0.055$.

The outlet velocity is:

$$c_2 = q / A_2 = 0.2 / 0.0779 = 2.57 \text{ m·s}^{-1}$$

90° segmented bend (T)

The Reynolds number is given by:

$$Re = \rho c d / \eta = 1.16 \times 2.57 \times 0.315 / (18.55 \times 10^{-6})$$
$$= 0.51 \times 10^5$$

Diffuser (V)

Provisionally, take:

$$\Delta p = 20 \text{ Pa}$$

2.A5.1.3 Calculation of pressure drop

For each duct fitting, along what is believed to be the index run, the pressure drop is given by:

$$\Delta p_t = \zeta \, {}^1/_2 \, \rho c^2$$

Appropriate values have already been obtained in section 2.A5.1.2 above, and a table of the calculations is shown as Table 2.A6.1.

For the straight lengths of duct, Figure 2.33 is used to obtain the pressure drop per unit length. The calculations are shown in Table 2.A5.2.

The pressure drops obtained in Tables 2.A5.1 and 2.A5.2 are summed to give a drop in total pressure of 70.4 Pa.

2.A5.1.4 Amendment to duct sizes to improve balance

Although the duct sizing has, by normal criteria, been on the generous side, the pressure drop along the index run is nevertheless dominated by the pressure drop along G–I and L–Q. If the design is left as it is, then branch run (I–D1–V1) will require considerable additional resistance by closing damper D1, which could cause additional noise generation. Furthermore, the system pressure drop will consequently always be greater and incur constant additional fan power and energy costs. Consideration should always be given to the alternative solution of reducing the pressure loss in the index run by increasing the duct size along the 'problem' runs. To illustrate this, the duct size from L–S could be increased to the next size up.

Table 2.A5.3 illustrates the effect of increasing the diameter of duct run (L–S) from 355 mm 400 mm. The effect is to reduce friction pressure drop by 10.8, some 16% of the total pressure drop, which would be worth achieving.

Table 2.A5.4 gives a break-down of the pressure drop incurred along the index run to V6 with the increased duct sizes. The drop in total pressure is now 59.7 Pa.

Before finally accepting these design sizes, it is worth checking on the pressure drop incurred by the airflow along the shortest duct run, namely E to V1, see Table 2.A6.5.

Note that the pressure drops along the index run (see Table 2.A5.4) and along the shortest run (see Table 2.A5.5) are now almost in balance, being 59.7 and 61.2 Pa respectively. This is due to the decision to employ larger size ductwork along the index run, and also to the fact that flow round to the branch at tee I is considerably more than along the straight, despite the shoe. Normally the control damper D1 would need to provide an additional pressure drop, but in this instance it is not necessary. Similar calculations should be carried out for each air route.

Assuming that all the air flow runs can be adjusted to have the same loss of total pressure, the 'design flow rates' should then occur. Note that the total pressure drop for the circuit is only that for one circuit as all the routes are in parallel.

At this stage the return ductwork has been neither designed nor sized. The exercise is similar to the above calculations for the supply ductwork. In this example, only 60% of the total air flow is to be recirculated. The pressure drops calculated would in general be very similar, except to note that the pressure drop through an extract grille will, or should be, considerably less than that through a supply diffuser. For the purposes of this example, a return airflow of 0.72 $\text{m}^3\text{·s}^{-1}$ is assumed, incurring a pressure drop of 50 Pa. This would give rise to a total pressure drop for the circuit of (60 + 50) Pa = 110 Pa.

Note that a cost–benefit analysis of enlarging duct L–S might not in isolation justify such enlargement. However, the 'knock-on' effects should not be overlooked; i.e. the pressure drop on the other four air routes would be affected such that dampers in non-index run routes might require less trimming. It has already been shown that, for example, damper D1 will require no measurable trimming.

The final duct layout using the amended duct sizes is shown in Figure 2.A6.2.

2.A5.1.5 Outdoor air supply

Note that, up to this point, the effect of the outdoor air inlet has not been considered because it does not constitute part of the main airflow loop. A few assumptions will now be made to illustrate the effect.

Suppose that the air leaks from each room to the external air resulted in the air within each room having a pressure of 15 Pa above the pressure outside the building. The pressure drop in the return ductwork (Δp_t) was found to be 50 Pa (see section 2.A5.1.4). Thus, the total pressure just before the air handling unit (E), will be (–50 + 15) Pa =–35 Pa.

Table 2.A5.6 draws together the fresh air inlet duct calculations from Tables 2.A5.1 and 2.A5.2. This shows that, for the design flow of outdoor air, the pressure drop is 15.0 Pa. This needs to be 35 Pa so that the right quantity of outdoor air is drawn in. This can be achieved either by closing down damper B considerably, or by selecting a smaller louvre and mesh screen.

These considerations of the outdoor air supply duct have no bearing on the fan selection which follows.

2.A5.2 Choice of fan or air handling unit (AHU)

2.A5.2.1 Fan specification

The air handling unit will be required to provide, external to the unit, an increase in total pressure of 110 Pa for a volumetric airflow rate of 1.2 m^3·s^{-1}.

The question of margins or safety factors sometimes arises. There is little point in adding a margin to both the air flow and to the pressure drop since an increased air flow in the calculations automatically causes a larger pressure drop. For low pressure ductwork, air leakage is likely to be trivial so there is no need to add a safety margin. However, although the accuracy of the pressure drop data has

Table 2.A5.5 Final pressure drops for shortest run (E–V1)

Item	Description	Length, l / m	Dimensions / (mm × mm)	Pressure drop, Δp / Pa
D–G	Straight duct	2.0	1000 × 600	0

(315 Ø) etc: circular duct diameter (mm)

Figure 2.A5.2 Final duct layout with lengths (m) and sizes (mm)

improved considerably over recent years, the published values are not precise. Therefore a margin of 10% could be added.

If a margin of 10% is added to the estimated pressure loss calculation of the ductwork, the air handling unit would be required to provide a rise in total pressure of 121 Pa for a flow of 1.2 $m^3 \cdot s^{-1}$.

Within the air handling unit there will be a considerable pressure drop through the filter and through the heat exchanger (also know as the 'heating coil'). However, for packaged units it is the responsibility of the supplier to select the fan so as to meet the pressure drop of the components within the unit and the ductwork.

If the fan is selected independently of any packaged air handling unit, then it is to be hoped that matching the system characteristic to the fan performance characteristic will result in an operating point somewhere near the point of maximum efficiency. If not, further amendments to the duct sizes might prove advisable. If the estimated level of the fan noise is found to be excessive, then the inclusion of sound attenuators may be necessary; this would add appreciably to the pressure drop and may require a different fan to be chosen.

2.A5.2.2 Specific fan power

Building Regulations Approved Document L imposes a limit on 'specific fan power'. This is defined as the sum of the design total circuit-watts, including all losses through switchgear and controls such as inverters, of all fans that supply air and exhaust it back outdoors (i.e. the sum of the supply and extract fans), divided by the design ventilation rate through the building.

For AC/MV systems in new buildings, the SFP should be no greater than 2 $W \cdot s \cdot litre^{-1}$, i.e. 2 $kW \cdot s \cdot m^{-3}$.

Table 2.A5.6 Pressure drops for outdoor air supply (A–E)

Item	Description	Length, l / m	Dimensions / (mm × mm)	Pressure drop Δp / Pa
A–B	Straight duct	1.0	500 × 500	0.1
C–E	Straight duct	3.0	1000 × 600	0
A	Louvre/mesh screen	—	500 × 500	12.3
B	Outdoor air inlet damper	—	500 × 500	1.2
C	Expansion taper	—	—	0.8
D	Tee, shoe, converging (straight flow)	—	—	0.5
			Total (A–E):	15.0

It is impossible at this stage to predict the electrical power consumption of the AHU, which has yet to be selected. However, since the total outside air requirement is 1.2 $m^3 \cdot s^{-1}$, the SFP will limit the consumption to 2.4 kW.

To illustrate the consequences, the following assumptions will be made:

— fan total efficiency, $\eta_f = 80\%$

— fan motor efficiency, $\eta_m = 85\%$

— pressure drop across the filter and heat exchanger = 200 Pa

From section 2.A5.1.4, the pressure drops for the supply and return ductwork are 60 Pa and 50 Pa, respectively. Therefore, the total pressure rise (including 10% margin) required is given by:

$$[(\Delta p_{t(supply)} + \Delta p_{t(return)}) \times 1.1] + \Delta p_{t(other\ components)} = (110 \times 1.1) + 200 = 321 \text{ Pa}$$

The air power required is:

$$q\,\Delta p = 1.2 \times 321 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa} = 385 \text{ W}$$

Total electrical power required for fans:

$$P_e = (q\,\Delta p) / \eta_f\,\eta_m = 385 / (0.8 \times 0.85) = 0.566 \text{ kW}$$

Specific fan power:

$$\text{SFP} = P_e / q = 0.566 / 1.2 = 0.472 \text{ kW} \cdot \text{s} \cdot \text{m}^{-3}$$

This is well within the limit imposed by Approved Document L2, as would be expected for the very simple system used in the example. A larger, more realistic system, with more tortuous duct runs and sound attenuators, would incur much greater pressure losses, necessitating a more powerful fan and motor, and thus lead to a higher specific fan power.

2.A5.3 Air leakage

Up to this point, only total pressure and drops in total pressure of the air have been considered. However, air leakage depends upon the actual pressure (static pressure) of the air in the duct relative to that outside the duct. It is impossible to predict this value, though it can be measured after installation. The following illustrates the calculation of the permissible air leakage.

Air leakage is given by:

$$q_L = C\,A_s\,p^{0.65} \qquad (2.A5.1)$$

where q_L is the air leakage rate (litre·s^{-1}), C is a constant (litre·s^{-1}·m^{-2}·$Pa^{-0.65}$) and p is the static pressure in the duct relative to the air outside the duct (Pa).

For low pressure ductwork, $C = 0.025$ litre·s^{-1}·m^{-2}·$Pa^{-0.65}$.

It is possible to calculate the leakage progressively along the duct in accordance with the change in pressure of the duct air. However, for simplicity, the pressure at the mid-length position only of each length of duct will be considered.

The mean pressure in a duct will be approximately equal to the pressure half way along the duct, and is given by:

$$p = p_{t1} - {}^1/_2\,\Delta p - {}^1/_2\,\rho\,c_2 \qquad (2.A5.2)$$

where p is the mean pressure in the duct (Pa), p_{t1} is the total pressure at the beginning of the duct (Pa), Δp is the pressure loss along the duct (Pa), ρ is the density of the air in the duct (kg·m^{-3}) and c is the air velocity in the duct (m·s^{-1}).

The drop in total pressure along the supply air ductwork is 59.7 Pa (see section 2.A5.1.4). This means that the total pressure at the exit from the AHU will be 59.7 Pa above that of the room. That is the starting point for the calculations shown in Table 2.A5.7. However, to illustrate the procedure, the leakage from duct run J–K is calculated as follows.

Surface area of duct = duct length × perimeter. Hence:

$$A_s = 4 \times [2 \times (0.5 + 0.4)] = 7.2 \text{ m}^2$$

The pressure loss up to and just past tee J is the sum of the first eight items of Table 2.A5.4, i.e.:

$$\Delta p = 21.6 \text{ Pa}$$

Total pressure at start of duct run J–K is the total pressure at E minus the pressure drop up to tee J:

$$p_{t1} = 59.7 - 21.6 = 38.1 \text{ Pa}$$

From Table 2.A5.4, ${}^1/_2\,\rho\,c^2$ for duct run J–K is 5.22 Pa. The pressure drop halfway along J–K is (0.5 × 1.2) Pa. Therefore, using equation 2.A5.2, the mean static pressure half way along duct run J–K is:

$$p = 38.1 - 0.6 - 5.22 = 32.3 \text{ Pa}$$

Hence, using equation 2.A5.1, the air leakage is:

$$q_L = 0.025 \times 7.2 \times 32.3^{0.65} = 1.72 \text{ l} \cdot \text{s}^{-1}$$

In Table 2.A5.7, note that although the value of total pressure has been dropping consistently along the duct, in this portion of duct J–K, the actual pressure of the air is greater than in the preceding section. This is due to an accidental element of 'static regain'. At tee I, the main duct section has not changed although less air flows along the main duct after the branch. Thus in this section the air velocity, and thus the value of (${}^1/_2\,\rho\,c_2$), has diminished. This occurs at every tee, as shown in Table 2.A5.7 for runs K–L and Q–S.

Table 2.A5.7 suggests that the maximum leakage would be 20.8 l·s^{-1}. Therefore the permissible fraction lost through air leakage is 1.7% of the original flow rate of 1.2 $m^3 \cdot s^{-1}$ (i.e. 1200 l·s^{-1}). This does not justify specifying a higher flow rate, nor a recalculation of the pressure drop.

Note that the air in much of the return ductwork will be found to have negative static pressure, i.e. the pressure in the duct will be lower than the surroundings, so there will be air leaks into the ductwork.

2.A5.4 Drop in air temperature along the duct

2.A5.4.1 Uninsulated ductwork

Table 2.A5.8 shows the calculation of heat loss from the index run assuming uninsulated ductwork having a thermal

transmittance (U-value) of 7.89 W·m^{-2}·K^{-1}. The air temperatures inside and outside the duct are:

— temperature of air inside the duct at beginning of run, t_{ad1} = 30 °C

— temperature of air surrounding the duct, t_{as} = 20 °C.

Table 2.A5.8 shows that, along the index run E–V6, the heat loss is 4.98 kW, possibly being dissipated into a region that does not require heating. If the ductwork were situated in ceiling voids, which consequently became over-heated, then the heat loss would be less due to the higher temperature outside the duct. Of greater importance is that the temperature of the air at the end of the run will be significantly below the desired supply temperature of 30 °C. Table 2.A5.8 shows that the temperature of the supply air to zone V6 will be 23.5 °C, which will be inadequate. Clearly, it is recommended that ductwork carrying heated or cooled air should be insulated.

2.A5.4.2 Insulated ductwork

Table 3.8 gives recommended thickness of insulation for ductwork depending on the thermal conductivity (λ) of the insulation material. In the following example, λ = 0.035 W·m^{-1}·K^{-1}. The duct air temperature is nominally 30 °C and the temperature of the surrounding air is 20 °C, i.e. ($t_{ad1} - t_a$) = 10 K.

From Table 2.21, the recommended thickness for a duct carrying air at a temperature 10 K greater (or less) than the surroundings, and for a thermal conductivity λ = 0.035 W·m^{-1}·K^{-1}, is 50 mm. From Table 3.7, the overall thermal transmittance is U = 0.64 W·m^{-2}·K^{-1}.

For simplicity, it is assumed that the temperature drop along a section is trivial.

Taking duct run I–J as an example:

Surface area of duct = duct length × perimeter. Hence:

$$A_s = 4 \times [2 \times (0.5 + 0.4)] = 7.2 \text{ m}^2$$

The thermal transmittance is related to the surface area of the ductwork, not to the outer surface area of the insulation. The air has already cooled such that at (I) its temperature is 29.85 °C. In the first instance, it is assumed that this remains constant through I–J. Hence, using equation 3.2, the heat loss is given by:

$$\phi = U A_s (t_{ad} - t_{as}) = 0.64 \times 7.2 \, (29.85 - 20) = 45.3 \text{ W}$$

The temperature drop along duct run I–J is:

$$t_{ad1} - t_{ad2} = \phi / (q_m c_p) = \phi / (q \rho c_p)$$

where t_{ad1} is the temperature at the beginning of the duct run (°C), t_{ad2} is the temperature at the end of the duct run (°C), ϕ is the heat flux (W), q_m is the mass flow rate (kg·s^{-1}), c_p is the specific heat capacity of air (J·kg^{-1}·K^{-1}), q is the

T	—	—	—	—	23.48	—	—	—
						Totals:	4984	6.52

* Temperature difference between beginning and end of duct run

volumetric flow rate ($m^3 \cdot s^{-1}$) and ρ the density of the air ($kg \cdot m^{-3}$).

Therefore:

$$t_{ad1} - t_{ad2} = 45.3 / (1.0 \times 1.16 \times 1.030 \times 103) = 0.04 \text{ K}$$

The temperature at (J) is:

$$t_{a2} = 29.85 - 0.04 = 29.81°C$$

Hence, mean temperature in duct I–J = $^1/_2$ (29.85 + 29.81) = 29.83°C.

In principle, the heat loss ϕ should be re-calculated at the mean temperature, but in this instance the difference is trivial and may be ignored.

Note that though the heat loss from the next duct run J–K is the same (i.e. 45 W), the temperature drop is greater (0.06 K as opposed to 0.04 K). This is because, although the air temperature in the duct is almost the same, the airflow through section J–K is appreciably less (i.e. 0.6 $m^3 \cdot s^{-1}$ as opposed to 1.0 $m^3 \cdot s^{-1}$).

In summary, Table 2.A5.9 shows that the total heat loss from the index run is 522 W, the temperature drop is 0.83 K and the supply air temperature to V6 is 29.2 °C. This is sufficiently close to the required supply temperature at V1 of 29.8 °C for there to be no significant control problems. However the delivered heat to zone V6 is reduced by 8%, therefore there is a case for increasing the design outlet temperature of the air handling unit from 30 °C to 30.5 °C.

2.A5.5 Effects on airflows when closing down one branch

Figure 2.A5.3 shows a simplified duct network where boxes 1, 2 and 3 represent the ductwork circuits for supplying three zones. Box 5 represents the return ductwork. D is a damper which is initially open, but which will be closed down.

The design conditions are as follows:

— *duct system 1*: $q = 0.2$ $m^3 \cdot s^{-1}$; $\Delta p = 70$ Pa

— *duct system 2*: $q = 0.2$ $m^3 \cdot s^{-1}$; $\Delta p = 50$ Pa

— *duct system 3*: $q = 0.2$ $m^3 \cdot s^{-1}$; $\Delta p = 40$ Pa

— *duct system 4*: $q = 0.4$ $m^3 \cdot s^{-1}$; $\Delta p = 20$ Pa

— *duct system 5*: $q = 0.6$ $m^3 \cdot s^{-1}$; $\Delta p = 20$ Pa

— *damper D*: $q = 0.2$ $m^3 \cdot s^{-1}$; $\Delta p = 10$ Pa

From the above design requirement, the fan must produce a pressure rise of 70 Pa for a volume flow of 0.6 $m^3 \cdot s^{-1}$.

We can use the approximate simplification that the pressure drop of the system is proportional to the square of the velocity, and thus proportional to the square of the flow rate. (*Note*: not true where there are HEPA filters in the system). Thus pressure drop at any flow rate is easily obtained using:

$$\Delta p \mu q^2 \qquad (2.A5.3)$$

where Δp is the pressure drop (Pa) and q is the volumetric flow rate ($m^3 \cdot s^{-1}$).

Hence, from such values the 'system characteristic' can be constructed as shown in Figure 2.A5.4.

A fan would be chosen such that the intersection of the fan characteristic and the system characteristic gives the design requirement, as shown, of 0.6 $m^3 \cdot s^{-1}$ and a total pressure drop Δp_t of 70 Pa.

The following illustrates what happens to the flow in the various branches of the system when the resistance of one branch is changed as a result of closing damper D.

The problem can be resolved using either circuit resistances or capacities. Since valve manufacturers always give valve capacities, the following uses the capacity method for consistency. (See also Guide C, section 4, Appendix 4.A5.)

Capacity K is given by the relationship:

$$q = K \Delta p_p \qquad (2.A5.4)$$

where K is the capacity ($m^3 \cdot s^{-1} \cdot Pa^{-0.5}$)

Using equation 2.A5.4, the capacity of each leg of the network can be calculated, as follows:

$$K_1 = q_1 / \Delta p_{p1} = 0.2 / \div 70 = 0.02390 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa}^{-0.5}$$

$$K_2 = q_2 / \Delta p_{p2} = 0.2 / \div 50 = 0.02828 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa}^{-0.5}$$

$$K_3 = q_3 / \Delta p_{p3} = 0.2 / \div 40 = 0.03162 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa}^{-0.5}$$

$$K_4 = q_4 / \Delta p_{p4} = 0.4 / \div 20 = 0.08944 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa}^{-0.5}$$

$$K_5 = q_5 / \Delta p_{p5} = 0.6 / \div 20 = 0.13416 \text{ m}^3 \cdot \text{s}^{-1} \cdot \text{Pa}^{-0.5}$$

* Temperature difference between beginning and end of duct run

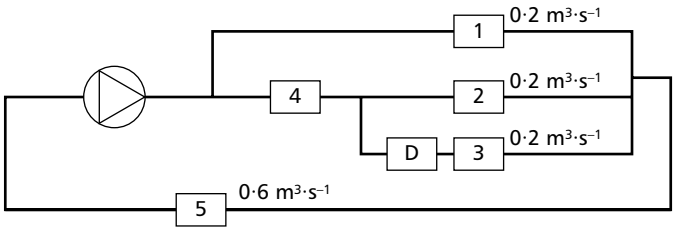

Figure 2.A5.3 Simplified duct network

With damper D closed, no flow will pass through leg 3.

K_2 and K_4 are in series, giving an effective capacity of $K_{2,4}$, i.e:

$$\frac{1}{K_{2,4}^2} = \frac{1}{K_2^2} + \frac{1}{K_4^2} = \frac{1}{0.02828^2} + \frac{1}{0.08944^2}$$

Hence:

$$K_{2,4} = 0.02696 \text{ m}^3\cdot\text{s}^{-1}\cdot\text{Pa}^{-0.5}$$

$K_{2,4}$ and K_1 are in parallel, i.e:

$$K_{1,2,4} = K_{2,4} + K_1$$
$$= 0.02696 + 0.02390 = 0.05086 \text{ m}^3\cdot\text{s}^{-1}\cdot\text{Pa}^{-0.5}$$

The total system capacity K_0 is the result of $K_{1,2,4}$ in series with K_5, i.e:

$$\frac{1}{K_0^2} = \frac{1}{K1_{1,2,4}^2} + \frac{1}{K_5^2} = \frac{1}{0.05086^2} + \frac{1}{0.13416^2}$$

Hence:

$$K_0 = 0.04756 \text{ m}^3\cdot\text{s}^{-1}\cdot\text{Pa}^{-0.5}$$

Had the capacity been calculated for the original system, it would have been found to be 0.0717 $\text{m}^3\cdot\text{s}^{-1}\cdot\text{Pa}^{-0.5}$.

A new system characteristic can now be determined from equation 2.A5.4 using the calculated value of K_o, e.g. for q = 0.55 $\text{m}^3\cdot\text{s}^{-1}$:

$$\Delta p = (0.55 / 0.04756)^2 = 133.7 \text{ Pa}$$

With the damper closed, the system has a new system characteristic, see Figure 2.A5.4. The intersection with the fan characteristic now gives a flow of 0.516 $\text{m}^3\cdot\text{s}^{-1}$ and a pressure drop of Δp = 117.7 Pa.

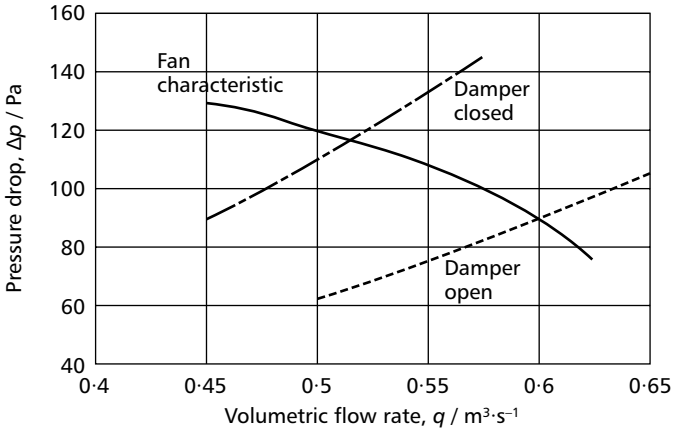

Figure 2.A5.4 System characteristic for simplified duct network; (*a*) characteristic with damper D open and (*b*) characteristic with damper D closed

It is now necessary to ascertain the proportions in which this total flow is apportioned between supply legs 1 and 2.

Knowing the flow through leg 5 (being either the return ductwork, or extract to the outside and inlet from the outside), the pressure loss through leg 5 can be calculated using equation 2.A5.4:

$$0.55 = 0.13416 \div \Delta p_5$$

Hence:

$$\Delta p_5 = (0.55 / 0.13416)^2 = 16.8 \text{ Pa}$$

The remainder is the pressure drop existing across leg 1, and across leg 4/2:

$$\Delta p_1 = \Delta p_o - \Delta p_5 = 117.7 - 16.8 = 100.9 \text{ Pa}$$

The flow through leg 1 can now be determined using equation 2.A5.4:

$$q_1 = 0.02390 \div 100.9 = 0.2401 \text{ m}^3\cdot\text{s}^{-1}$$

The rest of the flow passes along leg 4/2, i.e:

$$q_4 = q_o - q_5 = 0.516 - 0.240 = 0.276 \text{ m}^3\cdot\text{s}^{-1}$$

The flow rates resulting from closure of damper D are shown on Figure 2.A5.5.

It should be noted that, although the supplies to legs 1 and 2 were initially equal, this is no longer the case once any change is made to any other branch.

Appendix 2.A6: Techniques for assessment of ventilation

2.A6.1 General

There are a number of assessment techniques available to calculate ventilation and cooling requirements and to look in detail at air movement. This appendix provides an overview of some of these techniques. CIBSE AM11 (2015a) and AM10 (2005) provide more detail on dynamic thermal simulation and assessment techniques for natural ventilation respectively.

2.A6.2 Ventilation and cooling

Section 2.2 includes airflow rate requirements for ventilation purposes. Airflow rate requirements for cooling purposes are normally based either on restricting peak summer temperatures in passive buildings or to meet the peak cooling load. Analyses may start by looking at peak temperatures to evaluate of the building's potential without mechanical cooling. These would assess the ventilation rates (natural and/or mechanical) and passive measures needed to meet summer temperature limits. Where cooling is to be provided, the cooling needed to maintain the temperature limits would be assessed. Airflow rates may then be calculated to deliver this cooling to the space.

There is a range of analysis methods available to suit different applications and stages in the design process. Design charts based on parametric analysis may be used (e.g. the BRE's *Environmental Design Guide*, 1998), although the user can work only within the range of variables covered by the charts. Section 5 of CIBSE Guide A (2015b) provides design information on the use of thermal dynamic models for calculating peak summertime temperatures and peak space cooling loads. Simple (dynamic) models (e.g. the admittance procedure) may be used to assess cooling loads and the probability of overheating. These approaches are based on a 24-hour design cycle and are suitable for mechanically cooled buildings with a repetitive diurnal operating cycle. However, where this is not an accurate reflection of building operation due to thermal mass or passive operation, dynamic thermal simulation may be used.

Appropriate consideration should be given to issues of weather data, control and thermal mass depending on the application. Selection of appropriate weather data is discussed in CIBSE AM10 (2005). Different data will be required for different purposes. For example, to estimate energy consumption, average weather data for the region will usually be the most appropriate. Data, including more extreme conditions, will be appropriate to test the ability of the building to accommodate various levels of internal heat gain and predict peak temperatures. Site-specific weather data can be of interest, but may have been collected over a relatively short period and may not necessarily be representative. It is frequently impossible to use such data to construct meaningful statistics to identify the percentage of time a specified internal temperature would be likely to be exceeded. There is also a danger that the design may lack robustness, being tailored to a unique weather sequence and reacting in a different and unpredicted way to more normal weather peaks. A more robust choice will often be to analyse the building in relation to appropriate national UK data and to make simple corrections to suit the differences between this and the site data; e.g. August average temperature and diurnal swing and August 2.5% exceeded peak temperature and the associated diurnal swing.

Loads and system performance often depend on more than one weather variable. Cooling and humidity conditions will be a function of wet bulb as well as dry bulb temperature. The performance of natural ventilation systems in particular can be affected by solar and wind conditions as well as temperatures, as these are often used to drive the ventilation. Design conditions for the individual weather variables will rarely coincide.

Controls used in the thermal model should reflect what can be expected to occur in practice. This is a particular issue in natural ventilation systems with manual control. Account should be taken of the way occupants use windows. Data are available on occupancy effects on natural ventilation, primarily based on the domestic sector. This work is summarised in AIVC Technical Note 23 (Dubrul, 1988).

Thermal mass should be modelled with appropriate surface heat transfer values and representation of heat flow within the mass. High thermal mass buildings must be allowed to come to their natural thermal equilibrium by having a lengthy period of simulation prior to the period over which the modelling results are reported and compared; 15 days is usually enough for this 'pre-conditioning' period, although a few buildings require longer. This can be tried first with 10 and 20 days and the results compared to check for significant differences. If a hot spell is being simulated, peak weather data should not be used throughout, as this will under-value the heat-absorbing benefits of the thermal mass. Instead, pre-conditioning with average weather for the season concerned can be undertaken, followed by a step change to the peak weather sequence — which in the UK seldom lasts more than 5 days. The design day is typically the third in the peak weather sequence.

2.A6.3 Air movement

Analyses of air movement may be needed, particularly for natural ventilation applications and air movement in large spaces such as atria. These provide information on air velocity, movement and temperature; volume flow rate; and optimal opening sizes, shapes and positions. Techniques available include computational fluid dynamics (CFD), physical models and air flow models. For room air distribution, performance is sometimes critically dependent on details of equipment design, and full-scale mock-ups may be required.

2.A6.3.1 Computational fluid dynamics (CFD)

CFD is a technique for predicting air movement that can address questions such as stratification and local air

movement. It therefore has particular application to consideration of large spaces such as atria. CFD methods can predict temperature and velocity distributions in a space and can be applied to assessments of comfort involving more of the influencing parameters than is possible in zonal models. Because of the extensive nature of the computations and the time varying nature of the natural driving forces, CFD is normally only used to generate 'snapshots' of how the design would work at a given point in time.

Another potential application for CFD is external flows around the building. The purpose is to generate the wind pressure coefficients needed by all models to predict natural airflow rates.

2.A6.3.2 Physical models

Physical models are especially useful for giving the non-technical members of the client and design team a good visualisation of airflow behaviour. By their nature, physical models are implicit design tools; assumptions need to be made then tested. The two main techniques relating to natural ventilation design are the salt bath technique and wind tunnel testing.

Salt bath

The salt bath technique is used to test stack driven ventilation strategies. Stack-driven flows are analysed at small scale in the laboratory using a model of the building immersed in a perspex bath containing saline solutions of different concentrations. The method models fluid flow, not surface heat transfer, and therefore cannot predict local effects such as solar patching on the floor of an atrium. Like the CFD technique it provides only a snapshot of performance.

Wind tunnel

Wind tunnel testing is the main source of information on wind pressure coefficients. It is not a method for proving the design of a natural ventilation system, since it only deals with external flows around a building.

Air flow models

Air flow models may be used to analyse natural ventilation air flow rates based on driving pressure differences and openings. These range from single zone models to more complex multi-zone models. Single zone models (Liddament, 1996) are appropriate where the building is open plan and there is no temperature stratification in the space. Building types that approximate to these requirements are dwellings, many industrial buildings and small open plan office buildings. Multi-zone models subdivide the building into a number of individual spaces, substantially increasing the complexity of the analysis (Feustel, 1991).

Software combining multi-zone flow models with thermal simulation analysis is also available. This software can provide an integrated analysis the internal temperature distribution and the stack induced natural ventilation flow rates (Kendrick, 1993).

Preface

About Health Building Notes

Health Building Notes give "best practice" guidance on the design and planning of new healthcare buildings and on the adaptation/extension of existing facilities.

They provide information to support the briefing and design processes for individual projects in the NHS building programme.

The Health Building Note suite

Healthcare delivery is constantly changing, and so too are the boundaries between primary, secondary and tertiary care. The focus now is on delivering healthcare closer to people's homes.

The Health Building Note framework (shown below) is based on the patient's experience across the spectrum of care from home to healthcare setting and back, using the national service frameworks (NSFs) as a model.

Health Building Note structure

The Health Building Notes have been organised into a suite of 17 core subjects.

Care-group-based Health Building Notes provide information about a specific care group or pathway but cross-refer to Health Building Notes on **generic (clinical) activities** or **support systems** as appropriate.

Core subjects are subdivided into specific topics and classified by a two-digit suffix (-01, -02 etc), and may be further subdivided into Supplements A, B etc.

All Health Building Notes are supported by the overarching Health Building Note 00 in which the key areas of design and building are dealt with.

Example

The Health Building Note on accommodation for adult in-patients is represented as follows:

> "Health Building Note 04-01: Adult in-patient facilities"

The supplement to Health Building Note 04-01 on isolation facilities is represented as follows:

> "Health Building Note 04-01: Supplement 1 – Isolation facilities for infectious patients in acute settings"

Health Building Note number and series title	Type of Health Building Note
Health Building Note 00 – Core elements	Support-system-based
Health Building Note 01 – Cardiac care	Care-group-based
Health Building Note 02 – Cancer care	Care-group-based
Health Building Note 03 – Mental health	Care-group-based
Health Building Note 04 – In-patient care	Generic-activity-based
Health Building Note 05 – Older people	Care-group-based
Health Building Note 06 – Diagnostics	Generic-activity-based
Health Building Note 07 – Renal care	Care-group-based
Health Building Note 08 – Long-term conditions/long-stay care	Care-group-based
Health Building Note 09 – Children, young people and maternity services	Care-group-based
Health Building Note 10 – Surgery	Generic-activity-based
Health Building Note 11 – Community care	Generic-activity-based
Health Building Note 12 – Out-patient care	Generic-activity-based
Health Building Note 13 – Decontamination	Support-system-based
Health Building Note 14 – Medicines management	Support-system-based
Health Building Note 15 – Emergency care	Care-group-based
Health Building Note 16 – Pathology	Support-system-based

Other resources in the DH Estates and Facilities knowledge series

Health Technical Memoranda

Health Technical Memoranda give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare (for example medical gas pipeline systems, and ventilation systems).

They are applicable to new and existing sites, and are for use at various stages during the inception, design, construction, refurbishment and maintenance of a building.

All Health Building Notes should be read in conjunction with the relevant parts of the Health Technical Memorandum series.

Activity DataBase (ADB)

The Activity DataBase (ADB) data and software assists project teams with the briefing and design of the healthcare environment. Data is based on guidance given in the Health Building Notes, Health Technical Memoranda and Health Technical Memorandum Building Component series.

1. Room data sheets provide an activity-based approach to building design and include data on personnel, planning relationships, environmental considerations, design character, space requirements and graphical layouts.
2. Schedules of equipment/components are included for each room, which may be grouped into ergonomically arranged assemblies.
3. Schedules of equipment can also be obtained at department and project level.
4. Fully loaded drawings may be produced from the database.
5. Reference data is supplied with ADB that may be adapted and modified to suit the users' project-specific needs.

Note

The sequence of numbering within each subject area does not necessarily indicate the order in which the Health Building Notes were or will be published/printed. However, the overall structure/number format will be maintained as described.

Executive summary

This Health Building Note provides guidance on critical care units that admit patients whose dependency levels are classified as level 2 or 3 (see 'Comprehensive Critical Care', DH 2000, for definitions of levels of critical care). However, it does not distinguish between the different requirements for level 2 and 3 patients.

It excludes facilities for the high-security isolation of patients, dedicated centres for burns patients and areas within the hospital where level 2 or 3 patients are managed on a time-limited basis.

Contents

1 Policy context

1.1 'Comprehensive Critical Care' (DH, 2000) was a pivotal publication. It introduced the concept of "critical care without walls"; identifying for the first time that a patient's clinical needs and not their location of care determined the required level and type of organ support. Patients thereafter have been described according to their required level of organ support (see levels of care on the Intensive Care Society website).

1.2 In addition 'Comprehensive Critical Care' highlighted the need for early recognition of deteriorating health and appropriate comprehensive transfer arrangements for patients to wards after recovery from critical illness. These concepts and guidance on operational service delivery such as the role of critical care networks were reinforced in 'Quality Critical Care – Beyond Comprehensive Critical Care' (DH, 2005).

1.3 NICE has subsequently issued guidance on 'Acutely ill patients in hospital' (Clinical guidelines CG50, July 2007) and 'Rehabilitation after critical illness' (Clinical guidelines CG83, 2009). Accompanying CG50, 75 acute care competencies have been detailed in 'Competencies for recognising and responding to acutely ill patients in hospital' (DH, 2009). Such guidance has led to the development of critical care outreach services.

1.4 The operational changes that have followed the release of 'Comprehensive Critical Care' have been significant. Critical care networks have developed, many of which are delivered now as managed clinical networks. The provision of mutual and collective planning of services is essential for service resilience. This means that critical care units across a conurbation will work together to meet needs.

1.5 The building blocks for commissioning of critical care services are now in place. A new dataset, Critical Care Minimum Dataset, was mandated from April 2006; annual reference cost submission followed and from 1 April 2011 a new model for commissioning of critical care services has been used. This model uses the mandated dataset and derivation of seven healthcare resources groups for critical care as the currency, but uses local tariffs ('Payment by Results Guidance for 2011–12', DH).

Mixed-sex accommodation in critical care units

1.6 Patient acuity determines the need for access to critical care, and although every effort is made to group members of the same sex together, this is frequently not possible. Nevertheless, it is imperative that the highest standards of privacy and dignity are maintained at all times.

1.7 For guidance on the justification for mixed sex accommodation in critical care units see PL/CNO/2010/3 – 'Eliminating Mixed Sex Accommodation'.

2 Service context

2.1 The Department of Health collects data on the number of critical care beds twice a year. For details see 'Census on number of critical care beds in England'.

3 Scope of guidance

3.1 This Health Building Note describes spaces that are unique to a critical care unit. It also describes any variations to common hospital spaces and clarifies requirements for these spaces, where necessary.

3.2 For a full list of space requirements see the following example schedules of accommodation for an 8-bed, 16-bed and 32-bed critical care unit. The example schedules provide a basis for sizing facilities at initial planning stages but exact requirements should be determined locally based on the number and case mix of patients, hospital policy for the provision of supplies and waste disposal, and the layout of the unit. Links to guidance on common spaces are provided from the schedules.

Example schedules of accommodation for critical care units

Version 1, published 15.09.11

				Cost guide allowances:	Circulation and communication	Engineering		
				Public	35%	23%		
				Clinical	35%	35%		
				Staff	35%	21%		

Example 1: 8-bed critical care unit

	Room name/function	Unit area allowance	Quantity	Net internal area	Circulation and communication allowance	Engineering allowance	Gross internal area	Notes
Public spaces								
	Entrance: visitors		1					
	Entrance: patients, staff and supplies		1					Separate entrance for staff and supplies is an option.
J0232	Reception desk (size based on number of places)	5.5	1	5.5	1.9	1.3	8.7	1-place reception for small/medium sized units; 2-place reception for large units (>30 beds).
J1155/J1414	Waiting area: 10 places	22.5	1	22.5	7.9	5.2	35.6	Includes children's play area and 10% wheelchair places. 1 place per bed with minimum of 10.
P0711	Mini kitchen	5.0	1	5.0	1.8	1.2	7.9	1 per unit.
	WC: independent wheelchair	4.5	1	4.5	1.6	1.0	7.1	1 per small/medium sized unit; 2 per large unit (>30 beds).
Clinical spaces								
T0214-03	Staff communication base: 2 places	13.0	1	13.0	4.6	4.6	22.1	2 places per 8 beds.
B1603	Isolation room: critical care	26.0	4	104.0	36.4	36.4	176.8	Planning and design manual specifies 20% singles (subject to case mix); in an 8-bed unit with a standard 4-bed bay arrangement 50% singles may be provided.
G0510	Gowning lobby	6.0	4	24.0	8.4	8.4	40.8	
B1610	4-bed bay: critical care	143.0	1	143.0	50.1	50.1	243.1	
M0727	Interview room: 7 places	12.0	1	12.0	4.2	4.2	20.4	1 per 10 beds.
V1635	Shower room: assisted	8.0	1	8.0	2.8	2.8	13.6	Nominal allowance. Requirement subject to case mix of unit.
Clinical support spaces								
T0535	Clean utility room	16.0	1	16.0	5.6	5.6	27.2	1 per 12 beds.
G0605	Ice-making machine bay	1.5	1	1.5	0.5	0.5	2.6	1 per unit.
L1308	Near patient testing room	8.0	1	8.0	2.8	2.8	13.6	1 per 16 beds.
Y0331	Dirty utility room for bedpan processing	12.0	1	12.0	4.2	4.2	20.4	1 per 16 beds.
P0627	Pantry/refreshment room	12.0	1	12.0	4.2	4.2	20.4	1 per unit.
W0540/1450/ 1590/1594	Storage: bulky consumables, medical gas cylinders, linen and furniture	4.0	8	32.0	11.2	11.2	54.4	4 m^2 allowance per bed. Based on a review of a number of reference sites.
W1584-06	Store: clinical equipment	24.0	1	24.0	8.4	8.4	40.8	1 for small/medium sized units; 2 for large units (>30 beds).
Y0335	Decontamination room: clinical equipment	16.0	1	16.0	5.6	5.6	27.2	1 per unit. Located adjacent to clinical equipment store.
G0171	Parking bay: imaging equipment	6.0	1	6.0	2.1	2.1	10.2	1 per small/medium sized unit; 2 per large unit (>30 beds).
G0180-01	Parking bay: resuscitation trolley	2.0	1	2.0	0.7	0.7	3.4	1 per 8 beds.
Y0642	Disposal hold: 1700 litres	8.0	1	8.0	2.8	2.8	13.6	Minimum 1500 litres per 8 beds
Y1510	Cleaners' room	8.0	1	8.0	2.8	2.8	13.6	1 for small/medium sized units; 2 for large units (>30 beds).
Staff spaces								
M0251	Office: 1-person	8.0	3	24.0	8.4	5.0	37.4	For clinical director, lead nurse and tutor.
M0278-01/M0281/ M0410/M0731	Admin area: shared use (size based on number of workstations)	6.6	5	33.0	11.6	6.9	51.5	For consultants and outreach staff.
M0727	Meeting room: 7 places	16.0	1	16.0	5.6	3.4	25.0	
H1304-01	Seminar room: 8 places	17.0	1	17.0	6.0	3.6	26.5	May be sized up and shared with other departments.
D0434-01	Rest room with mini kitchen (size based on number of seats)	1.9	8	15.2	5.3	3.2	23.7	
V0554-03/V0667-01/ V0725/V1321	Changing area: staff (size based on number of lockers)	1.4	35	49.0	17.2	10.3	76.4	Includes uniform exchange area, showers and a number of individual changing rooms. Based on 32 staff who need a locker (allowing for shift changeover), plus a 10% contingency to allow for male/female split (suggested apportionment 2/3 female to 1/3 male).
V0725	Changing room: semi-ambulant	2.0	1	2.0	0.7	0.4	3.1	Additional individual changing room to allow for male and female segregation.
V1321	Shower room: ambulant	2.5	1	2.5	0.9	0.5	3.9	Additional shower room to allow for male and female segregation.
V1010	WC: ambulant	2.0	4	8.0	2.8	1.7	12.5	Serving up to 50 staff, with additional WC to allow for gender segregation.
Total allowance				**653.7**	**228.8**	**201.0**	**1083.5**	
Optional accommodation								
W0652	Blood refrigerator bay	2.0	1	2.0				Only required if blood storage not available nearby.
L1804-03	Service room: clinical equipment	12.0	1	12.0				Only required if biomedical engineering workshop not available nearby.
G0171-02	Parking bay: mobile image intensifier	2.0	1	2.0				
P0808	Vending machine	3.0	1	3.0				In lieu of visitors' mini kitchen.
D1120	Sitting room: 7 places	12.0	1	12.0				For visitors.
D1312	Relatives' overnight stay	17.0	1	17.0				For visitors. Requirement based on case mix of patients.
V1323	Shower room: semi-ambulant: standing use	5.0	2	10.0				For visitors. Requirement based on case mix of patients.

Example schedules of accommodation for critical care units

Version 1, published 15.09.11

				Cost guide allowances:	Circulation and communication	Engineering		
				Public	35%	23%		
				Clinical	35%	35%		
				Staff	35%	21%		

Example 2: 16-bed critical care unit

	Room name/function	Unit area allowance	Quantity	Net internal area	Circulation and communication allowance	Engineering allowance	Gross internal area	Notes
Public spaces								
	Entrance: visitors		1					
	Entrance: patients, staff and supplies		1					Separate entrance for staff and supplies is an option.
J0232	Reception desk (size based on number of places)	5.5	1	5.5	1.9	1.3	8.7	1-place reception for small/medium sized units; 2-place reception for large units (>30 beds).
J1155/J1414	Waiting area: 16 places	33.0	1	33.0	11.6	7.6	52.1	Includes children's play area and 10% wheelchair places. 1 place per bed with minimum of 10.
P0711	Mini kitchen	5.0	1	5.0	1.8	1.2	7.9	1 per unit.
V0922	WC: independent wheelchair	4.5	1	4.5	1.6	1.0	7.1	1 per small/medium sized unit; 2 per large unit (>30 beds).
Clinical spaces								
T0214	Staff communication base: 4 places	19.0	1	19.0	6.7	6.7	32.3	2 places per 8 beds.
B1603	Isolation room: critical care	26.0	4	104.0	36.4	36.4	176.8	Planning and design manual specifies 20% singles (subject to case mix); in a 16-bed unit with a standard 4-bed bay arrangement 25% singles may be provided.

V1323	Shower room: semi-ambulant: standing use	5.0	2	10.0				For visitors. Requirement based on case mix of patients.

4 Whole unit planning and design considerations

Departmental relationships

4.1 A critical care unit should be centrally located within an acute hospital development. It should be adjacent to and/or have easy access to (and be easily accessible from) imaging facilities and operating theatres. The emergency department should be adjacent and/or have easy access to the critical care unit.

4.2 The critical care unit requires close links to the main hospital pharmacy and microbiology laboratory; where a pneumatic tube system is used to transport specimens and computers are used for transmitting test results and placing prescription orders, physical proximity is less important.

Bed spaces

4.3 Each bed space should include the following:

- an electric bed capable of attaining chair and Trendelenberg positions, and fitted with a pressure-relieving mattress;
- a high-backed chair with foot elevation and tilting facility for the patient;
- a ceiling-mounted twin-armed pendant to accommodate a range of equipment and for the provision of medical gases and electrical and data connectivity;
- a clinical wash-hand basin;

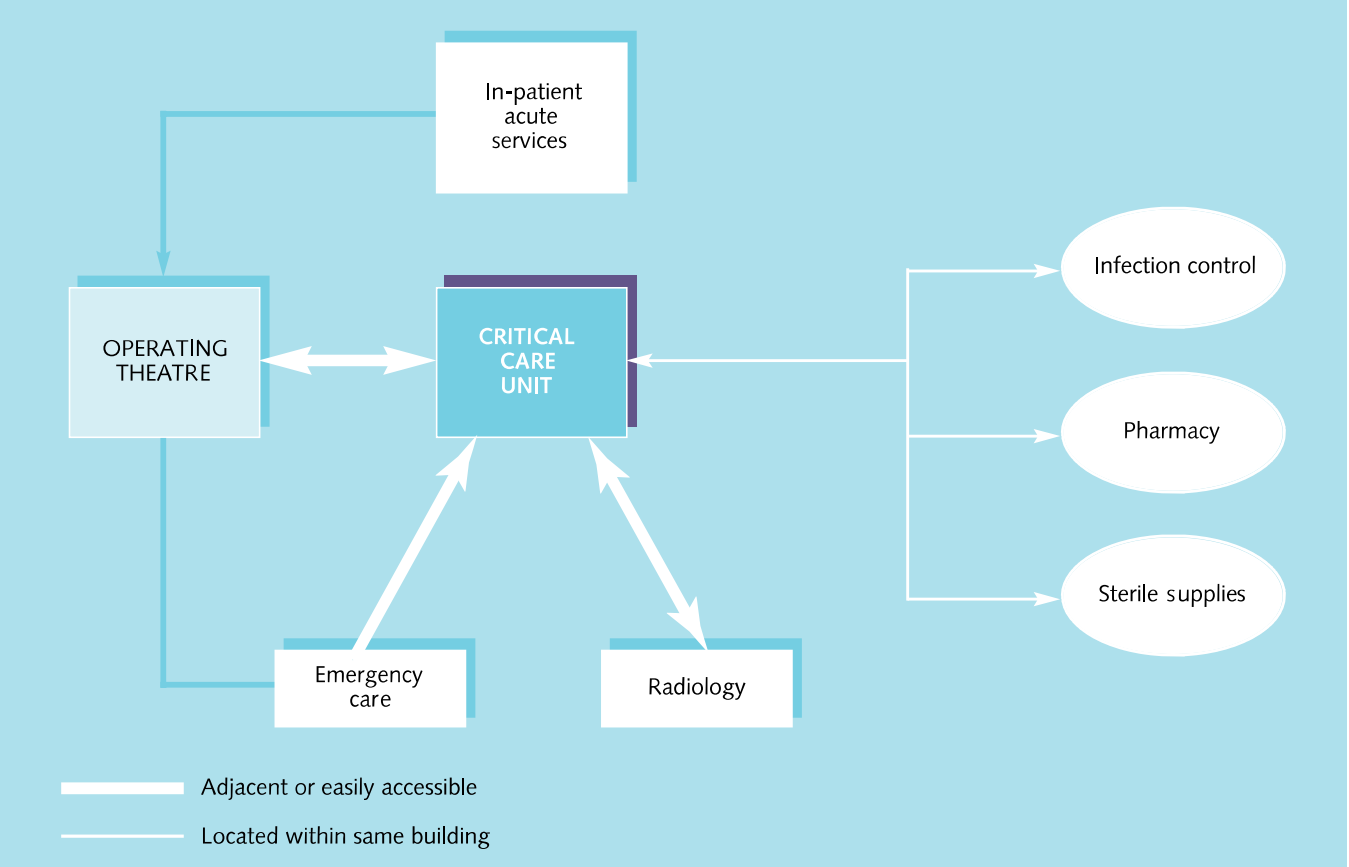

Figure 1 Departmental relationships for a critical care unit

- enclosed storage for a small quantity of consumables;
- drugs storage (wall-mounted drugs cabinet or within the patient's bedside locker);
- a ceiling-mounted hoist for lifting patients.

4.4 Storage of patients' clothes and personal effects should be dealt with in accordance with whole-hospital policy. They should not normally be kept at the bedside; however, some personal items such as family photographs can help the patient's orientation and provide emotional support.

4.5 The following outlets should be located on the pendant:

- at least 28 unswitched single socket-outlets;
- up to four data outlets, one of which should be networked to the hospital's patient record system;
- 3–4 oxygen outlets;
- two 4-bar air outlets;
- one 7-bar air outlet (where surgical equipment is used), clearly labelled with the appropriate warning;
- 2–4 medical vacuum outlets;
- anaesthetic gas scavenging points, if anaesthetic inhalation gases and/ or inhalation antibiotics are used;
- patient/staff and staff emergency call systems, including a separate switch for crash call;
- telephone outlet for internal and external calls;
- TV outlet.

4.6 The following equipment should be located on the pendant:

- computer with flat-screen monitor;
- multi-parameter patient monitoring equipment;
- 3–6 infusion pumps;
- 4–10 syringe pumps;
- blood warmer;
- feeding pump;
- ventilation and humidification equipment.

4.7 Ceiling-mounted rather than floor-mounted pendants are recommended since they avoid the need to trail cables across the floor, thereby providing better access to the patient and improved safety for staff and visitors. They are also easier to keep clean. Powered ceiling-mounted pendants enable staff of all heights to operate them easily. Care should be taken in the positioning of the pendants to ensure convenient access by staff.

4.8 The pendant should be connected to an isolated power supply and provide an uninterruptable power supply (UPS) to an agreed number of electrical outlets. IPS and UPS sockets should be colour-coded to differentiate them from one another. Additional switched and shuttered sockets, connected to ring circuits, may be provided at the bedhead for portable non-medical equipment.

4.9 The temperature within bed spaces is usually controlled by the ventilation system rather than radiators. Facilities for temperature and humidity adjustment should be provided, to parameters agreed with clinical representatives on the project team. Children should only be placed in bed spaces that provide local temperature control (due to the need to elevate the room temperature for this patient group).

4.10 The ventilation system should include mechanical cooling and provide for a range of temperatures that can be adjusted by staff, taking particular care to establish and accommodate the unusually high heat gains that may be anticipated from medical equipment. The position of ventilation grilles should minimise the risk of patients experiencing discomfort through down drafts.

4.11 The following equipment may be required at the bedside on an intermittent or continuous basis:

- mobile X-ray machine;
- haemodialysis machine;
- haemofiltration machine;
- peritoneal dialysis machine;
- EEG machines;
- electrocardiography machines;
- echocardiography machines;
- transoesophageal echocardiography machines;
- invasive cardiac output monitoring devices;
- ultrasound machines;
- gamma cameras;
- endoscopes (fibre-optic light source);

- defibrillators;
- non-invasive respiratory equipment (continuous positive airway pressure (CPAP)/bi-level positive airway pressure (BIPAP)): this may be mounted on the pendant;
- vacuum dressings.

4.12 A wall-mounted renal dialysis panel with water supply and drainage may be provided at some bed spaces to facilitate haemodialysis. Alternatively, it may be more economical to supply potable water to small water treatment units at the bed space. The specification for the water quality should be agreed with the project team.

4.13 A clock with an elapsed time control should be clearly visible from each bed space.

4.14 The bed space should be a minimum of 25.5 m^2 in order to accommodate the above equipment/ furniture. This will also allow:

- staff access to the patient from all sides of the bed;
- staff to manoeuvre the patient, themselves and equipment safely;
- five members of staff to attend to the patient in an emergency situation;
- two visitors to sit at the bedside.

4.15 All bed spaces should be capable of providing visual privacy and reasonable auditory privacy, when required. All bed spaces should have natural daylight with outside views wherever possible. Artificial lighting should be dimmable and of sufficient strength to enable surgical interventions and response to life-threatening situations at the bedside. Lighting may be provided as part of the pendant system.

4.16 Glass walls (in the case of single-bed rooms) or partitions (in the case of multi-bed areas), which can be obscured for privacy when appropriate, aid observation of patients.

4.17 A ceiling height of 3 m in bed areas is recommended in order to accommodate pendants and ceiling-mounted hoists. The position of overhead equipment requires careful consideration. The construction of the ceiling should take account of weight-bearing requirements.

5 Public spaces

Entrances

5.1 Patients and visitors should not share the same entrance, to ensure that visitors do not observe patients coming in and out of the critical care unit. Deceased patients should be transported using the patients' entrance. Staff may share an entrance with either visitors or patients. However, a dedicated entrance for visitors may provide them with a calmer, less busy environment. Supplies should be delivered via the same entrance used by staff.

5.2 The entrance for visitors requires an intercom-controlled entry system or similar linked to the reception desk and staff communication base(s). CCTV should also be considered, with monitors at the reception desk and staff communication base(s) to assist with identification of visitors out-of-hours.

5.3 Where access control measures are in place, close-proximity cards rather than swipe cards or keypads should be used, as they are easier to clean and offer better infection control.

Reception desk

5.4 The entry system for the visitors' entrance, CCTV monitor, if provided, and a telephone for internal and external calls should be located here. The reception desk should have natural surveillance of the visitors' entrance and/or point of entry to clinical areas.

Visitors' waiting area and associated facilities

5.5 On arrival, visitors will be admitted immediately to the appropriate clinical area or asked to wait in the waiting area. There should be a door between the waiting area and clinical areas, controlled by staff, to prevent visitors wandering into clinical areas. Beverage-making facilities and WCs should be available nearby. The waiting area may include a TV. A separate visitors' sitting room may be of value for those spending long periods of time within the vicinity of the critical care unit.

Visitors' overnight accommodation

5.6 Overnight accommodation for visitors may be provided within the hospital, or the hospital may have an arrangement with a nearby hotel. Where children are being treated, overnight accommodation for parents should be provided. Enlarged single bedrooms provide the option of adding an extra bed for parents to stay overnight.

6 Clinical spaces

Staff communication base(s)

6.1 Ideally, staff at the base(s) should be able to see all multi-bed spaces under their control and the entry point to clinical areas. Control of the visitors' entry system will be transferred from the reception desk to the communication base(s) at night.

6.2 Alarms to signify the failure of medical gas and power outlets within the bed spaces should be located here. Central consoles for multi-parameter patient monitoring equipment should also be located here.

6.3 A telephone for internal and external calls will be required. Task lighting should be provided for use at night to prevent disturbing patients. Each base should be partially enclosed to control noise transfer.

Isolation rooms

6.4 Single-bed rooms with lobbies are required for the isolation of patients to control the spread of infection or for the protection of immuno-suppressed patients.

6.5 Single-bed rooms should be rectangular, not L-shaped, with an entrance wide enough to allow bulky equipment to pass easily – at least a door and a half wide. Care should be taken to ensure that the door opening is sufficient to allow the passage of the bed and equipment.

6.6 The ventilation system should be designed to provide simultaneous source and protective isolation. A balanced supply and extract ventilation to each isolation room and gowning lobby is, therefore, proposed. The lobby, which functions as

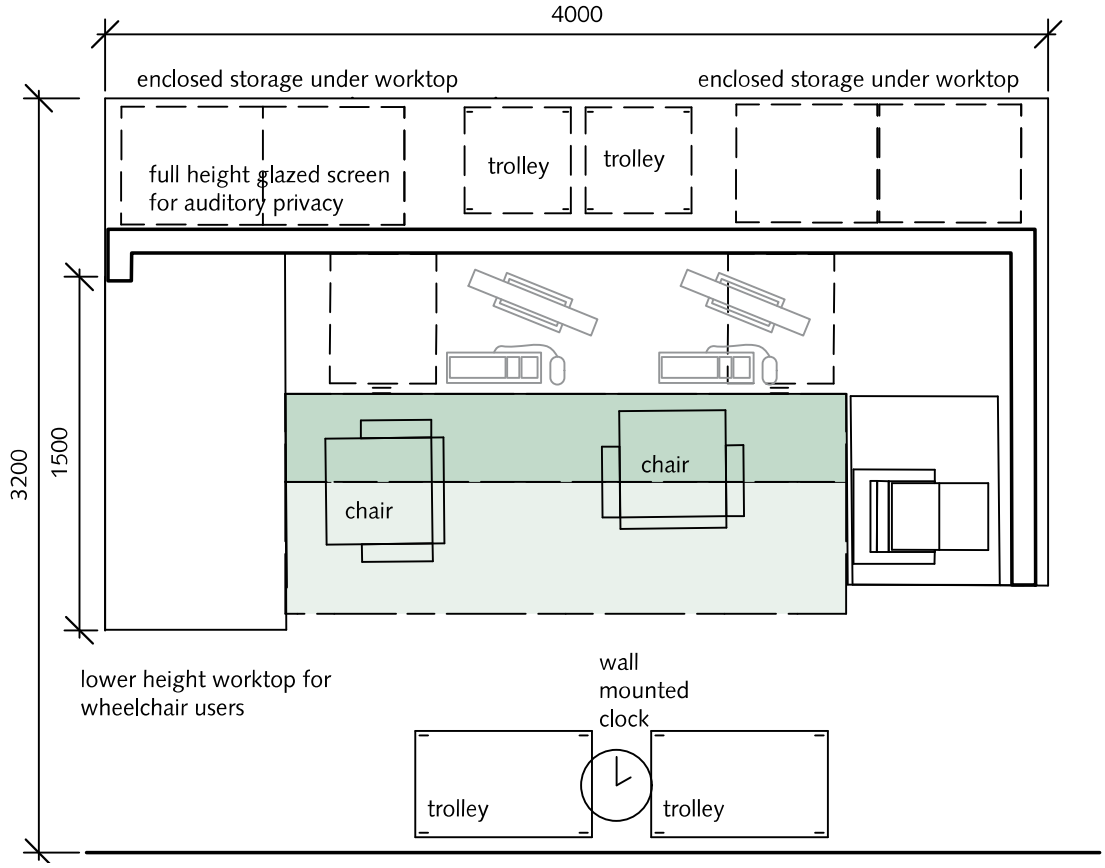

Figure 2 Critical care 2-place staff communication base

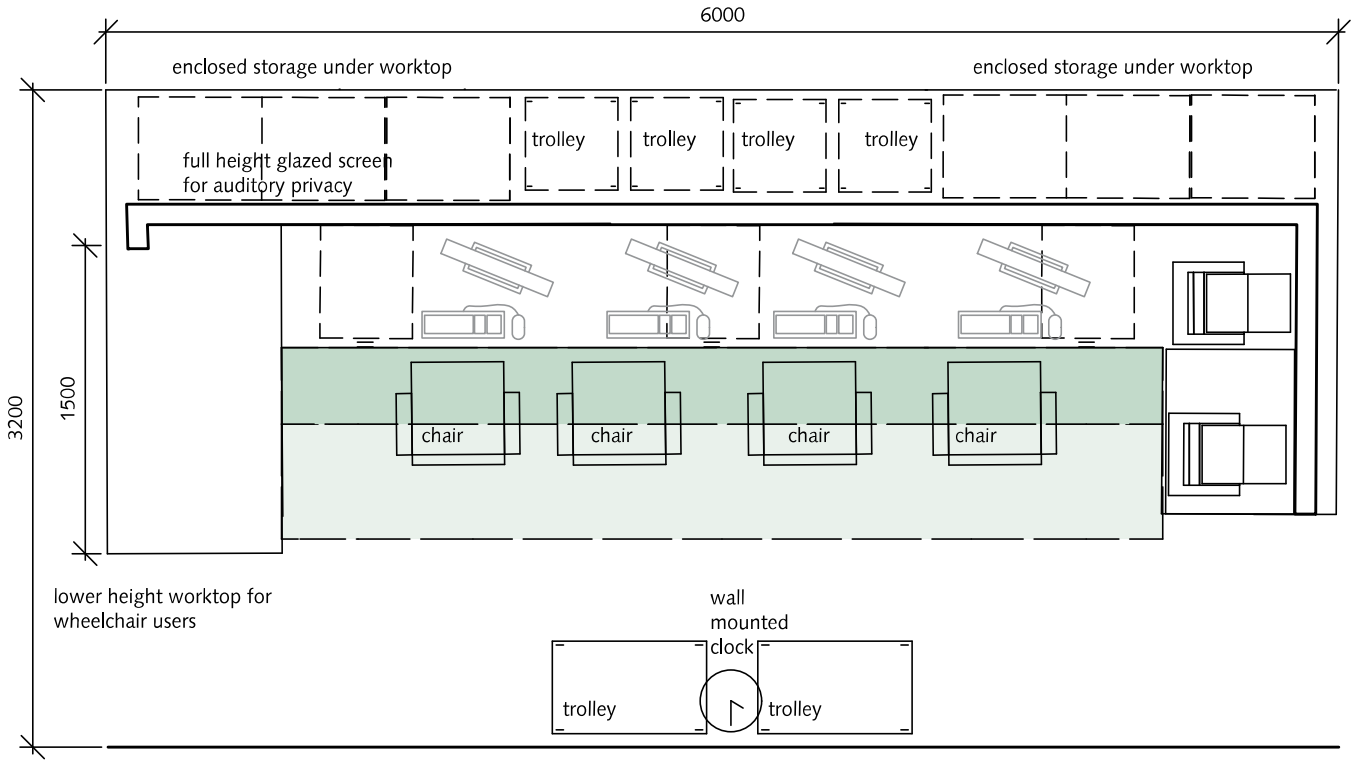

Figure 3 Critical care 4-place staff communication base

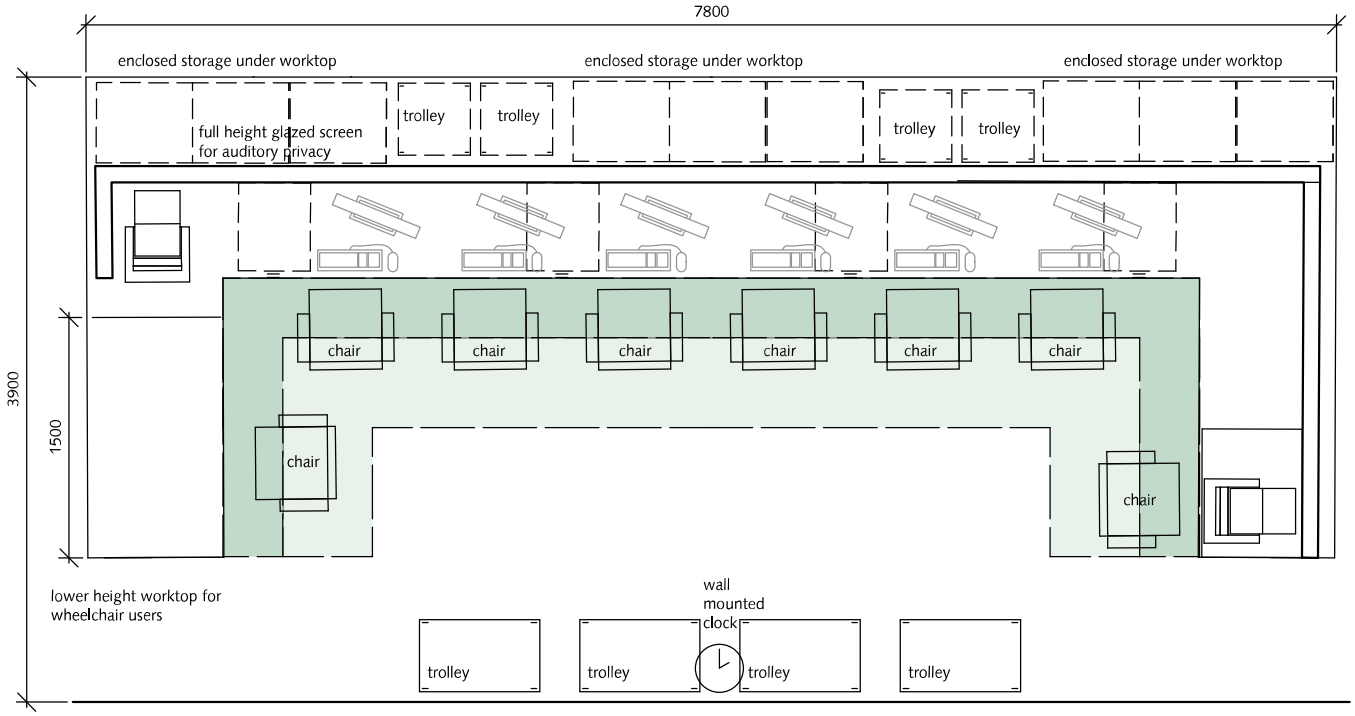

Figure 4 Critical care 8-place staff communication base

an airlock, requires a relatively high and balanced supply and extract air change rate to be effective against airborne organisms moving between circulation areas and isolation rooms.

6.7 Ceilings and windows should be sealed. Doors should be tight-fitting, with seals to minimise air transfer.

6.8 Isolation rooms should have local temperature controls that are accessible to nursing staff and may require humidity within the range 40–60% Rh, depending on the specialty.

6.9 The precise number of isolation rooms will depend on the case mix of the critical care unit. For example, units that routinely admit neutropenic haematology patients may require up to 50% of their beds to be provided as isolation rooms with lobbies. No unit should, however, have less than 20% of their beds as isolation rooms.

Multi-bed areas

6.10 A 2.5 m-wide unobstructed circulation space should be provided at the foot of each bed space. It is imperative to maintain the required bed separation for infection control reasons and to aid positioning of equipment.

6.11 The temperature in the multi-bed areas should be centrally controlled.

6.12 Requirements for scrub troughs should be determined locally based on patient case mix.

6.13 Project teams should select a curtain system that meets the following criteria:

- when the curtains are pulled around the bed space, there should be 100% visual privacy;
- it should be possible to pull the curtains back completely against the wall;

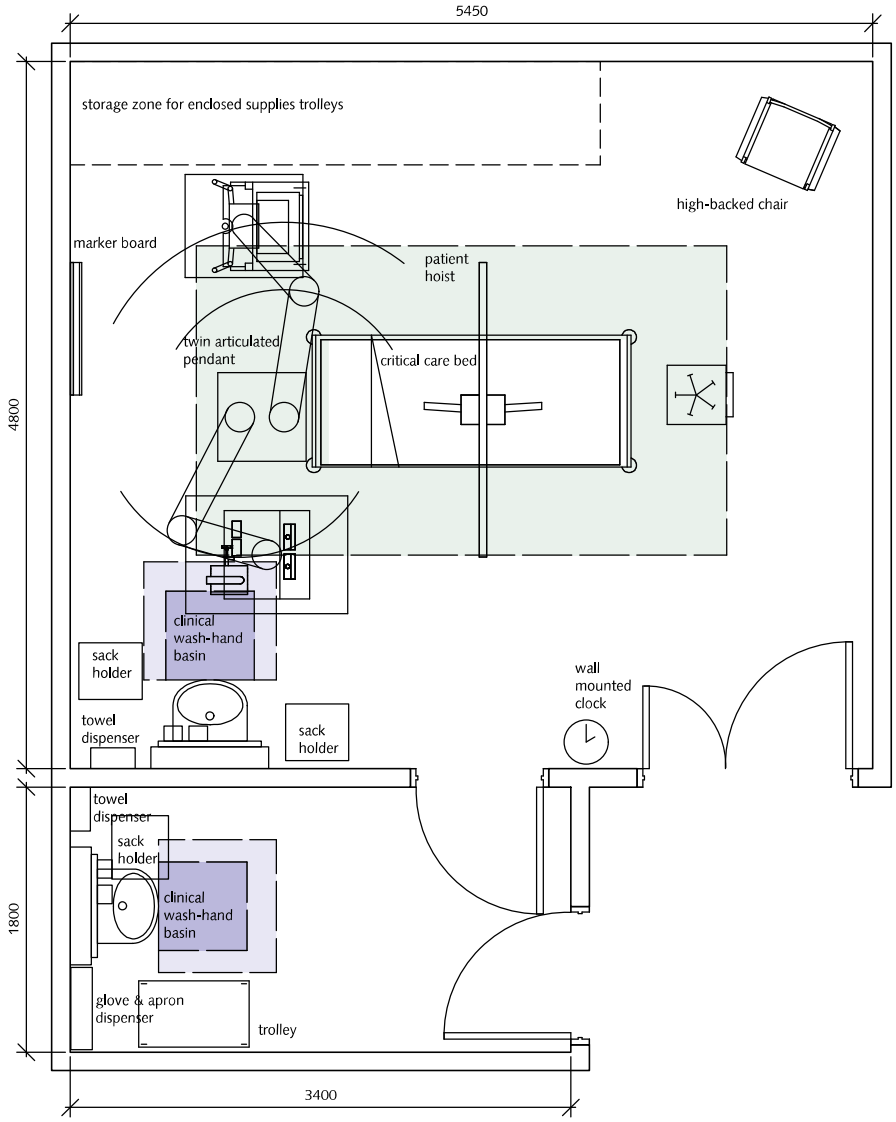

Figure 5 Critical care isolation room and lobby

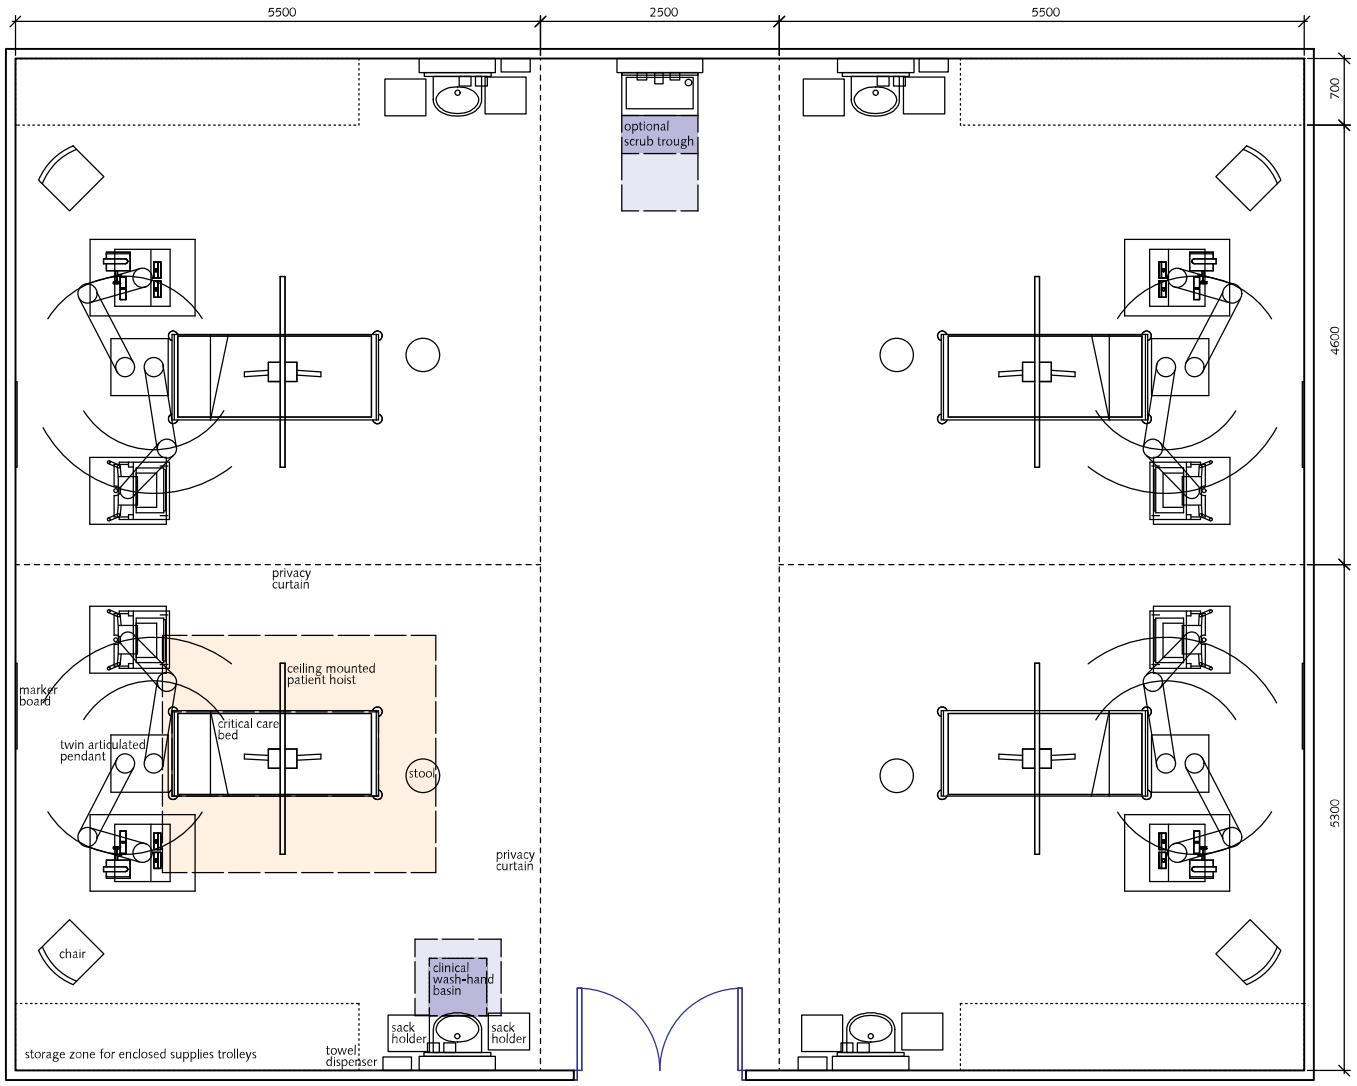

Figure 6 Critical care 4-bed bay

- the density of the curtains should reduce the level of general noise transmitted and also improve the level of auditory privacy in the bed-space;
- the curtains should be easily movable and disposable.

Interview rooms

6.14 Interview rooms should be provided within the vicinity of the bed spaces to enable staff to speak to visitors in privacy. The rooms should be in a quiet location.

7 Clinical support spaces

Ice-making machine bay

7.1 An industrial ice-making machine should be provided to facilitate hypothermic interventions. It should be located in a designated bay.

Storage for bulky consumables, medical gas cylinders, linen and furniture

7.2 The example schedules include a combined storage allowance for bulky consumables, medical gas cylinders, linen and furniture. However, these four categories of item should be stored separately. (It is assumed that non-bulky sterile supplies and consumables are held in the clean utility rooms.)

7.3 The project team should ensure that the provision of standby medical gases reflects the emergency procedures and contingency plans for the unit. The medical gas cylinder store(s) should be easily accessible from clinical areas and enclosed in fire-resisting construction.

7.4 The furniture store(s) will need to accommodate bulky equipment, including mattresses, when not in use, chairs, bariatric equipment and cots.

Clinical equipment store(s)

7.5 A dedicated area should be provided for the storage and charging of transfer equipment (transport trolley, monitors, syringes, ventilators, suction pumps). Dedicated ventilation may be required to remove gases and heat from chargers. An area for hanging endoscopes and transoesophageal echocardiography probes is also required. The clinical equipment store(s) should be within easy access of the bed areas.

Clinical equipment decontamination room

7.6 Clinical equipment should be cleaned following use prior to transfer to the clinical equipment store(s) or, if the equipment requires maintenance, to the equipment servicing room. A clinical equipment decontamination room should be provided for this purpose. This room should be adjacent to the clinical equipment store(s).

Imaging equipment bay

7.7 An open bay should be provided close to the clinical equipment store(s) for the storage of imaging equipment and protective lead aprons. A socket-outlet should be provided for charging equipment.

7.8 Lead aprons should be stored vertically to maintain their protective capability. Suitable wall brackets attached to a load-bearing wall, or mobile stands, are required for this purpose. The bay should also accommodate a mobile X-ray machine, a minimum of one ultrasound machine, and a transoesophageal echocardiography machine. A larger bay is required if mobile image intensifiers are used.

7.9 Regulations pertaining to the use of ionising radiation, such as IR(ME)R 2000 and IRR99, must be complied with.

Resuscitation trolley bays

7.10 It is essential that adequate provision is made for siting resuscitation trolleys within the critical care unit. The precise equipment positioned on these trolleys should be determined locally.

Blood refrigerator bay (optional)

7.11 A blood refrigerator will only be required if a blood store is not available nearby. If provided, the fridge should be located in a designated bay and should be networked to the central system to permit traceability of blood. The use of blood refrigerators is governed by national and local blood transfusion service regulations.

Clinical equipment service room (optional)

7.12 Facilities are required for equipment servicing as defined in equipment manufacturers' user manuals, supplemented by any formally agreed local instructions. A dedicated room should be provided in the critical care unit for this purpose if an existing biomedical engineering workshop is not located nearby. When provided as part of the critical care unit, this room should be adjacent to the clinical equipment decontamination room.

8 Staff spaces

1-person offices

8.1 The clinical director, lead nurse and Faculty of Intensive Care Medicine tutor require dedicated 1-person offices.

Admin areas

8.2 The following staff may require access to a workstation, but these may be provided in an open-plan office environment:

- clinical staff (doctors, nurses, allied health professions);
- outreach staff;
- audit clerk;
- technician;
- secretarial staff;
- IM&T staff;
- organ donation staff;
- research staff.

8.3 Workstations for clinical staff should provide quick and easy access to the patient bed areas in case of an emergency.

Seminar room

8.4 Access to a seminar room within the vicinity of the critical care unit must be provided. An intercom system should be installed between the seminar room and the clinical areas to recall staff in an emergency. The seminar room may double up as a skills laboratory, for example for training in resuscitation, using mannikins, defibrillators, and simulated body parts for venepuncture or suture practice.

Rest rooms

8.5 Staff rest rooms should be located far enough away from patient bed areas for staff to withdraw, but also close enough for them to return quickly to the patient bed areas in case of an emergency. Rest rooms require call systems to recall staff to the clinical areas in case of an emergency.

Changing areas

8.6 Space is required within the changing areas for the storage and disposal of scrub suits and footwear.

Delivering Same Sex Accommodation – Review of Health Building Note Guidance

The Department of Health's Delivering Same-Sex Accommodation (DSSA) programme aims to all but eliminate mixed-sex accommodation from hospitals in England by 2010. Although DSSA is primarily an operational issue, the design and layout of healthcare facilities can help support the provision of same-sex accommodation. With this in mind, the Department's Health Building Note (HBN) series of publications has been reviewed against DSSA requirements.

Amendments have been made to this document at **paragraph 3.41**.

This review makes particular reference to the letter (PL/CNO/2009/2) from the Chief Nursing Officer and Director General NHS Finance, Performance and Operations at:

www.dh.gov.uk/en/Publicationsandstatistics/Lettersandcirculars/Professionalletters/Chiefnursingofficerletters/DH_098894

Full details of the DSSA programme are at:

Preface

About Health Building Notes

Health Building Notes give "best practice" guidance on the design and planning of new healthcare buildings and on the adaptation/extension of existing facilities.

They provide information to support the briefing and design processes for individual projects in the NHS building programme.

Restructuring of the Health Building Note suite

Healthcare delivery is constantly changing, and so too are the boundaries between primary, secondary and tertiary care. The focus now is on delivering healthcare closer to people's homes.

The traditional division of Health Building Notes into discrete books of information based on hospital departments is therefore no longer appropriate.

Instead, the new Health Building Note framework (shown below) is based on the patient's experience across the spectrum of care from home to healthcare setting and back, using the national service frameworks (NSFs) as a model. This structure better reflects current policy and service delivery.

New Health Building Note structure

The Health Building Notes have been organised into a suite of 17 core subjects.

Care-group-based Health Building Notes will provide information about a specific care group or pathway but will cross-refer to Health Building Notes on **generic (clinical) activities** or **support systems** as appropriate.

Core subjects will be subdivided into specific topics and classified by a two-digit suffix (-01, -02 etc), and may be further subdivided into Supplements A, B etc.

All Health Building Notes are supported by the overarching Health Building Note 00 in which the key areas of design and building are dealt with.

Example

The Health Building Note on accommodation for adult in-patients will be represented as follows:

> "Health Building Note 04-01: Adult in-patient facilities"

The supplement to Health Building Note 04-01 on isolation facilities will be represented as follows:

> "Health Building Note 04-01: Supplement A – Isolation facilities in acute settings"

New Health Building Note number and series title	Type of Health Building Note
Health Building Note 00 – Core elements	Support-system-based
Health Building Note 01 – Cardiac care	Care-group-based
Health Building Note 02 – Cancer care	Care-group-based
Health Building Note 03 – Mental health	Care-group-based
Health Building Note 04 – In-patient care	Generic-activity-based
Health Building Note 05 – Older people	Care-group-based
Health Building Note 06 – Diagnostics	Generic-activity-based
Health Building Note 07 – Renal care	Care-group-based
Health Building Note 08 – Long-term conditions/long-stay care	Care-group-based
Health Building Note 09 – Children, young people and maternity services	Care-group-based
Health Building Note 10 – Surgery	Generic-activity-based
Health Building Note 11 – Community care	Generic-activity-based
Health Building Note 12 – Out-patient care	Generic-activity-based
Health Building Note 13 – Decontamination	Support-system-based
Health Building Note 14 – Medicines management	Support-system-based
Health Building Note 15 – Emergency care	Care-group-based
Health Building Note 16 – Pathology	Support-system-based

Other resources in the DH Estates and Facilities knowledge series

Health Technical Memoranda

Health Technical Memoranda give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare (for example medical gas pipeline systems, and ventilation systems).

They are applicable to new and existing sites, and are for use at various stages during the inception, design, construction, refurbishment and maintenance of a building.

All Health Building Notes should be read in conjunction with the relevant parts of the Health Technical Memorandum series.

Health Technical Memorandum Building Component series

All Health Building Notes refer to Health Technical Memorandum Building Component documents for specifications and design guidance on building components for healthcare buildings. All Health Building Notes should therefore be read in conjunction with the relevant parts of the Health Technical Memorandum Building Component series.

Activity DataBase (ADB)

The Activity DataBase (ADB) data and software assists project teams with the briefing and design of the healthcare environment. Data is based on guidance given in the Health Building Notes, Health Technical Memoranda and Health Technical Memorandum Building Component series.

1. Room data sheets provide an activity-based approach to building design and include data on personnel, planning relationships, environmental considerations, design character, space requirements and graphical layouts.
2. Schedules of equipment/components are included for each room, which may be grouped into ergonomically arranged assemblies.
3. Schedules of equipment can also be obtained at department and project level.
4. Fully loaded drawings may be produced from the database.
5. Reference data is supplied with ADB that may be adapted and modified to suit the users' project-specific needs.

For further information please refer to the Space for Health website: www.nhs.uk/spaceforhealth.

How to obtain publications

- To find out about publications that are finalised and currently being published, look under "Publications" on the Space for Health website at: www.nhs.uk/spaceforhealth.
  NOTE that users should also check this site for latest versions of all publications, including Health Building Notes, and for any amendments to publications.
- Hard copies of published documents are also available from Space for Health.

For further information, contact Jock Graham on 0113 346 6071; email: jock.graham@coi.gsi.gov.uk.

Note

The new Health Building Notes have been progressively rolled out from spring 2007 onwards.

The sequence of numbering within each subject area does not necessarily indicate the order in which the Health Building Notes will be published/printed. However, the overall structure/number format will be maintained as described.

To find out how to access information on published documents, see the "How to obtain publications" section.

Acknowledgements

The Department of Health would like to acknowledge the help and advice kindly given by all the contributors to this guidance, including directors of nursing, infection control specialists, healthcare planners and nursing representatives from a variety of NHS trusts.

The Department of Health also wishes to express thanks to those who contributed to the en-suite shower room research project:

Leaderflush Shapland

Ophardt Products

Hillingdon Hospital NHS Trust

Significant changes since the 1997 edition of this guidance

Health Building Note 4 (1997) 'In-patient accommodation: Options for choice' provided an evidence-based approach to the planning of facilities, which was based on providing a minimum of 50% single-bed rooms. In this respect the new edition has not changed. Further evidence has been gathered on the benefits of single-bed rooms and, in addition, an ergonomic study has established how much space is needed around the hospital bed for various tasks. The results have shown that the provision of a minimum clear space around the bed is essential in achieving an efficient and effective environment. The full report is entitled 'Ward layouts with single rooms for space and flexibility' (DH, 2005).

In addition, a study has been carried out to determine a space-efficient layout for an en-suite shower room for a single-bed room that meets the needs of the majority of patients. The study resulted in two new layouts for an en-suite shower room, both of which are referred to in this guidance.

In 2001, as part of the consumerism agenda to deliver the NHS Plan, the Departmental Cost Allowance Guides (DCAGs) were reviewed. The review concluded that an additional 2.5 m^2 per bed should be added to the schedules of accommodation for single-bed rooms and multi-bed rooms.

Since the 1997 edition the following changes have been made:

1. Single-bed rooms. The size of single-bed rooms has increased from 21 m^2 to 23.5 m^2 as a result of the review of DCAGs, which added 2.5 m^2 to each bed space.
2. Multi-bed rooms. The size of multi-bed rooms has increased from 60 m^2 to 72.5 m^2 as a result of:
    a. the 2001 review of DCAGs, which added 2.5 m^2 to each bed space;
    b. the impact of the Disability Discrimination Act, which requires that sanitary facilities should be provided for independent users and those requiring assistance from staff. As a result the assisted shower room, which now includes a WC as well as a shower and wash-hand basin, has increased in area from 4.5 m^2 to 6.5 m^2. This has increased the overall dimensions of the multi-bed room.
3. Space increase around the bed. The minimum recommended clear space around the bed is now 3600 mm (width) × 3700 mm (depth). This can be achieved within the new space allowances for single-bed rooms and multi-bed rooms.
4. En-suite sanitary facilities for single-bed rooms. The recommended new en-suite shower room layouts for a single-bed room are the same dimensions as in previous guidance but they are more flexible in terms of use and accessibility. They are suitable for ambulant and semi-ambulant patients, the majority of independent wheelchair users, and patients requiring assistance from staff.
5. Isolation suites. Single-bed rooms provide effective isolation for many patients. In some cases, however, a greater degree of isolation may be required. Health Building Note 4 Supplement 1 – 'Isolation facilities in acute settings' gives detailed guidance on isolation suites (bedroom, en-suite sanitary facilities, and lobby).
6. Dirty utility rooms. Ideally, a dirty utility room should serve no more than 15 beds. This reduces travel distances for staff, making better use of nursing time and reducing the risk of spillage and cross-contamination. A second dirty utility room on a ward is also helpful during outbreaks of illness or infectious diseases. Dirty utility rooms in previous guidance served 24 to 30 beds.
7. Schedules of accommodation. The previous Health Building Note was based on a modular approach to planning. The schedules of accommodation were presented in modules for eight-bed clusters. This guidance is based on 24 beds, which provides a typical example of an average-sized ward. Where smaller or larger wards are required, design teams can adapt the guidance to suit local clinical need.

Summary of changes in space requirements for a single-bed room since 1997

Area	HBN 04 1997 (m^2)	Healthcare Capital Investment (Consumerism) (m^2)	Difference (m^2)	Schedules of Accommodation 2003 (m^2)	HBN 04-01 2009 (m^2)	Difference (m^2)
Single-bed room	13.5	16.0		16.0	19.0	
Family and clinical support area	3.0	3.0		3.0	included above	
Sub-total	16.5	19.0	+ 2.5	19.0	19.0	0.0
En-suite shower room	4.5	4.5	0.0	4.5	4.5	0.0
Total single-bed room	**21.0**	**23.5**	**+ 2.5**	**23.5**	**23.5**	**0.0**

Summary of changes in space requirements for a multi-bed room since 1997

Area	HBN 04 1997 (m^2)	Healthcare Capital Investment (Consumerism) (m^2)	Difference (m^2)	Schedules of Accommodation 2003 (m^2)	HBN 04-01 2009 (m^2)	Difference (m^2)
4-bed room	48.0	58.0		58.0	64.0	
Clinical support area	3.0	3.0		3.0	included above	
Sub-total	51.0	61.0	+ 10.0	61.0	64.0	+ 3.0
En-suite assisted shower & wash	4.5	4.5	0.0	4.5	not included	– 4.5
En-suite assisted WC/ wash	4.5	4.5	0.0	4.5	not included	– 4.5
Assisted shower room (en-suite)	not included	not included		not included	6.5	+ 6.5
Semi-ambulant WC without luggage space (en-suite)	not included	not included		not included	2.0	+ 2.0
Total 4-bed room	**60.0**	**70.0**	**+ 10.0**	**70.0**	**72.5**	**+ 2.5**

Executive summary

This Health Building Note provides best practice guidance on the planning and design of in-patient facilities for adults. The accommodation described includes:

- bed and sanitary facilities;
- patient support facilities;
- storage facilities;
- utility facilities;
- administration area and staff facilities.

The recommended space standards for bed areas are applicable to in-patient rooms in any setting, including acute, day surgery and community facilities.

The schedules of accommodation for this Health Building Note are based on a 24-bed ward, with options for 50%, 80% and 100% single-bed rooms.

This best practice guidance essentially applies to new-build facilities. However, the principles are equally valid, and should be applied, when existing accommodation is being upgraded or new accommodation is being constructed within an existing building that may previously have been used for other purposes.

The document gives guidance on general and specific design considerations in patient and support areas. It also covers general functional design requirements and engineering services.

Example room layouts are provided in the appendices along with a comprehensive list of references.

Contents

1 Introduction

1.1 This Health Building Note, which replaces Health Building Note 4 (1997 and 2008 editions), provides guidance on the planning and design of in-patient facilities for adults.

1.2 The space standards for bed areas are applicable to in-patient rooms in any setting, including acute (critical care at levels 1 and 0[1]), day surgery and community facilities.

1.3 The schedules of accommodation for this Health Building Note are based on a 24-bed ward, with options for 50%, 80% and 100% single-bed rooms. The 24-bed ward is provided only as an example of a typical ward, although the 50% option is the recommended minimum for single-room accommodation. Planning teams should determine the number of beds per ward and the percentage of single-bed rooms based on local clinical need.

Policy background

Impact of the 2006 White Paper on in-patient accommodation

1.4 The 2006 White Paper 'Our health, our care, our say: a new direction for community services' (DH 2006) signalled a shift of care into community settings. This includes activity that can be safely and effectively provided outside the acute hospital. In-patient accommodation remains largely in acute settings, particularly for complex cases or where major surgery requiring general anaesthesia is required. However, in-patient accommodation may also be provided in community settings for those patients with less complex conditions. Planning teams will need to consider the number of in-patient beds required and where they may be most appropriately located.

Patient expectations and choice

1.5 Patients will have higher expectations of the environment in which they are to be treated and more say about how and where healthcare is provided, as reflected in 'Creating a Patient-led NHS' (DH 2005). The provision of high-quality facilities, with the option of a single-bed room, is likely to be an influencing factor on patient choice in the near future.

1.6 A key element that should be addressed in all patient accommodation is that of privacy and dignity. 'The Essence of Care' (DH 2001) identified several benchmarks of good practice, focusing on the issue of respect for the individual so that:

- patients feel that they matter all of the time;
- patients experience care in an environment that actively encompasses individual values, beliefs and personal relationships;
- patients' personal space is actively promoted by all staff;
- communication between patients takes place in a manner that respects their individuality;
- the care of patients actively promotes their privacy and dignity and respects their modesty, including gender segregation; and
- patients can access an area that safely provides privacy.

1.7 See also 'Privacy and dignity – a report by the Chief Nursing Officer into mixed sex accommodation in hospitals' (DH 2007).

Prevention of healthcare-associated infection

1.8 Planning teams should note the contents of the Health Act 2006: Code of practice for the

1 Levels of critical care as described in 'Comprehensive critical care' (DH 2000):
Level 1 Patients at risk of their condition deteriorating, or those recently relocated from higher levels of care, whose needs can be met on an acute ward with additional advice and support from the critical care team.
Level 0 Patients whose needs can be met through normal care in an acute hospital.
For higher levels of critical care see Health Building Note 57 – 'Facilities for critical care'

prevention and control of healthcare associated infections (DH 2008). This code of practice sets out criteria by which managers of NHS organisations are to ensure that patients are cared for in a clean environment and where the risk of healthcare-associated infections is kept as low as possible. The document contains a comprehensive list of the Department's guidance on the prevention of healthcare-associated infection. See www.dh.gov.uk/en/Publicationsandstatistics/Publications/PublicationsPolicyAndGuidance/DH_081927.

Scale of provision

1.9 The number of patients admitted to hospital each year depends on local workload patterns. The number of bed spaces required will be calculated from factors such as:

- data on number of admissions, number of refused admissions, number of premature discharges, bed occupancy and length of stay;
- local admissions policy;
- future developments influencing demand for acute services, for example increasing day case surgery rates, improved chronic disease management, and the potential for more care at home;
- availability of beds in other settings, for example community hospitals.

Evidence base for this guidance

1.10 Since the previous editions of this guidance (1997 and 2008), considerable work has been carried out to establish how much space is needed around a bed for patient and staff safety, accessibility and clinical need. The full report on this work, which comprised literature reviews, ergonomic studies and mock-up trials, is published in 'Ward layouts with single rooms and space for flexibility' (DH 2005).

1.11 In addition, with the need for accessibility to en-suite sanitary facilities and the implications for increasing space, an evidence-based study has been carried out to design an en-suite shower room that will meet the needs of the majority of patients without increasing current space standards. The result of this work is available through the UKHOs' "Space for Health" website at www.nhs.gov.uk/spaceforhealth.

2 General functional and design considerations

Location and departmental relationships

2.1 Historically, in-patient accommodation has been the core of the hospital. Although current trends in the delivery of health services have eliminated in-patient care for some patients who previously would have been admitted, in-patient accommodation still accounts for a significant proportion of space in a hospital.

2.2 Patients who are admitted are often acutely ill and in need of observation. One of the primary goals of designers, therefore, is to minimise the distance between patient rooms and staff workstations, and the distances between all patient rooms.

2.3 Traditionally, in-patient accommodation has been located either above the diagnostic and treatment floors of a hospital or adjacent to them. Critical care beds are prioritised to be closest to surgical or medical interventions, whereas rehabilitation and long-stay beds can be significantly further away from the core clinical services. Beds can be organised horizontally over large floor areas or stacked into towers. A recent tendency in the UK has been to put beds into multi-storey wings that are separate from diagnostic and treatment facilities. This allows more consistent planning of in-patient accommodation, increases flexibility in the way that beds can be organised, and enables maintenance and refurbishment to be carried out more easily.

2.4 The location of wards needs to ensure privacy, particularly at night. Ground-floor locations should be considered only where the adjacent environment is free of hospital traffic and publicly accessible areas. Views outside, together with access to sunshine or direct daylight, have been shown to benefit a patient's recovery. The orientation and aspect of in-patient accommodation should be prioritised when developing a hospital masterplan.

2.5 The ability to isolate components of in-patient accommodation is important for infection control, particularly during outbreaks of infectious illness. It is also important in the event of a fire or other emergency, when patients will generally be evacuated to a safe space on the same floor.

2.6 The ability to combine clusters of beds will allow for different needs over time. Support facilities can be more flexibly located.

2.7 Because in-patient accommodation is such a large component of the hospital, its departmental relationships are mostly dependent on the number and location of access points, lifts, and distance from diagnostic and treatment facilities. Small, discrete and specialist wards such as oncology will require direct access to their own specialist diagnostic and treatment centre within the whole hospital or within the same floor.

Key features of a desirable environment

2.8 Studies (Malkin J, 1992 and Scher P, 1996) have shown that the following features are necessary to provide a desirable in-patient environment:

- Space for:
  - clinical activity at the bedside
  - clinical activity elsewhere
  - storage/display of patients' possessions
  - storage of bulky equipment
  - staff support and training
  - social support of patient
- Suitability of:
  - services and supplies at the bedside for clinical activity
  - access to and within area for physically and sensory impaired people
  - services to enable personal communication by patient
  - services to enable direct admin/clinical communication from the bedside

  - a reassuring, stress reducing, environment
  - a safe and hazard free facility
- Privacy:
  - during clerking and clinical discussions between patient and staff
  - during clinical treatment
  - for bodily functions and personal care
  - for personal discussions and telephone calls
  - for staff communications
  - for staff rest and beverage breaks
- Choice, control, comfort:
  - to be alone or in company, including visitors
  - of temperature, ventilation, lighting and sound
  - of diversion, outlook, entertainment
  - with access to beverages for patients and relatives
  - with local storage of personal belongings of staff
  - with access to the outside world.

Space requirements

2.9 The provision of sufficient space in clinical areas, particularly for each bed space, is one of the most important considerations in the planning and design of in-patient accommodation. Ergonomic studies have established that most activities carried out at the bedside can be accommodated within the dimensions 3600 mm (width) × 3700 mm (depth). This represents the clear bed space and does not include space for fixed storage, preparation and worktops. Space requirements are discussed more fully in Chapter 3.

Sanitary facilities

2.10 For infection control purposes, in-patients, clinical staff and visitors should be provided with separate sanitary facilities, which should be clearly labelled. Facilities for visitors and non-clinical staff should be located close to the ward reception and waiting area. Sanitary facilities for clinical staff may be provided in association with staff changing and rest room areas. Where staff changing and rest rooms are located away from the ward, a designated WC for clinical staff should be provided. Sanitary facilities for in-patients should be located en-suite to bed areas.

2.11 All single-bed rooms and multi-bed rooms should have en-suite sanitary facilities. The increasing acuity of illness of in-patients means that a great proportion of patients may require assistance during their hospital stay. For greatest flexibility of use, all sanitary facilities in in-patient areas should be accessible and manageable by people with physical or sensory disabilities with or without assistance.

2.12 As part of the revision of this Health Building Note the Department of Health commissioned research into the size and layout of en-suite shower rooms to identify a space-efficient design that would, as far as possible, meet the needs of the majority of patients. It was acknowledged during the research that some aspects of ambulant/semi-ambulant/independent wheelchair access and assisted use are not compatible. For example, the provision of a hand-rinse basin next to the WC for independent wheelchair users would have conflicted with access for patients requiring assistance. As the number of patients requiring assistance is likely to be greater than the number of independent wheelchair users in in-patient accommodation, the primary concern should be to provide space and facilities for people requiring assistance. Certain limitations on independent access are therefore considered acceptable within a healthcare setting.

2.13 The new layout for an en-suite shower room forms the basis for the guidance and example layouts in this Health Building Note. There should also be access to a fully assisted bathroom or shower room where shower trolleys may be used. This could be shared between wards and is listed as essential complementary accommodation in the schedules of accommodation. Alternative layouts for en-suite sanitary facilities are described in Health Building Note 00-02 – 'Sanitary spaces'.

2.14 The research project to develop the new en-suite shower room design is described on the Space for Health website at www.nhs.gov.uk/spaceforhealth.

Hand hygiene

2.15 Antibacterial hand-rub dispensers should be provided at the ward entrance.

2.16 Each single-bed room should contain a clinical wash-hand basin. The basin should be located to be highly visible to staff entering and leaving the room

and convenient for them to use. The use of sensor taps may be appropriate to reduce the risk of infection. Multi-bed rooms should contain two clinical wash-hand basins, one close to the entrance to the room and the other placed in a convenient position for staff working at the other end of the room. The multi-bed room layout in Appendix 1 indicates the possible location of clinical wash-hand basins.

2.17 For further guidance on clinical wash-hand basins refer to HTM 64 – 'Sanitary assemblies' and Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Isolation facilities

2.18 Single-bed rooms provide an effective facility for isolating patients with a variety of infections, such as MRSA. However, in some circumstances it may be necessary to provide a higher level of isolation, particularly for those patients with airborne diseases or for immuno-suppressed patients who may be at risk of infection from others. In these cases, an isolation suite – which includes an entrance lobby, bedroom and en-suite sanitary facilities – will be required. This is listed as optional in the schedule of accommodation for this Health Building Note. The need for and number of isolation suites should be decided locally and in consultation with local Health Protection Agency staff.

2.19 Isolation suites are described in paragraph 3.29.

Cleaning services

2.20 Recent research ('An integrated approach to hospital cleaning', DH 2007) indicates that a microfibre system for day-to-day cleaning in combination with periodic steam cleaning is an effective approach to cleaning in-patient facilities. The guidance in this Health Building Note is based on this approach. If other cleaning systems are to be adopted, design teams should give careful consideration to the facilities required in each case.

2.21 In terms of facilities, a microfibre system requires:

- space for storing the microfibre cleaning trolley and clean microfibre cloths and mops (the cleaners' room, see paragraph 3.57);
- space for holding dirty microfibre cloths (the disposal hold, see paragraph 3.59);
- laundry facilities for washing and drying used microfibre cloths.

2.22 The laundering of microfibre cloths and mops requires special conditions and dedicated facilities. The laundry process should be carefully managed. Project teams should decide locally whether laundry facilities are provided in-house or contracted out. More information on the laundering of microfibre cloths is contained in the research and development report, available through the Space for Health website at www.nhs.gov.uk/spaceforhealth.

2.23 A supply of disposable cleaning materials should also be stored for clinical staff to use when cleaning staff are not available. These may be held separately in the dirty utility room.

2.24 This Health Building Note assumes that steam cleaning equipment for periodic deep cleaning will be stored centrally and brought to the ward as required. Storage space for this equipment on the ward is not required.

Decontamination of equipment

2.25 The effective decontamination of medical devices is essential in reducing the risks to patients from HCAI (see the Health Act 2006: Code of practice for the prevention and control of healthcare associated infections). Facilities for decontaminating medical devices should be provided centrally.

2.26 Reference should be made to advice and guidance in HTM 01-01 – 'Decontamination of reusable medical devices' (DH 2007). Further information can be obtained from the Medicines and Healthcare products Regulatory Agency (MHRA) – see www.mhra.gov.uk/Safetyinformation/Generalsafetyinformationandadvice/Technicalinformation/Decontaminationandinfectioncontrol/CON019632.

2.27 Reference should also be made to Health Building Note 13 – 'Sterile services department' and Health Facilities Note 30 – 'Infection control in the built environment'.

Ward size

2.28 The schedule of accommodation for this Health Building Note is based on a ward of 24 beds.

2.29 The 24-bed ward has been selected as an example only, chiefly because this size is common throughout NHS hospitals. It also supports the assumption that an eight-bed cohort is the preferred workforce planning unit, with one

clinician and one support worker caring for each cohort, although this may vary according to the dependency level of patients in a cohort. Wards may be larger or smaller than the 24-bed example. The number of beds in each ward should be determined locally.

Observation and communication

2.30 Clinical staff should be able to observe and communicate easily with patients. Some clinicians may feel that single-bed rooms make observation more difficult, whereas others find that engagement with patients improves in a single-room environment because they are able to complete a whole episode of care privately without being disturbed by others.

2.31 Careful design can support good observation. For example, glazed walls or very large windows between rooms and corridors will enable staff to observe patients and, equally importantly, patients to see staff. Views into busy internal spaces such as circulation areas can provide a distraction for patients and are just as important as views of the outside world. Patients should have the means to obscure windows if required. For example, integral Venetian blinds can be lowered and closed to provide privacy.

2.32 In addition to observation through windows, the use of electronic surveillance equipment such as cameras may be considered. However, in order to guard against the potential invasion of privacy, patients must be able to choose whether cameras in their bedroom are switched on or off. In particular, the dignity and safety of patients with mental health conditions and patients who may be in a state of confusion should be carefully considered.

2.33 Use of a two-way speech facility as part of the help call system can be reassuring for patients and can reduce journey times for staff.

2.34 Two-way speech facilities can be made significantly more effective by including an option to enable staff to key in and out of rooms (staff presence). Smart technology allows such systems to be automated so that each member of staff wears a radio frequency identification (RFID) tag that remotely indicates their presence. This function allows staff to locate, and communicate with, each other more effectively. These facilities are particularly relevant in wards with a high

Figure 1 An example of good observation into a single-bed room

percentage of single rooms. Call systems should operate on a "follow the light" principle whereby over-door lights and discrete indicator units mounted at strategic positions (staff rest rooms etc) guide staff to the call origin. In addition this can be supplemented by the use of Wi-Fi/IP technology, which can be interfaced with other site communication facilities (for example single staff handset, which combines phone, pager, cardiac and help call facilities).

Clinical administration

2.35 Advances in IT are enabling clinicians to move away from traditional paper-based patient records towards more flexible computer-based systems. Electronic patient records (EPR) and picture archiving and communication systems (PACS) mean that a significant amount of direct clinical administration can now take place at the bedside using a computer.

2.36 Wireless and infra-red technologies provide an alternative to networked computers in fixed locations. They enable EPRs to be accessed from laptops and other mobile and hand-held devices that can move with staff between clinical spaces. Where computers are fixed in bed areas, design teams should ensure that patients will not be disturbed by the light from VDUs or by staff entering data at night-time.

2.37 This Health Building Note describes two locations for clinical administration close to the patient:

- in bedrooms: a clinical support zone with space for recording clinical data. In multi-bed rooms, one clinical support zone serving all four beds is sufficient;
- touchdown base: a workstation located close to patients but not within single rooms or multi-bed rooms. This is where EPRs can be accessed and updated. The touchdown base is at standing height with a perching stool. There should be a number of touchdown bases throughout the ward, which may be located in a variety of ways:
  - a dedicated touchdown base immediately outside each bedroom; or
  - a touchdown base shared between a pair of bedrooms; or
  - a touchdown base serving a small cluster of bedrooms.

2.38 This Health Building Note assumes that there is no central staff base, as staff will be working locally throughout the ward unit. It is recognised, however, that this is only one design solution and

Figure 2 Working at a touchdown base

that planning teams may wish to include a central staff base. For guidance on staff communication bases, refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

2.39 The greeting of patients and visitors, and general administration, will be carried out at the ward reception desk by clerical staff. Depending on the layout of wards, the reception desk could be shared between two or more wards.

2.40 Pre-admission and post-discharge correspondence, private telephone calls and patient handover meetings may take place in the office/meeting room.

2.41 See Chapter 3 for detailed descriptions of clinical administration spaces.

Moving and handling patients

2.42 Patient moving/handling tasks are associated with the greatest proportion of musculoskeletal disorders in the health services (HSE 2001). One way of avoiding such injury is to move patients by use of a hoist, which requires sufficient space around the bed for staff to perform these tasks.

2.43 If mobile hoists are to be used, design teams should ensure that there is sufficient space within the ward to store them. Other devices for transferring patients will also need to be stored.

2.44 If ceiling-mounted hoists are preferred, design teams will need to consider the potential conflict with medical service units and patient entertainment systems. Consideration should also be given to the "parking" of the hoist sling when not in use. Where ceiling-mounted hoists are installed, there will still be a need for some mobile hoists, for example for lifting patients who may have fallen beyond the reach of the ceiling track. Design teams will need to consider adequate storage space for these.

2.45 The use of ceiling-mounted hoists in isolation suites requires careful consideration. See paragraph 3.31.

2.46 In multi-bed rooms, the hoisting of patients around the bed space may compromise their privacy and dignity. The use of hoists should be restricted to bed-to-chair/trolley/wheelchair transfers only.

2.47 The decision on the extent of lifting equipment provided will depend on several factors including the patient profile, and should be decided locally.

2.48 For further guidance on the space required for moving and handling patients see 'Ward layouts with single rooms and space for flexibility'.

Separate treatment room

2.49 In a ward of 100% single-bed rooms the provision of a separate treatment room is optional, as procedures that cannot be undertaken at the patient's bedside will take place in the appropriate departments. Wards with a combination of single-bed rooms and multi-bed rooms will require a separate treatment room. For further guidance see paragraph 3.35.

Supplies, storage and disposal

2.50 Supplies, storage and disposal are whole-hospital issues. An increasing number of UK hospitals have adopted a "just-in-time" supplies system, which involves a large centralised store on each site where all non-specialised clinical supplies are kept for regular distribution on a "top-up" basis to the different departments when required. Local policy will influence how much storage space is needed within acute wards.

2.51 Two options for delivering and storing clean supplies and consumables are:

- **Option 1: Local clean utility room**

  Each ward contains a clean utility room, which is restocked regularly from the hospital's central stores and pharmacy. Clinical supplies for individual bedrooms are held on supplies trolleys, which are topped up in the clean utility room and then parked in the clinical support area of each bedroom. Medicines are stored and prepared in the clean utility room. See Figure 3.

- **Option 2: Shared clean supply room plus local medicine store/preparation room**

  Clinical supplies are stored in a clean supply room serving a number of wards. Clinical supplies trolleys are restocked here and then returned to patient bedrooms where they are parked in the clinical support area. Medicines are stored and prepared separately in the ward's medicine store/preparation room. See Figure 4.

2.52 The schedules of accommodation for this Health Building Note are based on Option 2, that is, the provision of a shared clean supply room (essential complementary accommodation) and a local medicine store/preparation room. The provision of

Figure 3 Central store and clean utility room

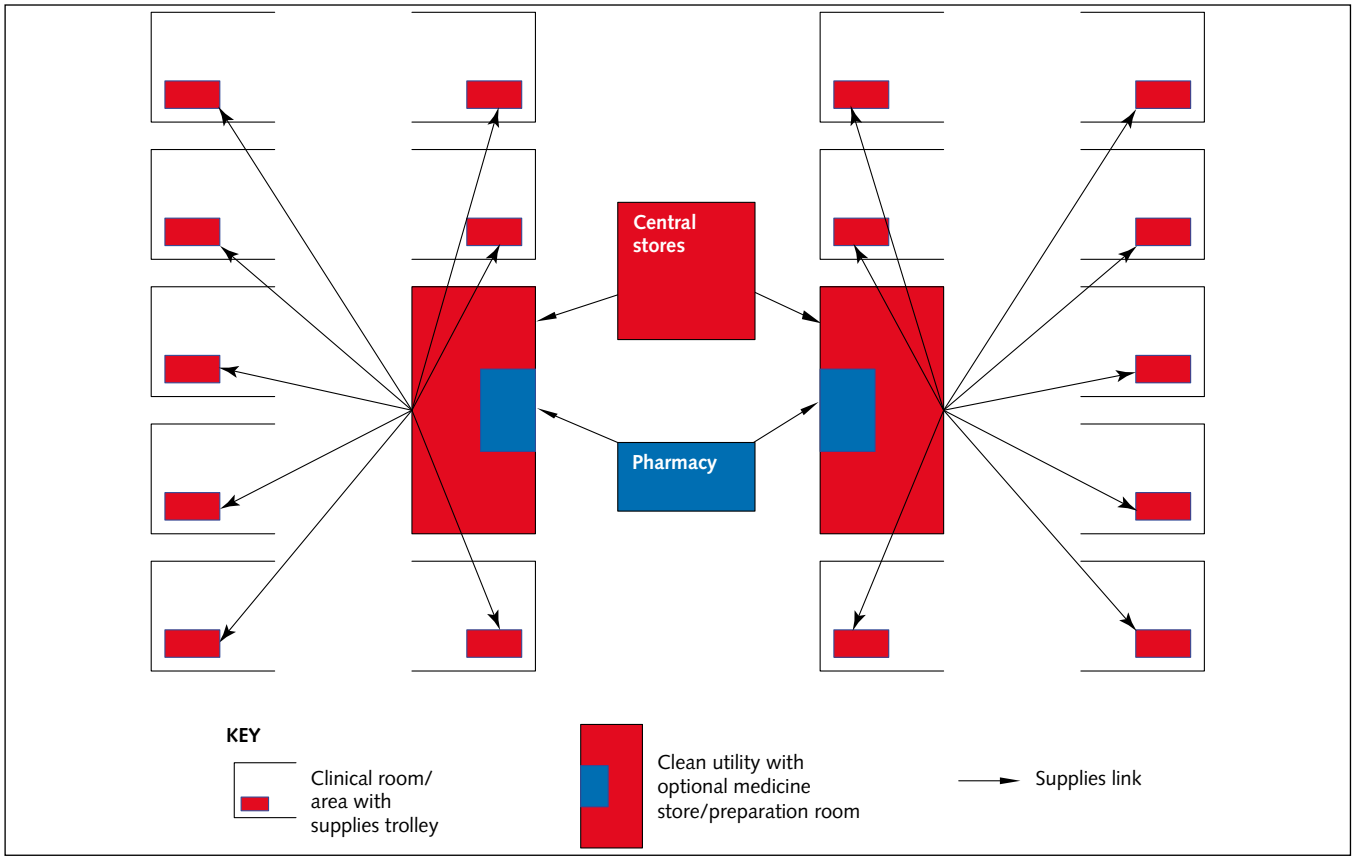

Figure 4 Clean supply room and medicine store/preparation room

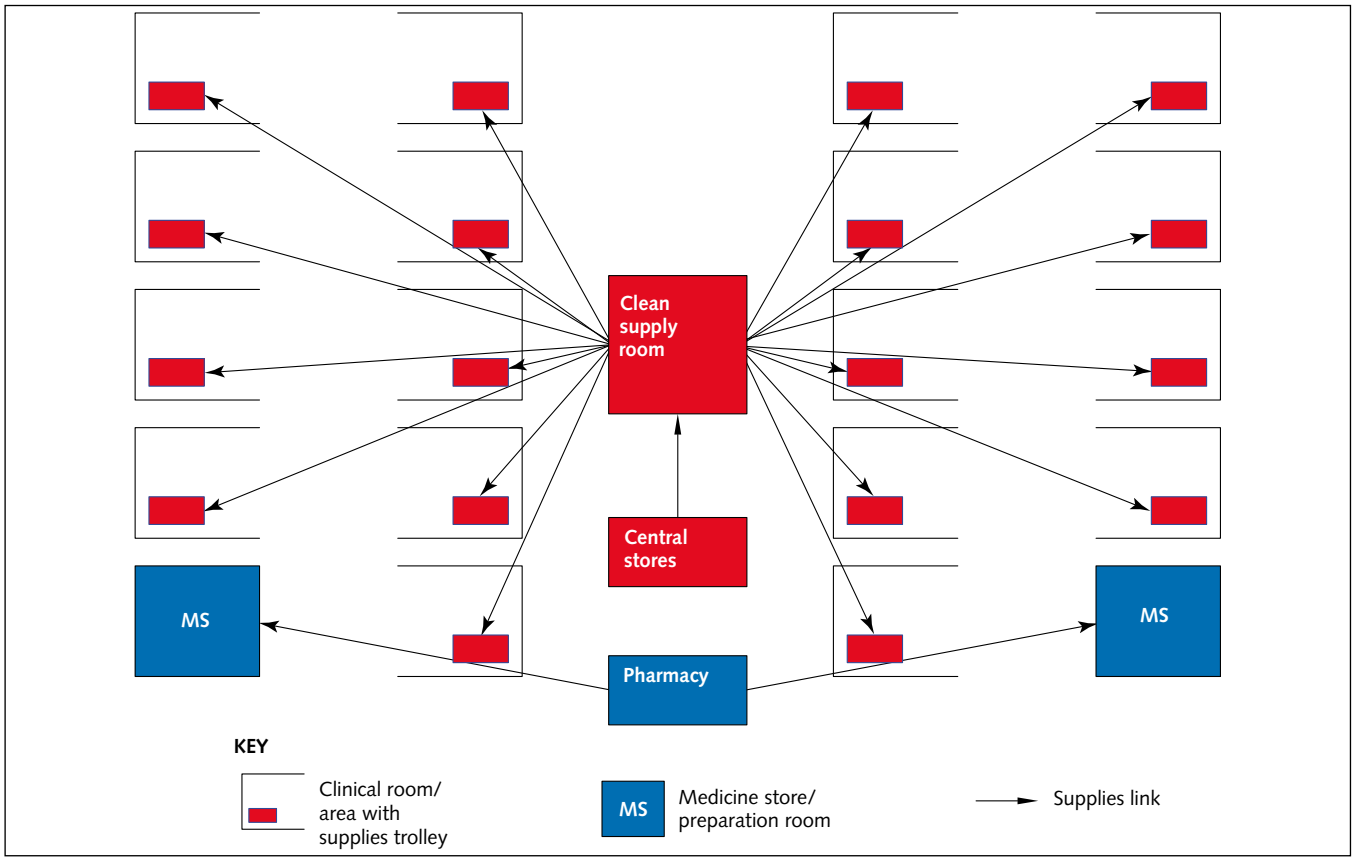


a clean utility room instead of a clean supply room and medicine store/preparation room is optional.

2.53 Items for disposal will be placed in the disposal hold. Some items will be held temporarily in the dirty utility room before being transferred to the disposal room.

2.54 For further guidance refer to Health Technical Memorandum 71 – 'Materials management and modular storage'. Design teams should ensure that supplies policies and storage systems are agreed early in the design process, as they can have a significant impact on planning and room areas. See also paragraphs 3.49 and 3.54.

Dirty utility room

2.55 Ideally, a dirty utility room should serve no more than 15 beds. This reduces travel distances for staff, making better use of nursing time and reducing the risk of spillages and cross-contamination. A second dirty utility room on a ward is also helpful during outbreaks of illness or infectious diseases. The schedules of accommodation for this Health Building Note include two dirty utility rooms per 24-bed ward.

Education and training facilities

2.56 Education is important in acute wards, and appropriate facilities should be provided. Trainee clinical staff will form a proportion of staff working in acute areas. While some teaching takes place in the clinical area on a one-to-one basis or in small groups, the teaching of large groups can be an imposition on the function of the area. A seminar room, which may be shared with other wards, should be provided as essential complementary accommodation. See paragraph 3.80 for design requirements.

Lighting

2.57 Scientific evidence indicates that daylight has beneficial effects on patients (Rubin & Owens 1996), visitors and staff. It has been shown to reduce psychological problems and improve patient outcomes, and increase morale and reduce sickness levels amongst staff. An external view is also beneficial, even if limited. Windows with no significant view are preferable to no natural light at all.

2.58 All bed areas should receive natural daylight. Where artificial lighting is provided in spaces where patients are examined or treated, it should enable changes in skin tone and colour to be clearly defined and easily identified. The quality of lighting will need to be considered if video consultation is likely to take place. Lighting is also important for effective cleaning of corners and edges that can harbour dust. Adjustable task lighting should be provided at the bedhead for patients who wish to read.

2.59 Ceiling-mounted fixed luminaires should not be sited immediately above positions where people lie on a bed, couch or trolley to avoid glare. This applies to all spaces where people are consulted, examined and treated.

2.60 Refer to paragraph 4.54 for more detailed guidance.

Views from windows

2.61 Wherever possible, beds should be positioned to enable patients to have a view of the outside world, which might include landscaped gardens or a courtyard with good-quality natural planting. Sill heights of windows should be low enough to allow seated people to see outside. Views out over flat roofs and roof-top plantrooms should be avoided.

2.62 The means for patients to control curtains or blinds for privacy should be included (motorised curtains are an option for non-ambulant patients). For further guidance refer to Health Technical Memorandum 55 – 'Windows'.

Courtyards

2.63 Well-proportioned courtyards enable rooms to receive natural daylight and ventilation in addition to providing a stimulating outlook from bedrooms, day spaces and staff areas. Layout and planting can help to preserve privacy in surrounding rooms. Courtyards may also provide a suitable location for artwork.

2.64 It is desirable to provide access to courtyards wherever possible, and thresholds should be designed to facilitate access. Short lengths of handrail should be provided at strategic points around the courtyard for patients who need support. Seating should also be provided. Access for maintenance and cleaning should be sited so that patients and staff are not disturbed. Adequate water points, power points and lighting, if necessary, should be provided in all courtyards..

Courtyard, York Hospital (reproduced with the permission of the King's Fund Enhancing the Healing Environment Programme, and York Hospitals NHS Trust)

Art

2.65 There is sufficient evidence to demonstrate that appropriate art and decor reduces the physical and emotional stress of patients and staff. It can also be used to assist wayfinding. Art should be integrated into a scheme rather than added as an afterthought.

2.66 Art need not be limited to pictures on a wall. It may also include murals, prints, photographs, sculptures, decorative tiles, ceramics and textile hangings. Works of art by local artists and craftspeople may lend a special identity to the facility.

2.67 Artworks should be easy to clean and as dust-free as possible. Design teams should seek the advice of the infection control team.

2.68 For further guidance refer to 'The art of good health – A practical handbook' and 'The art of good health – Using visual arts in healthcare'.

Environmental control

2.69 As noise is such a significant issue for patients, design that separates busy activity areas and patient bed spaces and the use of sound-absorbing materials should be adopted. Partitions between areas for confidential discussions should also be sufficient to prevent overhearing.

Telephone, TV and radio facilities

2.70 It is beneficial for patients to have convenient access to telephone, TV and radio facilities. Planning teams should identify suitable systems to meet local requirements.

Finishes

2.71 The choice of finishes should form an integral part of the design process and be co-ordinated within the overall design scheme. The selection of colours and reflectances can have a significant impact on the lighting within the room and will need to be coordinated with the lighting design. Finishes

should be functional and compatible with the need for comfort, cleanliness and safety. Cleaning regimens should be considered when materials are selected. The advice of the infection control team should be sought throughout the project.

Floors

2.72 Flooring should be smooth, easily cleanable and wear-resistant. There should be coved skirtings, which allow easy cleaning and avoid microbial colonisation. The material used for skirtings should be integral with, and have properties similar to, the floor finish. In areas where frequent wet cleaning methods are employed, the flooring material should be unaffected by disinfectants.

2.73 Carpets should not be used in clinical areas. Short-pile carpets may be considered for use in offices and staff rest rooms, but not the reception area. Carpets are extremely difficult to keep clean and need to be meticulously maintained.

2.74 All flooring should be slip-resistant. Design teams might also consider the use of impact-absorbing floor finishes, which will reduce the severity of injury should a patient fall.

2.75 For further guidance on flooring refer to Health Technical Memorandum 61 – 'Flooring' and 'Safer surfaces to walk on – reducing the risk of slipping' (CIRIA 2006).

Walls

2.76 Wall finishes should be durable and able to withstand wet cleaning and the accidental impact of trolleys and mobile equipment. Especially vulnerable points should have additional protection. Smooth paint surfaces are the easiest for cleaning – eggshell or vinyl silk emulsion. A matte finish is not recommended.

2.77 Walls in kitchen, shower and toilet areas should be easily cleanable. The advice of the infection control team should be sought.

2.78 For guidance on handrails on walls in circulation areas, refer to Health Building Note 00-04 – 'Circulation and communication spaces'.

Ceilings

2.79 Adequate ceiling heights in clinical areas are crucial. The underside of a finished ceiling in bedded areas should be at least 2700 mm from the floor. There may be a difficulty in complying with ceiling heights throughout the hospital in the case of refurbishments, but within a new-build this difficulty should be overcome.

2.80 Care should be taken when calculating the correct position and weight-bearing factors for hoists and other lifting equipment, lighting, patient entertainment and data management systems.

2.81 The use of acoustic ceiling materials in corridors and public spaces such as waiting areas may be helpful in reducing noise levels.

2.82 The design team, infection control officer and facilities manager should work together to ensure that the choice of ceiling and the maintenance routines are satisfactory. Service access panels should be avoided in bedrooms wherever possible.

2.83 For further guidance refer to Health Technical Memorandum 60 – 'Ceilings'.

Doors and frames

2.84 Materials used for doors and frames should be able to withstand frequent impact from mobile equipment and should be easily cleanable. All double-swing doors should incorporate appropriate glass vision panels; however, privacy, safety and other considerations may require the panels on bedroom doors to be capable of being obscured, possibly with integral blinds.

2.85 Where necessary it should be possible to secure doors in the open position. In the case of fire doors, this should only be by means of an approved or recognised product linked to the fire alarm and detection system, which is designed to fail to safety. Magnetic door retainers should not restrict the movement of traffic.

2.86 Reference should be made to Health Technical Memorandum 55 – 'Internal doorsets', Health Building Note 00-04 – 'Circulation and communication spaces' and Health Technical Memorandum 05-01 – 'Managing healthcare fire safety'.

Windows

2.87 Guidance on types of window and on the safety aspects is available in Health Technical Memorandum 55 – 'Windows'.

2.88 In addition to the guidance and various statutory requirements, the following issues require consideration:

- daylight and natural ventilation;

- safety;
- attenuation against noise;
- user comfort;
- energy conservation;
- solar control;
- the prevention of glare; and
- the provision of a visual link with the outside world balanced with the need to obscure the views into some areas from the outside.

2.89 Windows in single-bed rooms should be openable but with safety restrictions. They should be double-glazed as a minimum to provide thermal and sound insulation.

2.90 It should be possible for cleaners to gain easy access to the inside and outside of windows.

Maintenance and cleaning

2.91 Materials and finishes should be selected to minimise maintenance and be compatible with their intended function. Building elements that require frequent redecoration or are difficult to service or clean should be avoided. Special design consideration should be given to entrances, corners, partitions, counters and other elements that may be subjected to heavy use. Wall coverings should be chosen with cleaning in mind.

Wayfinding

2.92 The use of colour and art to identify particular routes and rooms can help to reduce the number of signs required. Certain doors, for example fire exit doors, will require conventional labelling. Where signs are used they should not detract from the overall ambience, and should be simple yet sufficiently explicit to be understood without confusing.

2.93 Reference should be made to 'Wayfinding: Effective wayfinding and signing systems. Guidance for healthcare facilities'.

Security

2.94 There are a number of security issues to be considered in the planning and design of in-patient accommodation: natural and mechanical surveillance (CCTV), natural ventilation and the night-time cooling of spaces, lighting, wayfinding, access control, security of property and assets, security of drugs, and the protection of NHS staff against violence. The Local Security Management Specialist (LSMS) will be able to identify security risks and offer advice on measures that can be implemented to reduce them.

2.95 Where entryphone/intercom systems and CCTV are installed, they should be linked to the reception desk and appropriate touchdown bases to control access through the main entrance. The LSMS should be consulted on the installation of all access control systems.

Fire safety

2.96 It is important to establish during the design stage those aspects of fire safety strategy that affect the design, configuration and structure of in-patient accommodation. The design team should discuss and verify their proposals with the Trust Fire Officer and the Building Control Authority or Approved Inspector, and ensure that the design team and all other design staff are fully acquainted with the fire safety strategy for the design in terms of operation (staff responsibilities, equipment provision, and building and engineering layouts). For further guidance refer to Health Technical Memorandum 05-01 – 'Managing healthcare fire safety'.

Compliance with statutory and other requirements

2.97 This Health Building Note takes account, as far as possible, of all statutory and other requirements and guidance in force or available at the time of publication. The following is intended only as a brief summary of compliance requirements.

People with accessibility difficulties (Disability Discrimination Act 1995)

2.98 Authorities should comply with the provisions of the Disability Discrimination Act (1995) and the Building Regulations Approved Document M 'Access to and use of buildings' (ODPM 2003). See also BS 8300:2001 'Design of buildings and their approaches to meet the needs of disabled people – Code of Practice'. Design teams should also refer to Health Building Note 00-02 – 'Sanitary spaces', Health Building Note 00-03 – 'Clinical and clinical support spaces', and Health Building Note 00-04 – 'Circulation and communication spaces', as these set out the standards required specifically for healthcare

premises and are in some cases more demanding than other more general guidance. Reference should also be made to 'Wayfinding: Effective wayfinding and signing systems. Guidance for healthcare facilities'.

Manual Handling Operations Regulations 1992

2.99 Manual handling and health and safety regulations relate to lifting and turning patients and moving heavy equipment. Planning and design teams should take these into account when designing facilities. Refer also to paragraph 2.42.

The Construction (Design and Management) Regulations 2007

2.100 These regulations, and the related Approved Code of Practice, focus attention on health and safety planning and management throughout construction projects, from design concept onwards. Designers have a duty to eliminate hazards and reduce risks. Planning teams have a duty to provide project-specific health and safety information needed to identify hazards and risks.

Safety regulations

2.101 For health and safety regulations see Health Technical Memorandum 00 – 'Policies and principles'.

Environmental Protection Act 1990

2.102 See Health Technical Memorandum 07 – 'Environment and sustainability'.

3 Specific functional and design requirements

Functional relationships

3.1 A 24-bed ward may function as a stand-alone unit within which beds are grouped into two or more clusters. Alternatively, depending on the layout of in-patient floors, some bed clusters may be configured to be shared between wards to provide flexibility. See Figure 5.

3.2 Each bed cluster will be serviced by staff and support facilities, therefore access to supplies and means of disposal should ideally be local to each cluster. It is recommended that rooms be serviced by trolley, like hotels, so that staff do not need to walk far from their bed cluster unless they require access to a shared facility, for example the medicine store/preparation room. The preferred option will be to stock each room for linen, clinical consumables and disposable items, and rely on "just-in-time" and "top-up" supplies.

3.3 The reception desk will be at the entrance to a ward, together with a waiting area and facilities for visitors. The entrance to accommodation is usually controlled by staff via intercom.

3.4 Regeneration kitchens should not be situated centrally within a ward, although the food trolley bay will need to be located between the clusters.

3.5 Ward layouts will depend on local conditions and overall bed numbers.

Description of room spaces

BED AND SANITARY FACILITIES

Bed spaces

3.6 The number of activities taking place at the bedside is increasing. The period that a patient spends in hospital is shortening, and is limited to active interventions for diagnosis, treatment and immediate recovery. The level of acuity and dependence of patients once interventions begin until discharge is relatively high; movement by staff around the patient may be considerable, and there is likely to be an increasing but intermittent use of equipment and aids at the bedside. The activities and the patient's response to interventions are recorded, increasingly on computer-held databases. Relatives and visitors are encouraged to be more involved in patient care and support.

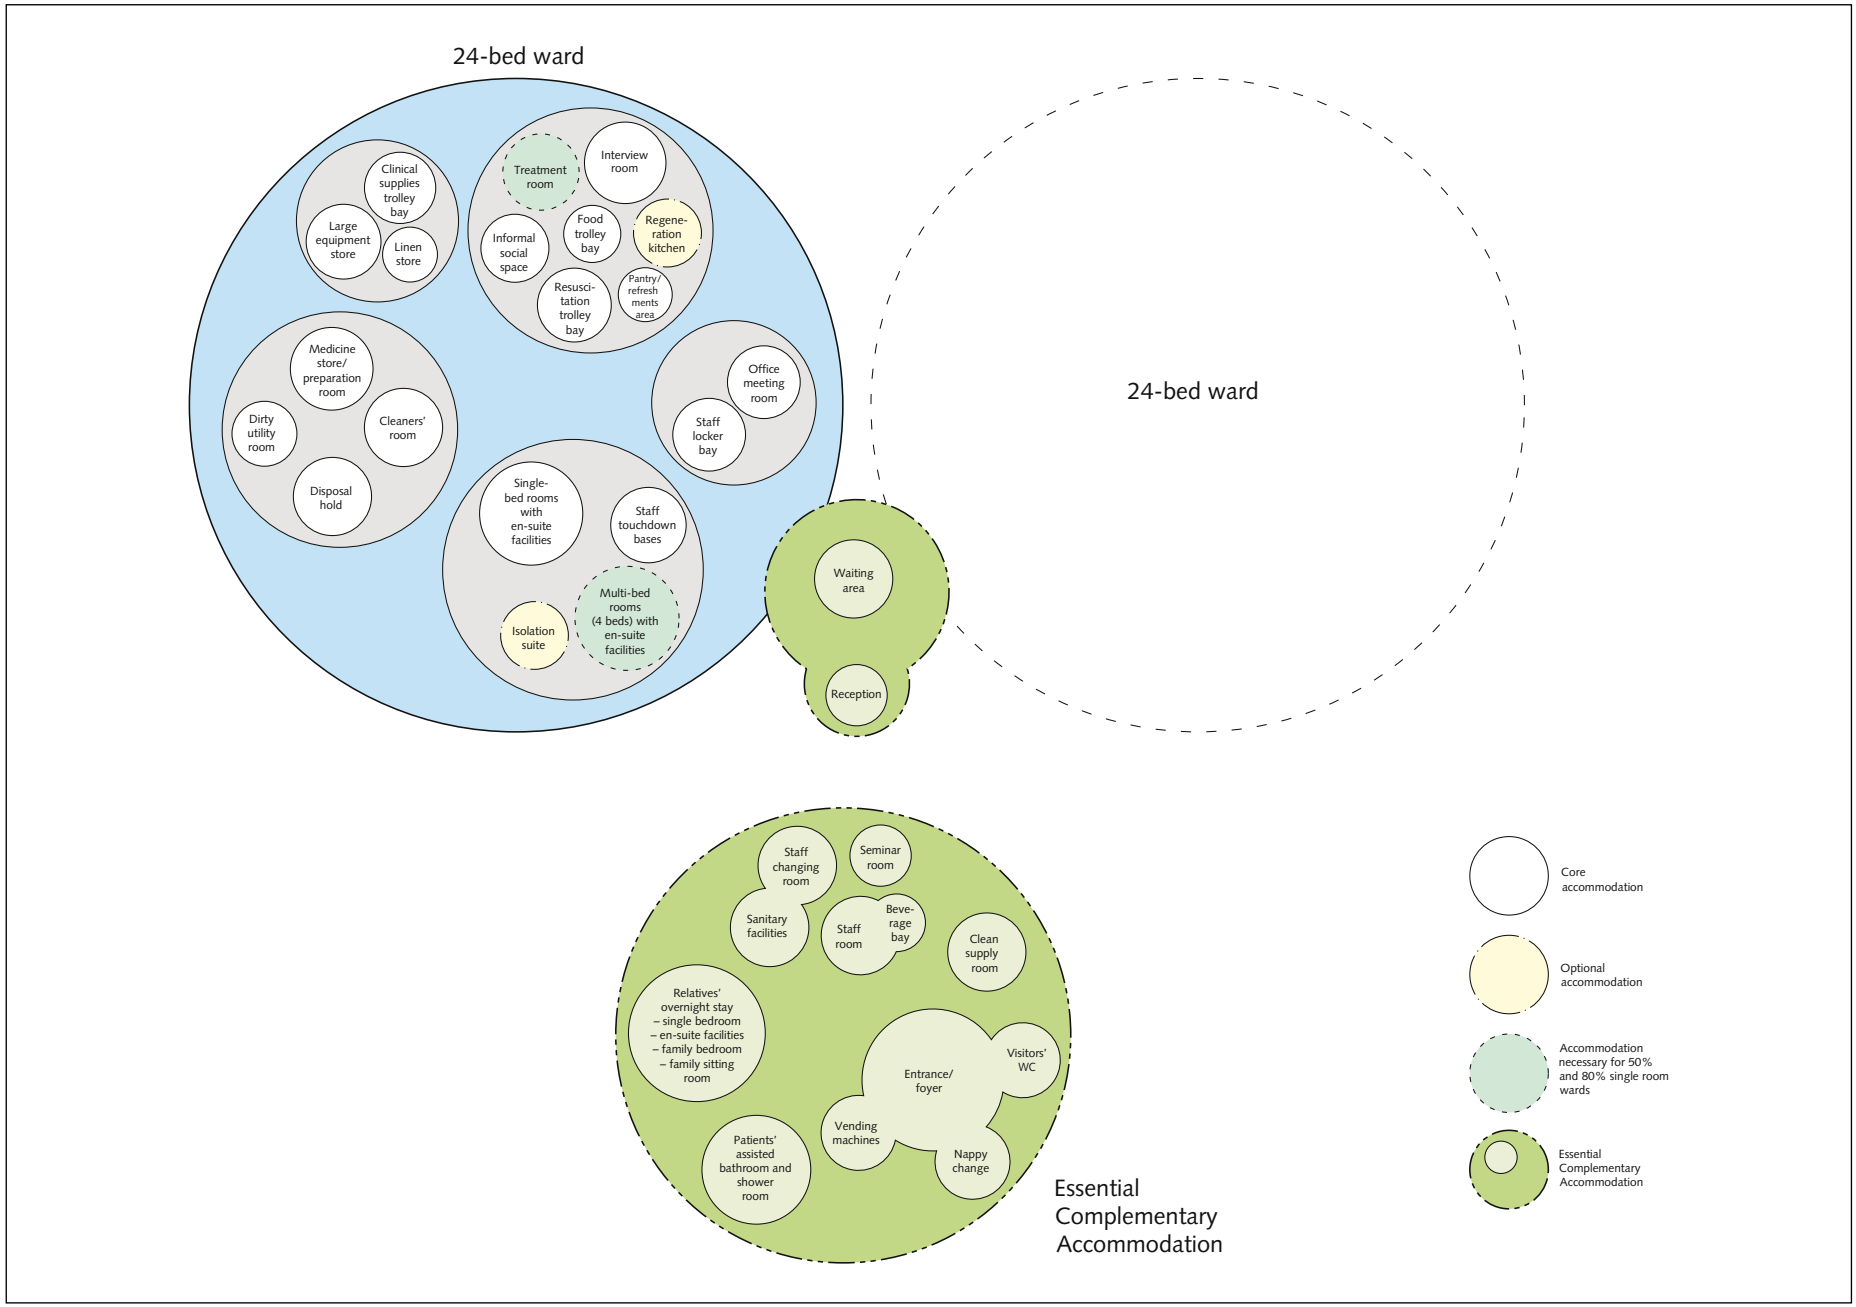
3.7 There are three distinct categories of direct activity that take place:

- clinical treatment and care:
  - admission, with the intimate discussion of personal matters;
  - specific medical and nursing interventions and observation;
  - rehabilitation;
  - informing, discussing, listening and advising both patients and relatives;
- personal care and maintenance:
  - sleeping and resting;
  - eating, drinking, washing and toileting;
  - entertainment/diversion, reading, watching the television;
  - receiving visitors;
- support activities:
  - preparation of clinical procedures;
  - maintaining records;
  - holding stores;
  - communicating;
  - developing staff skills.

3.8 The example layout for a single-bed room in Appendix 1 shows the zones to enable these activities to take place around a bed space.

3.9 The bed space should allow procedures to be carried out from either side of the bed with adequate circulation space so that medical emergency teams and equipment can gain access to

Figure 5 Functional relationships



the patient. There should be adequate space for moveable furniture and unobstructed access for wheelchairs, as well as space to accommodate overnight visitors.

3.10 The alternative to a single-bed room is a multi-bed room, in which the different activity zones move to a greater or lesser degree further away from the bedside, and may be shared to support all the beds in the multi-bed room. The preferred maximum number of beds in a multi-bed room is four. This enables the potential for better gender separation and improved privacy within a 24-bed ward comprising six four-bed rooms. It also gives each patient a corner as a "home base" and a neighbour on one side only.

3.11 All single- and multi-bed rooms should be provided with en-suite sanitary facilities and, whether in a single- or a multi-bed room, all bed spaces should be provided with:

- furniture:
  - a variable-height bed;
  - a bedside locker, with a lockable compartment for storing medication;
  - an overbed table;
  - an easy chair;
  - a bedhead luminaire;
- a co-ordinated bedhead services arrangement incorporating:
  - electrical socket-outlets;
  - luminaire control switch;
  - oxygen, medical air and vacuum outlets (refer to Health Technical Memorandum 02-01 – 'Medical gas pipeline systems');
- a patient services system (which may be incorporated into the bedhead services panel) including:
  - help call button, including two-way speech facilities (consideration might also be given to alternative call systems, such as blow devices, for patients who cannot use their hands);
  - reassurance light;
  - luminaire switch;

Kidderminster Treatment Centre (Photographer: David Whyte, Copyright: MAAP Architects Ltd)

- patient entertainment facilities including:
  - radio;
  - TV;
  - telephone;
  - headset outlet.
- Additionally, in single rooms:
  - space for storing clothes and shoes;
  - space for a relative's overnight stay bed;
  - a small refrigerator for a patient's personal use (optional).
- Facilities for staff:
  - space for clinical administration, including data outlet;
  - a clinical wash-hand basin, plus antibacterial hand-rub dispensers;
  - storage for a day's supply of linen and surgical goods/supplies.

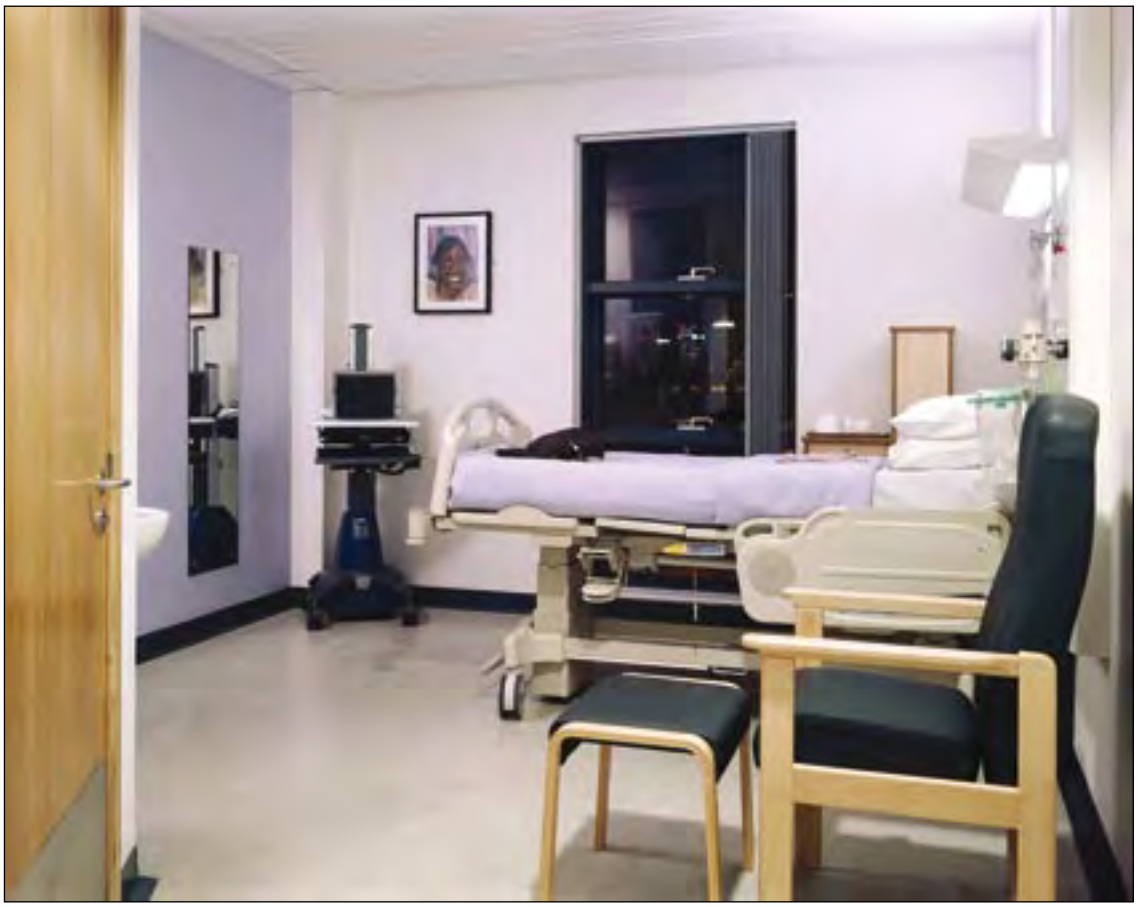
These provisions are necessary as the basis of a desirable environment.

3.12 In multi-bed rooms each bed space should be separated to provide a degree of privacy. If curtains are used they should be shadow-proof and flame-retardant. When full-height curtains are drawn, the bed space should still be well illuminated and ventilated. Curtains may be disposable. Highly-patterned curtains should be avoided, as they can cause visual disturbances in patients who are confused or heavily sedated.

3.13 Each four-bed room should include two clinical wash-hand basins for staff use. These should be located to be highly visible and convenient for staff to use, both on entering and leaving the room and when moving from one patient to another. A clinical support zone with space for a computer and storage for a day's supply of linen and clinical goods is required for each multi-bed bay. A single workstation will suffice for a group of beds.

3.14 Design teams should decide in consultation with the local fire authority whether multi-bed rooms should or should not be fitted with doors for fire safety reasons, for example to limit the spread of smoke. The infection control team should also be consulted on the use of doors in multi-bed rooms.

Brent Emergency Care and Diagnostic Centre, North West London Hospitals NHS Trust (Photographer: Lisa Payne)



Newham Gateway Surgical Centre, Newham University Hospitals NHS Trust

Design for four-bed room. MAS Project, Sherwood Forest Hospitals NHS Foundation Trust
(Swanke Hayden Connell Architects on behalf of Skanska Central Nottinghamshire Joint Venture)

3.15 Each multi-bed room should have easy access to informal social space, as the majority of patients, although highly dependent, are encouraged out of bed.

3.16 Example layouts of single and multi-bed rooms are contained in Appendix 1.

Sanitary facilities

Single room en-suite shower room

3.17 Each single-bed room should have an en-suite WC, shower and wash basin.

3.18 For detailed guidance on this en-suite and alternative designs for sanitary facilities, refer to Health Building Note 00-02 – 'Sanitary spaces'.

Multi-bed room sanitary facilities

3.19 A multi-bed room should have en-suite sanitary facilities, which can be accessed by patients without the need for them to travel or cross circulation routes. It is convenient to provide an assisted shower room (with WC, shower and wash-hand basin) and a separate ambulant WC (with hand-rinse basin), both en-suite to the bed area. Thus one person showering does not prevent others from using the WC. However, privacy and dignity should be ensured by the provision of appropriate security devices, locks etc. En-suite doors should not open directly onto immediate bed areas.

3.20 Appendix 1 provides an example layout for multi-bed room sanitary facilities. For detailed guidance on sanitary facilities for multi-bed rooms, refer to Health Building Note 00-02 – 'Sanitary spaces'.

General

3.21 Design teams should consider motion sensors for lighting in sanitary facilities. This may help to avoid the problem of fragile patients using sanitary facilities in the dark. An electronic sensor for the WC flush is also a project option.

3.22 The wet shower area of the compartment should be separated by a curtain from the remainder, which should serve as the drying area. There should not be a step between the wet and dry areas, but there is a requirement for sufficient slope of the floor to the outlet, so as to assure proper drainage and prevent spillage of water into the dry areas. The floor surface should be slip-resistant. The gradient of the floor of the wet area should ensure effective drainage to the waste outlet to prevent ponding.

3.23 The cord of the help call system should be easily identifiable, accessible from the wet area, and should descend far enough to be within the reach of a patient who has fallen or collapsed.

3.24 Ventilation should preclude excessive heat, humidity and odours.

3.25 For more detailed guidance on sanitary facilities, refer to Health Building Note 00-02 – 'Sanitary spaces'.

Assisted bathroom or shower room (Essential complementary accommodation)

3.26 In addition to en-suite facilities, an assisted bathroom or shower room is required, although this may be shared with other wards.

3.27 Patients using an assisted bathroom or shower room may arrive in a wheelchair or on a shower trolley. Staff assist the patient in bathing/showering and associated activities, and may also give treatments. In bathrooms a variable-height peninsular bath is essential. In both bathrooms and shower rooms there should be sufficient space to accommodate three staff, and to permit the manoeuvring of support equipment such as a hoist. The room should also contain a WC and wash basin.

3.28 For more detailed guidance refer to Health Building Note 00-02 – 'Sanitary spaces'.

Isolation suite (Optional accommodation)

3.29 An isolation suite comprises a single-bed room, en-suite shower room and a ventilated lobby.

3.30 For detailed guidance on isolation suites and example layouts see Health Building Note 4 Supplement 1 – 'Isolation facilities in acute settings'.

3.31 If it is proposed to install a ceiling hoist track system between an isolation room and en-suite shower room, the design should not compromise the airflow pattern between the two rooms. The design of the isolation suite works on the principle of supplying air from the lobby at high level to the bedroom and removing it at low level via a transfer grille in the en-suite door. This ensures good mixing of the air in the bedroom, with a consequent dilution of possible contaminants. The wall area above the outward-opening door that is penetrated by the track and suspension system should not therefore allow unrestricted airflow between the bedroom and en-suite at high level.

Suitably profiled filler boards and the use of brush seals will ensure an adequate resistance to flow and prevent short-circuiting.

Touchdown bases

3.32 In addition to workstations in bedrooms, space is required close to patients, but not within bedrooms, for clinical administration. The touchdown base provides a place for accessing and updating EPRs and other computer work.

3.33 For detailed guidance on touchdown bases see Health Building Note 00-03 – 'Clinical and clinical support spaces'.

PATIENT SUPPORT FACILITIES

3.34 A variety of support facilities are required for patients. For example, where multi-bed rooms are used there should also be separate rooms for treatment and for one-to-one discussions, interviews or education.

Treatment room

3.35 In wards with multi-bed bays, a treatment room will be required where clinical procedures can be carried out in private. In wards with 100% single rooms, the provision of a treatment room is optional.

3.36 Patients using the treatment room may be ambulant, in a wheelchair, on a trolley or on a bed; the door width should be sufficient to permit their passage.

3.37 Refer to Health Building Note 00-03 – 'Clinical and clinical support spaces' for detailed guidance.

Interview room

3.38 Discussions with patients and relatives may be carried out in an interview room. The room may also be used by staff for staff interviews, appraisal and counselling. Good acoustic privacy is required; refer to Health Technical Memorandum 08-01 – 'Acoustics'. Visual privacy should also be ensured through the use of blinds or curtains at the windows. Glazed panels in doors should be capable of being obscured, preferably with integrated blinds.

3.39 The designer should aim to create an environment that is cheerful, comfortable and warm. Appropriate lighting and decorative textures such as pictures and plants can help to provide a pleasant atmosphere. Finishes and furniture will have an important influence on the room. Easy chairs and coffee tables should be provided. It is important that rooms in which patients will be sitting are free from draughts.

3.40 Refer to Health Building Note 00-03 – 'Clinical and clinical support spaces' for detailed guidance.

Informal social space

3.41 For patients – whether in single-bed rooms or multi-bed bays – open yet intimate areas recognisably intended for casual meeting and talking may be all that is required to enable patients who wish to socialise without the provision of dedicated day rooms. Planning decisions should take account of patient culture and preferences in terms of privacy, modesty and same-sex accommodation. Where day rooms are provided they should be as inviting as possible, with hotel-style or domestic furnishing. It should be possible for patients to control environmental features such as lighting.

Pantry/refreshments area

3.42 The pantry/refreshments area should be equipped with facilities for:

a. the preparation of beverages and light snacks;

b. the filling of patients' water jugs;

c. storage of dry goods, and a limited amount of crockery and cutlery;

d. refrigeration of perishable food.

3.43 An industrial-grade mechanical dishwasher is required in order to meet the rinse cycle temperatures required for infection control purposes. Separate facilities for washing-up and wash-handing are required. Crockery and cutlery used for main meals is returned to the central washing-up service. There should be adequate storage for jugs.

3.44 For further guidance refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Regeneration kitchen (Optional accommodation)

3.45 A regeneration kitchen will be required where the local catering policy requires food to be delivered to a department for regeneration and then distributed to a number of wards. The design of the regeneration kitchen should be determined by the catering contractor.

Parking bay: food trolley

3.46 A bay is required for parking the food trolley while meals are distributed to patients.

Resuscitation trolley bay

3.47 Emergency equipment – such as the resuscitation trolley, which includes a defibrillator, medical gas cylinder and portable suction machine – should be parked in a bay where it is accessible from the bedrooms, but should not obstruct circulation areas.

STORAGE SPACES

3.48 Store rooms are a costly means of providing storage, as they require internal circulation space. Storage in relatively shallow cupboards or doored alcoves opening directly from circulation areas may be more convenient and cheaper. The latter is particularly useful for goods for which stocks are maintained by an exchange trolley service. Cupboards in corridors may need to be recessed so that the doors, when open, do not obstruct movement in the corridor.

Clean supply room (Essential complementary accommodation)

3.49 This room provides storage for sterile supplies and consumables for a number of wards. Supplies trolleys are brought here for restocking. For detailed guidance on the clean supply room see Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Clinical supplies trolley

3.50 Clean and sterile goods for daily use will be held on trolleys, at the point of use in bedrooms.

Large equipment store

3.51 This store is required for bulky items of equipment, bed accessories and therapy aids. Open shelving, hanging rails and hooks as well as free-standing space for heavy equipment such as hoists and weighing machines is required. Sockets may be useful for equipment that needs charging. Disposable items delivered in bulk packages to the clinical area will require storage.

3.52 Design teams may decide that more than one large equipment store is required. A number of local stores adjacent to single-bed rooms or multi-bed rooms might be more efficient.

Linen store

3.53 For infection control purposes, clean linen should be kept in a closed store rather than on open trolleys. Local policy will determine whether linen is stored in single-bed rooms or in a central store.

UTILITIES

Medicine store/preparation room

Large equipment store

3.54 The medicine store/preparation room is required for the storage and preparation of all the medicines to be used on the ward. This will include controlled drugs, medicines requiring refrigeration, and consumables such as syringes and needles. Rechargeable syringe drivers and infusers may be stored here. For detailed guidance refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

bedpans etc. Such equipment may generate significant noise levels, and care should be taken to eliminate this. Colour-coded disposal bags for the bagging of waste materials should be kept here.

3.56 For detailed guidance refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Cleaners' room

3.57 The cleaners' room is the base from which domestic service staff provide the immediate day-to-day cleaning service.

3.58 For detailed guidance refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Disposal hold

3.59 The disposal hold is the temporary storage point for all items of supplies and equipment which have to be removed for cleaning, reprocessing or destruction, for example clinical and non-clinical waste and sterile services department items.

3.60 The waste disposal of used items should be consistent with the current hospital policy for the disposal of clinical waste.

3.61 For detailed guidance refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Switchgear cupboard

3.62 A departmental switchcupboard housing the main isolators and distribution switchgear should be:

a. accessible directly from the circulation area (access space may be part of the circulation area);

b. sited away from water services;

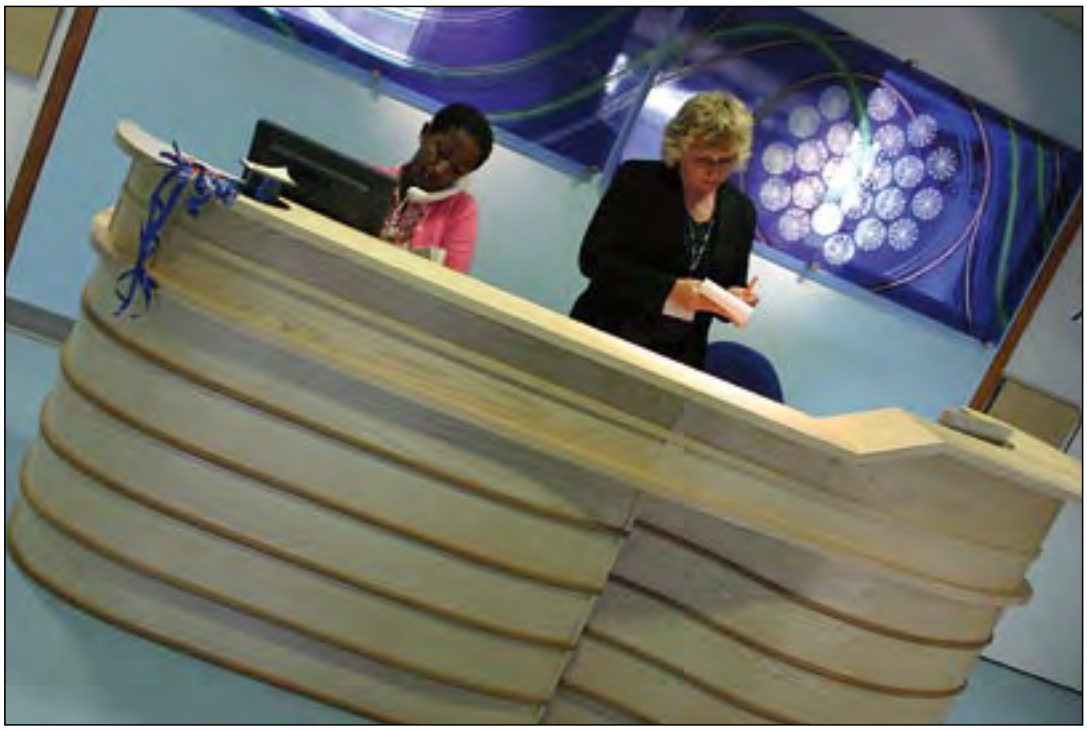
c. lockable.

3.63 Where possible, the cupboard should be sited within the department. There should be clear and safe access for maintenance staff, and care should be taken to ensure that safety is not compromised, during maintenance, from passing traffic or the opening of adjacent doors.

ADMINISTRATION AREAS AND STAFF FACILITIES

Reception and waiting area (Essential complementary accommodation)

3.64 The reception desk should be in a prominent position at the entrance to the ward. The counter needs to be stepped so that a person in a wheelchair can see and speak easily to the receptionist. The desk requires sufficient working space for a receptionist and one other who will welcome patients, relatives and staff, and undertake the local clerical and administrative duties. The reception



Reception desk at East Somerset NHS Trust (Reproduced with the permission of the King's Fund Enhancing the Healing Environment Programme, and East Somerset NHS Trust)

desk and waiting area may be shared between wards.

3.65 The reception desk will be linked by computer to all areas. Space is required for a computer terminal and associated equipment, including a printer. The reception desk should be designed to allow natural surveillance of all entrances and waiting areas and, where possible, corridors leading to treatment rooms. CCTV should be installed in all reception and waiting areas.

3.66 A seated area should be provided near the reception desk for patients, relatives and visitors waiting to be received. Access to visitors' WCs, nappy change facilities and vending machines is required. The waiting area may also serve as additional informal day space for patients.

Office/meeting room

3.67 This office is a multi-purpose office, but is likely to be used principally by clinical staff to complete notes on discharged patients, hold patient handover meetings, undertake telephone calls and for staff discussions.

3.68 It should be located close to bed areas and sized to accommodate two computer workstations, a table and eight to ten people. A cupboard or shelves for storing a limited amount of stationery should be provided.

3.69 There is no separate medical staff or ward manager's office.

Staff locker bay

3.70 Staff will require local lockers to hold small personal belongings while on duty. It may be convenient to locate lockers within or adjacent to the staff room/beverage bay where provided.

3.71 In wards that contain the staff changing facilities, staff will have easy access to the lockers in the changing rooms and a separate locker bay will not be necessary.

Staff WC

3.72 A WC is required for clinical staff working on the ward. In wards that contain the staff changing facilities, staff will have easy access to sanitary facilities and a separate WC will not be necessary.

Staff changing room (Essential complementary accommodation)

3.73 Facilities are required for staff changing, clothes storage, showers and sanitary facilities. These facilities may be shared between several wards. Estimates of the amount of changing space and locker provision should take into account the numbers of full-time and part-time staff, including trainees and students.

3.74 Separate changing rooms for males and females are needed, each with their own shower rooms, WCs, shaving point, power points for hair dryers and a large, well-illuminated mirror with a shelf. The sanitary and shower facilities should be self-contained, full-height rooms to provide maximum privacy. The provision of cubicle partitions is not an acceptable alternative.

3.75 Access control should be fitted to all staff changing and sanitary facilities.

3.76 Refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Staff rest room (Essential complementary accommodation)

3.77 Rest room facilities are required where staff can relax and take beverages. These may be shared between several wards. Rest rooms should have windows and a pleasant outlook and be comfortably furnished.

3.78 The rest room should include a beverage bay with facilities for preparing beverages for staff, for washing and storing crockery and cutlery, for storing a limited quantity of dry goods, and for the refrigerated storage of milk etc.

3.79 Refer to Health Building Note 00-03 – 'Clinical and clinical support spaces'.

Seminar room (Essential complementary accommodation)

3.80 It is assumed that a designated education centre with conference facilities for multi-disciplinary use will be available on site.

4 General engineering principles

Introduction

4.1 This chapter provides general guidance on the engineering, technical and environmental aspects of healthcare building design. Specific guidance in relation to in-patient facilities for adults is shown in **bold**.

4.2 Consultation should take place at project and design team level to ensure understanding of key issues, healthcare delivery and the appropriate standards for healthcare engineering services.

4.3 Designers should ensure that they read this publication as a whole, since further engineering guidance may be outlined in and cross-referenced within other sections.

4.4 The Health Technical Memorandum series is supported by an overarching publication, 'Policies and Principles – Best Practice Guidance for Healthcare Engineering' (Health Technical Memorandum 00), which covers the following issues:

a. overview of engineering services guidance;

b. statutory and legislative requirements;

c. professional support;

d. operational policy;

e. training and workforce development;

f. emergency procedures and contingency planning;

g. training, information and communications;

h. maintenance;

j. engineering services.

4.5 Guidance on specific types of engineering services can be found within the Health Technical Memorandum '0' series of documents as follows:

a. Decontamination (Health Technical Memorandum 01);

b. Medical gases (Health Technical Memorandum 02);

c. Ventilation systems (Health Technical Memorandum 03;

d. Water systems (Health Technical Memorandum 04;

e. Fire safety (Health Technical Memorandum 05);

f. Electrical services (Health Technical Memorandum 06);

g. Environment and sustainability (Health Technical Memorandum 07);

h Specialist services (Health Technical Memorandum 08);

j. other existing HTM 2000 series guidance documents.

Space requirements for services and plant

4.6 A high level of availability of engineering plant and services is critical to the ability of the facility to function safely and efficiently. It is therefore essential that the building design should incorporate adequate space for the full range of building services and the requirements for installation and maintenance of plant, ductwork, pipework and cabling.

4.7 Space for plant and services should provide:

a. easy and safe means of access;

b. secure accommodation protected from unauthorised access;

c. adequate space around the plant services to permit inspection maintenance and replacement.

4.8 Guidance on spatial requirements for engineering plant and services is contained in Health Technical Memorandum 00 – 'Policies and principles – best practice guidance for healthcare engineering'. Further useful information regarding the provision

of space for plant is contained in BSRIA Technical Note TN 9/92, and for building services distribution systems in BSRIA Technical Note TN 10/92.

4.9 With the exception of drainage and some heating pipework, engineering services should not be brought from the above-ceiling space of a floor below. Service distribution to a particular area should be contained within service spaces on that floor.

4.10 Plantrooms, particularly for air-conditioning and ventilation, should be located as close as possible to the areas they serve, thus minimising the amount of space necessary to accommodate large ducts.

4.11 Care should be taken to ensure that noise and structure-borne vibration cannot be transmitted beyond the plantroom. Further guidance on acoustics and vibration can be found in Health Technical Memorandum 08-01 – 'Acoustics'.

Decontamination

4.12 Decontamination is the combination of processes (including cleaning, disinfection and sterilization) used to render a re-usable item safe for further use on patients and handling by staff. The effective decontamination of re-usable surgical instruments is essential in minimising the risk of transmission of infectious agents. Further guidance is set out in Health Technical Memorandum 01-01 – 'Decontamination of reusable medical devices' (Parts A and B plus guidance for specific facilities).

Mechanical services

Piped medical gases

4.13 Piped medical gases should be designed in accordance with the requirements of Health Technical Memorandum 02-01 – 'Medical gas pipeline systems'.

Heating

4.14 General space heating requirements may be met by a variety of systems including radiators and radiant panels, or within the air-conditioning system. Designers should ensure that the most appropriate method is employed with regard to the healthcare environment being provided.

4.15 Where heat emitters are used, the surface temperature should not exceed 43ºC. Exposed heating pipework, accessible to touch, should be encased and/or insulated. Further information is given in Health Guidance Note '"Safe" hot water and surface temperatures'. Particular care should be taken when providing systems within mental health facilities.

4.16 Care should be taken to ensure that heat emitters do not adversely affect the local temperature conditions of adjacent storage and preparation areas.

4.17 Where used, radiators should be located under windows or against exposed walls. There should be space between the top of the radiator and the windowsill to prevent curtains reducing the output. There should be adequate space underneath to allow cleaning equipment to be used.

4.18 Where appropriate, heating controls should be provided to modulate heating circuit flow temperatures in accordance with external temperature. Radiators or radiant panels may also be used to offset building fabric heat losses in mechanically ventilated spaces. The system should be designed to ensure that the heating and ventilation systems operate in a coordinated manner and do not cause the space to overheat. Heat emitters in single-bed rooms should be provided with controls so that patients can adjust the room temperature.

4.19 Ceiling-mounted heating panels can operate at higher surface temperatures than 43ºC as long as the surface is not easily accessible. Heating panels should preferably run around the perimeter of the building. Panels should not be located over beds, patient trolley positions, or in other locations where they might radiate directly onto a patient or member of staff for a prolonged period.

4.20 Ceiling panels should be selected to aesthetically match the adjacent ceiling, and should be sealed to the adjacent ceiling by means of a gasket of similar.

Ventilation

4.21 For areas where it is absolutely necessary to install mechanical ventilation, ventilation systems should be designed in accordance with the requirements of Health Technical Memorandum 03-01 – 'Specialised ventilation for healthcare premises'.

4.22 Air movement induced by mechanical ventilation should be from clean to dirty areas, where these areas can be defined. The design should allow for adequate flow of air into any spaces having only mechanical extract ventilation, via transfer grilles in

doors or walls. However, such arrangements should avoid the introduction of untempered air and should not prejudice fire safety or privacy.

4.23 Local exhaust ventilation (LEV) will be required where exposure (by inhalation) to substances hazardous to health cannot be controlled by other means. The Health and Safety Executive publishes guidance notes, updated annually, on occupational exposure limits (Guidance Note EH40 – 'Occupational Exposure Limits') for the control of exposure by inhalation of substances hazardous to health. The limits specified form part of the requirements of compliance with the Control of Substances Hazardous to Health Regulations 2002 (COSHH).

4.24 Further guidance on the design of LEV systems may be found in Health Technical Memorandum 03-01.

Hot and cold water systems

4.25 Hot and cold water storage and distribution systems should be designed in accordance with the requirements of Health Technical Memorandum 04-01 – 'The control of *Legionella*, hygiene, "safe" hot water, cold water and drinking water systems'.

4.26 Exposed hot-water pipework, accessible to touch, should be encased or insulated. Special care should be taken when facilities are being provided for older, confused or mental health patients.

Building management systems

4.27 All engineering plant and equipment associated with the internal environment should, where possible, be controlled, monitored and regulated by a building management system (BMS) in accordance with the provisions of Health Technical Memorandum 2005 – 'Building management systems'.

4.28 Requirements for the monitoring and control of plant and systems are also covered in the Health Technical Memorandum that relates to the particular plant or system.

Internal drainage

4.29 A system of soil and waste drainage including anti-siphon and ventilation pipework should be provided in accordance with BS EN 12056.

4.30 Where plastic pipework materials are used, suitable intumescent collars should be fitted when breaching fire compartments, and acoustic wrapping should be applied where drainage runs above wards and other sensitive areas.

4.31 The gradient of branch drains should be uniform and adequate to convey the maximum discharge to the stack without blockage. Practical considerations such as available angles of bends, junctions and their assembly, as well as space constraints, will normally limit the gradient to about 1:50 (20 mm/m).

4.32 For larger pipes, for example 100 mm in diameter, the gradient may be less, but this will require high-quality workmanship if an adequate self-cleaning flow is to be maintained. **Bedpan washers or macerators should discharge with a short branch to a vertical stack or horizontal drain. The waste pipe should not be installed above or close to heating or hot-water mains. If a bedpan washer or macerator discharges to a 100 mm drain, frequently used large-volume appliances should be situated upstream of its connection to provide additional flushing.**

4.33 Provision for inspection, rodding and maintenance should ensure "full bore" access and be located outside user accommodation. The location of manholes within the building should be avoided.

4.34 To prevent the ingress of bacteria, waste outlets from distillation plant and refrigerators should be connected outside of the department, should not be directly connected to the drainage system, and should discharge via a trapped tundish or gully.

4.35 Drainage/waste systems from air-conditioning units should be installed to prevent Legionnaires' disease and other bacteria back-feeding.

Acoustics

4.36 Consideration should be given at the earliest opportunity to the requirements for privacy and the impact of any intrusive noise that may affect the function of the healthcare facility. Guidance in relation to functional relationships is given in Health Technical Memorandum 08-01 'Acoustics'.

Fire safety

4.37 Fire safety standards in healthcare premises need to be high owing to the vulnerability of occupants. The policy in respect of fire safety is set out in Health Technical Memorandum 05-01 – 'Managing healthcare fire safety'. The design team should satisfy itself that the design meets the

objectives of this guidance or provide a fire-engineered solution that achieves similar objectives.

4.38 It is important to establish during the design stage those aspects of fire strategy that may affect the planning of a project. At appropriate stages of the design process, the appropriate design team members should discuss their proposals with the relevant Building Control/Approved Inspector, and ensure that the project team and all other planning staff are fully acquainted with the fire strategy for the design. This will include operational aspects (staff responsibilities etc), equipment provision, and building and engineering layouts.

Fire detection and control systems

4.39 Fire detection, alarm and control systems are an integral part of the overall fire plan for a building. Close coordination between the architect and design engineer is essential to ensure that compartmentation, high-risk processes, dangerous goods and other fire-related risk issues are fully understood and embraced in the fire management solution.

4.40 For guidance see the 'Firecode' suite of documents (Health Technical Memorandum 05).

Electrical services

General

4.41 Electrical installations should comply with the current edition of BS 7671 IEE Wiring Regulations together with Guidance Note 7 (Special Locations) and Health Technical Memorandum 06-01 – 'Electrical services supply and distribution'. See also 'Medical Electrical Installation Guidance Notes' (MEIGaN; MHRA).

4.42 Prior to final design, a full assessment should be made of the risk, function, occupation, equipment and resilience requirements for the area. This will influence the extent and location of services, the availability of alternative electrical supply distribution and the need for local standby supplies if appropriate.

Electromagnetic compatibility

4.43 Care should be taken to avoid mains-borne and electrical radio frequency interference affecting diagnostic and monitoring equipment, computers or other sensitive electronic equipment. Guidance on the avoidance and abatement of electrical interference is given in Health Technical Memorandum 06-01 – 'Electrical services supply and distribution'.

Main intake switchgear and distribution boards

4.44 The main electrical supply should be part of the whole site/building network, and should provide adequate capacity for both normal and all assessed business-critical needs.

4.45 Main intake and distribution equipment should be sited away from patient areas and areas where access would disrupt normal communication routes.

4.46 Careful consideration should also be given to the impact from flooding, pipework leaks and mechanical damage.

Emergency electrical supplies

4.47 Emergency electrical provision should comply with the requirements of Health Technical Memorandum 06-01.

Small power distribution systems

4.48 Depending upon the capacity of the emergency generator installation and risk assessment (see paragraphs 4.44–4.46), it may be appropriate to provide separate essential and non-essential small power distribution systems.

4.49 Adequate provision should be made in circulation areas, for example corridors and lobbies, to allow the use of domestic cleaning equipment having flexible cords up to 9 m long.

Lighting systems

4.50 Lighting services, including lighting controls, should comply with CIBSE 'Code for Lighting'; Guide LG2: 'Hospitals and Health Care Buildings'; and Guide F: 'Energy Efficiency in Buildings'.

4.51 In areas where VDUs are in use, lighting should be designed to comply with the guidance given in CIBSE Guide 7: 'Office lighting'.

4.52 To achieve energy efficiency, lighting systems should be designed to:

a. maximise use of natural daylight;

b. avoid unnecessarily high levels of illumination;

c. incorporate efficient luminaires, control gear and lamps;

d. incorporate effective controls.

4.53 Lighting and the appearance of luminaires should be coordinated with architectural design. In particular there should be collaboration to ensure that decorative finishes are compatible with the colour-rendering properties of lamps and that the spectral distribution of the light source is not adversely affected. See also 'Lighting and colour for hospital design – a report on an NHS funded research project' (Dalke et al, 2004). Refer to CIBSE 'Code for Lighting' for minimum recommended daylight factors.

4.54 Light switches should be provided in easily accessible positions and at appropriate locations in corridors and general circulation areas. In areas with multiple luminaires, switches should permit the selection of luminaires appropriate to the area requiring illumination.

4.55 Where local circumstances permit, the provision of time switches or occupancy controls using infrared, acoustic or ultrasonic detectors should be encouraged. Additionally, low-energy or ultra-low-energy lighting should be considered as the primary lighting source.

4.56 Safety escape lighting should be provided on primary escape routes in accordance with the provisions of Health Technical Memorandum 06-01, Health Technical Memorandum 05-02 – 'Firecode' and the CIBSE Lighting Guide LG2 – 'Hospitals and Health Care Buildings'.

4.57 It is essential that fluorescent lighting in all areas where medicines or containers are processed, including stores, is derived from lamps having suitable colour-rendering characteristics.

Help call systems

4.58 Help call systems should comply with the requirements of Health Technical Memorandum 08-03 – 'Bedhead services'.

4.59 Patient/staff call points should be provided in all spaces where a patient/attendee may be left alone temporarily – for example consulting, examination and treatment rooms and WCs.

4.60 Staff emergency call points are for a member of staff to call for assistance from another member of staff. They should be provided in all spaces where staff consult, examine and treat attendees/patients. Call facilities may also be provided on hand-held devices.

4.61 The help call systems may be hard-wired or secure wireless or secure radio systems.

4.62 Where considered necessary, staff crash call points may be specifically provided for members of staff to call the crash team. This is not required as a standard installation, and needs to be specified for individual rooms where the patient is at high risk of suffering a cardiac arrest.

4.63 A visual and audible indication of the operation of each system should be provided to give responding staff unambiguous identification of the call source, with a repeater unit in a suitable location.

Security

4.64 Measures should be incorporated in the design of all NHS buildings to help protect the safety of staff, patients and visitors and the security of the premises. Security systems will require a local risk assessment and crime prevention survey to be carried out for both daytime and out of hours, to include swipe cards, smart cards, CCTV and other available technological solutions. The project team should discuss security with the local police crime prevention officer and the trust's nominated local security management specialist (LSMS) at an early stage in the design process.

4.65 See the Directions to NHS Bodies on Security Management Measures 2004 (Amendment) Directions 2006 and 'A Professional Approach to Managing Security in the NHS' (NHS Security Management Service, 2003).

4.66 The local fire officer and LSMS should be consulted concurrently to avoid the possibility of the demands of security and fire safety conflicting.

IT and telephone wiring systems

4.67 The IT and telephone infrastructure within the facility may be determined by existing systems within the building. However, where possible, a structured wiring system as described in Heath Guidance Note 'Structured cabling for IT systems' should be provided. This will permit a unified approach to the provision of cabling for:

a. voice systems;

b. data systems;

c. imaging systems;

d. alarm systems.

4.68 While this "universal" cabling system is initially more expensive than separate voice and data systems, the long-term cost of ownership may prove beneficial.

4.69 In determining the nature of the IT system to be provided, it is necessary to identify:

a. areas to be served;

b. whether structured cabling will be used;

c. what density of outlets is to be provided (not fewer than two per workstation);

d. whether wiring will be on a "flood" or "as required" basis.

Bedhead services and entertainment systems

4.70 Allowance should be made for the introduction of television and radio systems in waiting areas, to create a relaxing atmosphere, staff rest areas, and in locations where it would be beneficial in masking sound transfer.

4.71 Other services should be provided in accordance with Health Technical Memorandum 08-03 'Bedhead services'.

Pneumatic tube transport systems

4.72 If a new pneumatic tube system is to be installed, significant investigation needs to be undertaken to ensure that the system will meet the needs of the whole or that part of the hospital site. For further guidance on the design of pneumatic tube systems, see Health Technical Memorandum 2009.

Lifts

4.73 Lifts may be required in order to comply with the requirements of the DDA or Part M of the Building Regulations. For further guidance on the design of lift installations, see HTM 2024.

Controlled Drugs storage

4.74 Controlled Drugs cupboards within wards or clinical areas should be fitted with a red lamp indicating when the cupboard is unlocked. A repeater lamp should be sited outside the doorway of the room in which the cupboard is located. If appropriate, a secondary repeater should be taken to a permanently staffed station.

4.75 The normal power supply for each cupboard should be backed up by a small integral battery to cover the short period between mains failure and the generator becoming available.

4.76 To assist in keeping their contents secure, controlled drugs cupboards should be fitted with a seven-lever mortice lock designed to meet BS 3621.

Sustainability and energy efficiency

4.77 The environment in which people live and work has a key influence on their health. Environmental considerations should therefore be taken into account when building or adapting facilities. The minimising of environmental impact by ensuring that energy is only used necessarily and efficiently is considered in this guidance with respect to:

a. natural daylighting;

b. natural ventilation;

c. night set-back;

d. building regulations;

e. heat recovery;

f. water conservation;

g. minimising solar gain.

4.78 Efforts should be made to maximise the use of natural lighting. Passive solar design (PSD) should be employed to ensure that, as far as possible, areas such as wards, recovery units and offices are located where they can benefit from natural daylight, while other areas, for example stores, WCs and utility rooms, are located towards the core of the facility.

4.79 Areas where glare may be a problem, for example rooms where VDUs are routinely used, should similarly be located away from direct natural daylight.

4.80 Natural ventilation of rooms should be employed wherever possible and appropriate. Design should incorporate measures for minimising solar heat gains, which, if controlled, will avoid the need for mechanical ventilation. Measures to minimise the need for cooling should include locating temperature-sensitive accommodation away from south-facing fascias, shading windows, and using reflecting glass where appropriate and cost-effective.

4.81 Energy-using systems including heating, ventilation, cooling and lighting should be controlled to minimise consumption. Consideration may be given to utilising the thermal properties of the building when the facility is not in

use, for example at night or weekends, where circumstances permit.

4.82 Energy recovery systems should be employed when possible, and particularly on ventilation systems.

4.83 For further guidance on energy efficiency, see Health Technical Memorandum 07-02 – 'Encode: making energy work in healthcare'.

Commissioning and maintenance

4.84 It is important that, on completion of an installation and prior to hand-over, the performance of engineering services and equipment is fully commissioned to validate their function and achievement of performance.

4.85 The final acceptable performance details should be recorded and, together with full manufacturers' details, made available to users and the maintenance organisation before the facilities are handed over.

4.86 Once the facilities are operational, the overall performance should again be further performance tested when full operational conditions are achieved. This will check that the interface between systems has not been compromised and that the systems operate to the designed criteria.

4.87 Risk management, operational procedures and contingency plans should be fully evaluated with staff to ensure that, in the event of an emergency, procedures can be put in place to maximise the safety of patients, staff and visitors. Opportunities should be taken to practise these procedures when it is safe to do so, in order that staff remain fully conversant with what is required of them and can fully appreciate the issues involved.

5 Cost information

Introduction

5.1 For all types of health building, it is important that building costs and revenue expenditure are best-value and consistent with acceptable standards. In applying this guidance, the need for economy should always be of prime concern. Where appropriate, space should be shared between similar activities taking place at different times. However, this solution should not be detrimental to the proper functioning of the spaces involved, nor to the needs of users.

Departmental Cost Allowance Guides

5.2 Departmental Cost Allowance Guides (DCAGs) related to this Health Building Note are officially notified in 'Quarterly Briefing', published by the Department of Health (see www.dh.gov.uk). For a full listing of all DCAGs see 'Healthcare Capital Investment' on the Space for Health website at www.nhs.uk/spaceforhealth.

5.3 The attention of the project team is drawn to the Capital Investment Manual (CIM – Business Case Guide; www.dh.gov.uk). This aims to reduce planning work and to encourage the production of sound business case support of both capital and revenue expenditure. Capital works estimates should be based, wherever applicable, on industry norms, such as DCAGs plus a percentage to cover on-costs.

5.4 The DCAGs for this Health Building Note reflect the total building, engineering and accommodation requirements for adult in-patient facilities located on an acute hospital site, where common services are shared. Costs are based on a typical two-storey new-build unit on a greenfield site with no planning constraints.

5.5 DCAGs are exclusive of VAT, building and planning fees and all local authority charges, and are based on a location factor of 1.00.

On-costs

5.6 An allowance for on-costs (such as communication space, external works, external engineering services and abnormals) should be added to the DCAGs. Abnormals will largely be determined by site characteristics (such as an inner-city location or poor ground conditions) and by the condition or type of any building to be refurbished.

5.7 Project teams should assess all likely on-cost implications of individual sites and schemes at the earliest opportunity.

Locational factors

5.8 Locational factor adjustments should be applied to works costs (that is, DCAGs plus established on-costs) to take account of local market conditions. For further information, see 'Quarterly Briefing' (www.dh.gov.uk).

Schedules of accommodation

5.9 The schedules of accommodation show a notional whole department, which highlights the scope for sharing accommodation. The examples are not to be taken as ideal provision for any particular project.

5.10 The examples are as follows:

- Example 1: 24-bed ward, 50% single-bed rooms;
- Example 2: 24-bed ward, 80% single-bed rooms;
- Example 3: 24-bed ward, 100% single-bed rooms.

5.11 The schedules of accommodation for this document may be updated from time to time. For the latest version check the latest version of this publication on the Space for Health website at www.nhs.uk/spaceforhealth.

Dimensions and areas

5.12 The critical dimensions of an area are determined by the spatial requirements of any activities to be carried out within it. Space requirements for various generic activities appear in Health Building Notes 00-02 – 'Sanitary spaces', 00-03 – 'Clinical and clinical support spaces' and 00-04 – 'Circulation and communication spaces'.

5.13 Planning teams should have data available at the earliest stages of a project to enable the approximate assessment of sizes involved. Areas used for the purpose of establishing cost allowances are listed in the schedules of accommodation. These areas do not represent recommended sizes and should not be regarded as specific individual entitlements.

5.14 The efficient planning of a building may necessitate a variation to the areas given. For example, in the refurbishment/conversion of older property:

- rooms tend to be larger than the areas given;
- some rooms may be too small or in the wrong location for efficient use;
- circulation space tends to form a larger than normal proportion of the total area.

Circulation spaces

5.15 All internal corridors, small vertical ducts, spaces occupied by partitions/walls and other space for circulation, are costed in the DCAGs. Provision is also made for a 5% planning zone and 3% engineering zone adjacent to the external walls.

5.16 Circulation figures included in the DCAGs are those anticipated for new-build facilities. Where constraints are encountered, for example in refurbishment/conversion of older types of property, this figure may increase.

Communication spaces

5.17 Hospital "streets", staircases and lifts (linking spaces) are not included in the DCAGs. Costs related to these elements, along with a suitable space allowance, should be made in the on-costs.

Land costs

5.18 DCAGs are exclusive of all land costs and associated fees. However, costs associated with land costs should be included in business case submissions (as detailed in the Capital Investment Manual) and may therefore have an important impact on the overall cost viability of a scheme.

Engineering services

5.19 The following engineering services are included in the cost allowances (see Chapter 4 and Activity DataBase for further information). Primary engineering services are assumed to be conveniently available at the boundary of the department.

5.20 Mechanical services:

- heating – low-pressure hot water system;
- ventilation – mechanical supply to, and extraction from, clinical areas, and other areas requiring mechanical ventilation such as WCs and showers (excludes ventilation plant, such as air handling units or extract fans);
- cold water – central supply to service points including drinking water (excludes storage tanks);
- hot water – supply from a central system (excludes storage and generation);
- piped medical gases – oxygen, nitrous oxide and medical air (400 kPa).

5.21 Electrical services:

- departmental distribution boards;
- general lighting, as required by task;
- examination lighting (examination lamps);
- staff location system;
- help call systems;
- emergency luminaires, as appropriate;
- socket-outlets and other power outlets for fixed and portable equipment;
- supplementary equipotential earth bonding;
- uninterruptible power supply (UPS) and equipment;
- fire, security, and Controlled Drug cupboard alarm systems;
- TV/radio wireways;
- telephone internal cabling distribution and outlets (excludes handsets);
- data wireways;
- building management system.

5.22 Equipment (Group 1):

- Controlled Drugs cupboards;
- dishwasher;
- impulse clocks.

Example schedules of accommodation for Health Building Note 04-01 - 'Adult in-patient facilities'

Version 3, published June 2010

New system of separate allowances for circulation, communication and engineering space applied

ADB code	Room name/function	Unit area allowanc	Example 1: 24-bed ward, 50% sing bed rooms Quantity	Example 1 Total area	Example 2: 24-bed ward, 83% sing bed rooms Quantity	Example 2 Total area	Example 3: 24-bed ward, 100% sing bed rooms Quantity	Example 3 Total area	Paragraph referenc	Notes

Allowance include For details of unit area allowance s
V0554	*Staff communal changing room*									
V0725	*Semi-ambulant changing room*									
V1321	*Shower room: ambu ant*									
V0667	*Uniform exchange*									
V1010	WC: ambulant	2.0	1	2.0	1	2.0	1	2.0	Para 3.73	1 for up to 20 lockers.
	Net internal area (NIA)			**84.6**		**84.6**		**84.6**		
	Optional accommodation									
V1131	Nappy changing room	5.0	1	5.0					Para 3 66	Optional addition to waiting space.
P0808	Vending machine	3.0	1	3.0					Para 3 66	Optional addition to waiting space.
G0510	Lobby to isolation room	5.0	1	5.0					Para 3 29	
B0308	Isolation room	19 0	1	19 0					Para 3 29	In lieu of standard single-bed room provision.
T0535	Clean utility room	16 0	1	16 0					Para 2 51	Alternative to clean supply and medicine store/preparation room.
V1635	Shower room: assisted	8.0	1	8.0					Para 3 26	Alternative to assisted bathroom in wards with multi-bed bays.
M0727	Sitting room: 7 places (including 1 wheelchair place)	12 0	1	12 0					Para 3.41	Alternative to patient breakout space.
NA	Regeneration kitchen								Para 3.45	Project specific. Requirements by catering contractor.

Note 1	**Relationship of schedule to ADB room names** The ADB room codes listed may not carry a title, in ADB, identical to the room function in the schedules. Use of the appropriate ADB room code will, however, result in the correct room being accessed
Note 2	**Relationship of schedule to ADB for scalable rooms (i.e. those for which a recommended room size in ADB does not exist)** ADB room code relates to one example size of this space and does not reflect space requirements of these schedules. Projects will scale up/down according to schedule.
Note 3	**Essential complementary accommodation** Accommodation to which the department needs access but may be shared with nearby departments.
Note 4	**Optional accommodation** Accommodation which is not expected in all departments, but, dependent on local policy, may be needed in addition to or instead of the rooms listed in the schedule.
Note 5	**Circulation allowance** The circulation allowance is based upon the study and calculations contained within 'Ward layouts with single rooms and space for flexibility' (DH, May 2005).
Note 6	**Engineering space allowance** For the purposes of calculating the engineering space allowances it has been assumed that each ward is located on an acute (multi-purpose) hospital site with a GIA of 25,000 sqm. For larger or smaller facilities, or where there needs to be largely dedicated enginee allowances will vary, generally downwards as GIA increases.
Note 7	**Status of defined metrics** All of the defined metrics (calculations for quantifying spaces) in the notes column have been included as a reasonable basis for initial briefing. They are not intended as and should not be considered requirements.

Appendix 1 – Example bedroom layouts

Introduction

Single-bed room

The layout for a single-bed room in this appendix is an example only. Its purpose is to illustrate how the different elements of the room – bed space, en-suite, clinical support zone, and family zone – can be brought together. Other configurations are possible.

In the design of the example layout, the following issues have been considered:

- clear space around the bed (3600 mm × 3700 mm);
- position of the en-suite shower room;
- bedroom door width into the room;
- location of the clinical wash-hand basin;
- provision of support facilities including space for a fold-down divan;
- sightlines from the corridor (at the doorway).

It is assumed that conventional bedhead services are used, although the use of ceiling- or wall-mounted pendant fittings is possible.

The en-suite – comprising WC, washbasin and shower – is shown with a chamfered profile. For a rectangular layout, refer to Health Building Note 00-02 – 'Sanitary spaces'.

The location of the en-suite can have a significant impact on the bedroom in terms of floor area, views to and from the bed, and support facilities such as the touchdown base. Four layouts, each showing a different location for the en-suite, have been included for illustrative purposes.

Multi-bed room

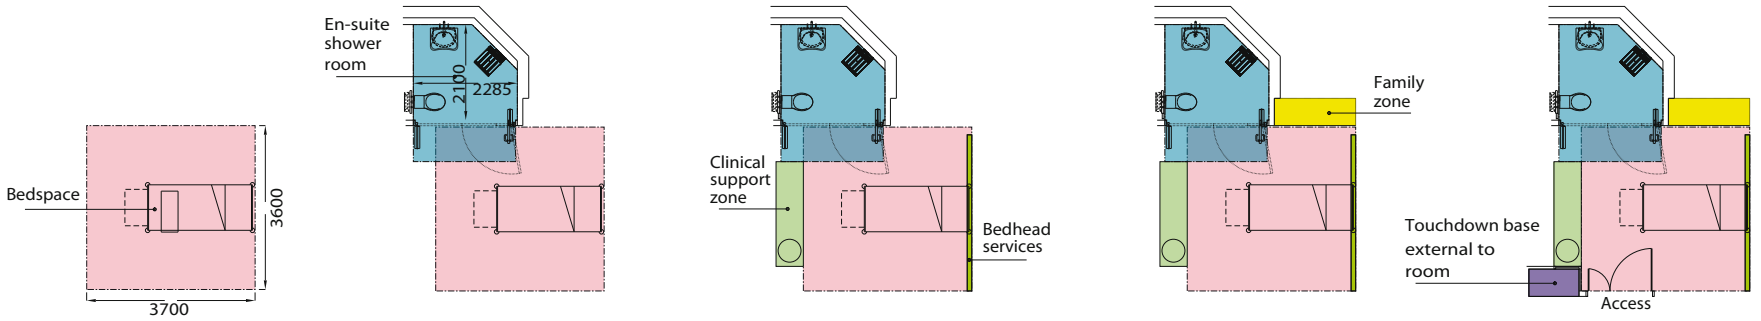
The layout for a multi-bed room is an example only. It shows a four-bed room with an assisted shower room and a second semi-ambulant WC, both en-suite. Full details of these en-suite facilities are contained in Health Building Note 00-02 – 'Sanitary spaces'.

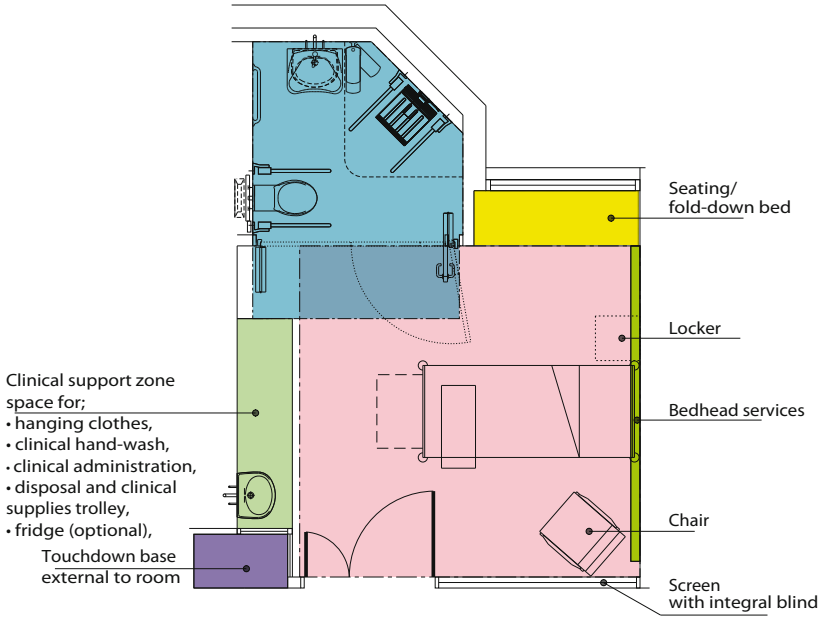
An en-suite with fully opening wall cannot be used in this layout because of the loss of privacy in a multiple-occupancy room. Each en-suite has an outward-opening single-leaf door.

The two en-suites are located inboard, forming a recess at the entrance to the bed areas, providing some privacy to the bed areas.

Two clinical wash-hand basins are located centrally, one next to the room entrance and the other on the outside wall. There is room for one clinical support zone.

Example layout for a single-bed room





Bedspace
This is the clear space required for access around the bed for:
- moving and handling of patients
- patient transfers into and out of bed (including ceiling-mounted hoists)
- clinical activity including resuscitation
- bed making
- manoeuvring the bed in and out of the room
- manoeuvring equipment

Note: it does not include space for built-in or fixed furniture. It does include space for door swings.

En-suite shower room
The space required for the en-suite includes not only the enclosed area but also the temporary manoeuvring space for assisting a patient on both sides of the WC which overlaps the bed space.

Clinical support zone
This includes space for clinical support, hand-washing, clinical administration, storage and space for movable equipment such as supply or disposal trolleys.
Note: This space does not overlap the clear bed space.

Social (family) support zone
Space can be provided for overnight stay either as built-in furniture or space for demountable bed or recliner. This should not impede access to the bedside or into the room. The illustration shows one of the options. Alternatives include window seat and wall-mounted fold-down bed settee.

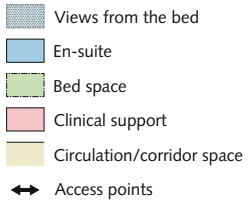
Touchdown base (nurses' workstation)
Clinical nursing stations or "touchdown" bases will be provided adjacent to individual rooms, paired rooms or clusters of rooms. These are best located near to room entrances so that it is possible to observe the patient from outside the room. The location of these workstations should not obstruct the primary circulation space and will be dependent on the location of the room entrance.

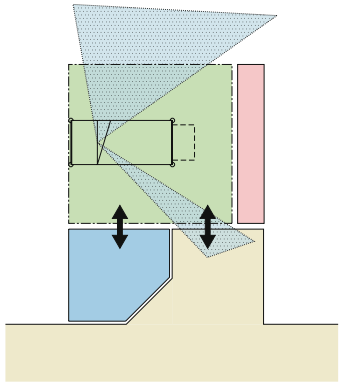
Note: This layout is not intended as a design solution but defines spatial requirements only

En-suite location

The location of the en-suite has a major influence on the subject room in terms of:

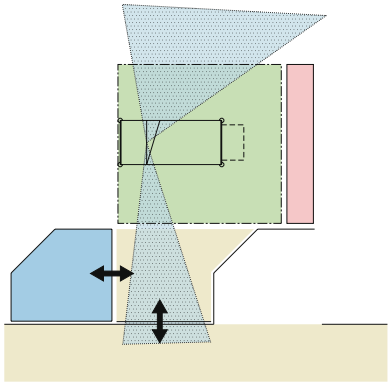
- Access points
- Support facilities including the nurse "touchdown" base
- Views to and from the bed
- Privacy
- Floor area





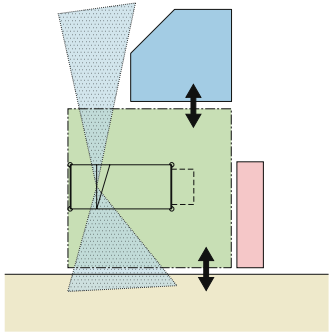
Internal en-suite

a) Access to en-suite and to the room are on the same side and this determines the minimum width of the room.
b) Views of the bed from the corridor are restricted.
c) External views are maximised.
d) Privacy for the patient is maximised especially for views into the en-suite.
e) There are two options for support services: external wall or partition wall.
f) Bed turning can be accommodated adjacent to the bedroom, which increases the circulation space but minimises corridor width.
g) The door position can be optimised to increase or decrease space within the room.
h) A nurse "touchdown" base can be accommodated adjacent to the bedroom door.



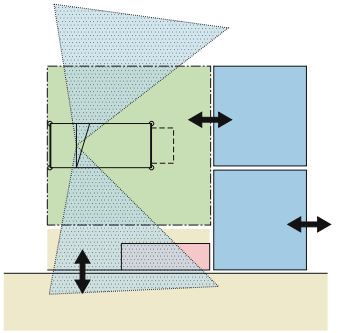
Internal adjacent en-suite

a) Access to en-suite and to the room are on the same side and this determines the minimum width of the room.
b) Views of the bed from the corridor are improved in comparison to the inboard option.
c) External views are maximised.
d) Privacy for the patient is reduced. Entry to the en-suite can be seen from the corridor.
e) There are two options for support services: external wall or partition wall.
f) To accommodate bed turning, either the corridor or the bedroom doors will need to be wider.
g) The bedroom door position is fixed.
h) Accommodating the nurse "touchdown" base is difficult without adding additional width to the corridor.



External en-suite

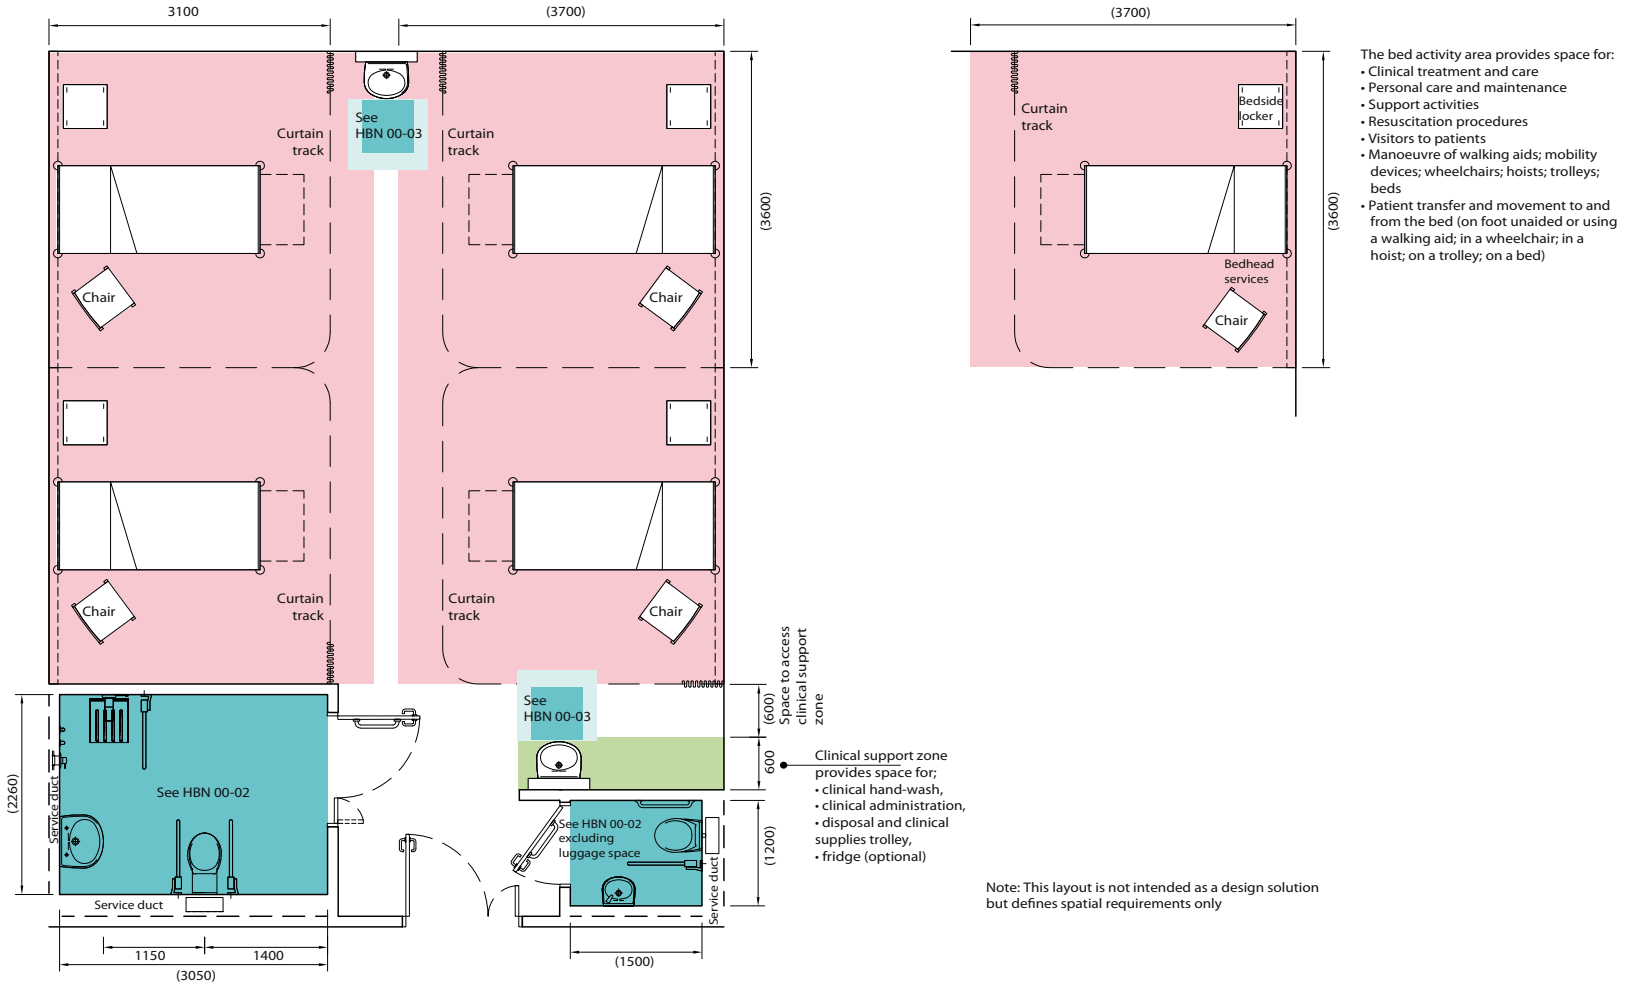
a) Access to room and en-suite are on opposite sides, which is less restrictive on room width.
b) View of the bed from the corridor is maximised.
c) External views are minimised.
d) Privacy for the patient is minimised and entry into the en-suite can be observed from the corridor.
e) There are three options for support services: part external wall, part corridor partitions and room partitions.
f) To accommodate bed turning, either the corridor or the bedroom doors will need to be wider.
g) The bedroom doors can be located flexibly on the corridor wall.
h) A nurse "touchdown base" can be accommodated adjacent to the bedroom door.



In-between en-suite

a) Interlocking en-suites increases overall width and depth of the room.
b) Views of the bed from the corridor are maximised.
c) External views are maximised.
d) Privacy for the patient is minimised and entry into the en-suite can be observed from the corridor.
e) There are two options for clinical support services: external wall or corridor partitions. This will be influenced by whether the en-suite is "nested" on the external or internal wall.
f) To accommodate bed turning, either the corridor or the bedroom doors will need to be wider.
g) The bedroom doors can be located flexibly on the corridor wall.
h) A nurse "touchdown" base can be accommodated adjacent to the bedroom door.

Example layout for a multi-bed room



NOTE: Whilst the evidence base for the layout of this multi-bed room (as set out in 'Ward layouts with single rooms for space and flexibility') was based on optimum space standards, there has been a move towards providing minimum space standards, therefore some dimensions may have been marginally reduced.

Introduction

IOM were appointed by NHS Lothian Health Board to validate the critical ventilation systems at the new Sick Children's Hospital at Edinburgh Royal Infirmary. We were provided with a list of critical areas and associated critical air handling units for the site.

The validation process involves undertaking a number of measurements and checks with the overall purpose of ensuring that the whole system operates correctly and meets the requirements of SHTM 03-01 or standard agreed as part of the design process.

Validation reports for each system are being prepared and will be sent to the Health Board.

Background

The validation work commenced on site on the 17 h June 2019 and it was anticipated it would take approximately 2 weeks. During the first week it became clear that significant amounts of work were still being undertaken to the M+E services on site and the first week was beset with delays to our work from plant interruptions and systems not controlling properly (e.g. temperature control in theatres which meant we were unable to achieve required test conditions). Our work therefore took longer than anticipated. During the course of the validation, it also became apparent that some systems were not performing to the correct standard.

There were shortcomings in many 'critical' areas including theatres, HDU areas, isolation rooms and the air handling units (AHU's) serving those areas.

The shortcomings in the HDU areas were identified relatively early in our work but we were advised that there was a derogation in place to reduce the number of air changes required by the client. However, later it appears there was some confusion over the scope of the derogation and the shortcomings in the HDU areas were the subject of discussion between the Health Board and the PFI supply chain. We were made aware that some changes were to be made in the short term to bolster up the performance of HDU areas with a longer term solution being proposed involving an additional AHU and ductwork installations.

During the first week of our work we did an initial round of testing to isolation rooms. We were planning to test these facilities in 'maintenance mode' but the backup system was not fully operational so that final test could not be done at the time and still has not been possible as the backup system is not operational.

Any issues identified in normal mode were being addressed by Multiplex and we were confirming acceptable performance as we re-tested. The exception to this was the individual isolation rooms which were part of the AHU supply to the HDU areas. As large scale adjustments were being made to areas supplied on that AHU system to HDU areas it would have been likely to affect these individual isolation rooms. It was agreed that these rooms would be re-tested on completion of the balancing. Now that the short term system changes have been deferred, once the system settings are restored, it will be necessary to re-test these rooms.

Issues with operating theatres also began to emerge during the second week. There was an expectation/pressure to have these items corrected alongside our validation work. We were formally requested to move into a phase of witnessing planned adjustments to theatre air systems to bring them up to the required standards. This involved IOM, H+V commissioning and Medical Air Technology MAT (where needed for UCV canopies) working alongside each other to make adjustments and agree the numerical values of any

measurements taken; and to come to a consensus that the theatre performance was acceptable for them to be put into use.

Work method

IOM and H+V commissioning re-measured the systems which had shortcomings. During this work it became apparent that for a number of theatres that the volume of the scrub had not been included in the calculation for air supply rates and as such the commissioning engineers had been commissioning to incorrect values. Each theatre was subject to a thorough re-measurement to establish an agreed spacial volume.

Both parties used their own calibrated instruments. All parties relied on H+V to take duct traverse readings and get the supply air volumes to the theatres to the correct level. Thereafter joint readings were taken to establish grille volume readings and pressure differentials around the suite.

There was a slightly different approach on taking balometer readings. IOM used back pressure compensation on their balometer as the equipment manufacturers state that more accurate readings are obtained in this mode. H+V were unable to alter their balometer to use that facility. IOM readings were higher than H+V's, so it was accepted that if satisfactory readings were obtained by H+V then the IOM readings would exceed theirs and also be satisfactory.

Where UCV canopy quadrants were out of balance, correct supply air volumes were set for the system prior to MAT being invited to test the canopies.

In theatres with UCV canopies all grille and differential pressure readings were taken in both modes.

Operating Theatres

As stated earlier, the theatres on site were formally validated by IOM as part of the overall validation exercise. It became apparent as work progressed that there were some elements of their performance that were unsatisfactory and would need further work before theatre spaces were deemed suitable for use. The validation reports are in production, however, the Health Board were facing a tight deadline to be able to open the facility. The Health Board requested all parties to undertake a programme of testing, adjustment and measuring to come to a consensus that the theatre airflows and pressure cascades were satisfactory for safe use of the facility.

Detailed results for the theatres are attached in Appendix 1

Theatre 32 results are not included here as after re-balancing the required results were not achieved It is proposed to re-test theatre 32 during week commencing 15th July and it may be possible to include results in the final version of this report.

Isolation Suites

Positive pressure ventilated lobby (PPVL) isolation suites consist of 3 rooms, a lobby, bedroom and en suite. They can generally be used for source and protective isolation.

The PPVL isolation suites were initially validated during w/com 20th June 2019 and a summary was provided to the health Board w/com 1st July. Since that date, rooms which did not meet the requirements have been adjusted and re-tested. At the date of this report out of all PPVL isolation suites there was only one room (Room 3-C1.1-004) which was a borderline fail and still needed to be adjusted.

A summary of the results for the isolation rooms is listed below:

Room Designation	Facility type	Room No	Bedroom Ach rate	Lobby to corridor pressure (pa)	Comment
Single bed isolation room 1	PPVL	1-H2-021	13.0	13.0	requires 10 ac/hr supply and 10pa
Single bed isolation room 5	PPVL	3-C1.4-072	13.0	20.0	requires 10 ac/hr supply and 10pa
Single bed isolation room 1	PPVL	3-C1.4-052	12.6	12.0	requires 10 ac/hr supply and 10pa
Single bed isolation room 2	PPVL	3-C1.4-049	11.5	10.1	requires 10 ac/hr supply and 10pa
Single bed isolation room 3	PPVL	3-C1.4-043	12.4	12.3	requires 10 ac/hr supply and 10pa
Single bed isolation room 4	PPVL	3-C1.4-040	11.6	12.1	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	3-C1.3-008	13.3	12.0	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	3-C1.1-040	9.4	13.0	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	3-C1.1-036	11.5	11.4	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	3-C1.1-033	10.0	11.0	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	3-C1.1-004	10.8	11.0	requires 10 ac/hr supply and 10pa
Single bed isolation room 5	PPVL	1-L1-068	10.1	10.5	requires 10 ac/hr supply and 10pa
Single bed isolation room	PPVL	1-G-A2-072	10.3	10.5	requires 10 ac/hr supply and 10pa

Single bed isolation room 17	PPVL	2-L2-039	12.2	11.9	requires 10 ac/hr supply and 10pa
Single bed isolation room 16	PPVL	2-L2-135	10.3	14.4	requires 10 ac/hr supply and 10pa

High Dependency areas.

Testing of the high dependency areas identified that the air change rates and pressure cascades did not meet the requirements. In early discussion with the Health Boards Technical Advisors (Mott MacDonald) we were advised that there was derogation in place which reduced the requirements from 10 ac/hr to 4.

The test information was summarised in an initial briefing to the Health Board during w/com 2nd July.

It later transpired that there was some confusion on the detail of the derogation and the Construction supply chain and the Health Board began working on both an interim solution to improve the situation and a longer term permanent solution.

The final results for the high dependency areas were as follows.

Area/Room	Room No	Supply Ac/hr rate	Extract Ac/hr rate	Pressure Differential	Comment
HDU 4 bed bay	1-B1-009	3.4	1.3	8 pa	requires 10 ac/hr supply and 10 pa
HDU 4 bed bay	1-B1-031	3.1	1.3	0.5 and 3.2 pa(2 doors)	requires 10 ac/hr supply and 10 pa
HDU 4 bed bay	1-B1-063	3.2	1.9	+1.5 pa	requires 10 ac/hr supply and 10 pa
HDU single bed cubicle	1-B1-037	3.4	1.5	+ 6.3 pa	requires 10 ac/hr supply, design pressure tba
NNU 3 cot bay	1-B1-065	4.2	1.5	4.3pa to corridor	requires 10 ac/hr supply, design pressure tba
NNU single cot cubicle	1-B1-035	3.2	2.4	-2.3pa to NNU	requires 10 ac/hr supply, design pressure tba
Area/Room	**Room No**	**Supply Ac/hr rate**	**Extract Ac/hr rate**	**Lobby to corridor pressure**	**Comment**
Single bed isolation cubicle 10	1-B1-036	N/A	9.8	9.5	-ve pressure room. Requires 10 ac/hr supply, design pressure tba.
Single bed isolation cubicle 15	1-B1-026	N/A	9.3	8.0	-ve pressure room. Requires 10 ac/hr supply, design pressure tba.

Single bed isolation cubicle 19	1-B1-017	N/A	11.1	12.0	-ve pressure room. Requires 10 ac/hr supply, design pressure tba
Single bed isolation cubicle 20	1-B1-016	N/a	4.6	45.0	-ve pressure room. Requires 10 ac/hr supply, design pressure tba

tba- to be advised

Recovery areas

The recovery areas have been tested as part of the validation work. The SHTM requires 15 air changes supply and extract to these areas and the room pressure would be expected to be relatively neutral to adjacent areas. The results from our tests are shown below. The test results show that many areas do not meet the requirements and in particular the extract rates for all areas are weak. The overall supply and extract systems should be re-balanced to achieve the required results.

Area/Room	Description	Room No	Supply Ac/hr rate	Extract Ac/hr rate	Pressure Differential
Recovery - DCN	Main area	1-P1-109	11.8	10.2	Recovery to corridor, +1 pa and - 1pa (2 doors)
Recovery - DCN	side room	1-P1-025	18.6	13.8	Room to recovery - 0 pa
Recovery - DCN	side room	1-P1-026	13.5	12.6	Room to recovery, +1pa
Recovery - Paeds	Main area	1-P1-029	18.6	13.8	Room to adjacent spaces, -1.6pa and -1.2 pa (2 doors)
Recovery - Paeds	side room	1-P1-030	19.2	12.4	Room to recovery, +2pa
Recovery - Paeds	Side room	1-P1-031	12.4	14.4	Room to recovery, +2pa

Other Issues

The thrust of the validation and witnessing work was to establish whether facilities were fit to use. During the course of the work, it has become apparent that there are other issues with the completed facility which do not meet the requirements of the SHTM or are defects which need to be attended to in due course.

Some initial findings were notified to the Health Board on 27th June. The validation and witnessing exercises have identified some additional items which may need to be addressed depending on the agreed design standard. We have been asked to identify any issues to be included on an issues log to allow all parties to decide who the responsible parties are and on how these should be resolved. The key additional items identified are listed in Appendix 2.

Summary and conclusions

SHTM 03-01 Part A, section 8 describes Validation as 'A process of proving that the system is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that "*The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.*"

In the case of the critical ventilation systems at the Hospital for Sick Children at Edinburgh Royal infirmary, this is not currently the case.

In particular:

- Theatre 32 needs to be finally witnesses – see appendix 3 for theatre 32
- There is one PPVL isolation room that needs adjustment
- Isolation rooms supplied by the HDU AHU will need to be re-tested once improvement works are completed
- The isolation rooms need to be tested in 'maintenance' mode.
- The ventilation to the HDU areas needs to be altered to meet the required standard.
- There are a number of recovery areas where the supply rates are below requirements
- All recovery areas need the extract rates improving to meet requirements.

The Health Board should therefore insist on further remedial works being undertaken by the PFI supply chain.

Some of the remedial works could be very disruptive to operations so consideration should be given to having some of the work completed prior to occupation.

The Health Board should also consider employing a subject matter expert to ensure that remedial work takes place to a satisfactory standard and to ensure where necessary the Board has the necessary expertise to ensure the supply chain is held to account to meet the contractual responsibilities.

Appendix 1 – Theatre performance data.

The following data was collected as part of the theatre performance improvement and witnessing work with H+V. The final results for Theatre 32 have not been established at this time.

Theatre 30

Remedial works to theatre 30 included:

- Balancing of the 4 grilles to the theatre
- Improvement of extract rate in the dirty utility to meet requirements
- Increasing the extract air in the anaesthetic room to achieve 15 ac/hr/hr.

A summary of the final results are shown below:

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply	1425	26.8	Y
Prep supply	105	11.4	Y
Anaesthetic supply	245	17.4	Y
Anaesthetic extract	261	18.5	Y
Dirty utility extract*	421*	40	Y
Theatre LL extract	377		No figure in SHTM
Scrub extract	103		failed smoke visualisation 27/09/2019
Open door protection	944	N/A	Yes – needs 750 l/s

*Includes extract from a grille supplied by the adjacent theatre

Pressure Differentials

From	To	Measured pressure	Meets requirements **
Theatre	Corridor	24	Y
Theatre	Anaesthetic	13	Y
Theatre	Dirty utility	37	Y
Theatre	Prep	0	Y
Prep	Corridor	24	Y
Anaesthetic	Corridor	11	Y
Corridor	Dirty Utility	8	Y

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 31

Remedial works to theatre 31 on site undertaken by H+V commissioning and MAT as follows:

- Increasing AHU supply volumes to meet requirements in conventional mode
- Increasing the supply volume to the prep room to meet the requirements.

The results are set out below:

UCV Canopy

Test	Result	Comment
2m av. Velocity above 0.38m/s	Pass	
Quadrant balance not exceeding +/- 6%	Pass	
1m velocity – no cells below 0.2m/s	Pass	
Filter integrity/Particle count	Pass	
Entrainment	Pass	

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 33

Remedial works to theatre 33 on site undertaken by H+V commissioning and MAT as follows:

- Re balancing canopy to eliminate failing cells at 1m and out of balance quadrants.
- Increasing the extract volume to the dirty utility room to meet the requirement for 410 l/s. ac/hr/hr.
- Increasing the supply and extract volumes to the anaesthetic room to achieve 15 ac/hr/hr.
- Increasing the prep room supply volume to achieve 100l/s and 10 ac/hr/hr

The results are set out below:

UCV Canopy

Test	Result	Comment
2m av. Velocity above 0.38m/s	Pass	
Quadrant balance not exceeding +/- 6%	Pass	
1m velocity – no cells below 0.2m/s	Pass

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 34

Remedial works to theatre 34 on site undertaken by H+V commissioning as follows:

- Balancing of the theatre grilles to within 10%
- Resolving the lack of air in the theatre to provide open door protection
- The broken blade to a pressure stabiliser has been replaced.
- The anaesthetic room extract rate has been increased to meet requirements.

A summary of the results are shown below:

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply	1267	25.7	Y
Prep supply (SPS)	109	11.8	Y
Anaesthetic supply	248	17.7	Y
Anaesthetic extract	235	16.8	Y
Dirty utility extract*	463*	46.1	Y
Theatre LL extract	384		No figure in SHTM
Scrub extract	90		failed smoke visualisation 27/09/2019
Open door protection	793	N/A	Yes – needs 750 l/s

*Includes extract from a grille supplied by the adjacent theatre

Pressure Differentials

From	To	Measured pressure	Meets requirements **
Theatre	Corridor	25	Y
Theatre	Anaesthetic	10	Y
Theatre	Dirty utility	40	Y
Theatre	Prep	0	Y
Prep	Corridor	27	Y
Anaesthetic	Corridor	14	Y
Corridor	Dirty Utility	23	Y

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 35

Remedial works to theatre 35 on site undertaken by H+V commissioning as follows:

- Resolving the lack of air in the theatre to provide open door protection
- Increasing supply air volume to the prep room.
- The anaesthetic room extract rate has been increased to meet requirements.

The theatre grille readings to the theatre seem to be fluctuating over time and there were discrepancies in readings from the 2 different air capture hoods being used.

We have taken the worst case readings which meet requirements but it would be useful if the underlying reasons for pressure fluctuation in the supply AHU and to establishing whether a change in controls set up would help address this.

A summary of the results are shown below:

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply	1312	27.5	Y
Prep supply(SPS)	109	11.9	Y
Anaesthetic supply	225	16.0	Y

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply (UCV)	1483	27.7	Y
Theatre supply (conv)	1383	25.8	Y
Prep supply (SPS)	113	10.6	Y
Anaesthetic supply	277	19.6	Y
Anaesthetic extract	269	19.0	Y
Dirty utility extract*	504*	47.5	Y
Theatre LL extract	411		No figure in SHTM
Scrub extract	100		failed smoke visualisation 27/09/2019
Open door protection	872 – worst case (conv)	N/A	Y – needs 750 l/s

*Includes extract air from a grille supplied by the adjacent theatre

Pressure Differentials

From	To	Measured pressure	Meets requirements **
Theatre	corridor	22	Y
Theatre	Anaesthetic	9.5	Y
Theatre	Dirty utility	28	Y
Theatre	Prep	0	Y
Prep	Corridor	18	Y
Anaesthetic	Corridor	11	Y
Corridor	Dirty Utility	9	Y

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 38

Remedial works to theatre 38 on site undertaken by H+V commissioning as follows:

- Increasing AHU supply volumes to meet requirements
- Increasing the air volume to the prep room
- Increasing the extract volume to the dirty utility room to meet the requirement for 410 l/s.
- Increasing the extract volume to the anaesthetic room to achieve 15 ac/hr/hr.

The results are set out below:

UCV Canopy

Test	Result	Comment
2m av. Velocity above 0.38m/s	Pass	
Quadrant balance not exceeding +/- 6%	Pass	
1m velocity – no cells below 0.2m/s	Pass	
Filter integrity/Particle count	Pass	
Entrainment	Pass	

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply (UCV)	1526	27.3	Y
Theatre supply (conv)	1443	25.8	Y
Prep supply (SPS)	120	13.8	Y
Anaesthetic supply	250	17.4	Y
Anaesthetic extract	251	17.4	Y
Dirty utility extract*	536*	50.5	Y
Theatre LL extract	441		No figure in SHTM
Scrub extract	122		failed smoke visualisation 27/09/2019
Open door protection	880 – worst case (conv)	N/A	Y – needs 750 l/s

*Includes extract air from a grille supplied by the adjacent theatre

Pressure Differentials

From	To	Measured pressure	Meets requirements **
Theatre	corridor	37	Y
Theatre	Anaesthetic	19	Y
Theatre	Dirty utility	50	Y
Theatre	Prep	0	Y
Prep	Corridor	38	Y
Anaesthetic	Corridor	15	Y
Corridor	Dirty Utility	10	Y

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Theatre 39

Remedial works to theatre 39 on site undertaken by H+V commissioning and MAT as follows:

- Increasing AHU supply volumes to meet requirements
- Increasing the extract volume to the anaesthetic room to achieve15 ac/hr/hr.
- Checking canopy balance which had one quadrant out of balance by 13%.

The results are set out below:

UCV Canopy

Test	Result	Comment
2m av. Velocity above 0.38m/s	Pass	
Quadrant balance not exceeding +/- 6%	Pass	
1m velocity – no cells below 0.2m/s	Pass	
Filter integrity/Particle count	Pass	
Entrainment	Pass	

Air volumes and air changes

Room	Measured air volume (l/s)	Air changes	Meets requirements?
Theatre supply (UCV)	1546	28.7	Y
Theatre supply (conv)	1388	25.8	Y
Prep supply(SPS)	116	12.8	Y
Anaesthetic supply	244	17.4	Y

Theatre LL extract	373		No figure in SHTM
Scrub extract	106		failed smoke visualisation 27/09/2019
Open door protection	909 – worst case (conv)	N/A	Y – needs 750 l/s

*Includes extract air from a grille supplied by the adjacent theatre

Pressure Differentials

From	To	Measured pressure	Meets requirements **
Theatre	corridor	36	Y
Theatre	Anaesthetic	22	Y
Theatre	Dirty utility	61	Y
Theatre	Prep	0	Y
Prep	Corridor	36	Y
Anaesthetic	Corridor	15	Y
Corridor	Dirty Utility	11	Y

**The SHTM states (in Notes applicable to Table A2, Part A): 'Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved'.

Appendix 2 - Other Issues

Listed below are other issues identified as part of the validation and witnessing work. Further details of relevant SHTM/HBN references will be provided as part of the issues log. Items identified are:

- There is a very limited amount of extract in the theatre corridors. Corridors are not at 0 pascal's absolute pressure and the excess air is holding fire doors open and in some cases reducing pressure differentials from theatres to corridors. The installation does not meet required 7 ac/hr/hr (SHTM03-01 part A appendix 2 Table A2)

- There is a large amount of cabling, plastic containment and electrical connectors inside the AHU. In some cases these electrical connectors are very close to filters and the moving parts of the thermal wheels. SHTM 03-01 part A para 1.41 states: 'The equipment built into the ventilation system and its ductwork should be of a type that will neither cause nor sustain combustion'. This arrangement also gives rise to potential electrical faults to cause smoke within the airstream and makes the units difficult to clean effectively. In addition, use of soapy water in cleaning the AHU's can impact on the electrical connections. Where this has happened on other sites the Trust insisted this was removed before the hospital went live due to fire and smoke risk within the AHUs (this was a new high profile NHS emergency hospital and detail of the site can be obtained from IOM).

- There is evidence of excess usage of flexible spiral ductwork in theatre ceilings. SHTM 03-01 part A paras 5.54 and 5.55 state that 'flexible ductwork should never exceed 1m in length' and 'never be used in lieu of a bend'. In addition it should be constructed to meet fire precautions recommended in BS8313. There are several cases where the length of ducting exceeds 1m and is used as bends. Theatre 35 is an example where in one case an 's' bend is formed of flexible ductwork to one of the 4 theatre grilles. The material did not appear to be of a fire rated quality.

- It is believed that the air supply volumes to the theatres were incorrectly calculated by the designers as they did not include the scrub bay volume into the volume calculation for the theatre. Although adjustments have been made to overcome this it has eroded the amount of spare plant capacity/motor speed variation available to overcome additional system pressure drops caused by blocked filters, which occurs with normal use as they get dirty

- The design of some of the supply ductwork to theatres is sub optimal. In some cases the 4 ducts to UCV canopies are off different ducts from the plant areas and the link in points for anaesthetic and prep rooms are not well located. This is likely to leave the UCV's to be vulnerable to the quadrants going out of balance over time. It is an out of balance design.

- There is limited access for maintenance to some parts of the UHU's. As they are regularly located side by side in pair's one whole side of the unit is in accessible. The supply motor located adjacent to the control panel in each AHU looks extremely difficult to change in the event of a failure which could result in excessive down times to Theatres. This is exacerbated by theatres having to operate in pairs due to the dirty utility extract arrangements.

- We have concerns about use of pressure control on the AHU outputs in systems with UCV's. The use of pressure sensors downstream of the AHU and upstream of

UCV canopy theatres has been shown at other hospitals to cause fluctuating or hunting airflows within the UCV canopy. The use of airflow sensors appears to enable a much more stable situation with far less fluctuation

- The extract grilles in scrub areas should have been located at low level to encourage a suitable clean air path and route for any aerosols created to be away from users and also reducing the risk of aerosol from becoming airborne around the theatre suite

- The air system design for dirty utility rooms was for one grille supply volume to ramp up supply when the adjacent theatre was not in use. This has not been achieved in the installation so both theatres must run when one is in use. This represents a complete waste in energy and means that 2 theatres will be unusable in the event of a failure or shutdown of plant.

- The UCV in Theatre 39 was operational and there was no alarm on the surgeon's panel when the supply AHU was not running. Similarly in theatre 34 the surgeon's panel indicated system healthy when the AHU was not running. The cause/effect and alarm indication of each theatre should be re-tested to confirm correct operation

- Supply grilles in anaesthetic rooms are relatively close to the low level extract which can short circuit the clear airflow pathway across the patient in that room.

- There is no user control or indicator panel in the Angio procedure room which allows users to control the plant or indicates whether the plant is operational.

- The noise levels in some rooms are higher than recommended by SHTM 03-01. Although the excess noise is limited, it would not be expected in a new development.

- Several isolation rooms on one AHU. HBN 04-01 supplement 1 (2013) Para 2.37 states that ideally each isolation suite should have its own supply and extract system. Several isolation rooms are supplied by certain air handling units. Although there is a maintenance mode on some rooms, the failure of one of the key AHU's will result in a significant impact on the number of isolation rooms available. In addition, although not yet tested, it is understood that the maintenance mode arrangements were not designed to keep the room air changes and pressures to the full Health Building Note (HBN) requirements.

- We have concerns regarding the thermal wheels used on theatre systems. During the course of our work we have issues when they have been operating. For example it is considered that the high rotational speed will overcome the relatively small purge section and transfer extract air into the supply air path. It is recognised even by manufacturers that thermal wheels have inherent leakage of air between sections so it is unusual for them to be used in theatre systems. We believe the manufacturers should be asked to attend site and witness/confirm that the units are correctly installed and controls are properly set up.

- There are some volume control dampers (VCD's) in theatres which are not accessible for adjustment. (e.g. Theatre 34 – the two grilles nearest to anaesthetic/prep wall). Proper access is needed to these for future adjustments.

- There is insufficient access for cleaning to some parts of the system (e.g. inlets) and multiple access hatches are too small for cleaning/maintenance activities

- Some duct traverse test points are in poor locations (e.g theatre 30 close to a bend) and in some cases holes are not plugged/capped.

- There is a surplus drip tray in most AHU's (possibly where a humidifier was removed). The drip tray drain is not blanked off

- The filter pleat orientation incorrect on top row of final filters and there is some evidence of bypass on pre filters (e.g. Theatre 36).
- The theatre AHU inspection lights on theatre 32 do not operate when the unit is isolated. This would be the case when the unit was being maintained so need to be changed..

- Most glass traps on systems are dirty and most are connected the wrong way around with inadequate air gaps.

- Cooling coil drip tray area not easy to clean. Cooling coil baffles cannot be easily removed due to cable and trunking installation in the AHU.

- The scale of the graduations on the magnahelic gauges is too large to give accurate readings on the filter pressure drop. In addition, they are not marked to show clean and dirty pressure limits.

- Motorised dampers take a long time to open and close which impacts on the speed of auto-changeover. In addition, they do not appear to be spring return (motorised dampers should close in the event of the power failure).

- Auto change over arrangements need to be fully tested. Some MD's do not close on plant isolation and some units will not re-start after both motors have been isolated.

- There is a noisy quadrant fan in the canopy of theatre 38 so this has limited life.

- The plant does not seem to benefit from close control. Theatre 35 air volumes are erratic and give differing readings at different times. Several theatres do not achieve the close temperature control as would be expected from modern controls (eg theatres 34 and 35 had fluctuating temperatures which were mirrored by altering RH readings suggesting that temperature control is partially being met by use of cooling rather than closure of heating valves, i.e. heating and cooling batteries compensating for each other. It is essential that the underlying reasons for these fluctuations is understood and resolved by changes to controls.

- Plant labelling incorrect and shows incorrect areas served. Some direction arrows on ductwork are incorrect and branch ducts where they leave plant areas are not fully marked up to show areas served

- Some AHU motors are running at over 95% speed so there is limited scope for systems to overcome dirty filter pressure drop and maintain system performance.

- There were communication problems between the BMS and one AHU (serving theatre 33). This has probably been corrected but we witnessed regular plant/AHU failures which could not be explained by construction or maintenance staff on site.

- We were unable to locate any duct traverse test points on the Angio and MRI AHU's so could not fully confirm air supply volumes to the area.

- It is not clear if critical plant will operate in stand-alone mode in the event of issues with the BMS or communications systems.

Appendix 3 – Theatre 32 witnessing and subsequent additional findings

Theatre 32 airflows were checked by IOM on Tuesday 1st October 2019

Room	Measured air volume (l/s) UCV	Con	Air changes	Meets requirements?
Theatre suite supply (UCV)	1584			Y
Theatre supply (conv)		1462		Y
Prep supply(SPS)	101	126	10.6/13.21	Y
Anaesthetic supply	235	260	16.5/18.6	Y
Theatre room supply UCV	1248		22.94 including scrub area	N
Theatre room supply conventional		1076	19.8 including scrub area	N
Anaesthetic extract	234	249	16.48/17.5	Y
Dirty utility extract*	512	521	49/50	Y
Theatre LL extract	421	401		No figure in SHTM
Scrub extract	118	111		failed smoke visualisation 27/09/2019
Open door protection	587– worst case (conv)		N/A	N – needs 750 l/s

Note H&V duct traverse 03/07/2019 indicated 1859 l/s which would have been satisfactory in terms of both air change rates in theatre and door protection

Due to the results of the theatre 32 having a significant difference in duct traverse readings, NHS Lothian agreed to IOM carrying out a set of duct traverse readings on 3/10/2019.

This is summarised in the following table

Theatre suite	Design from H&V documents	3/07/2019 H&V Traverse l/s	3/10/2019 IOM Traverse l/s
Theatre 30 AHU 02-09 conventional	1525	1520	1410
Theatre 31 UCV AHU 02-10	1477 total	1885 total ucv 892 TH1 626 TH2 1881 con	1729 total
Comments on T31		892+626=1518 367 l/s less than measured at main traverse	
Theatre 32 UCV AHU 02-12	1850	1859 ucv 1913 con	1584 ucv 1462 con
Theatre 33 UCV AHU 02-11	1800	1775 ucv 1806 con	1896
Theatre 34 Con AHU 14	1525	1797	1717
Theatre 35 AHU 13	1525	1767	1718
Theatre 36 Intra-operative	1800	1847 ucv 1746 con	Not measured due to Work being carried
Theatre 37 UCV AHU 02-16	1477	1827 ucv 1757 con	1548
Theatre 38 UCV ahu 02-15	1750	1863 ucv 1842 con	1948
Theatre 39 AHU 02 -17	1800	1897 ucv 1765 con	1800

This has indicated that theatres 30, 32 and 37 have airflows significantly lower than three months ago.
This impacts on the available door protection in these theatres
At this stage it is uncertain why the airflows have decreased in these theatres and it will be necessary to ensure that following AHU improvements, airflows are re measured and then monitored to ensure that the systems are delivering the correct quantity of air between each planned preventative maintenance period.

MULTIPLEX

Certificate of Sub-Contract Practical Completion

Contractor: Multiplex Construction Europe Limited (Company No 03808946) and having its Registered Office at, One Broadgate, 1st Floor, London EC2M 2QS

Sub-Contractor: Mercury Engineering (Registered in the Republic of Ireland Company No 225667) and having its Registered Office at Mercury House, Sandyford Industrial Estate, Dublin 18

Sub-Contract: Sub-Contract between Multiplex Construction Europe Limited and Mercury Engineering dated 6 and 13 February 2015, Sub-Contract Order Ref 17158/031

Sub-Contract Works: the Mechanical, Electrical and Public Health (MEP) Services comprising part of the design and construction of the re-provision of the RHSC, and DCN at Little France, Edinburgh

Under the terms of the above noted Sub-Contract we hereby certify that in our opinion the Sub-Contract Works were complete in accordance with the Completion Criteria, as set out in the Contractor's Requirements on 22nd February 2019, subject to the exceptions noted in Appendix 1 to this Certificate.

Please note that the issue of this Certificate of Sub-Contract Practical Completion shall in no way affect the obligations of the Sub-Contractor under the Sub-Contract, including in respect of any Defects.

For the avoidance of doubt, this Certificate of Practical Completion is issued on the condition that the Outstanding Works, Defects and/or Snagging Matters specified in Appendix 1 to this Certificate shall be completed/rectified no later than the time periods specified in Appendix 1 to this Certificate.

Signed ---------- **Dated----------**

Appendix 1 to the Certificate of Sub-Contract Practical Completion

Outstanding Work

- **Water Testing**

  - As per the requirements of SHTM 04-01 and L8, the Sub-Contractor shall undertake a full suite of water analysis for all relevant water systems including storage tanks, domestic water, mains water, hot and cold water, and category 5 water systems in full compliance with SHTM04-01, and using the methodology of water testing undertaken by the Sub-Contractor in January 2019, including any further points agreed with the Contractor. The foregoing tests were undertaken by the Sub-Contractor on or around 27 February 2019 ("Water Tests").

  - The indicative results of the Water Tests shall be made available to the Contractor by the Sub-Contractor on or before 5 March 2019. The complete results of the Water Tests have been made available to the Contractor.

  - If the Water Tests results identify any non-compliance with SHTM 04-01, or give reasonable cause for concern by the IT that a future non-compliance may occur, the Sub-Contractor undertakes to address said non-compliance and / or potential non-compliance as a matter of urgency in accordance with the Sub-Contractor's obligations pursuant to the Sub-Contract, taking account of any submissions from the Contractor.

- **Water management regime**

  In accordance with SHTM 04-01, the Sub-Contractor shall provide a suitable and sufficient water safety management regime, specifying the water safety management regime

  The Sub-Contractor shall include in the water safety management regime a flushing regime during the Board's commissioning period which ensures there are no Little Used Water Outlets on the system.

  The Sub-Contractor will be responsible for, and shall provide maintenance services to, the water systems, including without limitation storage tanks, domestic water, mains water, hot and cold water and category 5 water systems until all tests required within the Water Testing section above are complete, and the relevant results demonstrate a compliant water system in accordance with SHTM 04-01 and L8. Where any tests required are returned with out of specification results, the relevant part of the water system, and the maintenance thereof, will remain the responsibility of the Sub-Contractor. Such maintenance obligations shall include the cleaning, disinfection and flushing as appropriate of the part of the water system which is non-compliant. Once such maintenance obligations are complete, the Sub-Contractor shall repeat the tests required and provide the results to the Contractor.

  The process shall be repeated until the relevant results demonstrate a compliant water system in accordance with SHTM 04-01 and L8 and the water systems are handed back to the Service Provider in a compliant manner, together with all associated test results and water management records.

- **Fire detection**

  - Where voids contain either natural gas, medical gas or IPS (Isolated Power Supply) circuitry, automatic smoke detection will be added within these voids.

  - For the fire alarm manual call point, the Sub-Contractor shall provide additional manual call points developed on the basis of the Risk Assessment. The Sub-Contractor shall carry

out and complete works to the fire detection and alarm system in accordance with the Contractors Instructions..

- Completion Criteria – Sub-Contractor shall demonstrate that the following criteria has been achieved:

- The fire detector, manual call point and fire-alarm are re-tested and re-commissioned.

- Cause and effect testing of the fire detector, manual call point and fire-alarm in each zone are complete and proven.

- All mechanical and electrical plant and systems associated with the void detection shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Sub-Contract

Deadline for completion: 6 June 2019

- **Isolation room heating**

  Completion of Instructed works

  Completion Criteria - Sub-Contractor shall demonstrate that the following criteria has been achieved:

  - The radiant panels are tested, commissioned and operating satisfactorily in accordance with the specified design criteria and any manufacturers' operating requirements.

  - All mechanical and electrical plant and systems associated with the heater batteries shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements and all other relevant terms of the Sub-Contract.

  Deadline for completion: 18 May 2019

- **Internal and external foul drainage**

  Completion of Instructed works

  Completion Criteria - Sub-Contractor shall demonstrate that the following criteria has been achieved:

  - The Building Management System is operating satisfactorily in relation to the drainage sump and pumps.

  - All mechanical and electrical plant and systems associated with the internal and external foul drainage shall be tested, commissioned and operate satisfactorily in accordance with the specified design criteria, any manufacturers' operating requirements.

  Deadline for completion: 18 April 2019

- **Other Outstanding Works**

  - Security System – rectify access control doors not operating correctly & CCTV system not showing all camera images on head end
  - Plant room Insulation – rectify insulation within plant rooms that are contributing to overheating issues
  - Outstanding Commissioning
  - NCR's – close out all open NCR's

- Energy Centre Lighting – resolve compliance issue raised by Board to the satisfaction of the Independent Tester
- Oil pipework – rectify leaks currently on system
- Bin Washer pipework – complete trace heating and insulation
- Bib tap pipework – complete trace heating and insulation
- AHU pipework – complete installation of step-overs in plantrooms
- Electrical labelling – complete all labelling to all cables at panels
- Cold Water Storage Tank – complete handrails
- Lab and filter tanks –complete glass traps & early warning pipe
- Complete all outstanding Instructed works
- HV Gas Suppression Controls Demonstration
- BMS critical alarm –
    - SMS & email alerts not proven
    - Environmental proving and trend logs
- Boiler - oil system pressure regulating valve
- Resolution of HV mimic diagram
-

Deadline for completion of above items: 10 May 2019

- Completion of O&M's & BIM Model

Deadline for completion of above items: 13 June 2019

Defects

The Sub-Contractor shall remedy or repair the Defects noted in the Defects Tracker attached at Appendix 2 to this Certificate within the time period noted within the Defects Tracker (Schedule Part 12 Section 1 Appendix C to the Building Contract refers).

Snagging Matters

The Sub-Contractor shall carry out and complete the Snagging Matters outlined in the attached document titled 'Task Management PC' (10 pages) Appendix 3 to this certificate

All Snagging Matters shall be rectified by the Sub-Contractor within eight (8) Business Days of the issue of this Certificate of Sub-Contract Practical Completion.

CONTENTS

EXECUTIVE SUMMARY

SHTM 03-01 requires that critical ventilation systems are verified against design/SHTM standards and that any inability to achieve the recommended standards is classed as a failure. It is not in the remit of a validation/verification company to state whether an HDU suite is fit for use. Rather, this is a judgement for the client and/or clinical department to make, given their knowledge of the particular clinical procedures to be carried out.

This summary highlights where standards have or have not been achieved and is expanded upon in the relevant "Results" sections.

Air Change Rates

HDU Supply: ***did not meet recommendations***

Pressure Differentials

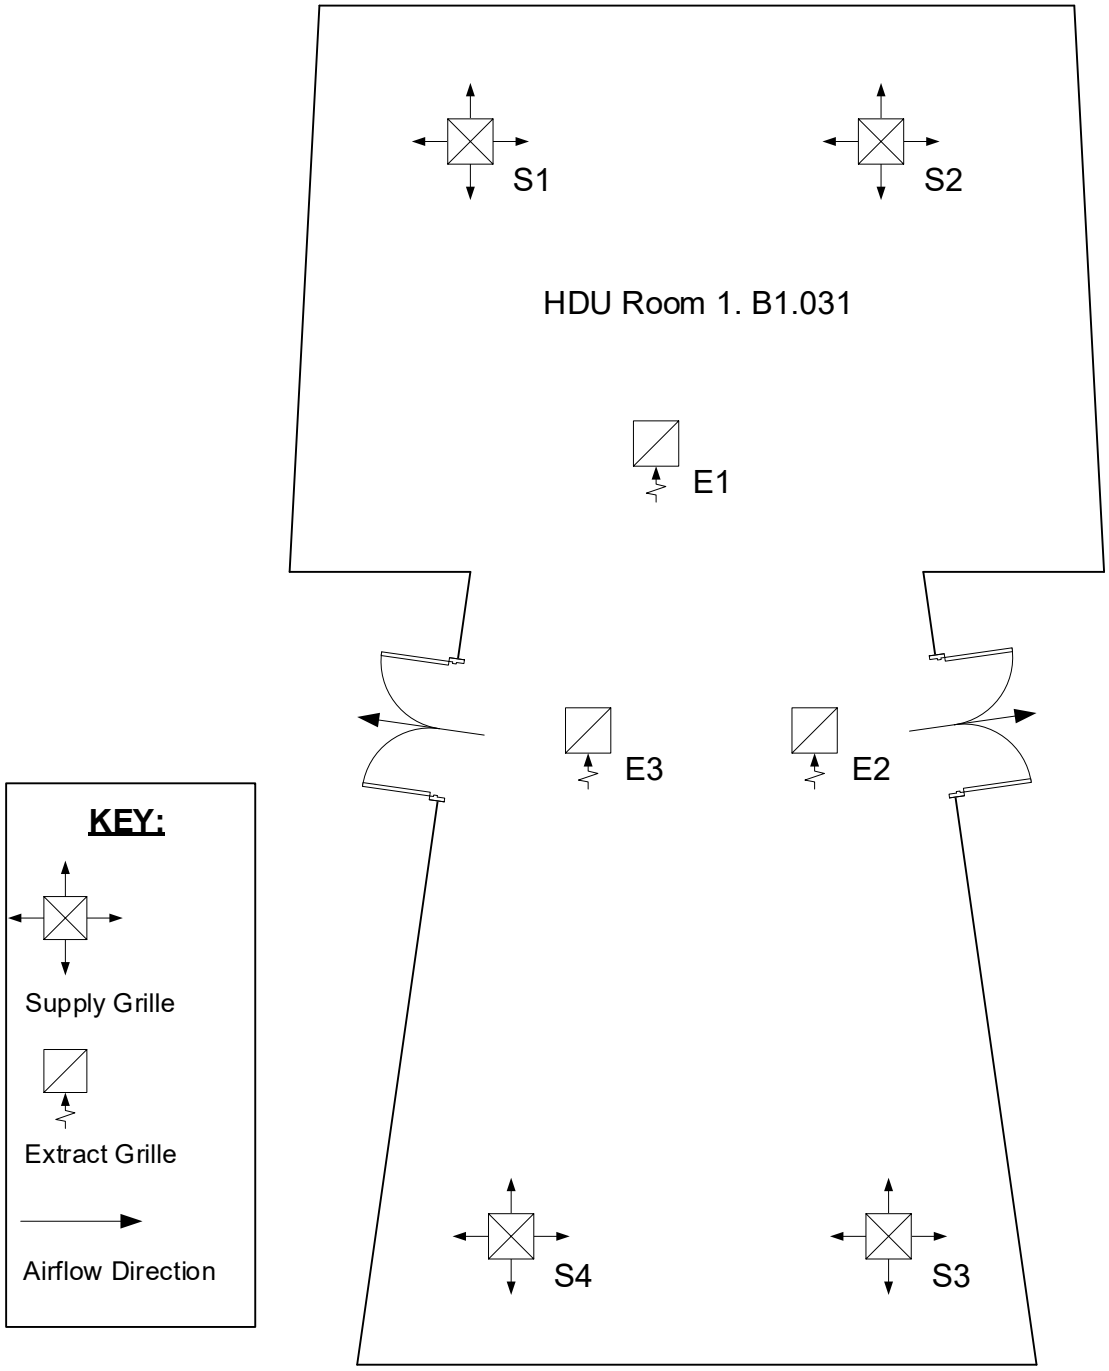
HDU: ***did not meet recommendations***

Noise Levels

HDU: **satisfactory**

SCHEMATIC DIAGRAM

(not to scale)



INTRODUCTION

IOM Consulting Ltd. was requested to undertake the validation of this HDU as required by Healthcare Facilities Scotland; Scottish Health Technical Memorandum 03-01 (SHTM 03-01) - Ventilation for Healthcare Premises.

1 PROCEDURES - Summary

This assessment has been undertaken in compliance with SHTM 03-01

The following tests were carried out;

- Airflow measurements at supply and extract grilles throughout the suite
- Pressure differential measurements throughout the suite
- Noise level measurements as appropriate

A full description of procedures can be found in Appendix 1.

Equipment used:-

Instrument	Manufacturer	Serial number
Balometer	TSI	PH 7311922002
Micromanometer	DPM	8176
Type 1 integrated noise meter	Rion NA 28	00680931
Noise calibrator (calibrated yearly)	CEL 110/2	117453

2 RESULTS

Test criteria: SHTM 03-01 gives recommended minimum quantities of fresh air to be supplied to or extracted from locations in the Critical care areas.

2.1 AIRFLOW VOLUMES

Supply Grilles

HDU

Grille Number/ Location	Measured airflow l/s
S1 / HDU	66
S2 / HDU	62
S3 / HDU	59
S4 / HDU	72
HDU Total	**259**

Extract Grilles

HDU

Grille Number/ Location	Measured airflow l/s
E1 / HDU	25
E2 / HDU	37
E3 / HDU	43
HDU Total	**105**

2.2 AIR CHANGE RATES

Test criteria: SHTM 03-01 recommends air change rates per hour (AC/hr) for the Critical Care Area and Isolation Rooms. The AC/hr is determined by dividing the supply or extract airflow rate per hour by the room volume.

Room	Room Volume m^3	Measured AC/hr	SHTM 03-01 recommended AC/hr
HDU	298.4.	3.1(S)	10

(S) = supply, (E) = extract

2.2.1 Conclusions

HDU supply air change rate **did not meet** the recommendations.

2.2.2 Recommendations

Upgrade the ventilation system to improve the air change rates to the SHTM 03-01 recommendation.

2.3 PRESSURE DIFFERENTIALS

Test criteria: For design calculations, SHTM 03-01 gives nominal room pressure values, the purpose of which is to maintain a hierarchy of cleanliness within the HDU by creating an airflow cascade from clean to less clean rooms. From these values, nominal differential pressures between the rooms can be derived.

Measurement Location	Measured Pressure Differential (Pa)	SHTM 03-01 Pressure Differential (Pa)
HDU to corridor to beds 9-15	3.2	+10
HDU to corridor to beds 16-21	0.5	+10

2.3.1 Conclusions

The pressure differentials **did not create** the correct cascade through the suites to maintain the hierarchy of cleanliness.

2.3.2 Recommendations

Airflows should be improved to provide the required cascade of air within the department.

2.4 NOISE

Location	Measured Noise Levels dB(A)	SHTM 08-01 Noise Limits dB(A)
HDU	33	35

The noise level of the HDU is within the recommended limit.

2.4.1 Recommendations

No further action. Re-verify within 12 months

APPENDIX 1 – PROCEDURES - Detailed

Grille Airflow Volume Measurements
Airflow measurements at supply and extract grilles are determined using an electronic balometer. The balometer incorporates a measuring grid connected to a micromanometer and has an air capture hood which fits over the grille. The hood captures all of the air supplied or extracted by the grille and displays the volume of air flowing. Automatic compensation is provided to allow for the balometer's resistance to airflow (back-pressure compensation).

Each grille is measured in turn and the airflow volume recorded in l/s.

Air Change Rates
The room supply/extract volumes are converted from l/s to m^3/hour and divided by the relevant room volume. This gives the number of air changes per hour (AC/hr) for each room.
HBN4, supp1 states that the air change rate within the isolation room is calculated from the sum total of the extract airflow from both isolation room and bathroom. The room volume is that of the isolation room only.

Pressure Differential Measurements
Pressure differentials in Pascals (Pa) are determined using a micromanometer. In order to measure the pressure across the doors a pitot tube is passed through the gap between or under the doors. This ensures the flexible tube is not trapped which can cause an incorrect reading.

Each pressure differential is measured in turn and the pressure recorded.

An assessment is made of the accuracy of the magnehelic gauge displaying the pressure differential between the lobby and corridor.

Noise Measurements
SHTM 03-01 requires noise levels to be tested using a Type 2 noise meter. For the avoidance of disputes, IOM uses Type 1 noise meters as they have a higher level of accuracy.

Although it is the noise level produced by the ventilation system that is being measured, equipment in the rooms or activity outside the rooms may increase sound levels thus rendering noise readings meaningless in relation to the ventilation system.

On occasion there is too much background noise from equipment within the room to accurately measure the ventilation noise level alone. This is recorded as ‘Excessive Background Noise’.

IOM Consulting Ltd.

CONTENTS

EXECUTIVE SUMMARY

SHTM 03-01 requires that critical ventilation systems are verified against design/SHTM standards and that any inability to achieve the recommended standards is classed as a failure. It is not in the remit of a validation/verification company to state whether an HDU suite is fit for use. Rather, this is a judgement for the client and/or clinical department to make, given their knowledge of the particular clinical procedures to be carried out.

This summary highlights where standards have or have not been achieved and is expanded upon in the relevant "Results" sections.

Air Change Rates

HDU Supply: ***did not meet recommendations***

Pressure Differentials

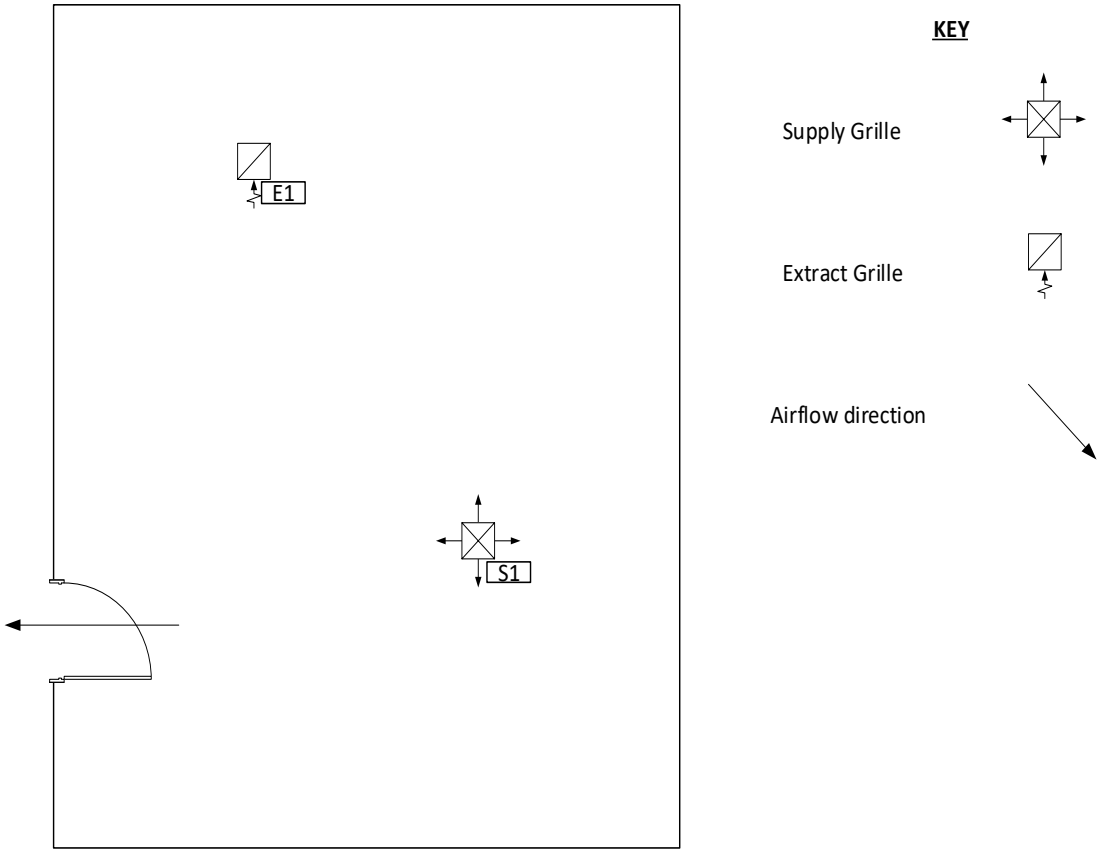
HDU: ***acceptable***

Noise Levels

HDU: **satisfactory**

SCHEMATIC DIAGRAM

(not to scale)



INTRODUCTION

IOM Consulting Ltd. was requested to undertake the validation of this HDU as required by Healthcare Facilities Scotland; Scottish Health Technical Memorandum 03-01 (SHTM 03-01) - Ventilation for Healthcare Premises.

1 PROCEDURES - Summary

This assessment has been undertaken in compliance with SHTM 03-01

The following tests were carried out;

- Airflow measurements at supply and extract grilles throughout the suite
- Pressure differential measurements throughout the suite
- Noise level measurements as appropriate

A full description of procedures can be found in Appendix 1.

Equipment used:-

Instrument	Manufacturer	Serial number
Balometer	TSI	PH 7311922002
Micromanometer	DPM	8176
Integrated noise meter	CEL	00680931
Noise Calibrator		117453

2 RESULTS

Test criteria: SHTM 03-01 gives recommended minimum quantities of fresh air to be supplied to or extracted from locations in the Critical care areas.

2.1 AIRFLOW VOLUMES

Supply Grilles

HDU

Grille Number/ Location	Measured airflow l/s
S1 / HDU	70

Extract Grilles

HDU

Grille Number/ Location	Measured airflow l/s
E1 / HDU	31

2.2 AIR CHANGE RATES

Test criteria: SHTM 03-01 recommends air change rates per hour (AC/hr) for the Critical Care Area and Isolation Rooms. The AC/hr is determined by dividing the supply or extract airflow rate per hour by the room volume.

Room	Room Volume m^3	Measured AC/hr	SHTM 03-01 recommended AC/hr
HDU	73.44	3.4 (S)	10

(S) = supply, (E) = extract

2.2.1 Conclusions

HDU supply air change rate **did not meet** the recommendations.

2.2.2 Recommendations

Upgrade the ventilation system to improve the air change rates to the SHTM 03-01 recommendation.

2.3 PRESSURE DIFFERENTIALS

Test criteria: For design calculations, SHTM 03-01 gives nominal room pressure values, the purpose of which is to maintain a hierarchy of cleanliness within the HDU by creating an airflow cascade from clean to less clean rooms. From these values, nominal differential pressures between the rooms can be derived.

Measurement Location	Measured Pressure Differential (Pa)	SHTM 03-01 Pressure Differential (Pa)
HDU to external corridor	6.3	+10

2.3.1 Conclusions

The pressure differentials **practically created** the correct cascade through the suites to maintain the hierarchy of cleanliness.

2.3.2 Recommendations

Airflows should be improved to provide the required cascade of air within the department.

2.4 NOISE

Location	Measured Noise Levels dB(A)	SHTM 03-01 Noise Limits dB(A)
HDU	33.9	35

The noise level of the HDU is within the recommended limit.

2.4.1 Recommendations

No further action. Re-verify within 12 months.

APPENDIX 1 – PROCEDURES - Detailed

Grille Airflow Volume Measurements
Airflow measurements at supply and extract grilles are determined using an electronic balometer. The balometer incorporates a measuring grid connected to a micromanometer and has an air capture hood which fits over the grille. The hood captures all of the air supplied or extracted by the grille and displays the volume of air flowing. Automatic compensation is provided to allow for the balometer's resistance to airflow (back-pressure compensation).

Each grille is measured in turn and the airflow volume recorded in l/s.

Air Change Rates
The room supply/extract volumes are converted from l/s to m^3/hour and divided by the relevant room volume. This gives the number of air changes per hour (AC/hr) for each room.
HBN4, supp1 states that the air change rate within the isolation room is calculated from the sum total of the extract airflow from both isolation room and bathroom. The room volume is that of the isolation room only.

Pressure Differential Measurements
Pressure differentials in Pascals (Pa) are determined using a micromanometer. In order to measure the pressure across the doors a pitot tube is passed through the gap between or under the doors. This ensures the flexible tube is not trapped which can cause an incorrect reading.

Each pressure differential is measured in turn and the pressure recorded.

An assessment is made of the accuracy of the magnehelic gauge displaying the pressure differential between the lobby and corridor.

Noise Measurements
SHTM 03-01 requires noise levels to be tested using a Type 2 noise meter. For the avoidance of disputes, IOM uses Type 1 noise meters as they have a higher level of accuracy.

Although it is the noise level produced by the ventilation system that is being measured, equipment in the rooms or activity outside the rooms may increase sound levels thus rendering noise readings meaningless in relation to the ventilation system.

On occasion there is too much background noise from equipment within the room to accurately measure the ventilation noise level alone. This is recorded as ‘Excessive Background Noise’.

APPENDIX 2 – CALIBRATION CERTIFICATES

RHCYP + DCN

Ventilation Action Log

Revised Date: 07/10/2019

Current Date for tracking: 09/10/2019

Issue No.	Item	Action Number	Requirements	Owner	Start Date	Target Date	Action to Close	Open /Closed	Priority to RHCYP	Priority to DCN
General										
V1	Swirl diffusers have been widely used in the development - Not normally used in critical areas like theatres as they can be difficult to measure accurately with balometers and they can impact on wound site velocity	1	These diffusers are compliant with SHTM 03-01		25/06/2019	09/08/2019	TUV Comment 26/07/19 - Air flow simulation issued The simulation demonstrates that the air flow patterns and velocities are in compliance with the requirements of SHTM 03-01 page 63, Section titled Diffuser and Grille Selection and Sizing. We would also note that they are also in accordance with CIBSE Guide B page 2-51, para 2.4.2 3 Grilles installed are as per design specification	CLOSED	YES	YES
V2	Potential discrepancies in Environmental Matrix	1	The project Environmental Matrix should be crossed referenced with what has been provided by IHSL and any discrepancies addressed. It is noted that IOM have, on behalf of NHS Lothian, carried out some validation but this work should be crossed referenced to the Environmental Matrix if not already done.	NHSL	11/09/2019	TBC	Schedule of all clinical accommodation underway listed SHTM/IHSL Design/IOM Measured on site. Matrix of air change rates showing guidance requirement, IHSL design, and IOM actual measurements to be produced with RAG rating of each location.	OPEN	YES	YES
V3	Recommissioning of ventilation system	1	Confirmation is required that all ventilation systems have been balanced and re-commissioned to meet the requirements of the environmental matrix	NHSL/IOM	11/09/2019	TBC	IOM to carry out validation checks Environ Matrix is not the correct reference point. Mandatory contract conditions are. Presumably IOM return visits will verify.	OPEN	YES	YES
V4	snagging inspection	1	Carry out a full snagging inspection of each supply and extract system including theatres, isolations rooms, general areas, catering, etc. This should be followed by “cause and effect” testing to prove all associated graphics, BMS control and graphics.	IOM	11/09/2019	TBC	IOM have already carried this out on each AHU, reports awaited	OPEN	YES	YES
V5	Fire dampers in some locations cannot be adequately tested as duct access has not been provided. Also, locations of fire dampers and fire rated ductwork has been questioned in relation to the requirements of SHTM 03-01 and confirmation of compliant provision is awaited.	1	Provide access so all fire dampers can be readily visually inspected to verify operation. Review fire damper provision and fire rated ductwork and confirm appropriate provision	MPX	11/09/2019	TBC	Access to fire dampers will be corrected as part of the work to air handling units.	OPEN	YES	YES
V6	Some areas are not completed and ready for handover. Eg ceiling tiles still missing	1	CT & Fluoroscopy only areas still affected due to Turnkey works	NHSL	25/06/2019	27/09/2019	IOM on site 25/9 for intraoperative MRI and will confirm status of all radiology areas at that time.	OPEN	YES	YES
V7	The general ward ventilation design is based on four air changes per hour mechanical ventilation plus a component of natural ventilation. With a few exceptions, the mechanical component has been validated. However, design and validation information for the natural component has not been proven.	1	Confirm that all areas served by this arrangement are suitable for categorisation as general ward areas or single rooms as listed in SHTM 03-01 Part a, Appendix 1. Undertake an IPCT risk assessment ward by ward/ speciality specific in relation to the guidance.	NHSL	11/09/2019	03/10/2019	A risk assessment undertaken by IPCT and clinical teams was approved by the OsB on 3/10/19.	CLOSED	YES	YES
V8	The pressure regimen detailed in the design, and reflecting the environmental matrix, will be affected by opening windows and the pressure between the room and the corridor, and therefore direction of air flow, cannot be relied upon when windows are open.	1	A full assessment of the services and patient population should be carried out and mechanisms for monitoring established.	NHSL	11/09/2019	03/10/2019	Ward level risk assessments will recognise the contribution of open windows to the ventilation provided mechanically. A risk assessment undertaken by IPCT and clinical teams was approved by the OsB on 3/10/19.	CLOSED	YES	YES

V9	Air intake location - Air intakes and opening windows are sited in the courtyard below the helipad and at the adjacent RIE. Information has not been provided on the impact of downdraft on air flows and pressures or entrainment of contaminants as per SHTM 03- 01.	1	Demonstrate the effect of helicopter landing on air flows in ventilation systems with intakes below through measurement when test flights take place or through modelling. This should include the air intakes of the RIE adjacent.	BYES	11/09/2019	31/10/2019	Modelling information has been shared with NSS. The effects of test flights on air flows will be measured, however, the date of the test flight is still TBC. BYES to confirm when the Monitor will be delivered.	OPEN	YES	TBC
Theatres										
V10	Preparation rooms	1	Staff should be made aware of the fact that the preparation rooms in the theatres are designated as sterile pack stores.	NHSL	11/09/2019	11/10/2019	Commissioning Managers action Evidence to be provided to HFS to show current NHSL policy is to use them in this way.	OPEN	YES	YES
V11	Some prep rooms do not meet required air supply volumes. (theatres 35, 31, 32, 33 and 38)	1	Should be 100l/s for SPS room. Resolved during validation process, verbally confirmed by Paul Jameson of IOM				SHTM 03-01 100l/s is based on a rooms size, where rooms are slightly smaller, flow rates calculated accordingly. Flow rate calculated on basis of achieving 10ac/h - THE 32 and 33 100l/s all others 90l/s. To avoid lengthy debate all Prep room design volumes increased to a minimum of 100l/s - CLOSED	CLOSED	YES	YES
V12	Very limited extract in theatre corridors. Corridors are not at 0 absolute pressure and do not meet required 7 ach/hr (SHTM03-01 part A appendix 2 Table A2). No escape for surplus air. Could impact on open door protection. Pressure in corridors is pushing fire doors open.	1	To be reviewed by IPCT, All pressure Cascades are compliant.	NHSL/MPX		30/09/2019	MPX have submitted further design information, NHSL to comment by end of 23/09/19. MPX are progressing with the work on the basis that the design meets criteria. Contractor review will take place on 25/09 and expected completion date will be advised after this.	OPEN	YES	YES
V13	Issues with doors, door actuators, closers and interlocking to DU's	1	Repairs now completed, confirmed verbally by Chris Wilson of Multiplex				Doors checked and completed - CLOSED	CLOSED	YES	YES
V14	Concerns about open door protection (eg theatre 34) - Theatre supply 1171, LLE365, scrub 73. Leaves 733 for open door vs required 750.	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM				Open door protection design was completed in conjunction with the pressure stabiliser specialist. Recorded flow rates noted (particularly theatre supply)looks lower than design and previously commissioned? All Theatres now checked and open door protection criteria achieved -CLOSED	CLOSED	YES	NO
V15	Most theatres do not properly control temperature - There are a number of faulty control valves on plant/heater batteries	1	Faulty valves and actuators replaced, confirmed by David Wilson of Multiplex				Faulty heating actuators / valves replaced. CLOSED	CLOSED	YES	YES
V16	UCV clean zone not marked in flooring - not tape but alternative coloured zone or lines in flooring.	1	Para 7.108 of SHTM 03-01 part A and Para 6.26of HBN 26 which states 'In theatres with ultra-clean ventilation the floor area enclosed by the hood should be marked with lines or contrasting coloured area of flooring'.				Floors now marked - CLOSED	CLOSED	YES	YES
V17	Some fabric issues in theatres (eg holes to fill and under benching gaps to fill)	1	Completed, confirmed by Multiplex				Area previously reviewed with NHSL - Works carried out by others- CLOSED	CLOSED	YES	YES
V18	Theatre 33 - 4 cells fail 0 2 test at 0.17m/s. Filter screen may have been adapted	1	Re-commission UCV - may need HEPA filters as pressure drop is 170pa vs typical 100/110 for clean filters.				Resolved during validation process, verbally confirmed by Paul Jameson of IOM, MAT confirm that filter change threshold is 240pa System passed as part of original commissioning - Re-checked and adjusted where required. Filter dirty condition approximately 240Pa- CLOSED	CLOSED	YES	NO
V19	It is understood that extract grilles in DU are supplied one from each theatre.	1	Systems will need to be interlocked so both theatres are running when any one is in use. Theatre Staff understand that theatres work as a pair	IOM / NHSL		27/09/2019	MPX have provided video evidence of airflow patterns, IOM reviewing information supplied and will comment. MPX/NHSL/IPCT witnessed demonstration on 20/09 and can confirm air flow was from clean to dirty on each occasion. Written confirmation awaited.	OPEN	YES	YES
V20	Dirty utility extract rates do not meet requirements in some Theatres 30, 36, 37, 33, 38. Should be 410l/s.	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM				Flow rates calculated base on achieving > 20ac/h and pressure cascade. To avoid lengthy debate all Prep room design volumes increased to a minimum of 410l/s - CLOSED	CLOSED	YES	YES
V21	issues on some theatre light stems, covers missing, not well fitted and cabling exposed	1	Ongoing AV works under control of NHSL	NHSL / MPX		27/09/2019	MPX/NHSL to visit area and establish extent of issue	OPEN	YES	YES

V22	Individual grilles in conventional theatres not balanced which can impact on air flows at patient wound site. - BSRIA Guide AG 3/89.3 Table 1 page 10 requires them to be within 10% of lowest grille reading.	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM				Reviewed and adjusted where required - CLOSED	CLOSED	YES	NO
V23	Noise slightly high in UCV theatres - measurements 3.5 dbA above requirements. We would expect new facilities to meet the SHTM standard.	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM. One location slightly high +2dba				Previously measured and within limits (UCV commissioning reports). Refer to item on THE38 re faulty fan to be replaced Comment 26/07/19 Theatre 36 & 38 affected - Theatre 36 fan replaced, Theatre 38 fan adjusted, MPX to monitor - IOM to review 09/08/19 RH discussed with IOM can now be closed	CLOSED	YES	YES
V24	UCV hepa filter pressure drops relatively high (140-170 pa) compared with expected 100/110 pa for new filters	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM, MAT confirm that filter change threshold is 240pa				No issue. Filter dirty condition approximately 240Pa - review by Bouygues regarding replacement MPX to confirm lifecycle of filters with MAT & Bouygues - Comment 26/07/19 - Clean filters 110-140Pa air floe dependant current filters range between 120-156Pa. MAT confirmed that filters were currently good and part of their 6 monthly Checks. Confirmation email sent re pressure and life cycle - CLOSED	CLOSED	YES	YES
V25	Hepa filter screens on UCV are distorted in places	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM				Any remedial works required carried out - CLOSED	CLOSED	YES	YES
V26	Excessive flexible ductwork in theatre ceilings - Flexible connections greater than 1m and not fire rated to BS8313	1		NHSL		20/09/2018	NHSL to issue close out statement 20/09 - ITEM CLOSED 20/09 this item has been addressed and future issues to be raised through the contact mechanisms	CLOSED	YES	YES
V27	Theatre 38 - Faulty UCV quadrant fan needs to be replaced	1					MAT attending on 25th July to replace the fan - THE36 to be looked at also - Comment 26/07/19 THE 36 fan replaced, THE 38 find adjusted and currently ok - CLOSED	CLOSED	YES	YES
V28	Theatre volumes incorrectly calculated - Scrub room not included in room volume	1					Now included - CLOSED	CLOSED	YES	YES
V29	Theatre Supply ductwork design - The design of ductwork to theatre is sub optimal. In some case the four ducts serving the UCV canopies are off different ducts from plant areas and the link in points for anaesthetic and prep rooms are not well located. The is likely to leave UCV to be vulnerable to the quadrants going out of balance. It is an out of balance design	1					Comments noted. Can be monitored during annual verification - HFS to review. RH to provide drawings to HFS. 06/08/19 drawings available on Aconex	CLOSED	YES	YES
V30	Anaesthetic Room grilles - The supply grilles are relatively close to the low level extract which can short circuit the clear airflow path across the patient in the room	1		IOM/NHSL		27/09/2019	MPX have provided video evidence of airflow patterns in anaesthetic rm 33, IOM reviewing information supplied and will comment. MPX/NHSL/IPCT witnessed demonstration on 20/09 in Anaesthetic rooms 30, 31, 33 & 34and can confirm air flow did not short circuit on each occasion. IOM carried out smoke visualisation test on 27/09 and report to be issued on results.	OPEN	YES	YES
V31	Anaesthetic rooms 31 and 34 do not demonstrate a clean air flow path to reduce exposure of staff to gasses as per SHTM 03-01. Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.	1	Move ceiling supply to opposite side of room from extract. In room 30, move supply away from door.		11/09/2019	TBC	Demonstration of a clean air path has been requested by 13 September 2019; otherwise the supply will be moved. IOM carried out smoke visualisation test on 27/09 and report to be issued on results.	OPEN	YES	NO
V32	Access to VCDs - There are some volume control dampers in theatres which are not accessible for adjustment (e g. THE 34 - the two grilles nearest to the anaesthetic / prep wall. Proper access needed.	1					Access to VCDs available via hatches and removable light fittings. MPX to check examples listed and confirm accessibility - w/c 29/07/19 02/08/19 MPX - Bracket moved to allow access to VCD when light fitting is removed. - CLOSED	CLOSED	YES	NO

V33	Scrub areas which are narrow and deep are unlikely to be scavenged effectively by theatre air changes and require e alternative means of achieving removal of contaminants as per SHTM 03-01. The efficacy of the high level extract to achieve sufficient dilution of contaminants or entrainment of heavier than air water droplets is not in accordance with the requirements of SHTM 03-01and has not demonstrated as equivalent.	1	The ability of the single high level extract provided in deep plan scrub areas to effectively prevent contaminants being dispersed into theatres should be demonstrated and/or additional low level ventilation provided.	NHSL	11/09/2019	TBC	Evidence to confirm the adequate dispersal of contaminants has been requested. If this not satisfactory then a Board change will be instructed to provide low level ventilation. MPX designers insist that they are compliant, NHSL/HFS to advise how they consider this to be non compliant. At the moment MPX intend to do no more unless this evidence is provided. NHSL to determine if via helpdesk/defect or Board Change. IHSL to undertake either via MPX or BYES Scrub rooms to be fitted with low level extract or IHSL to demonstrate that 25 ac/h is being achieved through scrub. IOM carried out smoke visualisation test on 27/09 and report to be issued on results. ~~IHSL to ev de ce doo p otect o at sc ub doo s co pl a t cu e t arrangement~~ ~~IHSL to nstall add t onal extract to corr dors to prov de 7 ac/h at bala ced p essu e~~	OPEN	YES	YES
V34	Theatre utility rooms Extract ventilation means theatres have to be used in pairs and taking a theatre out of service may reduce the extract in utility room below the levels as per SHTM 03-01.	1	Add supplementary extract ventilation to allow for one theatre being out of service or plan for service impact following the loss of a pair of theatres. NHS Lothian has advised that the appropriate pressure differentials are maintained when only one theatre is operation. Validation evidence is to be provided.		11/09/2019	18/10/2019	IHSL have provided evidence that this arrangement meets the standard. Final checks on this are being completed. IOM carried out smoke visualisation test on 27/09 and report to be issued on results.	OPEN	YES	YES
V35	Angio procedures room -There is no user indicator panel in the angio procedures room which allows the user to control the plant or indicates if there is a plant failure	1		NHSL	11/09/2019	27/09/2019	MPX assert that unit is compliant RH to visit with S Evans to demonstrate and confirm back if happy.	CLOSED	YES	YES
V36	Recovery Room Ventilation - Air change rates below requirement (15ac/h)	1		NHSL/IHSL		27/09/2019	IOM have rechecked, Report issued 30/09. NHSL/IHSL reviewing.	OPEN	YES	YES
Isolation Rooms										
V37	Some isolation rooms not achieving the required 10 ach/hr - Min running at 5 ach and some just under 10	1	Resolved during validation process, verbally confirmed by Paul Jameson of IOM				All rooms previously commissioned / validated and signed off (06/06/19). All rooms re-checked and compliant (note some Fans were found to be off when investigated? 4 rooms on level 1 to be re-checked. Comment 26/07/19 - MPX checked rooms and are as commissioned - to be demonstrated to IOM 29/07/19 Comment 30/07/19 - Demonstrated to IOM 29/07/19	CLOSED	YES	YES
V38	The “maintenance by-pass” associated with the AHU requires to be fully detailed and proven.	1	Details required include: - Full written details for each system Identification of systems which do not have a secondary source of ventilation. Identification of all spaces which will have no mechanical ventilation when by-pass is initiated. The minimum and maximum estimated times for a maintenance by-pass and for recovery of a major fault. The impact of these arrangements on the fire strategy. The strategy for advising clinical staff in the areas affected. Commissioning and validation certificates for the changeover system, all associated controls, revised room volumes and pressures. The clinical service plan should reflect the operational procedures in the event of failure of an air handling unit.	IHSL	11/09/2019	27/09/2019	Information awaited from IHSL: MPX will produce a matrix showing the effect on all rooms in each location when in bypass. - Satisfactory design List of systems that do have back up arrangement To be identified within satisfactory design documents Bouygues response and rectification times To be identified within satisfactory design documents Bouygues notification and escalation procedure To be provided at end of commissioning and validation process Following receipt of the above Full clinical risk assessment to be undertaken for impact in bypass mode and in total failure mode	OPEN	YES	YES

Critical Care										
V39	Critical Care ventilation not in accordance with SHTM 03-01	1	Finalise the design through the Change Process	IHSL	30/08/2019	TBC	IHSL to provide response to HVC 095. After Proposal received, NHSL to review and undertake risk assessment for effect of works on rest of facility; including HAI-SCRIBE	OPEN	YES	NO
AHUs										
V40	The AHU require to be compliant with healthcare guidance,	1	Define protocol for changing fans and components located within the AHU.	IHSL	11/09/2019	TBC	IHSL to undertake either via MPX or BYES	CLOSED	YES	YES
V41	The AHU require to be compliant with healthcare guidance,	1	Light switches to be at an accessible height.	IHSL	11/09/2019	TBC	IHSL to undertake either via MPX or BYES	OPEN	YES	YES
V42	Air tightness	1	To be rectified as part of AHU works. All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V43	AHU access		NHSL require confirmation that all access doors to AHU's are free from opening restrictions	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V44	Ductwork section changes		NHSL require confirmation that ductwork section changes comply with SHTM 03-01, Part A, paras 5.35 and 5.36	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V45	AHU Intake Louvres		NHSL require confirmation that access to intake louvre complies with SHTM 03-01, Part B, para 3.23	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V46	AHU Drainage		NHSL require confirmation that the borosilicate traps have been suitable cleaned and that a maintenance regime is in place to inspect and clean	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V47	AHU 04-07 drainage		NHSL require confirmation that brackets and impediments to the appropriate installation of drainage pipework have been removed and that pipe runs have been installed correctly	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V48	Air flow test points		NHSL require confirmation that appropriate and correctly labelled airflow test points are available on major branches to main ducts	MPX		TBC	To be reviewed when each AHU is rectified	OPEN	YES	YES
V49	cabling inside AHU also cable connectors inside AHU, potential for electrical faults to cause as source of fire within the airstream. Potential for smoke/fume to enter clinical areas. Cables and connectors will be difficult to clean and soapy water used to clean AHU internals may impact on connections		Cabling in airstream - SHTM 03-01 Part A Para 4.12 - "The plant and its distribution system must not contain any material or substance that could cause or support combustion."	MPX		TBC	AHU 02-06 will be available for review 27/09 PM. Intent is to have all associated work except damper closing on power failure completed for this review. NHSL/IPCT/IOM/HFS to attend	OPEN	YES	YES

V50	Filter pleat orientation incorrect on top row of final filters - Should be vertical		SHTM 03-01 Part A Para 8.26 - The quality of filter housing and in particular, the seals is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter panels. Therefore, the following checks should be made: - filter seals should be fitted and in good condition; - filters should be installed correctly with respect to air flow; - bag filters should be installed so that the bags are vertical and their pockets free; - HEPA filters should be installed in a sealed housing and their seals tested to DIN 1946 if specified; - all filters should be checked to ensure they are free of visible damage; - the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.	MPX		TBC		OPEN	YES	YES
V51	Filter gauges reading low in some cases suggesting filter bypass. Final filter clamping mechanism is ineffective in some units leading to filter bypass. Additionally air flow pushing filters onto the housing.		SHTM 03-01 Part A Para 4.117 - "Filters must be securely housed and sealed in well-fitting frames that minimise air by pass. Air by pass significantly reduces filter efficiency, the higher the filter grade the greater the effect. Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred."	MPX		TBC		OPEN	YES	YES
V52	Magnahelic gauges not marked for clean and dirty limits		Manometer/filter gauges - SHTM 03-01 Part A Para 4.120 - "All filters should be provided with a means of visually checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred."				All filters monitored by BMS and will alarm when dirty. -Gauges to be labelled clean / dirty as SHTM03-01 clause 4.120. 26/07/19 - Labels ordered. 23/08/19 MPX - Gauges now marked 30-08-19 - Item can be closed.	CLOSED	YES	YES
V53	Insufficient access for cleaning (eg inlets) and access hatches are too small for cleaning/maintenance						Ducts and AHUs have been successful cleaned on two previous occasions with no access issues. Particular attention to be paid to the inlet ductwork (louvre to AHU) some units have no hatch other are very small. Comment 26/07/19 - hatches to be installed in AHU02-13, AHU04-01, AHU04-07 and AHU04-08 Comment 30/07/19 - Access hatches to be fitted 06/08/19 09/08/19 - MPX Hatches now fitted. IOM to inspect	CLOSED	YES	YES
V54	Some duct traverse test points are not plugged							CLOSED	YES	YES
V55	Surplus drip tray in AHU (?humidifier removed?). Tray drain is not blanked off						Specification call for empty space for 'future humidifier c/w drip tray' Caps ordered for drains and will be fitted. MPX to confirm when complete. Comment 02/08/19 - Caps due 09/08/19 09/08/19 MPX - Caps fitted - IOM to check 09/08/19 RH discussed with IOM can now be closed.	CLOSED	YES	YES
V56	Cooling coil drip tray area not easy to clean. Cooling coil baffles cannot be easily removed due to cable installation						Drip tray is fully removable and droplet eliminator is fully removable - CLOSED	CLOSED	YES	YES
V57	Trap arrangements incorrect. No suitable air gaps and traps dirty and incorrectly installed					TBC	Traps installed as per manufactures guidance and sized in relation to AHU pressure designs. Dirty traps to be reviewed. HFS to review on site. 06/08/19 reviewed - insufficient air gap MPX to address	OPEN	YES	YES
V58	Magnahelic gauge scale too wide - 1-500pa whereas 1-250 reflects likely filter pressure drops						Gauges give a clear indication of pressure. The BMS all gives the required information as well. CLOSED	CLOSED	YES	YES

V59	Motorised dampers take a long time to open and close which impacts on the speed of auto-changeover Some MD's do not close on plant isolation No spring return fitted so may not close in the event of power failure.		SHTM 03-01 Part A Para 4.30 - "Motorised low-leakage shut-off dampers should be located immediately behind the intake and discharge of each supply and extract system respectively. They should be of the opposed-blade type, opening through a full 90º and must close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow."	MPX		TBC	MPX await statement of compliance from Schneider, will not be complete by 27/9 on demonstration unit but will be part of AHU works.	OPEN	YES	YES
V60	Dampers - Some of the backdraught dampers fitted had deteriorated badly and were in need of repair			MPX		TBC	AHU 02-06 will be available for review 27/09 PM. Intent is to have all associated work except damper closing on power failure completed for this review. NHSL/IPCT/IOM/HFS to attend	OPEN	YES	YES
V61	Plant labelling incorrect and shows incorrect areas served. - Temporary labelling installed. Needs to be permanent.		Identification of labelling - SHTM 03-01 Part B Para 3.60 - "All supply and extract ventilation systems should be clearly labelled. The label should identify both the AHU and the area that it serves. The lettering should be at least 50mm high and be mounted in an easily visible place near the fan of the unit. Any sub-systems and the principal branch ducts should be similarly labelled." Identification of labelling - SHTM 03-01 Part B Para 3.61 - "The direction of air-flow should be clearly marked on all main and branch ducts." Identification of labelling - SHTM 03-01 Part B Para 3.62 - "All air-flow test-points should be clearly identified and the size of the duct given."				Satisfactorily inspected by NHSL 20/09 - ITEM CLOSED	CLOSED	YES	YES
V62	Branch ducts not generally marked up to show areas served						Satisfactorily inspected by NHSL 20/09 - ITEM CLOSED	CLOSED	YES	YES
V63	Auto change over arrangements need to be fully tested. Some MD's do not close on plant isolation and some units will not re-start after both motors have been isolated. Item underlined and in red above moved to item 39 item 42 can now be closed		SHTM 03-01 Part A Para 4.63 - "It is necessary to ensure that - should the computer control system or its software develop a fault - then the fan can be switched to a direct-start, fixed-speed, manual operation. This is particularly important for critical care systems serving operating suites, high-dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites. Off-site software support is no substitute for the ability of on site staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff."				Previously tested and operational - please identify relevant AHUs to allow any faults to be rectified. NHSL to confirm with IOM 09/08/19 Update - IOM's concern is that AHU's appear to be difficult to control on manual setting local to AHU. MPX to confirm restart arrangements and manual operation. Confirm restart operations after Generator Test 16/08/19 MPX - AHUs will automatically start after power failure when power is restored. Manual operation can be achieved by turning speed controls / inverters to hand (as demonstrated during FM team training). Further demo to be arranged w/c 19/08/19 16/08/19 - MPX to demonstrate hand control and restart procedure to satisfaction of BYES. 23/08/19 MPX - demonstration successfully carried out 20/08/19 at 3pm - Present - David Wilson & Tony Anderson (MPX), David Gordon, Alan Herkes and James Taylor (BYES), Ronnie Henderson (NHSL), Kenny Whyte (Schneider) 30-08-19 - Item is partially closed. Auto change over arrangement has been demonstrated but issue regarding motorised dampers do not close on plant isolation has not been resolved. 06/09 Update - Close item after moving underlined element in column 1 to item 39	CLOSED	YES	YES
V64	Some motors running at over 95% speed so there is limited scope for system to overcome dirty filter pressure drop and maintain system performance			MPX		04/10/2019	Report expected by 27/09. NHSL & IOM to review information	OPEN	YES	YES
V65	AHU Inspection Light - Theatre 32 inspection lights do not operate when the unit is isolated						To be checked by MPX. Comment 26/07/19 - For safety reasons the main isolator isolates all power to the AHU including internal inspection lights . During maintenance the AHU can be switched off and the motors isolated / locked off locally allowing the lights to stay operational - IOM to comment - CLOSED	CLOSED	YES	NO
V66	Maintenance Access to AHUS - Limited maintenance access to some part of the AHUs As they are regularly located side by side in pairs. The supply motor located adjacent to the control panel in each AHU looks extremely difficult to change in the event of a failure which could result in excessive down time.						Sufficient access is provided to maintain AHUS. All access for maintenance is from one side. Fans and motors can be removed and replaced as has been previously completed on some units. Bouygues to review and comment. Comment 26/07/19 - AHU04-07 Extract has some potential restrictions. MPX/MER to review and rectify. Comment 30/07/19 - to be complete by 02/08/19 02/08/19 - Restriction removed and maintenance access achieved - CLOSED	CLOSED	YES	YES

V67	AHU Thermal Wheels- We have concerns regarding the use of thermal wheels on theatre systems. The high rotational speeds will overcome the relatively small purge section and transfer extract air to supply air path.		The manufacturer should attend site and confirm that they are installed and operating correctly				The Thermal wheels are part of the AHU which has been installed by the manufacturer. Operation has been checked by controls specialist. Schneider to confirm that the thermal wheel have all been checked and are running at the correct speed and that there is no carry over of extract air into supply air. 26/07/19 - NHSL IOM to check once MPX confirm purge section is not compromised. Comment 30/07/19 - Thermal wheel set between 6-12rpm as manufacturers recommendations. IOM to confirm if they experienced issues at 12rpm speed 06/08/19 MPX -Schneider / Qnis to carry out a re-check and record.by 13/08/19 16/08/19 MPX - All AHU thermal wheel checks now complete with all operating at a max level of 12rpm as per manufacturers instructions. report issued	CLOSED	YES	YES
V68	Angio & MRI AHUs - Unable to located main test points						Angio AHU (AHU02-18) has a main set of test holes within plantroom. AHU serving MRI (AHU02-20) has a test point serving majority of system but due to duct configuration a main test point was unachievable. AHU volume flowrate derived from pitot traverse (serving majority of system) plus summation of grille volume flowrates not captured by traverse. - CLOSED	CLOSED	YES	YES
V69	Cooling coil drip tray area not easy to clean. Cooling coil baffles cannot be easily removed due to cable installation		Witnessed the following comment: Drip trays and glass traps dirty. Some drip trays cannot be slid out/removed for cleaning due to pipework having been installed in the way.				Drip tray is fully removable and droplet eliminator is fully removable - demonstration of baffles being removed carried out 07/08/19 .	CLOSED	YES	YES
V70	Inverters - There are some units with inverters also within the airstream		SHTM 03-01 Part A Para 4.12 - "The plant and its distribution system must not contain any material or substance that could cause or support combustion."	MPX		TBC	AHU 02-06 will be available for review 27/09 PM. Intent is to have all associated work except damper closing on power failure completed for this review. NHSL/IPCT/IOM/HFS to attend	OPEN	YES	YES
V71	Dampers - Some multi fan units had no backdraught dampers so would not operate effectively in the event of any fan failure (air would re-circulate in fan section)						All duty / standby fans have backdraft dampers fitted. AHUs (non clinical areas) that use multiple fans to achieve design volumes that are not duty / standby have no requirement for backdraft dampers	CLOSED	YES	YES
V72	Cleaning - Internals of some units not clean.		SHTM 03-01 Part A Para 8.20 - "Should any doubt exist whether the guidance has been observed, the ducts must be cleaned internally to restore them to this standard before being taken into use." SHTM 03-01 Part B Para 5.19 - "AHUs should be vacuumed-out and/or washed down internally as necessary to remove obvious dust and dirt."	BYES		TBC	IHSL to confirm with Bouygues if complete	OPEN	YES	YES
V73	Thermal Wheels - The thermal wheels are on the suction side of the AHU fan meaning any leakage will be entrained into the supply air.		Position of heat recovery device - SHTM 03-01 Part A Figure 1 (Page 21) shows it after fan. Position of heat recovery unit - SHTM 03-01 Pat A Para 4.26 - "The AHU should be arranged so that the majority of items are under positive pressure. Any item of plant requiring a drain should be on the positive pressure side of the fan. A recommended layout is given in schematic from in Figure 3." Contradicted by SHTM 03-01 Part A Para 4.36 - "The following arrangement of plant components is typical although in many instances not all elements will be required: - fresh air intake; - motorised isolation damper; - frost / fog coil; - pre-filter;				16/08/19 As per cabling in AHU issue MPX to submit proposal 23/08/19 - Refer to separate AHU report 29/08/19 - Speed of thermal wheels rectified. Report sent to IOM for comment/Approval 06/09 Update - Item to be closed out as per discussion HFS/NHSL/IOM	CLOSED	YES	YES
V74	Inlet Section - No self-drain arrangements on inlet sections to ahu's		Fresh air inlet drainage - SHTM 03-01 Part A Para 5.10 - "In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in Paragraphs 4.20 - 4.25." SHTM 03-01 Part A Para 3.70 - "The duct behind louvres should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system."	MPX		27/09/2019	MPX progressing	OPEN	YES	YES
Pest Control										
V75	AHUs - Cleaning - Evidence of bird droppings to one unit and one unit has a dead mouse or small bird in the inlet section		SHTM03-01 Part B Para 5.18 - "The intake section of a ventilation system should be vacuumed-out as necessary to remove visible particles."	BYES		24/09/2019	IHSL to confirm with Bouygues if complete.	OPEN	YES	YES

V76	External doors to plant rooms		Alter/replace the external plant room doors to ensure that excessive gaps are removed and appropriate anti vermin measures are applied to all the doors and screens as per SHTM 03-01 and HFS Interim Guidance - Managing the Risk of Contamination of Ventilation Systems by Fungi from Bird Droppings – February 2019.		11/09/2019	30/09/2019	This will be addressed by the end of September. All doors will then comply with the guidance.	OPEN	YES	YES
BMS and Monitoring										
V77	Communication problems between BMS and AHU (eg theatre 33)		These are observations and were passed to IHSL (for Hard FM) on receipt for action				Fault rectified - communication now available - CLOSED	CLOSED	YES	YES
V78	It is not clear if critical plant will operate in stand alone mode in the event of issues with BMS or comms						Units can be switched to hand should there be a catastrophic failure of BMS. - CLOSED	CLOSED	YES	YES
V79	AHU Pressure Controls - The use of pressure control sensors downstream of AHU but upstream of UCV canopy has been shown at other hospitals to cause fluctuating or hunting airflows within UCV canopy. The use of air flow sensors appears to have be more stable THE 35 air volumes are erratic and give differing readings at different times			NHSL/IOM		27/09/2019	IOM still reviewing and have double checked some items while on site.	OPEN	YES	YES
V80	UCV and Theatre Surgeons panel alarms - When the UCV was operational in THE 39 but the AHU was not running there was no alarm on the Surgeons panel. Similarly in THE 34 the surgeons panel indicated healthy when the AHU was not running						Connectivity to be checked between Surgeons panels and BMS. MPX to confirm and evidence operating correctly. Comment 26/07/19 - Plant alarms checked and are replicated on Surgeons panel with the exception of when the AHU is locally switched off. Fault to be rectified by 31/07/19 02/08/19 MPX - rectified and checked. to be demoed to IOM 05/08/19 16/08/19 IOM checked and confirmed OK on 15/8 item closed	CLOSED	YES	YES
V81	Plant control temperature Control - The plant dose not appear to benefit from close control. Several Theatres do not achieve close temperature control (THE 34 and 35 had heater batteries operational and cooling coils open to reduce heat?		Various AHU heater batteries have been isolated?	MPX		11/10/2019	Logs expected from Schneider by 27/09. NHSL / IOM to review information	OPEN	YES	YES

OPEN	39
CLOSED	42

High Value Change Notice - DRAFT

Project:	**RHCYP + DCN – Little France Edinburgh**

1 – Issue of Change Notice to Project Co			
Title:	**Paediatric Critical Care and Haematology / Oncology Ventilation**		
Reference No: 0107		**Date:** **TBA**	
Target Cost Capital:	**£4.6m**	**Target Cost Revenue:**	**TBA**

High Value Change Requirements (Schedule Part 16, Section 4, Clause 2.1.3)

Single bedrooms and Multi-bedrooms in Paediatric Critical Care

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems which will deliver **10 air changes/hour at +10pa** as per SHTM 03-01, Appendix 1, Table A1 to the following rooms at the Facilities:

Room Number	Room Type
1-B1-065	*Neo Natal 3 cot area* including 1-B1-022 – *Corridor*, 1-B1-069 – *Staff Base*, 1-B1-066 – *Clean Utility* and 1- B1-071 – *Resus Bay* which are all open to 1-B1-065
1-B1-075	*Single cot cubicle neo natal* including *1-B1-074 en-suite*
1-B1-063	*Open plan bay 4 bed*
1-B1-037	*Single bed cubicle*
1-B1-031	*Open plan bay 4 bed*
1-B1-021	*Single bed cubicle*
1-B1-020	*Single bed cubicle*
1-B1-019	*Single bed cubicle*
1-B1-009	*Open plan bay 4 bed*

Isolation Rooms in Paediatric Critical Care

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems for a positive pressure ventilated lobby PPVL Single Bedroom Isolation Suite with a lobby air supply terminal with a HEPA filter, as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1, to the following rooms at the Facilities.

Project Co may utilise the supply and extract ventilation system description in SHPN 04-01, Supplement 1, Clause 4.5 for a dedicated ventilation system per Suite or SHPN 04-01, Supplement 1, Clause 4.8 for a common ventilation system to multiple Suites as the basis of their design. If Clause 4.8 is selected as the basis of design, a duplicate supply unit is considered necessary. A combination of both methods may be used provided Project Co, as far as is reasonably practical, reuse the existing ventilation installations. Regardless of option chosen, all aspects of the design and installation must be technically compliant with all relevant guidance.

NHSL require to remove or significantly reduce the risk of losing all isolations rooms due to a single point of failure. Ideally each isolation room would benefit from its own supply and extract, however, NHSL appreciate this may not be possible or practical due to other constraints e.g. space. Therefore, Project Co are requested to provide their best practical solution to reduce the risk as low as possible but maintaining guidance criteria as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1.

Room Number	Room Type
1-B1-016	Isolation Bedroom
1-B1-017	Isolation Bedroom
1-B1-026	Isolation Bedroom

1-B1-036	Isolation Bedroom

Single bedrooms and Multi-bedrooms in Haematology and Oncology

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems which will deliver **10 air changes/hour at +10pa** as per SHTM 03-01, Appendix 1, Table A1 and fit Hepa filters (H12 grade) to the air inlets to the following rooms at the Facilities:

Room Number	Room Type
3-C1.4-059	Single Bedroom
3-C1.4-057	Single Bedroom
3-C1.4-055	Single Bedroom
3-C1.4-046	Single Bedroom
3-C1.4-032	Single Bedroom
3-C1.4-018	Single Bedroom
3-C1.4-016	Single Bedroom
3-C1.4-013	Single Bedroom
3-C1.4-010	Single Bedroom
3-C1.4-074	Single Bedroom
3-C1.4-076	Single Bedroom
3-C1.4-078	Single Bedroom
3-C1.4-084	Multi-Bed (3) Day Care
3-C1.4-061	Multi-Bed (6) Day Care

Isolation Rooms in Haematology and Oncology

In accordance with Schedule Part 16 (Change Protocol), Project Co is required to design, manufacture, supply, construct, test, commission and complete, and thereafter throughout the Operational Term, provide Services to, maintain, repair, renew and replace, a ventilation system or systems for a positive pressure ventilated lobby PPVL Single Bedroom Isolation Suite with a lobby air supply terminal with a HEPA filter, as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1, to the following rooms at the Facilities.

Project Co may utilise the supply and extract ventilation system description in SHPN 04-01, Supplement 1, Clause 4.5 for a dedicated ventilation system per Suite or SHPN 04-01, Supplement 1, Clause 4.8 for a common ventilation system to multiple Suites as the basis of their design. If Clause 4.8 is selected as the basis of design, a duplicate supply unit is considered necessary. A combination of both methods may be used provided Project Co, as far as is reasonably practical, reuse the existing ventilation installations. Regardless of option chosen, all aspects of the design and installation must be technically compliant with all relevant guidance.

NHSL require to remove or significantly reduce the risk of losing all isolations rooms due to a single point of failure. Ideally each isolation room would benefit from its own supply and extract, however, NHSL appreciate this may not be possible or practical due to other constraints e.g. space. Therefore, Project Co are requested to provide their best practical solution to reduce the risk as low as possible but maintaining guidance criteria as per SHTM 03-01, SHPN 04-01, Supplement 1: Isolation Facilities in Acute Settings (Version 1.0 September 2008) Table 1.

Room Number	Room Type
3-C1.4-040	Isolation Bedroom
3-C1.4-043	Isolation Bedroom
3-C1.4-049	Isolation Bedroom

3-C1.4-052	Isolation Bedroom
3-C1.4-072	Isolation Bedroom

(the "**Ventilation Works and Services**").

All environmental requirements for all spaces in the Facilities served by or affected by the Ventilation Works and Services systems shall be met and maintained – including but not limited to, temperature and control, lighting levels, noise, and humidity. These should be consistent to the agreed parameters throughout the Facilities to meet the specific clinical and operational needs for each space in the Facilities.

The Ventilation Works and Services shall fully comply with SHTM 03-01 requirements which includes, without limitation, implementation of the Ventilation Works and Services so that the system installation, finishes and maintenance regime shall be in accordance with SHTM 03-01 requirements, together with the clinical and operational constraints identified below:

1. All Ventilation Works and Services shall be carried out and monitored after and with reference to a collaborative full Stage 3 HAI SCRIBE assessment being approved by the Board.
2. The fire strategy and systems agreed for the Facilities will be maintained throughout the Ventilation Works and Services and the Operational Term and such that the ventilation systems will integrate with the fire strategy and systems and all other building management systems comprised in the Facilities.
3. The location of the installation within the rooms, external areas, route across such spaces and the take out of any windows, etc, will enable the current operational functionality and safety policies and procedures to be maintained.
4. The design, layouts, finishes and other details etc for the Ventilation Works and Services, at all stages (including during the design development stages), will require to be agreed with the Board's Representative (and in turn the clinical service and related stakeholders and Project Co recognises that in order to achieve agreement from the Board's Representative's the Board's Representative will seek input from the Board and all appropriate stakeholders.
5. Design must provide resilience in compliance with SHTM 03-01 to ensure performance of ventilation to rooms during maintenance downtime.

The Board will, in consultation with Project Co, continue to review costs as the design develops and at other stages. In order for the Board to assess whether the High Value Change Stage 2 Submission offers it value for money the submission shall include as a minimum the following information:

- A detailed and fully quantified pricing schedule for the construction works
- A detailed breakdown of all Preliminaries and general cost items
- Construction issue drawings and specification
- Proposed, construction and commissioning/testing programme
- Construction phase method statement

Date by which parties are required to meet to review the High Value Change Notice and agree the content for the High Value Change Proposal (Schedule Part 16, Section 4, Clause 2.3.1)	**TBA**

To: **IHS Lothian**

We require the Change described above.
Please advise when Project Co will submit a High Value Change Proposal for the above.

Signed on behalf of NHS Lothian: ……..

CONTENTS

1 INTRODUCTION

IOM were appointed by NHS Lothian Health Board to validate the critical ventilation systems at the Royal Hospital for children and young people.

The validation process involved undertaking a number of measurements and checks with the overall purpose of ensuring that the whole system operates correctly and meets the requirements of SHTM 03-01 or standard agreed as part of the design process.

2 DESIGN ASSURANCE STATEMENT

John M Rayner, Authorising Engineer of Turner Professional Engineering Services (TPES) issued a design assurance statement on the 4th February 2021 following site visit on 19th to 21st January 2021; see Appendix A and B respectively for full statements. Turner confirmed the standard of installation and the commissioning activities of the new Air Handling Units meet the full requirements of SHTM 03-01. Turner further considered that the units are fit for their projected purpose if these installations are adequately maintained.

3 AHU FACTORY VISIT

Paul Jameson, Authorising Engineer (Ventilation) of the institute of Occupational Medicine undertook a factory visit on 20th July 2020; see Appendix C for Full Statement. Paul Jameson confirmed the Daikin Air Handling Units were superior to the original Sandometal Unit. Overall, Paul Jameson was satisfied the units were, in his opinion, satisfactory.

4 HEPA FILTER INTEGRITY TEST

Filter Integrity test were carried out to the Isolation Rooms in the PICU and HDU (1-B1) by H&V Commissioning Services Ltd on the 12 February 2021: See Appendix D. This was performed to confirm that installed filter systems are properly installed by verifying the absence of bypass leakage in the installation, and that the filters are free of defects in accordance to ISO 14664-3:2009.

All HEPA filters tested passed the integrity test of <0.01% particle penetration.

Room Number	Isolation Room	Particle Penetration Reading (%)
B1-033	Isolation Room 16	<0.01
B1-015	Isolation Room 05	<0.01
B1-018	Isolation Room 06	<0.01
B1-025	Isolation Room 10	<0.01

5 IOM CONFIRMATORY READINGS

IOM carried out confirmatory readings and compared data with H&V commissioning services of all the grilles in 1-B1, 1H1-1 and 1-J1 based on the Hoare Lea design data through January and February 2021. During this time all three parties along with the NHS Lothian made changes as required in line with SHTM 03-01. Section 6 is the final reading carried out by IOM. In line with the rest of the work carried out at RHCYP a k factor of 1.2 was applied throughout with the exception of

the Isolation rooms in which k factor of k 1.11 was applied based on reading supplied by H&V Commissioning Service Ltd.

6 AREAS VENTILATION DETAILS

Notes
1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom receives supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.

1-B1 PICU & HDU

7 CONCLUSIONS

Based on the information provided by NHS Lothian;

- Design Assurance Statement by Turner PES
- Site Visit by Turner PES
- AHU Factory Visit by IOM
- HEPA Filter Integrity Tests by H&V Commissioning Ltd
- IOM On-Site Grille Readings
- Hoare Lea RHYCP + DCN (HVC107) ACH Verification Document

The system is acceptable at the time of validation. It is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

4 February 2021

Dear Sirs,

Supplemental Agreement No.2 ("SA2"): Ventilation Works

Design Assurance Statement

References:

A. Hoare Lea – MEP Engineering, Stage 4 Report: Rev 7, dated 2 Feb 21.
B. Air Handling Unit Technical Specifications.
C. Air Handling Unit Manufacturer's Drawings
D. Requests for Information (RFIs) 01 – 063.
E. AE Trip Report 20210129 -RHCYP&DCN.

I confirm in my capacity as Lothian Health Board's Authorising Engineer (Ventilation) that I have completed a review of IHS Lothian Limited's design response to HVC 107 as detailed in the following documentation as it exists on 4 February 2021 (together Part B of the Scope) and confirm to the NHS Lothian Health Board my opinion that the contents and design proposals therein should allow Project Co to meet the requirements of Part A of the Scope.

I have monitored the design development and I consider that it should be possible for the design included in Part B of the Scope to meet the requirements of Part A of the Scope. This is not an acceptance on my part of any design liability.

I have witnessed the standard of installation and the commissioning activities of the new Air Handling Units and consider that they meet the full requirements of SHTM 03-01. I further consider that these units are fit for their projected purpose if these installations are adequately maintained.

Yours Faithfully [redacted]

Eur Ing John M Rayner, BSc (Eng), CEng, FIHEEM, FCMI, MIMechE, MIET, MSVHSoc, TechIOSH

APPENDIX B - TPES SITE VISIT

Trip Report - Ventilation
NHS Lothian Board – RHCYP & DCN
19 – 21 January 2021

Background

1. I was asked to visit the worksites and assess the quality and standards of remedial project work in early December. A lot of the work was incomplete at the time, and a subsequent visit was requested. Due to flight restrictions I arranged to travel to Edinburgh on Sun 17 Jan and then to carry out additional work for NHS Lothian on Mon 18 Jan. I visited the RCHYP & DCN working areas during the next few days. I also attended the in-house routine meetings on Tue 19 Jan in person rather than by MS "Teams".

2. I visited one large and all of the smaller AHUs to assess the standards of design and installation work. I was escorted by Dean Riddell (NHSL Project team) and Darren Forbes (Imtech Senior Projects Manager) throughout this visit.

AHU 04-07

3. This large equipment is located in the Level 4 plant room. The air intake is from the nearby roof area. The anti-vermin seals on this roof access double doorway were still incomplete as I had noted in Dec 20. Darren Forbes agreed to sort out this non-operational problem.

4. The intake louvres did not appear to have a separate anti-vermin screen but were constructed in an effective labyrinth pattern section. These louvres should be easy to maintain by pressure washers from the outside. The lower surface of the ductwork inside the building sloped down to the lower intake louvre level and there were no intake drainage issues.

5. The temperature sensors and anti-frost coil were well constructed. The primary filter housing frame was also well constructed, and the filters were soundly held on the upstream side. The heat recovery coils were in good condition and no problems with their operation were reported. The chiller and heater battery supply pipes were well insulated and included isolation valves. The chiller drainage tray was well constructed with good interior slopes. The borosilicate trap was not fitted as there was an interference fit with the other external water pipes in that area. Darren Forbes reported that this problem was currently being addressed.

6. The final filter frame was well constructed, and filters were held on the upstream side of the frame - the bag pleats were all vertical. The duct test points were in the nearby ductwork towards the end of a straight section. The test points were all plugged but were not labelled as the insulation had been removed in this area for IOM testing work.

7. In summary, the installation has been well designed, constructed and installed. The door to the roof still needs remedial anti-vermin sealing. The AHU drainage systems still need their final assembly and fitting.

Level 2 Roof AHUs

8. AHU Cabins. The two new AHU cabins that contain four and one AHU have now been almost fully fitted out. Their interior designs are sound and provide good access to the five AHUs for routine inspection and maintenance.

9. The AHU intakes are located on the side away from the building in separate louvred intakes. The exterior parts of these intakes have large louvred cowls to prevent rainwater, etc. ingress. These units include anti-vermin screens.

10. The intake sections were well designed. No problems were reported with the operation of the motorised dampers and the frost coils had conventional detector units. All of the hot water pipe systems were well insulated and additionally were fitted with trace element heating. The intake filter mounts were soundly constructed and the filter units securely mounted. I noted that while the lower bank of (large) filter cartridges had their pleats vertical the upper level bank of (small) filter units had their pleats vertical. All of these filter

pleats should be vertical. Darren Forbes noted that the manufacturer did not provide the small units with the filter pleats in the other orientation. I did not consider this to be a significant problem for these types of non-bag filter unit.

11. The two fans were mounted vertically in the airstream with VSD controls. No problems were reported with their operational characteristics. The energy recovery system uses a run around coil system with well insulated supply systems. These included isolation valves.

12. The chiller batteries were supplied with 30% glycol mix. The pipes were well insulated and had isolation valves fitted. The condensate trays were well designed with good drainage gradients. The borosilicate traps were not fitted at the time of my visit. The post trap drainage systems were amalgamated under the cabin floors and routed into the neighbouring plant room where the air gap was located. These systems were reportedly fitted with trace element heating systems and had the required drainage slopes.

13. The chiller drainage systems (borosilicate trap, air gap & tundish) were not in place at the time of my visit. See my later comments.

14. External roof areas. The main raised access walkways were in place. The inspection hatch for unit 4 crosses the walkway at a relatively low elevation and in addition there is an inspection hatch mounted on the lower surface, further reducing headroom. I strongly recommend that this is provided with adequate padding and warning notices.

15. In addition, the 4-AHU cabin escape route is alongside the parapet wall, squeezing between the 1-AHU cabin and the wall. This area has been used to route the LV power cables for both AHU cabins on a “big foot” support racking system. This has been damaged in this area and needs repair. It also needs to have the vertical support pillars reduced in height and a walkway installed at the lowest possible elevation so that the parapet wall is not at an unsafe relative height.

Level 1 Grassy Knoll AHUs

16. AHU Cabin. I visited this installation while Imtech were starting to assemble the AHU drainage system for these four smaller AHUs. They observed that the lower level AHU drainage system (borosilicate trap and tundish) would have to be located under the working floor level. I noted that this would be acceptable as the floor is a non-slip grid structure supported at a reasonable height above the local ground level. I considered that visual checks of this trap and maintenance access would be relatively easy to make by the operations & maintenance staff.

17. I recommended that one tundish should be positioned for each side of the cabin so that each vertical pair of units could use this as a common drainage route. The two drains could then be joined under the floor level for eventual transmission to the main hospital drainage system. Imtech agreed to this concept and noted that they may have to use a sump pump arrangement in this location because of the relative drainage elevations. I agreed that I would consider this to be an acceptable arrangement if it was located after the tundish assembly.

18. The AHUs in this cabin appeared to be identical in construction to the ones outside the Level 2 plantroom and the above drainage comments should also be applied to those cabins.

19. I was unable to closely inspect the AHUs in this area due to the drainage works described above. The detailed equipment comments made for the Level 2 cabins should be applied to this installation.

20. External areas. The emergency escape route from the cabin led to an area bounded by the AHU output ducts on both sides. There is then about a 3m clear space from the cabin to the area wall. If this is considered to be an insufficiently sized safe area it would be quite easy to climb over a lower level duct to further evacuate to the nearby escape door in the wall. I recommend that this latter route should be clearly marked on the insulated cover of the duct. I did not feel that any support structure was required.

Summary of outstanding problems

21. The Level 4 plant roof access door requires vermin proofing.

22. The AHU drainage system for AHU 04-07 should be completed in a satisfactory manner before handover.

23. The work in the three AHU cabins to install the chiller drainage systems was being undertaken at the time of my visit. This should be completed before handover.

24. Some practical problems concerning the access and emergency exit routes to the three AHU cabins at both areas need to be addressed.

Conclusion

25. I consider that these works meet the requirements of SHTM 03-01 if the problems summarised above are completed in a satisfactory manner.

[redacted]

J M Rayner
Authorising Engineer (Ventilation)

APPENDIX C – IOM AHU FACTORY VISIT

David Holmes

From: Paul Jameson [redacted]
Sent: 21 July 2020 13:51
To: Henderson, Ronnie
Cc: Darren.Forbes[redacted]
Subject: AHU factory visit

Hi Ronnie

It was nice to catch up yesterday and look at the proposed new air handling units for the changes to the critical care areas at the site.

I as discussed on the day the physical inspections we made indicate that the Dakin units look superior to the previous Sandometal units installed on site.

We used the 26 point checklist of issues developed by you from the previous units and no significant issues were identified.
seems to have been complied with on these units.

I would confirm that the filter housings were far superior to the previous air handling units and the airflow pushes both primary and final filters into the housings and onto sealing strips.

The drip trays were easily accessible for cleaning and we witnessed that water introduced to them flowed out smoothly and there was no ponding noted.

There were minor improvement opportunities noted on site with respect to magnahelic gauge scales and location of high level isolators and it was agreed that changes would be made prior to delivery to siste.

It was noted that the grid flooring may need an access panel to get to the glss traps when installed and that trps exposed to the elements would benefit from trace heating so they do not freeze and break in cold weather. It was agreed that these adjustments could be accommodated in the site installation work.

The large units will need access arrangements for maintenance and we witnessed the removal of one of the high level access doors which would be needed on site for maintenance.

We jointly witnessed the air handling unit volume supply test one large and one small unit. The small unit this demonstrated over 20% spare capacity and 40% on the largr unit.

The leakage test on both units also met requirements.

We had a discussion about the additional fine insect mesh on the louvers. The fine insect mesh is over and above the expectation of the HTM and could over time become blocked over time. However, if this was a request of Bouygues, as they are the maintainer, they will need to ensure they stay clean.

The units will be supplied without controls and Darren seems to be acutely aware of the need to avoid internal cabling and components.

The units come with lighting pre-installed and this was in steel conduit with robust electrical connectors which can be kept clean.

There was an outstanding question about the clearance for the spring return actuator on the motorized dampers particularly in the units contained in cabins. It is understood that Darren will be confirming that there is sufficient space for the actuators.

Overall, the units are in my opinion satisfactory and I stated earlier far superior to the previous units used on the site.

If you require any further input on this issue, please let me know.

Table of Contents

RHCYP & DCN - EDINBURGH

Section 1 – Scope of Works

To carry out HEPA Filter Integrity testing on the supply HEPA filters fitted in the Lobby of each of the 4 Isolation Rooms with the 1st floor of RHfC & YP, Edinburgh.

It is assumed that all rooms are commissioned to SHTM03-01 guidelines.

To pass, the HEPA filters will be tested to achieve a leakage rate of ≤0.01%.

RHCYP & DCN - EDINBURGH

Section 2 - Executive Summary/Observations:

All filters and seals tested and passed.

RHCYP & DCN - EDINBURGH

Section 3 - HEPA Filter Integrity

OBJECTIVE

Test performed to confirm that installed filter systems are properly installed by verifying the absence of bypass leakage in the installation, and that the filters are free of defects (small holes and other damage in the filter medium, frame, seal and leaks in the filter bank framework).

PRE-REQUISITES

- Supply airflow rates have been measured and within specification.
- **Smoke generator** – ISO14644-3:2019, 3.6.1 *aerosol generator*
- **Photometer** – ISO14644-3:2019, 3.6.2 *aerosol photometer*
- **Calibration certificates** – required for the above and appended to the test report.

METHODOLOGY

The test will be performed by introducing an aerosol challenge upstream of each HEPA filter and scanning immediately downstream of the filters and support frame, in accordance with ISO14644-3:2019, B.7.2 *Procedure for installed filter system leakage scan test with an aerosol photometer.*
A test report will be prepared which will include confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail**, the location of any detected leaks and indication of the position and extent of any repairs and calibration certificates for all test equipment used.

ACCEPTANCE CRITERIA

- Aerosol concentration readings must be $\leq$ 0.01 % of the upstream concentration within Grade A (ISO 5) and Grade B (ISO 5) of the upstream concentration within Grade C (ISO 7) and Grade D (ISO 8) rooms.
- A test report is prepared which includes confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail.** If a fail is recorded replace the filter and retest.
- Attach copy of calibration certificates for all test equipment.

AEROSOL GENERATOR CERTIFICATE OF C0MPLIANCE

Certificate No:	17345	Test Date:	2nd December 2020.
Manufacturer:	CONCEPT	Model:	1300/135/1.1
Serial No :	1025732	Test Due :	2nd December 2021.
Customer :	H & V Commissioning Services Limited Kilknowe Office, 16 Barrmill Road, Galston, Ayrshire KA4 8HH.	Contact :	Ms. Karen Gavin.

Upon receipt by S & M Electronics Limited, on first inspection & testing, the Generator Heater Block Temperature was 334°C (Tolerance +/- 10 °C) & the instrument was found to be in good working order.

This instrument has been serviced by S & M Electronics Limited in accordance with the Manufacturer's requirements, having been fully tested and found to be in good order.

This equipment has been calibrated using instruments traceable to National Standard. The measurements were correct at the time of calibration.

The calibration was performed in the service area at room temperature of 21 °C +/- 5 °C.
Environmental considerations are not relevant to the performance of the instrument.

Results :

Heater Block Temperature : 335 °C +/- 10 °C. Regulator : 0 - 100 PSI
Heater Assembly: 240V 1.1 K Watts. Output: Variable 0 – 120 psi Particle Size: 0.2-0.3 micron(mmd)
Oil/Gas ratio: Smear free at 20 P.S.I. Smoke Output: 0-150m³min @ 1.5 visibility.
Only **Shell Ondina X420 Oil** is recommended for this equipment.

Calibration Completed by :.....[redacted]..... Mr. A. Patel (Engineer).

Certified Test Equipment : Model TLK - 38 S/N: S&M CAL-4 UKAS Cert. No: C32868.

Rooms associated with Isolation Rooms in Paediatric Critical Care & Isolation Rooms in Haematology and Oncology

Negative/Negative Isolation Room

Achieves Compliance

Notes

1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom recieves supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.

Negative/Negative Isolation Room

Achieves Compliance

Notes

1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom recieves supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.

CONTENTS

1 INTRODUCTION

IOM were appointed by NHS Lothian Health Board to validate the critical ventilation systems at the Royal Hospital for children and young people.

The validation process involves undertaking a number of measurements and checks with the overall purpose of ensuring that the whole system operates correctly and meets the requirements of SHTM 03-01 or standard agreed as part of the design process.

2 DESIGN ASSURANCE STATEMENT

John M Rayner, Authorising Engineer of Turner Professional Engineering Services (TPES) issued a design assurance statement on the 4th February 2021 following site visit on 19th to 21st January 2021; see Appendix A and B respectively for full statements. Turner confirmed the standard of installation and the commissioning activities of the new Air Handling Units meet the full requirements of SHTM 03-01. Turner further considered that the units are fit for their projected purpose if these installations are adequately maintained.

3 AHU FACTORY VISIT

Paul Jameson, Authorising Engineer (Ventilation) of the institute of Occupational Medicine undertook a factory visit on 20th July 2020; see Appendix C for Full Statement. Paul Jameson confirmed the Daikin Air Handling Units were superior to the original Sandometal Unit. Overall, Paul Jameson was satisfied the units were, in his opinion, satisfactory.

4 HEPA FILTER INTEGRITY TEST

Filter Integrity test were carried out to the Isolation/Critical Care Rooms by H&V Commissioning Service Ltd between the 12th and 23rd February 2021: See Appendix D, The was performed to confirm that installed filter systems are properly installed by verifying the absence of bypass leakage in the installation, and that the filters are free of defects in accordance to ISO 14664-3:2009.

All HEPA filters tested passed the integrity test of <0.01% particle penetration.

5 IOM CONFIRMATORY READINGS

IOM carried out confirmatory readings and compared data with H&V commissioning services of all the grilles in 3-C1.3, 3-C1.4 and 3-C1.5 based on the Hoare Lea design data through January and February 2021. During this time all three parties along with NHS Lothian made changes as required in line with SHTM 03-01. Section 6 is the final reading carried out by IOM. In line with the rest of the work carried out at RHCYP a k factor of 1.2 was applied throughout with the exception of the Isolation rooms in which a k factor of k 1.11 was applied based on reading supplied by H&V Commissioning Service Ltd

6 AREAS VENTILATION DETAILS

Notes
1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom receives supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air Haematology and Oncology from wet room (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wet room (3-C1.3-012) complies with the design ventilation air change rate.

7 CONCLUSIONS

Based on the information provided by NHS Lothian;

- Design Assurance Statement by Turner PES
- Site Visit by Turner TES
- AHU Factory Visit by IOM
- HEPA Filter Integrity Tests by H&V Commissioning Ltd
- IOM On-Site Grille Readings
- Hoare Lea RHYCP + DCN (HVC107) ACH Verification Document

The system is acceptable at the time of validation. It is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.

4 February 2021

Dear Sirs,

Supplemental Agreement No.2 ("SA2"): Ventilation Works

Design Assurance Statement

References:

A. Hoare Lea – MEP Engineering, Stage 4 Report: Rev 7, dated 2 Feb 21.
B. Air Handling Unit Technical Specifications.
C. Air Handling Unit Manufacturer's Drawings
D. Requests for Information (RFIs) 01 – 063.
E. AE Trip Report 20210129 -RHCYP&DCN.

I confirm in my capacity as Lothian Health Board's Authorising Engineer (Ventilation) that I have completed a review of IHS Lothian Limited's design response to HVC 107 as detailed in the following documentation as it exists on 4 February 2021 (together Part B of the Scope) and confirm to the NHS Lothian Health Board my opinion that the contents and design proposals therein should allow Project Co to meet the requirements of Part A of the Scope.

I have monitored the design development and I consider that it should be possible for the design included in Part B of the Scope to meet the requirements of Part A of the Scope. This is not an acceptance on my part of any design liability.

I have witnessed the standard of installation and the commissioning activities of the new Air Handling Units and consider that they meet the full requirements of SHTM 03-01. I further consider that these units are fit for their projected purpose if these installations are adequately maintained.

Yours Faithfully [redacted]

Eur Ing John M Rayner, BSc (Eng), CEng, FIHEEM, FCMI, MIMechE, MIET, MSVHSoc, TechIOSH

APPENDIX B - TPES SITE VISIT

Trip Report - Ventilation
NHS Lothian Board – RHCYP & DCN
19 – 21 January 2021

Background

1. I was asked to visit the worksites and assess the quality and standards of remedial project work in early December. A lot of the work was incomplete at the time, and a subsequent visit was requested. Due to flight restrictions I arranged to travel to Edinburgh on Sun 17 Jan and then to carry out additional work for NHS Lothian on Mon 18 Jan. I visited the RCHYP & DCN working areas during the next few days. I also attended the in-house routine meetings on Tue 19 Jan in person rather than by MS "Teams".

2. I visited one large and all of the smaller AHUs to assess the standards of design and installation work. I was escorted by Dean Riddell (NHSL Project team) and Darren Forbes (Imtech Senior Projects Manager) throughout this visit.

AHU 04-07

3. This large equipment is located in the Level 4 plant room. The air intake is from the nearby roof area. The anti-vermin seals on this roof access double doorway were still incomplete as I had noted in Dec 20. Darren Forbes agreed to sort out this non-operational problem.

4. The intake louvres did not appear to have a separate anti-vermin screen but were constructed in an effective labyrinth pattern section. These louvres should be easy to maintain by pressure washers from the outside. The lower surface of the ductwork inside the building sloped down to the lower intake louvre level and there were no intake drainage issues.

5. The temperature sensors and anti-frost coil were well constructed. The primary filter housing frame was also well constructed, and the filters were soundly held on the upstream side. The heat recovery coils were in good condition and no problems with their operation were reported. The chiller and heater battery supply pipes were well insulated and included isolation valves. The chiller drainage tray was well constructed with good interior slopes. The borosilicate trap was not fitted as there was an interference fit with the other external water pipes in that area. Darren Forbes reported that this problem was currently being addressed.

6. The final filter frame was well constructed, and filters were held on the upstream side of the frame - the bag pleats were all vertical. The duct test points were in the nearby ductwork towards the end of a straight section. The test points were all plugged but were not labelled as the insulation had been removed in this area for IOM testing work.

7. In summary, the installation has been well designed, constructed and installed. The door to the roof still needs remedial anti-vermin sealing. The AHU drainage systems still need their final assembly and fitting.

Level 2 Roof AHUs

8. AHU Cabins. The two new AHU cabins that contain four and one AHU have now been almost fully fitted out. Their interior designs are sound and provide good access to the five AHUs for routine inspection and maintenance.

9. The AHU intakes are located on the side away from the building in separate louvred intakes. The exterior parts of these intakes have large louvred cowls to prevent rainwater, etc. ingress. These units include anti-vermin screens.

10. The intake sections were well designed. No problems were reported with the operation of the motorised dampers and the frost coils had conventional detector units. All of the hot water pipe systems were well insulated and additionally were fitted with trace element heating. The intake filter mounts were soundly constructed and the filter units securely mounted. I noted that while the lower bank of (large) filter cartridges had their pleats vertical the upper level bank of (small) filter units had their pleats vertical. All of these filter

pleats should be vertical. Darren Forbes noted that the manufacturer did not provide the small units with the filter pleats in the other orientation. I did not consider this to be a significant problem for these types of non-bag filter unit.

11. The two fans were mounted vertically in the airstream with VSD controls. No problems were reported with their operational characteristics. The energy recovery system uses a run around coil system with well insulated supply systems. These included isolation valves.

12. The chiller batteries were supplied with 30% glycol mix. The pipes were well insulated and had isolation valves fitted. The condensate trays were well designed with good drainage gradients. The borosilicate traps were not fitted at the time of my visit. The post trap drainage systems were amalgamated under the cabin floors and routed into the neighbouring plant room where the air gap was located. These systems were reportedly fitted with trace element heating systems and had the required drainage slopes.

13. The chiller drainage systems (borosilicate trap, air gap & tundish) were not in place at the time of my visit. See my later comments.

14. External roof areas. The main raised access walkways were in place. The inspection hatch for unit 4 crosses the walkway at a relatively low elevation and in addition there is an inspection hatch mounted on the lower surface, further reducing headroom. I strongly recommend that this is provided with adequate padding and warning notices.

15. In addition, the 4-AHU cabin escape route is alongside the parapet wall, squeezing between the 1-AHU cabin and the wall. This area has been used to route the LV power cables for both AHU cabins on a “big foot” support racking system. This has been damaged in this area and needs repair. It also needs to have the vertical support pillars reduced in height and a walkway installed at the lowest possible elevation so that the parapet wall is not at an unsafe relative height.

Level 1 Grassy Knoll AHUs

16. AHU Cabin. I visited this installation while Imtech were starting to assemble the AHU drainage system for these four smaller AHUs. They observed that the lower level AHU drainage system (borosilicate trap and tundish) would have to be located under the working floor level. I noted that this would be acceptable as the floor is a non-slip grid structure supported at a reasonable height above the local ground level. I considered that visual checks of this trap and maintenance access would be relatively easy to make by the operations & maintenance staff.

17. I recommended that one tundish should be positioned for each side of the cabin so that each vertical pair of units could use this as a common drainage route. The two drains could then be joined under the floor level for eventual transmission to the main hospital drainage system. Imtech agreed to this concept and noted that they may have to use a sump pump arrangement in this location because of the relative drainage elevations. I agreed that I would consider this to be an acceptable arrangement if it was located after the tundish assembly.

18. The AHUs in this cabin appeared to be identical in construction to the ones outside the Level 2 plantroom and the above drainage comments should also be applied to those cabins.

19. I was unable to closely inspect the AHUs in this area due to the drainage works described above. The detailed equipment comments made for the Level 2 cabins should be applied to this installation.

20. External areas. The emergency escape route from the cabin led to an area bounded by the AHU output ducts on both sides. There is then about a 3m clear space from the cabin to the area wall. If this is considered to be an insufficiently sized safe area it would be quite easy to climb over a lower level duct to further evacuate to the nearby escape door in the wall. I recommend that this latter route should be clearly marked on the insulated cover of the duct. I did not feel that any support structure was required.

Summary of outstanding problems

21. The Level 4 plant roof access door requires vermin proofing.

22. The AHU drainage system for AHU 04-07 should be completed in a satisfactory manner before handover.

23. The work in the three AHU cabins to install the chiller drainage systems was being undertaken at the time of my visit. This should be completed before handover.

24. Some practical problems concerning the access and emergency exit routes to the three AHU cabins at both areas need to be addressed.

Conclusion

25. I consider that these works meet the requirements of SHTM 03-01 if the problems summarised above are completed in a satisfactory manner.

APPENDIX C – IOM AHU FACTORY VISIT

David Holmes

From: Paul Jameson [redacted]
Sent: 21 July 2020 13:51
To: Henderson, Ronnie
Cc: Darren.Forbes[redacted]
Subject: AHU factory visit

Hi Ronnie

It was nice to catch up yesterday and look at the proposed new air handling units for the changes to the critical care areas at the site.

I as discussed on the day the physical inspections we made indicate that the Dakin units look superior to the previous Sandometal units installed on site.

We used the 26 point checklist of issues developed by you from the previous units and no significant issues were identified.
seems to have been complied with on these units.

I would confirm that the filter housings were far superior to the previous air handling units and the airflow pushes both primary and final filters into the housings and onto sealing strips.

The drip trays were easily accessible for cleaning and we witnessed that water introduced to them flowed out smoothly and there was no ponding noted.

There were minor improvement opportunities noted on site with respect to magnahelic gauge scales and location of high level isolators and it was agreed that changes would be made prior to delivery to siste.

It was noted that the grid flooring may need an access panel to get to the glss traps when installed and that trps exposed to the elements would benefit from trace heating so they do not freeze and break in cold weather. It was agreed that these adjustments could be accommodated in the site installation work.

The large units will need access arrangements for maintenance and we witnessed the removal of one of the high level access doors which would be needed on site for maintenance.

We jointly witnessed the air handling unit volume supply test one large and one small unit. The small unit this demonstrated over 20% spare capacity and 40% on the largr unit.

The leakage test on both units also met requirements.

We had a discussion about the additional fine insect mesh on the louvers. The fine insect mesh is over and above the expectation of the HTM and could over time become blocked over time. However, if this was a request of Bouygues, as they are the maintainer, they will need to ensure they stay clean.

The units will be supplied without controls and Darren seems to be acutely aware of the need to avoid internal cabling and components.

The units come with lighting pre-installed and this was in steel conduit with robust electrical connectors which can be kept clean.

There was an outstanding question about the clearance for the spring return actuator on the motorized dampers particularly in the units contained in cabins. It is understood that Darren will be confirming that there is sufficient space for the actuators.

Overall, the units are in my opinion satisfactory and I stated earlier far superior to the previous units used on the site.

If you require any further input on this issue, please let me know.

Paul

Table of Contents

RHCYP & DCN – EDINBURGH

Section 1 – Scope of Works

To carry out HEPA Filter Integrity testing on the supply HEPA filters fitted in the Lobby of each of the 4 Isolation Rooms with the 1st floor of RHCYP & DCN, Edinburgh.

It is assumed that all rooms are commissioned to SHTM03-01 guidelines.

To pass, the HEPA filters will be tested to achieve a leakage rate of ≤0.01%.

RHCYP & DCN – EDINBURGH

Section 2 - Executive Summary/Observations:

All filters and seals tested and passed.

Equipment Used		
Equipment Type	Serial Number	Calibration Due Date
Smoke Generator	1025732	2nd December 2021
Smoke Generator	CAG14133	27th August 2021
Smoke Generator	CAG14138	17th August 2021

Photometer	14086	28th July 2021

RHCYP & DCN – EDINBURGH

Section 3 - HEPA Filter Integrity

OBJECTIVE

Test performed to confirm that installed filter systems are properly installed by verifying the absence of bypass leakage in the installation, and that the filters are free of defects (small holes and other damage in the filter medium, frame, seal and leaks in the filter bank framework).

PRE-REQUISITES

- Supply airflow rates have been measured and within specification.
- **Smoke generator** – ISO14644-3:2019, 3.6.1 *aerosol generator*
- **Photometer** – ISO14644-3:2019, 3.6.2 *aerosol photometer*
- **Calibration certificates** – required for the above and appended to the test report.

METHODOLOGY

The test will be performed by introducing an aerosol challenge upstream of each HEPA filter and scanning immediately downstream of the filters and support frame, in accordance with ISO14644-3:2019, B.7.2 *Procedure for installed filter system leakage scan test with an aerosol photometer.*
A test report will be prepared which will include confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail**, the location of any detected leaks and indication of the position and extent of any repairs and calibration certificates for all test equipment used.

ACCEPTANCE CRITERIA

- Aerosol concentration readings must be $\leq$ 0.01 % of the upstream concentration within Grade A (ISO 5) and Grade B (ISO 5) of the upstream concentration within Grade C (ISO 7) and Grade D (ISO 8) rooms.
- A test report is prepared which includes confirmation of the methodology used, results of testing for each filter, whether each test is a **pass** or **fail.** If a fail is recorded replace the filter and retest.
- Attach copy of calibration certificates for all test equipment.

AEROSOL GENERATOR CERTIFICATE OF C0MPLIANCE

Certificate No:	17345	Test Date:	2nd December 2020.
Manufacturer:	CONCEPT	Model:	1300/135/1.1
Serial No :	1025732	Test Due :	2nd December 2021.
Customer :	H & V Commissioning Services Limited Kilknowe Office, 16 Barrmill Road, Galston, Ayrshire KA4 8HH.	Contact :	Ms. Karen Gavin.

Upon receipt by S & M Electronics Limited, on first inspection & testing, the Generator Heater Block Temperature was 334°C (Tolerance +/- 10 °C) & the instrument was found to be in good working order.

This instrument has been serviced by S & M Electronics Limited in accordance with the Manufacturer's requirements, having been fully tested and found to be in good order.

This equipment has been calibrated using instruments traceable to National Standard. The measurements were correct at the time of calibration.

The calibration was performed in the service area at room temperature of 21 °C +/- 5 °C.
Environmental considerations are not relevant to the performance of the instrument.

Results :

Heater Block Temperature : 335 °C +/- 10 °C. Regulator : 0 - 100 PSI
Heater Assembly: 240V 1.1 K Watts. Output: Variable 0 – 120 psi Particle Size: 0.2-0.3 micron(mmd)
Oil/Gas ratio: Smear free at 20 P.S.I. Smoke Output: 0-150m³min @ 1.5 visibility.
Only **Shell Ondina X420 Oil** is recommended for this equipment.

Calibration Completed by :.....[redacted]..... Mr. A. Patel (Engineer).

Certified Test Equipment : Model TLK - 38 S/N: S&M CAL-4 UKAS Cert. No: C32868.

AEROSOL GENERATOR CERTIFICATE OF COMPLIANCE

Certificate No:	17069	Test Date:	17th August 2020.
Manufacturer:	S&M Electronics Limited	Model:	SCIENTIFIC
Serial No :	CAG 14138	Test Due :	17th August 2021.
Customer :	H & V Commissioning Services. Kilknowe Office, 16 Barrmill Road, Galston, Ayrshire KA4 8HH.	Contact :	Ms. Angela Daly

---

This instrument has been serviced by S & M Electronics Limited in accordance with the Manufacturer's requirements, having been fully tested and found to be in good order.

This equipment has been calibrated using instruments traceable to National Standard. The measurements were correct at the time of calibration.

The calibration was performed in the service area at room temperature of 21 °C +/- 5 °C.
Environmental considerations are not relevant to the performance of the instrument.

Results :

Heater Block Temperature : 343 °C +/- 10 °C.
Heater Assembly: 230V 1.00K Watts.
Smoke Output: 0- 200 m³min @ 1.5 visibility.
Oil/Gas ratio: Smear free at 20 P.S.I
Only **Shell Ondina Oil** is recommended for this equipment.

Regulator : 0 - 60 PSI
Output: Infinity Variable 1.0 – 60 PSI.
Particle Size: 0.2-0.4 micron(mmd)
Oil Metering Orifice: 0.0145"

Calibration Completed by :..... [redacted] ..... Mr. A. Patel (Engineer).

Certified Test Equipment : Model TLK - 38 S/N: S&M CAL-4 UKAS Cert. No: C32868.

Calibration Statement

The instrument listed on this certificate has been calibrated against standards traceable to NIST or other recognized national metrology institutes, derived from ratio type measurements, or compared to nationally recognized consensus standards. The uncertainty of the above concentration measurements are ±10%. All results contained within this certificate relate only to the item(s) calibrated. Any number of factors may cause the calibrated item to drift out of calibration before the instruments calibration interval has expired. This certificate shall not be reproduced except in full and with written consent of ATI. This unit has been calibrated to the most recent revis[redacted]

AEROSOL PHOTOMETER CERTIFICATE OF CALIBRATION

Certificate No:	17130	Test Date:	9th September 2020.
Manufacturer:	DOP Solutions	Model:	SP200DNS-B
Serial No :	4287913	Test Due :	9th September 2021
Customer :	H & V Commissioning Services Ltd Kilknowe Office, 16 Barrmill Road, Galston, KA4 8HH.	Contact :	Ms. Angela Daly.

This instrument has been tested & Calibrated in accordance with the manufacturer's specification against our Aerosol Test Rig & Certified to meet all current U.S.A. & U.K. requirements for filter testing. This includes the following: CS-1T,2T,6T; ANSI 101 & 150; NSF 49,ASTM D-1899; IEST-RP-CC-013-86-T, IEST-RP-CC-002.2, IEST-RP-CC-034.1,EN 12469:2000, ISO 14644-3 and British Standard BS5295 and BS EN 1822.

The Aerosol Test Rig is calibrated annually when the actual mass concentration is measured by collecting and weighing the particulate, using Sartorius Scale Model 1712 s/n 3308 087 which has been certified by Sartorius Limited, UKAS Certificate No: JH1990 to meet British Standard using weights traceable to NPL standard. **Shell Ondina Oil** is used for calibration of Aerosol Photometer.

Expanded Uncertainty of Measurement: ± 6.6%

Stated uncertainty based on a temperature, humidity and pressure within 18-25 ^{o} C, 35 to 70% RH and 960 to 1045 mbar.

Reported expanded uncertainty is based on a standard uncertainty multiplied by a coverage factor of k=2, providing a level of confidence of approximately 95%.

Calibration Completed by ..... [redacted] ..... Mr.A.Patel (Engineer).

Proposed Design Data

* All Open to 1-B1-065

** Windows will be locked shut

Rooms associated with Single bedrooms and Multi-bedrooms in Paediatric Critical Care & Single bedrooms and Multi-bedrooms in Haematology and Oncology

Rooms associated with Isolation Rooms in Paediatric Critical Care & Isolation Rooms in Haematology and Oncology

Negative/Negative Isolation Room

Achieves Compliance

Notes

1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom recieves supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.

Rooms associated with Single bedrooms and Multi-bedrooms in Paediatric Critical Care & Single bedrooms and Multi-bedrooms in Haematology and Oncology

Rooms associated with Isolation Rooms in Paediatric Critical Care & Isolation Rooms in Haematology and Oncology

Negative/Negative Isolation Room

Achieves Compliance

Notes

1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom recieves supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.

Proposed Design Data

* All Open to 1-B1-065

** Windows will be locked shut

Rooms associated with Single bedrooms and Multi-bedrooms in Paediatric Critical Care & Single bedrooms and Multi-bedrooms in Haematology and Oncology

Rooms associated with Isolation Rooms in Paediatric Critical Care & Isolation Rooms in Haematology and Oncology

Negative/Negative Isolation Room

Achieves Compliance

Notes

1.Open plan to larger area. Overall supply volume in larger area satisfies compliance.
2. Rooms with no supply air identified achieve fresh air make-up via corridor (excess supply air from other spaces).
3. Isolation bedroom recieves supply air from lobby through pressure stabiliser and extract via ensuite. This room achieves SHTM 03-01 compliance of 10AC/H.
4. Combined extract from bay 1 (3-C1.3-011) plus adjoining toilet (3-C1.3-010) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.
5. Combined extract from bay 2 (3-C1.3-013) plus adjoining toilet (3-C1.3-014) and half of the extract air from wetroom (3-C1.3-012) complies with the design ventilation air change rate.

Key Stage Assurance Review Workbook

Outline Business Case

June 2021

Version 1.0

A46676816

Contents

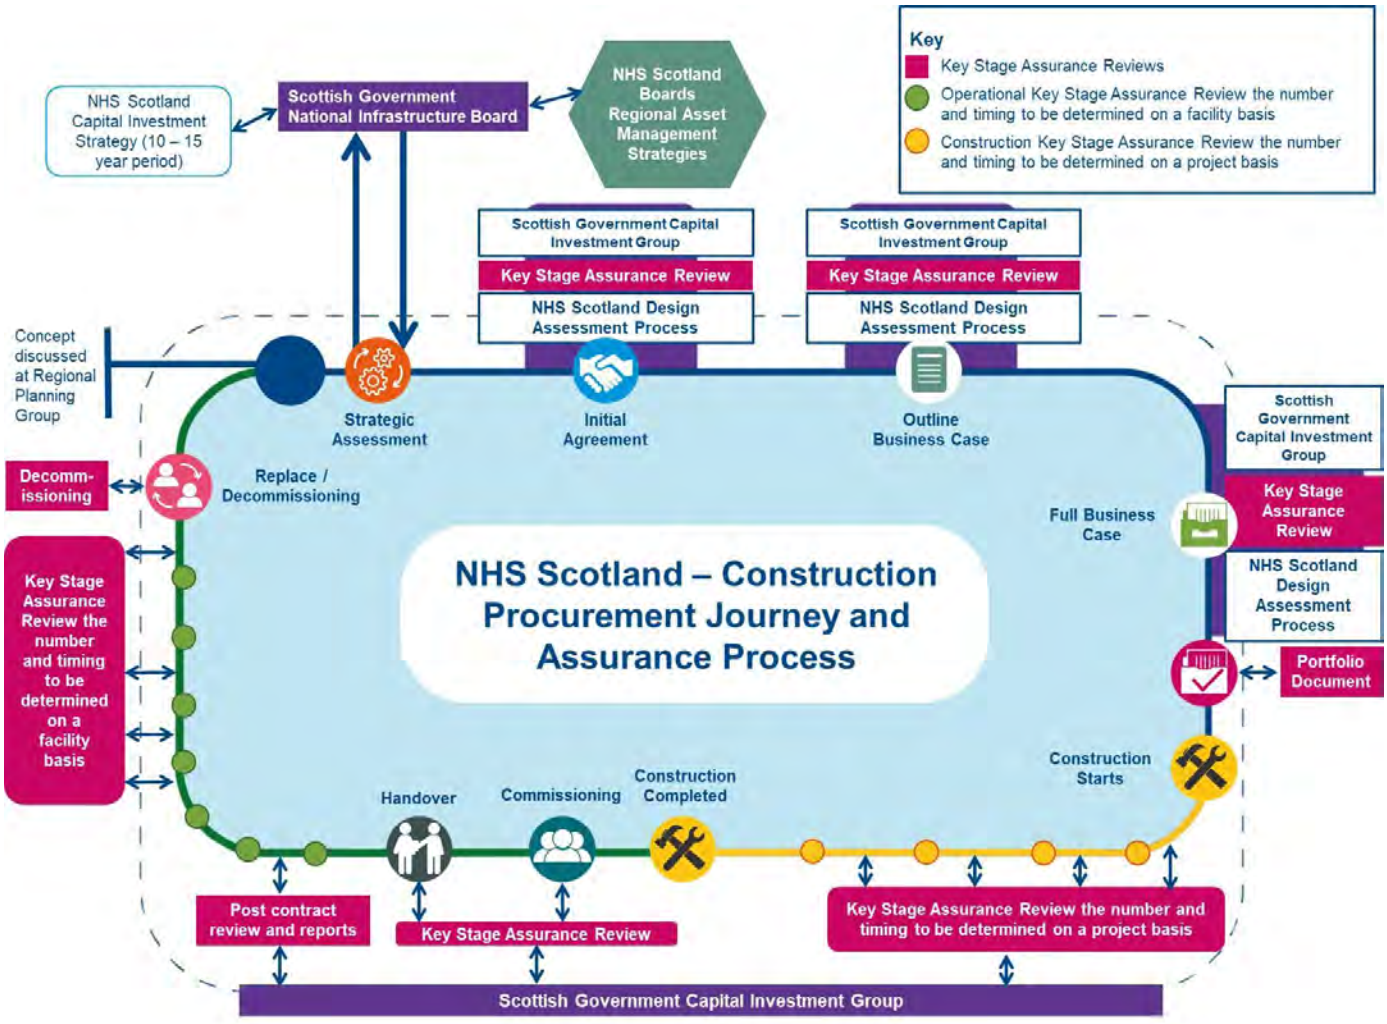
1. About this workbook

This workbook supports the Outline Business Case Key Stage Assurance Review (KSAR), delivered through the NHS Scotland Assure - Assurance Service.

Further information about the NHS Scotland Assure - Assurance Service and KSAR process is provided in section 2.

Figure 1. shows how the Outline Business Case stage in the procurement and construction journey commences following Initial Assessment. The timing and frequency of KSARs during this stage will vary dependent upon the facility. Specific workbooks have been developed for the other stages within this journey.

Figure 1: Construction Procurement Journey



KSARs are of a process ensuring facilities and the teams using them are able to deliver the standards required to provide the best and safest outcomes for patients, staff and visitors in the built environment.

KSARs deliver an independent peer review. NSS staff outside the project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility.

It is vital to receive feedback on the following elements of health facilities - Infection Prevention and Control (IPC), water, ventilation, electrical, plumbing, medical gases

installations and fire. This ensures they are designed, installed and functioning from initial commissioning of a new facility and throughout its lifetime. Health Boards are required to have appropriate governance in place at all stages of the construction procurement journey.

The KSAR workbook provides a transparent, structured framework for all clinical specialisms, facilities and operational management professionals to assess and manage a health care build or refurbishment. Allowing facilities to align with current standards as the assurance reviews are taking place, as well as aligning changes for patient cohort.

Using this workbook

The review at Outline Business Case stage investigates the approach taken by the Health Board in the development of the design, and how the appropriate level of knowledge and awareness of patient and user needs will influence the development of the design.

The purpose of the KSAR at Outline Business Case stage is to confirm there is a good and comprehensive understanding of the category of patient who will use the proposed facility and that the project team consider how appropriate quality and safety standards will influence the design. It looks to provide assurance that the project can proceed to the Full Business Case.

This workbook is predominantly intended to be used by NHS Scotland Assure KSAR review teams, Health Boards are encouraged to use its content to support their own projects. It provides guidance on the review structure and areas of investigation to be addressed by the review team and should be regarded as indicative and not prescriptive.

The review team will consider whether any emerging findings require additional topics to be addressed. If so, evidence relating to these areas, regarding the safety of the patients, staff and visitors should be provided.

2. Key Stage Assurance Review

Introduction to NHS Scotland Assure – Assurance Service

Good management effective control of projects is an essential element to the successful delivery and maintenance of healthcare facilities across NHS Scotland estates.

The initial delivery of the NHS Scotland Assure - Assurance Service will focus upon new builds and major refurbishments in the acute estate, submitted to the Scottish Government Capital Investment Group (CIG). In addition, a number of projects identified as being complex, primarily due to the needs of patients utilising the facilities, will be reviewed by this service. Whilst not an exhaustive list, these projects will cover oncology, maternity, theatre and critical care units, no matter of their financial value.

The NHS Scotland Assure - Assurance Service will deliver KSARs, designed to provide independent assurance to Scottish Government Health and Social Care Directorates (SGHSCD's).

It will assess if Health Boards Project Management teams (inclusive of clinicians, appointed construction consultants, and contractors) are briefed and following best practice procedures in the provision of facilities. We will review if projects are compliant in all aspects of safety, if specific engineering systems are designed, installed and commissioned, and for ongoing safety maintenance including IPC.

The KSAR process is applicable regardless of procurement route chosen.

The KSAR Process

The KSAR process examines projects at key points in their lifecycle. It does not remove any legal or contractual obligations from the NHS Health Board, their designers or contractors. It provides assurance to progress successfully to the next review point and the process will be mandated for projects requiring CIG approval. KSARs focus on the assessment of the delivery approach, and will work with the Health Board's project team to ensure there is comprehensive understanding of the patient cohorts utilising the facility. KSARs also ensure relevant guidance is fully implemented and any technical derogations have been fully reasoned, transparently discussed, the implications understood, recorded and signed off by the Health Board and their advisors.

With a focus on construction elements where previous reviews have demonstrated potential patient safety concerns, KSARs will concentrate on water; ventilation, electrical, plumbing, medical gases installations, fire, and associated IPC guidance. If further issues are raised with the review team, they will fully incorporate those issues into the reporting process.

Value of the KSAR Process

Key Stage Assurance Reviews (KSARs) deliver an independent peer review. NSS staff outside the Health Board's project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility. KSARs provide an external perspective and provide a challenge to the robustness of the Health Board's brief, plans and processes.

This includes work delivered by construction consultants, employed either directly or through construction contractors, and the work being delivered by the primary contractor, their sub-contractors and specialist suppliers.

The KSAR provides an independent report and action plan, which is shared with the Health Board to ensure:

- Appropriate skills and experience are deployed on the project by the Health Board, consultants, primary contractor and all sub-contractors.
- The clinicians and wider stakeholders covered by the project fully understand the project status, aims and the issues involved.
- Appropriate management structures put in place to ensure appropriate infection prevention and control measures are designed into the project to reduce the risk of transmission of infectious agent.
- There is assurance the project can progress to the next stage of development or implementation with particular emphasis on the safety of the patients, staff and visitors utilising the facility.
- Provision of advice and guidance to programme and project teams by fellow Practitioners.

The KSAR report and the Health Board's response and action plan is submitted to CIG along with a recommendation from the NHS Scotland Assure - Assurance Service regarding the projects' progression to the next stage of the construction procurement journey.

KSAR as part of the overall assurance framework

Each NHS Health Board will be fully responsible for the delivery of all projects, and its own internal process and resources for carrying out internal reviews and audits of its activities. The KSAR is seen as a complementary independent review, and not as a replacement for the responsibilities of the Health Board.

NHS Health Boards should have in place an effective framework to provide a suitable level of assurance for their programmes and projects. Health Boards are encouraged and expected to ensure adequate and timely coordination and sharing of information, including plans, between the various internal reviews and functions.

The KSAR process is not a substitute for a rigorous governance framework in the Board to manage key processes including business planning, investment appraisal, business case management, risk management and service and contract management.

The KSAR Process relationship with NHS Scotland Design Assessment Process (NDAP)

The Scottish Government's ambition for NHS Scotland's estate and the need for well-designed healthcare environments is articulated in the Policy on Design Quality for NHS Scotland. Good design in the built environment encompasses a wide range of inter-related factors such as, sustainability, engineering, architecture, fire safety, energy, environment, decontamination, space utilisation, landscaping, security, technology, lighting, access for visitors and mobility impaired persons.

The NDAP process is overseen by Health Facilities Scotland and Architecture and Design Scotland and holistically considers all of the above. It sets the principles for the resolution of potential conflicts of statutory or mandatory compliance to ensure the specific facility provides; the best balance of the technical requirements, meets clinical needs and fulfils the conceptual aims of the policy on Design Quality. The NDAP process begins at the initial agreement stage of a project and provides advice through to the Full Business Case. There is no change to either SCIM or NDAP processes.

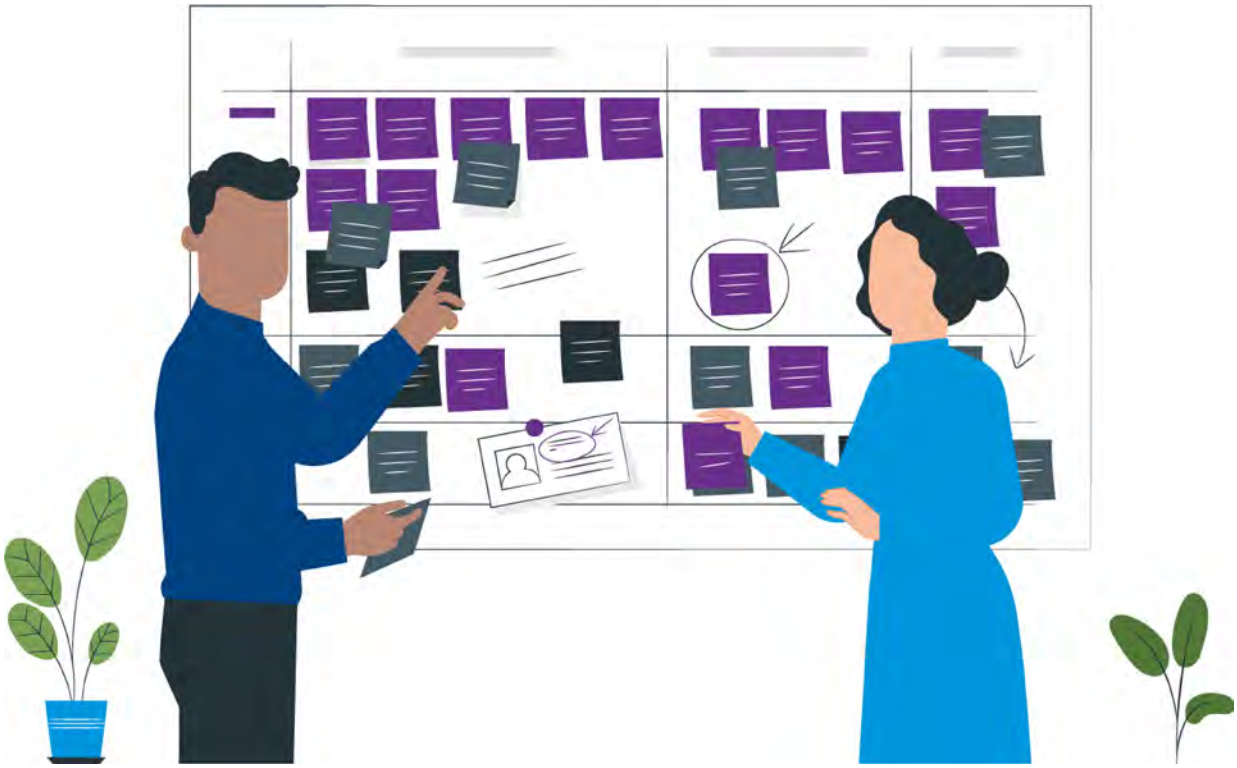
The Scottish Government is progressing policy to improve the safety of the healthcare environment in relation to the built environment risk. The Assurance Service delivered through NHS Scotland Assure is a response to this policy and the KSARs are integral to the compliance work. The aspiration is not to duplicate any of the work included in the NDAP process, but to provide assurance regarding the critical components highlighted throughout this workbook.

Integral to the KSARs will be a review of the balance between sustainability issues and patient safety.

The NDAP, working with Health Boards, will set the principles of the design solution, whereas the KSAR will provide a detailed technical review of the specifics of the design solution. Where possible the two reviews will be aligned to avoid duplication of work. For example, in instances where the NDAP has reviewed detail at a technical level, this will be used by the KSAR team rather than being separately requested and reviewed.

Sustainability

The review will provide assurance that the proposals for the project provide an effective balance in terms of patient, staff and visitors safety, whilst meeting required sustainability outcomes and complying with the guidance standards.



Outline Business Case (OBC) KSAR

This review investigates the approach taken by the Health Board in the development of the design, to confirm that there is a good and comprehensive understanding of the category of patient utilising the proposed facility, and that the project team are aware of how their needs and expectations for appropriate quality and safety standards will influence the design of the accommodation. It looks to provide assurance that the project can proceed to the Full Business Case.

The OBC KSAR will focus on how this understanding of patient needs and expectations have influenced the following critical components of design, particularly in relation to Infection Prevention and Control.

- Water systems
- Ventilation systems
- Plumbing and drainage
- Fire safety
- Electrical systems
- Medical gases
- Any other building or engineering component critical to the safety and welfare of a particular patient cohort (defined by the review team).

At all stages of design development, knowledge of compliance in design and implementation will need to encompass (not limited to) the following:

- NHS Scotland policy letters (DLs,CELs,CMOs)
- Scottish Health Planning Notes (SHPN)
- Scottish Health Facilities Notes (SHFN)
- Scottish Health Technical Memoranda (SHTM)
- Scottish Fire Practice Notes (SFPN)
- Health Building Notes (HBN)
- Health Technical Memoranda (HTM)
- Health Facilities Notes (HFN)
- UK construction industry bodies best practice or design guidance publications e.g. HSE, CIBSE, BRE, IHEEM, IET, BRE, BSRIA, sustainability, dementia and equality.
- Incident Reporting and Investigation Centre (IRIC) Alerts
- Relevant British Standards
- Other statutory requirements: Planning permission; Building Regulations compliance; Equality Act compliance; Health and Safety Executive (HSE) compliance; Construction (Design and Management) Regulations compliance; Fire Scotland Act.
- Other mandatory NHS Scotland use of:
  - Activity Data Base (ADB);
  - Achieving Excellence Design Evaluation Tool;
  - BREEAM Healthcare or equivalent (BRE environmental & sustainability tools);
  - Scottish Government BIM Policy (SPPN 1/2017; implementation of building information modelling within construction projects: March 2017);
  - The implementation of NHS Scotland Soft Landings (SL) guidance
- Confirm there are plans in place for risk management, issue management and these plans are being shared with suppliers and delivery partners.
- Evaluation of actions taken to implement recommendations made in earlier assessment of deliverability.
- Confirm there are plans in place to ensure the requirements of the NHS Scotland National Infection Prevention and Control Manual for Scotland are being incorporated which will allow the staff allocated to the role to deliver the services to the patients.

The review teams consist of experienced operational estates professionals and experienced Infection Control clinicians. The team will work with the Health Board's Project Team, inclusive of their clinicians and their appointed facility management consultants and contractor. Each review will result in a report being prepared for the Programme Director at the Board and a copy of the report will also be provided to Scottish Government Capital Investment Group

An appendix is provided which indicates the typical question set for OBC which the review Team will use as the basis of evidence finding for the KSAR. The review team will amend this as necessary depending on the project and areas of particular interest. The Health Board, their designers and contractors should be aware that this is the information which will be expected and the design should effectively be completed at OBC at the time of the KSAR to ensure the accuracy of the report.

3. Assessment of Delivery Approach

The review at Outline Business Case stage will need to demonstrate an awareness and knowledge of how the above will be used to influence the initial design.

Project Governance and General Arrangements

No.	Areas to probe	Evidence expected
1.1	Evaluation of changes detailed from previous KSAR.	• Assessment of any substantive changes in highlighted areas from previous review stage and all actions have been implemented.
1.2	Verification that CIG recommendations have been implemented with respect to prescribed in scope areas.	• Review of the implementation of all CIG recommendations. Evaluation of any deviation from previous submissions or reviews.
1.3	Has cross-referencing with NDAP and AEDET recommendations been implemented?	• An assessment if there is full compliance with the applicable recommendations and actions from the preceding step.
1.4	Does the Health Board continue to demonstrate service / clinical input into design decisions based on a current and comprehensive knowledge of patient cohorts?	• Recorded and updated input taken from service lead(s) / clinician(s) about relevant patient cohort characteristics and their typical needs in terms of the accommodation's environment, safety and infection control standards. • Demonstrable expertise of service lead(s) / clinician(s) in providing this advice.
1.5	Project team demonstrates a unified and recorded understanding of needs of main users and patient cohorts of the proposed accommodation and how this will influence the design of critical building, engineering and infection prevention and control quality and safety standards.	• Updated and current list available of all stakeholders, service users and patient cohorts impacted by this project, plus the identification of any high risk groups and their specialist needs. • Updated and recorded engagement on these designs issues having taken place between the project team and service lead(s) / clinician(s), infection control team, and other key stakeholders (e.g. Estates, Medical

No.	Areas to probe	Evidence expected
		Physics, IPC, the AEDET, NDAP or other design briefing workshops). • Details available of how service users / patient cohort needs and their expected use of the accommodation are influencing the design brief; including critical building, engineering and infection prevention and control quality and safety standards.
1.6	Planned approach towards determining the necessary standards for this accommodation.	• Updated and current list of the relevant NHS and non-NHS guidance that is being used and adopted (see previous section of workbook OBC KSAR (Page 9) for examples of appropriate guidance). • Updated and current list of all proposed derogations from NHS guidance with a detailed technical narrative on each derogation and / or list of known gaps in guidance that will need to be resolved in order to meet the needs of the patient / user cohort. • Knowledge of the role of infection prevention and control and microbiologist advisors to be used throughout the design stages, and details of the resource plan in place to ensure this advice will be available.
1.7	How does the Health Board demonstrate that there is an effective infection prevention and control management structure in place and how does it relate to the development of the project? How does the Board demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation, and that there is an effective IPC structure in place and how does it relate to the design development?	• Evidence IPC and clinical teams have been integrated into all decisions regarding any derogations through the design process and are satisfied this will not impact on patient safety such as, specific sign off, supporting meeting minutes, risk assessments, risk registers relating to IPC with evidence of escalation through the agreed NHS board governance process.

No.	Areas to probe	Evidence expected
1.8	Integration with Authority Policies and Operation. How does the Health Board demonstrate implementation of evidence based infection prevention and control measures?	• The Health Board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this (ask staff). • IPC are fully embedded in the project team and the OBC programme taking cognisance of any actual or perceived risks identified provided.
1.9	The Health Boards Infection Control Strategy	• Assessment of the Health Boards approach to all IPC related matters in relation to the development of the design, HAISCRIBE etc. • IPCT annual programme of work.
1.10	The Health Boards Monitoring and Records	• Evidence that the Health Board integrating this project with wider IPC requirements within the context of the OBC. For example, evidence that the proposals for equipping incorporate IPC requirements?
1.11	Planned approach for managing the design process to ensure successful compliance with agreed and approved standards.	• The project governance arrangements and resource plan in place to ensure that the necessary decision making authority and technical expertise is available to take responsibility for and deliver the project as planned and agreed. • Details of how gaps in expertise are being filled. • Details of how compliance with the appropriate guidance, design brief and other standards are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated throughout the design, construction and commissioning stages. • Details of how all stakeholders' interests are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated

No.	Areas to probe	Evidence expected
		throughout the design, construction and commissioning stages.
1.12	The Health Boards approach on the procurement journey, with evidence of the plans on how the Health Board will provide assurance, particularly emphasis on the critical system identified earlier.	• Evidence on how Infection Prevention and Control are involved with the conceptual procurement approach to the design stage and future plans for project. • Plans to identify any gaps in the procurement approach that may require to be addressed. • Evidence on how the Infection Control procedures and management will fit with the conceptual procurement approach and initial thinking on how it will be managed. • Evidence of a detailed procurement strategy report. • Evidence that the Health Boards selected procurement route has gone through the Health Board's Governance channels.
1.13	The Health Boards approach on those areas of design that the procurement route has provided identification as possibly being Contractors Designed Portions (CDP's).	• Evidence that the Health Board integrating this project with wider IPC requirements within the context of the OBC. For example, evidence that the proposals for equipping incorporate IPC requirements? • Evidence that the procurement of the lead designer will encompass these areas in their oversight and sign off of the complete design. • Evidence that a clear demarcation of design responsibility is being developed.
1.14	Evaluation of the Health Boards commissioning plan.	• Evidence that the Health Board has recorded plans that are comprehensive and adequate to address the needs of the project and that they are fully resourced.
1.15	Evaluation of the Health Boards duty holder matrix.	• Evidence that the Health Board have a fully recorded matrix of the required roles and responsibilities and have a

No.	Areas to probe	Evidence expected
		clear governance structure that is fully resourced together with plans in place for the implementation. • Evidence that Health Boards have appropriate number of competent, qualified staff to carry out specific duties throughout the life cycle of the project e.g., IPC, Engineers, Estates staff etc. The number of competent, qualified staff will depend on the type and size of the Build Project.

Water and Internal Plumbing / Drainage Systems

No.	Areas to probe	Evidence expected
2.1	Has the Health Board completed competency checks on the water and drainage consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Water (AE(W)) has been requested.
2.2	How does the Health Board ensure that water services are designed in a fashion which will retain space for minor additions and modifications to services in the future?	• Evidence that the engineers are presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Board. • Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the designers have presented each of the main service runs plus plant rooms to the Board's FM team, to highlight space for future flexibility. • Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant/tank rooms, IPS sections, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance.

No.	Areas to probe	Evidence expected
2.3	How does the Health Board assure itself that all variations / derogations which may be required to water systems are investigated and agreed by all parties before they are incorporated in the design?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their water management group, clinical, Estates, infection prevention and control and FM teams.
2.4	Water Management Strategy	• Assessment of Health Board proposed water management strategy and how this relates to the proposed specification, guidance and project requirements • What involvement has there been from the water management group?
2.5	Water Governance Arrangements	• Has the Health Board commenced its water governance planning and recorded how it will ensure appropriate numbers of trained staff (AP and CP) and AE(W) will be appointed, is there an established project water management group that ensures the water management strategy is adhered to for the Board, and is it clear how this project will interface with this existing group? • Evidence that the Health Boards AE(W) have been involved with and reviewed the design proposals to date.

Ventilation

No.	Areas to probe	Evidence expected
3.1	Has the Health Board completed competency checks on the ventilation consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Ventilation (AE(V)) has been requested.
3.2	How does the Health Board ensure that ventilation services are designed in a fashion which will retain space for minor additions and modifications to services in the future and there is an appropriate plant access strategy?	• Evidence that the engineers are presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Health Board. • Evidence that the design consultant has considered and agreed with the Health Board, space for future flexibility in the service installations. • Evidence that the designers have presented each of the main service runs plus plant rooms to the Board's FM team, to highlight space for future flexibility. • Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant/tank rooms, IPS sections, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance? • Evidence that a plant access strategy for the entire ventilation system has been provided to ensure safe, adequate access, including access for cleaning.

No.	Areas to probe	Evidence expected
3.3	How does the Health Board assure itself that all variations / derogations which may be required to the ventilation systems are investigated and agreed by all parties before they are incorporated in the design?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their ventilation safety group, clinical, Estates, infection prevention and control and FM teams.
3.4	Does the Health Board have a strategy for ventilation (for rooms where this is permitted within the SHTM/SHPN guidance)?	• Evidence of environmental matrix. • Evidence that the dynamic thermal modelling confirms what the design must include (e.g. structure, solar shading / protection, orientation, equipment optimisation, etc.) to ensure that room temperatures comply with SHTM guidance, in naturally ventilated rooms. • Floor plans with associated plant locations highlighted plus simple schematic of strategy. • This must also identify the air intake and exhaust strategy/locations.
3.5	Is there evidence of stakeholder input to ventilation strategies?	• Addition to or supplement to the Environmental Matrix which confirms the following, on a room by room basis: • a) the type of ventilation (to SHTM 03-01) b) patient group and/or function related to the space. • c) name of the Consultant, Clinical Lead or Department Lead who has agreed to the room requirements. • d) name of the Infection Prevention and Control Doctor or equivalent who has agreed to the room requirements. • e) name of the Infection Prevention and Control Nurse who has agreed to the room requirements. • f) name of the Estates / FM team representative who has agreed to the room requirements. • g) name of the NHS Project Manager who has agreed to the room requirements.

No.	Areas to probe	Evidence expected
		• h) name of the Decontamination Manager who has agreed to the room requirements (where this is part of the project).
3.6	Is there evidence of the Health Board developing Ventilation Commissioning Proposals?	• Evaluation of the suitability of the proposed plans in the context of the OBC, are these sufficient do the meet the requirements of the project, guidance and the design of the system?
3.7	Has the Health Board started developing its ventilation governance arrangements?	• Is the Heath Board considering how it will ensure appropriate numbers of trained staff (AP and CP) and AE(V) for the project? • Evidence that the Health Boards AE(V) have been involved with and reviewed the design proposals to date.

Electrical

No.	Areas to probe	Evidence expected
4.1	Has the Health Board completed competency checks on the electrical consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the consultant designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Electrical (AE(E)) has been requested.
4.2	How does the Health Board ensure that electrical services are being designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future?	• Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board. • Evidence that the designers have presented each of the main service runs plus plant rooms to the Board's FM team. • Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are sub stations, switch rooms, distribution board cupboards, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe, adequate maintenance?
4.3	How does the Health Board assure itself that all variations / derogations which may be required to electrical systems are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Health Board and agreed with their electrical safety group, clinical, Estates, infection prevention and control and FM teams.

No.	Areas to probe	Evidence expected
4.4	Has the Health Board assured itself of availability of adequate supply from the local utility infrastructure?	• Confirmation from the Regional Electricity Company as to how the supply will be provided from their network and if single or dual supplies are being made available.
4.5	Evidence of provisions for emergency supplies during loss of the utility incoming supply.	• Floor plans with standby generator locations highlighted plus simple schematic of strategy. • Capacity of generators • UPS provision
4.6	Is there a strategy for locating substations?	• Floor plans with substation locations highlighted plus simple schematic.
4.7	Is there a strategy for locating switchrooms?	• Floor plans with switchroom locations highlighted plus simple schematic
4.8	Is there a strategy for locating Medical IT distribution equipment?	• Floor plans with Medical IT board locations highlighted plus simple schematic of strategy. • Compliance with BS7671 section 710 • Compliance with SHTM 06-01
4.9	Is there a strategy for distribution?	• Floor plans with containment distribution routing (horizontal and vertical).
4.10	Is there evidence of the Health Board developing electrical commissioning proposals?	• Evaluation of the suitability of the proposed plans in the context of the OBC, are these sufficient do the meet the requirements of the project, guidance and the design of the system?
4.11	Has the Heath Board starting on its early thinking for the electrical governance arrangements for the operational phase?	• Is the Health Board considering how it will ensure appropriate numbers of trained staff (AP(HV), AP(LV), CP(HV), CP(LV), AE(HV) and AE(LV) for the project, inclusive of third party providers? • Evidence that the Health Boards AE(E) have been involved with and reviewed the design proposals to date.

Medical Gases

No.	Areas to probe	Evidence expected
5.1	Has the Health Board completed competency checks on the medical gases consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Medical Gases (AE(MG)) has been requested.
5.2	How does the Health Board assure itself that all variations / derogations' which may be required to medical gas systems are being investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their medical gas management group, clinical, Estates, infection prevention and control and FM teams.
5.3	How does the Health Board ensure that medical gas services are designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future?	• Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board. • Evidence that the designer has presented each of the main service runs to the Board's FM team.
5.4	Is there evidence of the Health Board developing medical gases commissioning proposals?	• Evaluation of the suitability of the proposed plans in the context of the OBC, are these sufficient do the meet the requirements of the project, guidance and the design of the system?
5.5	Has the Health Board started developing its medical gases governance arrangements for the operational phase?	• Is the Health Board considering how it will ensure appropriate numbers of trained staff (AP and CP) and AE(V) for the project?

No.	Areas to probe	Evidence expected
		• Evidence that the Health Boards AE(MG) have been involved with and reviewed the design proposals to date.
5.6	Is there recorded evidence of a strategy for bulk gas and bottle gas storage?	• Floor plans with cylinder locations highlighted • Site plan with VIE location(s) • Simple schematic • Confirmation that the medical gas strategy is adequate. • Floor plans with pipework distribution routing and manifold locations.
5.7	Is there recorded evidence of a strategy for medical gas plant?	• Description of medical; gas requirements signed off by clinical colleagues. • Floor plans with pipework distribution (horizontal and vertical) routing. • Details of all medical gas plant areas ensuring safe and adequate access.

No.	Areas to probe	Evidence expected
6.1	Has the Health Board completed competency checks on the Fire Engineering consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Fire Advisors has been requested.
6.2	Has a written fire strategy been completed and does it provide evidence, where there is a variance from statutory and mandatory guidance, that an equivalent level of safety has been achieved by alternative means?	• Is there documented evidence that fire suppression systems have been considered for life safety and property protection? • Is progressive horizontal evacuation available for all patient areas that continuously moves away from the fire area? • Does the design considerations of the fire and detection system provide L1 coverage including voids? • Does the design provide for a compliant emergency lighting system? • Are free swing arm self-closers fitted to all leafs of doors serving sleeping accommodation? • Have escape lifts been considered for the evacuation of patients and others with mobility issues? • Are multi sensor fire detectors installed to reduce the occurrence of unwanted fire alarm signals? • Are there adequate storage facilities to ensure escape routes are not used for this purpose? • Are measures in place to provide safe charging of electrical and personal electronic equipment? • Have fire hazard rooms been designated based on fire load? • Where there is a mechanical ventilation system - have all compartments, sub-

No.	Areas to probe	Evidence expected
		compartments and corridors serving sleeping accommodation been designed to be fitted with fire and smoke dampers?
6.3	How does the Health Board assure itself that all variations / derogations which may be required to fire systems are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation and any fire engineering proposals are being referred to the Board and agreed with their fire safety group, clinical, engineering, infection prevention and control and FM teams.
6.4	How does the Health Board assure itself that all fire dampers and fire/smoke dampers are designed to allow for inspection, resetting and maintenance?	• Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board. • Evidence that the designers have presented each of the fire dampers and smoke / fire dampers to the Board's FM team. • Safe and adequate access has been allocated on both sides of all fire dampers for maintenance.
6.5	How does the Health Board assure itself that any fire rated ductwork is correctly installed?	• Evidence that the system is certificated and that the installation follows the installation details which were used for the certification. • Written confirmation from the design consultant.
6.6	How does the Health Board assure itself that any smoke control and/or clearance systems are fit for purpose?	• Evidence that the smoke system is being designed by an accredited Fire Engineer. • Evidence that Building Control are being consulted. • Confirmation from the Building Services Design Consultant that the operating sequence for the smoke system has been discussed regarding being integrated into the control of other building systems.

No.	Areas to probe	Evidence expected
6.7	Evidence that the Health Board is ensuring fire safety input into the design process together with early design decision-making.	• Input from Fire lead(s) and HFS / SFRS on fire safety into site / option selection. Documents e.g. option appraisal report, fire strategy report, meeting minutes. • Demonstrable and appropriate engagement and expertise of relevant Fire lead(s). Signed off documents, e.g. reports, role profiles, minutes. • Evidence that the Health Boards Fire Advisor have been involved with and reviewed the design proposals to date.
6.8	Has the Health Board started the development of the fire system outline commissioning proposals?	• Has the Health Board designed appropriate trained staff and appointed a fire officer for the project, is there an established firer management group that will ensure the fire management strategy is adhered to?

No.	Areas to probe	Evidence expected
7.1	How does the Health Board demonstrate that there is an effective infection prevention and control management structure in place? How does the Board demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation and that there is an effective IPC structure in place; inputting into the design process?	• The Health Board provides evidence that there is an IPC Management Structure with the necessary. expertise and leadership skills to support the design work. • The Health Board provides evidence that there is an IPC Management Team with the necessary expertise and leadership skills to support the project. • Executive board reports or minutes. Risk registers or equivalent, Minutes from operational and governance groups, (and action points). • Structure of infection prevention and control team (IPCT) and qualifications held, previous experience supporting new build projects. • Evidence IPC and clinical teams have been involved with any derogation through the design process and are satisfied this will not impact on patient safety. This can be meeting minutes, risk assessments, and risk registers. There is IPC evidence of escalation through the agreed NHS board governance process. • Evidence the Executive board member assigned to lead on IPCT has been kept informed of IPC risks identified and associated with the project this can be demonstrated by the board. • Evidence that fixtures fitting and equipment have not been proposed for the project that would represent an IPC risk.
7.2	How does the Health Board demonstrate implementation of evidence based infection prevention and control measures during the design process?	• The Board evidences that: • The Health Board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this and it is being referred to during the design process.

No.	Areas to probe	Evidence expected
		• IPC work programme and planned IPC audit programme for new building taking cognisance of any actual or perceived risks identified.
7.3	How does the Health Board assure itself that the designers have a proper understanding of the infection prevention and control procedures and processes required?	• The Health Board evidences that: • All relevant staff within the designers organisation are provided with clear guidance on roles and responsibilities in relation to infection prevention and control. • The contractors organisation will provide evidence of education in relation to infection prevention in the built environment for all staff involved in the project.
7.4	How does the Health Board assure itself that equipment being proposed meets the required IPC standards?	• The IPC Team are involved and IPC advice followed in all procurement decisions for new equipment prior to purchase. IPCT are satisfied that all equipment purchased can be decontaminated safely in line with National Decontamination Guidance, NIPCM and manufacturers' instructions.

Key Stage Assurance Review Workbook

Full Business Case

June 2021

Version 1.0

A46676816

Contents

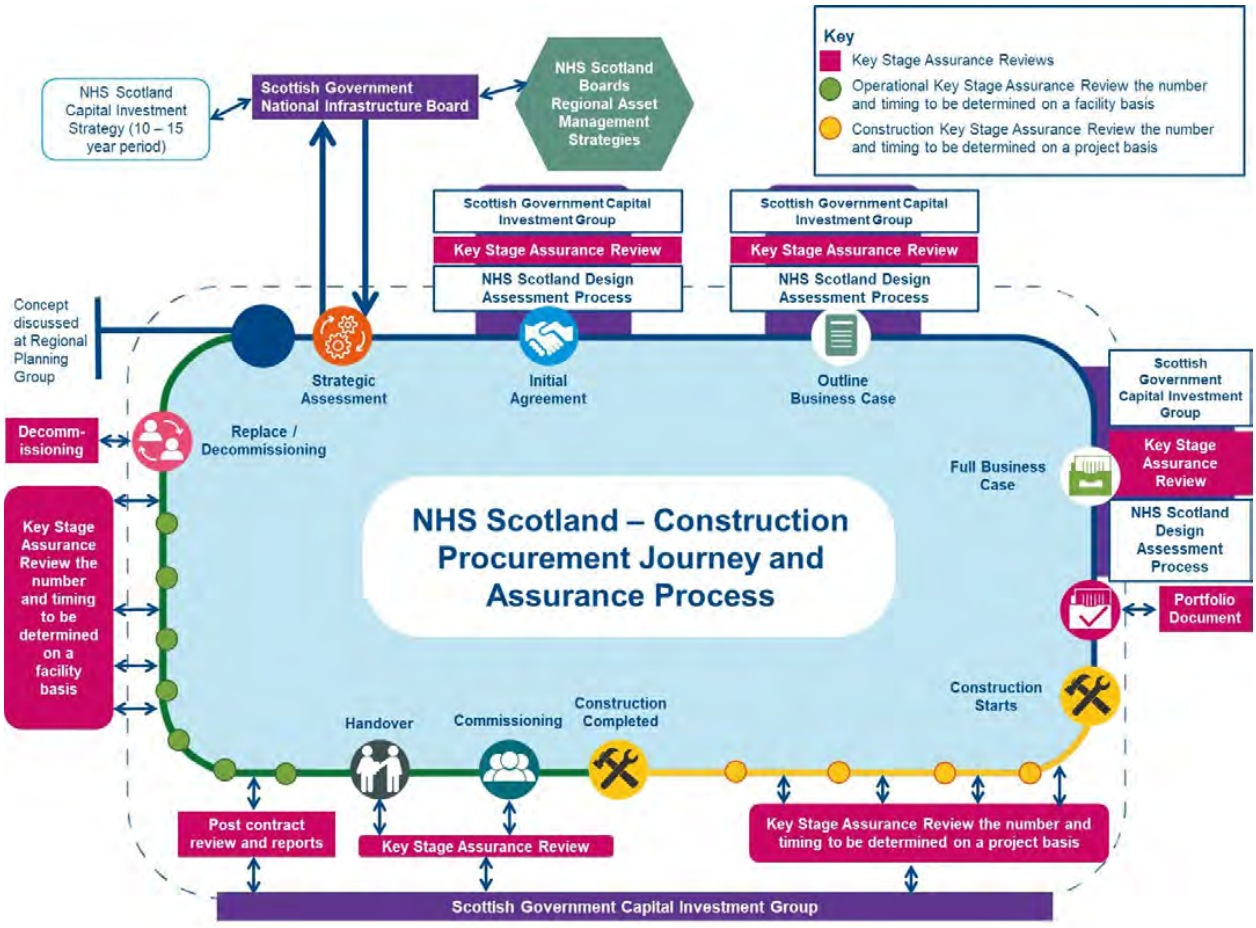
1. About this workbook

This workbook supports the Full Business Case Key Stage Assurance Review (KSAR), delivered by the NHS Scotland Assure Assurance service.

Further information about the NHS Scotland Assure Assurance service and KSAR process is provided in section 2.

Figure 1. shows how the Full Business Case stage in the procurement and construction journey commences following the Outline Buisness Case. The timing and frequency of KSARs during this stage will vary dependent upon the facility. Specific workbooks have been developed for the other stages within this journey.

Figure 1: Construction Procurement Journey



KSARs are of a process ensuring facilities and the teams using them are able to deliver the standards required to provide the best and safest outcomes for patients, staff and visitors in the built environment.

KSARs deliver an independent peer review. NSS staff outside the project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility.

It is vital to receive feedback on the following elements of health facilities - Infection Prevention and Control (IPC), water, ventilation, electrical, plumbing, medical gases installations and fire. This ensures they are designed, installed and functioning from

initial commissioning of a new facility and throughout its lifetime. Health Boards are required to have appropriate governance in place at all stages of the construction procurement journey.

The KSAR workbook provides a transparent, structured framework for all clinical specialisms, facilities and operational management professionals to assess and manage a health care build or refurbishment. Allowing facilities to align with current standards as the assurance reviews are taking place, as well as aligning changes for patient cohort.

Using this workbook

The review at Full Business Case stage investigates the approach taken by the Health Board in the development of the design, and how the appropriate level of knowledge and awareness of patient and user needs will influence the development of the design.

The purpose of the KSAR at Full Business Case stage is to confirm there is a good and comprehensive understanding of the category of patient who will use the proposed facility and that the project team consider how appropriate quality and safety standards will influence the design. It looks to provide assurance that the project can proceed to the Construction phase.

Additionally, the KSAR at Full Business Case will carry out an appropriate level of checking of the design calculations and solutions adopted. This level of checking will be set by the Review Team following their initial discussions on site.

The workbook is predominantly intended to be used by NHS Scotland Assure KSAR review teams, Health Boards are encouraged to use its content to support their own projects. It provides guidance on the review structure and areas of investigation to be addressed by the review team and should be regarded as indicative and not prescriptive.

The review team will consider whether any emerging findings require additional topics to be addressed. If so, evidence relating to these areas, regarding the safety of the patients, staff and visitors, should be provided.

2. Key Stage Assurance Review

Introduction to NHS Scotland Assure – Assurance Service

Good management effective control of projects is an essential element to the successful delivery and maintenance of healthcare facilities across NHS Scotland estates.

The initial delivery of the NHS Scotland Assure - Assurance Service will focus upon new builds and major refurbishments in the acute estate, submitted to the Scottish Government Capital Investment Group (CIG). In addition, a number of projects identified as being complex, primarily due to the needs of patients utilising the facilities, will be reviewed by this service. Whilst not an exhaustive list, these projects will cover oncology, maternity, theatre and critical care units, no matter of their financial value.

The NHS Scotland Assure - Assurance Service will deliver KSARs, designed to provide independent assurance to Scottish Government Health and Social Care Directorates (SGHSCD's).

It will assess if Health Boards Project Management teams (inclusive of clinicians, appointed construction consultants, and contractors) are briefed and following best practice procedures in the provision of facilities. We will review if projects are compliant in all aspects of safety, if specific engineering systems are designed, installed and commissioned, and for ongoing safety maintenance including IPC.

The KSAR process is applicable regardless of procurement route chosen.

The KSAR Process

The KSAR process examines projects at key points in their lifecycle. It does not remove any legal or contractual obligations from the NHS Health Board, their designers or contractors. It provides assurance to progress successfully to the next review point and the process will be mandated for projects requiring CIG approval. KSARs focus on the assessment of the delivery approach, and will work with the Health Board's project team to ensure there is comprehensive understanding of the patient cohorts utilising the facility. KSARs also ensure relevant guidance is fully implemented and any technical derogations have been fully reasoned, transparently discussed, the implications understood, recorded and signed off by the Health Board and their advisors.

With a focus on construction elements where previous reviews have demonstrated potential patient safety concerns, KSARs will concentrate on water; ventilation, electrical, plumbing, medical gases installations, fire, and associated IPC guidance. If further issues are raised with the review team, they will fully incorporate those issues into the reporting process.

Value of the KSAR Process

Key Stage Assurance Reviews (KSARs) deliver an independent peer review. NSS staff outside the Health Board's project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility. KSARs provide an external perspective and provide a challenge to the robustness of the Health Board's brief, plans and processes.

This includes work delivered by construction consultants, employed either directly or through construction contractors, and the work being delivered by the primary contractor, their sub-contractors and specialist suppliers.

The KSAR provides an independent report and action plan, which is shared with the Health Board to ensure:

- Appropriate skills and experience are deployed on the project by the Health Board, consultants, primary contractor and all sub-contractors.
- The clinicians and wider stakeholders covered by the project fully understand the project status, aims and the issues involved.
- Appropriate management structures put in place to ensure appropriate infection prevention and control measures are designed into the project to reduce the risk of transmission of infectious agent.
- There is assurance the project can progress to the next stage of development or implementation with particular emphasis on the safety of the patients, staff and visitors utilising the facility.
- Provision of advice and guidance to programme and project teams by fellow Practitioners.

The KSAR report and the Health Board's response and action plan is submitted to CIG along with a recommendation from the NHS Scotland Assure - Assurance Service regarding the projects' progression to the next stage of the construction procurement journey.

KSAR as part of the overall assurance framework

Each NHS Health Board will be fully responsible for the delivery of all projects, and its own internal process and resources for carrying out internal reviews and audits of its activities. The KSAR is seen as a complementary independent review, and not as a replacement for the responsibilities of the Health Board.

NHS Health Boards should have in place an effective framework to provide a suitable level of assurance for their programmes and projects. Health Boards are encouraged and expected to ensure adequate and timely coordination and sharing of information, including plans, between the various internal reviews and functions.

The KSAR process is not a substitute for a rigorous governance framework in the Board to manage key processes including business planning, investment appraisal, business case management, risk management and service and contract management.

The KSAR Process relationship with NHS Scotland Design Assessment Process (NDAP)

The Scottish Government's ambition for NHS Scotland's estate and the need for well-designed healthcare environments is articulated in the Policy on Design Quality for NHS Scotland. Good design in the built environment encompasses a wide range of inter-related factors such as, sustainability, engineering, architecture, fire safety, energy, environment, decontamination, space utilisation, landscaping, security, technology, lighting, access for visitors and mobility impaired persons.

The NDAP process is overseen by Health Facilities Scotland and Architecture and Design Scotland and holistically considers all of the above. It sets the principles for the resolution of potential conflicts of statutory or mandatory compliance to ensure the specific facility provides; the best balance of the technical requirements, meets clinical needs and fulfils the conceptual aims of the policy on Design Quality. The NDAP process begins at the initial agreement stage of a project and provides advice through to the Full Business Case. There is no change to either SCIM or NDAP processes.

The Scottish Government is progressing policy to improve the safety of the healthcare environment in relation to the built environment risk. The Assurance Service delivered through NHS Scotland Assure is a response to this policy and the KSARs are integral to the compliance work. The aspiration is not to duplicate any of the work included in the NDAP process, but to provide assurance regarding the critical components highlighted throughout this workbook.

Integral to the KSARs will be a review of the balance between sustainability issues and patient safety.

The NDAP, working with Health Boards, will set the principles of the design solution, whereas the KSAR will provide a detailed technical review of the specifics of the design solution. Where possible the two reviews will be aligned to avoid duplication of work. For example, in instances where the NDAP has reviewed detail at a technical level, this will be used by the KSAR team rather than being separately requested and reviewed.

Sustainability

The review will provide assurance that the proposals for the project provide an effective balance in terms of patient, staff and visitors safety, whilst meeting required sustainability outcomes and complying with the guidance standards.

Full Business Case (FBC) KSAR

This review investigates the approach taken by the Health Board in the development of the design, to confirm that there is a good and comprehensive understanding of the category of patient utilising the proposed facility, and that the project team are aware of how their needs and expectations for appropriate quality and safety standards will influence the design of the accommodation. It looks to provide assurance that the project can proceed to the Construction phase.

The FBC KSAR will focus on understanding how patient needs and expectations have influenced the following critical components of design, particularly in relation to Infection Prevention and Control.

- Water systems
- Ventilation systems
- Plumbing and drainage
- Fire safety
- Electrical systems
- Medical gases
- Any other building or engineering component critical to the safety and welfare of a particular patient cohort (defined by the review team).

At all stages of design development, knowledge of compliance in design and implementation will need to encompass (but is not limited to) the following:

- NHS Scotland policy letters (DLs,CELs,CMOs)
- Scottish Health Planning Notes (SHPN)
- Scottish Health Facilities Notes (SHFN)
- Scottish Health Technical Memoranda (SHTM)
- Scottish Fire Practice Notes (SFPN)
- Health Building Notes (HBN)
- Health Technical Memoranda (HTM)
- Health Facilities Notes (HFN)
- Incident Reporting and Investigation Centre (IRIC) Alerts
- Relevant British Standards
- UK construction industry bodies best practice or design guidance publications e.g. HSE, CIBSE, BRE, IHEEM, IET, BRE, BSRIA, sustainability, dementia and equality.
- Incident Reporting and Investigation Centre (IRIC) Alerts
- Relevant British Standards
- Other statutory requirements: Planning permission; Building Regulations compliance; Equality Act compliance; Health and Safety Executive (HSE)

compliance; Construction (Design and Management) Regulations compliance. Fire Scotland Act.

- Other mandatory NHS Scotland use of
  - Activity Data Base (ADB);
  - Achieving Excellence Design Evaluation Tool;
  - BREEAM Healthcare or equivalent (BRE environmental & sustainability tools);
  - Scottish Government BIM Policy (SPPN 1/2017; implementation of building information modelling within construction projects: March 2017).
- The implementation of NHS Scotland Soft Landings (SL) guidance.
- Confirm that there are plans in place for risk management, issue management and that these plans are being shared with suppliers and delivery partners.
- Evaluation of actions taken to implement recommendations made in earlier assessment of deliverability.
- Confirm there are plans in place to ensure the requirements of the NHS Scotland National Infection Prevention and Control Manual for Scotland are being incorporated into the development in a manner which will allow the staff allocated to the role to deliver the services to the patients.

Additionally, the FBC KSAR will carry out an appropriate level of checking of the design calculations and solutions adopted. This level of checking will be set by the review team following their initial discussions on site. One impact of this work may be that the review will take longer than the initial programme, dependant on the conclusions / findings from this in-depth assessment of the design.

The review teams consist of experienced operational estates professionals and experienced Infection Control clinicians. The team will work with the Health Board's Project Team, inclusive of their clinicians and their appointed facility management consultants and contractor. Each review will result in a report being prepared for the Programme Director at the Board and a copy of the report will also be provided to Scottish Government Capital Investment Group

An appendix is provided which indicates the typical question set for OBC which the review Team will use as the basis of evidence finding for the KSAR. The review team will amend this as necessary depending on the project and areas of particular interest. The Health Board, their designers and contractors should be aware that this is the information which will be expected and the design should effectively be completed at OBC at the time of the KSAR to ensure the accuracy of the report.

3. Assessment of Delivery Approach

The review at Full Business Case stage needs to demonstrate an awareness and knowledge of how the above will be used to influence the initial design.

Project Governance and General Arrangements

No.	Areas to probe	Evidence expected
1.1	Evaluation of changes detailed from previous KSAR.	• Assessment of any substantive changes in highlighted areas from previous review stage and all actions have been implemented.
1.2	Verification that CIG recommendations have been implemented with respect to prescribed in scope areas.	• Review of the implementation of all CIG recommendations. Evaluation of any deviation from previous submissions or reviews.
1.3	Has cross-referencing with NDAP and AEDET recommendations been implemented?	• An assessment if there is full compliance with the applicable recommendations and actions from the preceding step.
1.4	Does the Health Board continue to demonstrate service / clinical input into design decisions based on a current and comprehensive knowledge of patient cohorts?	• Recorded and updated input taken from service lead(s) / clinician(s) about relevant patient cohort characteristics and their typical needs in terms of the accommodation's environment, safety and infection control standards. • Demonstrable expertise of service lead(s) / clinician(s) in providing this advice.
1.5	Project team continues to demonstrate a unified and recorded understanding of needs of main users and patient cohorts of the proposed accommodation and how this has influenced the design of critical building, engineering and infection prevention and control quality and safety standards.	• Updated and current list available of all stakeholders, service users and patient cohorts impacted by this project, plus the identification of any high risk groups and their specialist needs. • Updated and recorded engagement on these designs issues having taken place between the project team and service lead(s) / clinician(s), infection prevention and control team, and other key stakeholders (e.g. Estates, Medical Physics, IPC, the AEDET, NDAP or other design briefing workshops).

No.	Areas to probe	Evidence expected
		• Details available of how service users / patient cohort needs and their expected use of the accommodation are influencing the design brief; including critical building, engineering and infection prevention and control quality and safety standards.
1.6	Planned approach towards determining the necessary standards for this accommodation.	• Updated and current list of the relevant NHS and non-NHS guidance that is being used and adopted (see previous section of workbook FBC KSAR (Page 9) for examples of appropriate guidance). • Updated and current list of all proposed derogations from NHS guidance with a detailed technical narrative on each derogation and/or list of known gaps in guidance that will need to be resolved in order to meet the needs of the patient / user cohort. • Knowledge of the role of infection prevention and control advisors (IPCN and ICD) to be used throughout the final design stages, and details of the resource plan in place to ensure continuity into the construction phase.
1.7	How does the Health Board demonstrate that there is an effective infection prevention and control management structure in place and how does it relate to the development of the project? How does the Health Board demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation and that there is an effective IPC structure in place and how does it relate to the design development?	• Evidence IPC and clinical teams have been integrated into all decisions regarding any derogations through the design process and are satisfied this will not impact on patient safety such as, specific sign off, supporting meeting minutes, risk assessments, risk registers relating to IPC with evidence of escalation through the agreed NHS board governance process.

No.	Areas to probe	Evidence expected
1.8	Integration with Authority Policies and Operation How does the Board demonstrate implementation of evidence based infection prevention and control measures?	• The Health Board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this. (Ask staff) • IPC are fully embedded in the project team and the FBC programme taking cognisance of any actual or perceived risks identified provided.
1.9	The Health Boards Infection Prevention and Control Strategy	• Assessment of the Health Boards approach to all IPC related matters in relation to the development of the design, HAISCRIBE etc.
1.10	The Health Boards Monitoring and Records	• Evidence that the Health Board integrating this project with wider IPC requirements within the context of the FBC. For example, evidence that the proposals for equipping incorporate IPC requirements?
1.11	Planned approach for managing the design process to ensure successful compliance with agreed and approved standards	• The project governance arrangements and resource plan in place to ensure that the necessary decision making authority and technical expertise is available to take responsibility for and deliver the project as planned and agreed. • Details of how gaps in expertise are being filled. • Details of how compliance with the appropriate guidance, design brief and other standards are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated throughout the design, construction and commissioning stages. • Details of how all stakeholders' interests are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated throughout the design, construction and commissioning stages.

No.	Areas to probe	Evidence expected
1.12	The Health Boards approach on the procurement journey with evidence of the plans on how the Board will provide assurance, particularly emphasis on the critical system identified earlier.	• Evidence on how this requirement is being managed and how it fits with the project governance arrangements • Plans to identify any gaps in the procurement approach that may require to be addressed. • Evidence on how Infection Prevention and Control are involved with the conceptual procurement approach to the design stage and future plans for project. • Evidence that the Health Boards selected procurement route has gone through the Board's Governance channels.
1.13	The Health Boards approach on those areas of design that the procurement route has provided identification as possibly being Contractors Designed Portions (CDP's).	• Evidence that the procurement of the lead designer will encompass these areas in their oversight and sign off of the complete design. • Evidence that a clear demarcation of design responsibility is being developed.
1.14	Evaluation of the Health Boards commissioning plan.	• Evidence that the Health Board has recorded plans that are comprehensive and adequate to address the needs of the project and that they are fully resourced.
1.15	Evaluation of the Health Boards duty holder matrix.	• Evidence that the Health Board have a fully recorded matrix of the required roles and responsibilities and have a clear governance structure that is fully resourced together with plans in place for the implementation. • Evidence that Health Boards have appropriate number of competent, qualified staff to carry out specific duties throughout the life cycle of the project e.g., IPC, Engineers, Estates staff etc. The number of competent, qualified staff will depend on the type and size of the Build Project.

No.	Areas to probe	Evidence expected
2.1	Has the Health Board completed competency checks on the water and drainage consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Authorising Engineer for Water (AE(W)) has been requested. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
2.2	How does the Health Board ensure that water services are designed in a fashion which will retain space for minor additions and modifications to services in the future?	• Evidence that the engineers are presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Board. • Evidence that the Design Consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the designers have presented each of the main service runs plus plant rooms to the Board's FM team, to highlight space for future flexibility. • Evidence that the Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant/tank rooms, IPS sections, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance.
2.3	How does the Health Board assure itself that all variations / derogations which may be required to water systems are	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their water management group clinical,

No.	Areas to probe	Evidence expected
	investigated and agreed by all parties before they are incorporated in the design?	engineering, Estates, infection prevention and control and FM teams.
2.4	Water Management Strategy	• Assessment of Board proposed water management strategy and how this relates to the specification, guidance and project requirements. • What involvement has there been from the water management group?
2.5	Water governance arrangements	• Has the Board commenced its planning and recorded how it will ensure appropriate numbers of trained staff (AP and CP) and AE(W) will be appointed, is there an established project water management group that ensures the water management strategy is adhered to for the Board and is it clear how this project will interface with this existing group?

2.6	Evidence that the Health Board is developing commissioning proposals.	• Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient to meet the requirements of the project, guidance and the design of the system.
		• Evidence that the design has considered the commissioning of the water system including:
		  ○ Safe storage of materials
		  ○ Agreed type of chemical (to avoid warranty and corrosion issues)
		  ○ Adequate time scale
		  ○ Competency checks on all contractors
		  ○ Water sampling scope
		• Water sampling test results and approval process.

2.7	Evaluation of the Health Boards planned preventative maintenance (PPM) proposals.	• Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance

No.	Areas to probe	Evidence expected
		and robust management processes, including: ○ Adequate numbers of staff ○ Water management PPM including all outlets, TMT & TMV, plumbing and drainage systems, etc.?

Ventilation

No.	Areas to probe	Evidence expected
3.1	Has the Health Board completed competency checks on the ventilation consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Ventilation (AE(V)) has been requested. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
3.2	How does the Health Board ensure that ventilation services are designed in a fashion which will retain space for minor additions and modifications to services in the future and there is an appropriate plant access strategy?	• Evidence that the design engineers have presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Board. • Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the design engineers have presented each of the main service runs plus plant rooms to the Board's Estates team and / or FM team, to highlight space for future flexibility. • Evidence that the ventilation solution has been agreed with clinical and IPC colleagues. • Evidence that the Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant rooms, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance? • Evidence that a plant access strategy for the entire ventilation system has been provided to ensure safe, adequate access, including access for cleaning.

No.	Areas to probe	Evidence expected
3.3	How does the Health Board assure itself that all variations / derogations which may be required to the ventilation systems are investigated and agreed by all parties before they are incorporated in the design?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their ventilation safety group, clinical, engineering, Estates, infection control and FM teams.
3.4	Does the Health Board have a strategy for ventilation (for rooms where this is permitted within the SHTM/SHPN guidance)?	• Evidence of agreed environmental matrix. • Evidence that the Dynamic thermal modelling confirms what the design must include (e.g. structure, solar shading/protection, orientation, equipment optimisation, etc.) to ensure that room temperatures comply with SHTM guidance, in naturally ventilated rooms. • Floor plans with associated plant locations highlighted plus simple schematic of strategy. This must also identify the air intake and exhaust strategy / locations.
3.5	Is there evidence of stakeholder input to ventilation strategies?	• Addition to or supplement to the Environmental Matrix which confirms the following, on a room by room basis: • a) the type of ventilation (to SHTM 03-01) b) patient group and / or function related to the space. • c) name of the Consultant, Clinical Lead or Department Lead who has agreed to the room requirements. • d) name of the Infection Prevention and Control Doctor or equivalent who has agreed to the room requirements. • e) name of the Infection Prevention and Control Nurse who has agreed to the room requirements. • f) name of the Estates / FM team representative who has agreed to the room requirements. • g) name of the NHS Project Manager who has agreed to the room requirements.

No.	Areas to probe	Evidence expected
		• h) name of the Decontamination Manager who has agreed to the room requirements (where this is part of the project).
3.6	Is there evidence of the Health Board developing Ventilation Commissioning Proposals?	• Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient do the meet the requirements of the project, guidance and the design of the system? • What plans have been made for independent validation of the ventilation systems? • What plans have been made for independent verification of the ventilation system? • What plant and ductwork cleaning has been specified? • What safe adequate access has been allowed for access to dampers?
3.7	Has the Health Board started developing its ventilation governance arrangements?	• Has the Health Board commenced its planning and recorded how it will ensure appropriate numbers of trained staff (AP and CP) staff and appointment of AE(V) for the project and is it clear how this project will interface with the Health Boards existing arrangements for management of the ventilation installations?
3.8	Evaluation of the Health Boards planned preventative maintenance (PPM) proposals.	• Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes?

No.	Areas to probe	Evidence expected
4.1	Has the Health Board completed competency checks on the electrical consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Electrical (AE(E)) has been requested. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
4.2	How does the Health Board ensure that electrical services are being designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future?	• Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board. • Evidence that the designers have presented each of the main service runs plus plant rooms to the Health Board's FM team. • Evidence that the Board has agreed a strategy (percentage) for spare capacity and a documented allowance has been incorporated into the design. • Are sub stations, switch rooms, distribution board cupboards, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe, adequate maintenance.
4.3	How does the Health Board assure itself that all variations / derogations which may be required to electrical systems are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their electrical safety group, clinical, Estates, infection prevention and control and FM teams.
4.4	Has the Health Board assured itself of	• Confirmation from the Regional Electricity Company as to how the supply will be

No.	Areas to probe	Evidence expected
	availability of adequate supply from the local utility infrastructure?	provided from their network and if single or dual supplies are being made available. • What is the Health Board's resilience strategy for the electrical infrastructure (including dual supplies, renewables, generators, UPS, etc.)?
4.5	Evidence of provisions for emergency supplies during loss of the utility incoming supply.	• Floor plans with standby generator locations highlighted plus simple schematic.
4.6	Is there a strategy for locating substations?	• Floor plans with substation locations highlighted plus simple schematic of strategy.
4.7	Is there a strategy for locating switchrooms?	• Floor plans with switchroom locations highlighted plus simple schematic.
4.8	Is there a strategy for locating Medical IT distribution equipment?	• Floor plans with Medical IT board locations highlighted plus simple schematic. • Compliance with BS7671 section 710 • Compliance with SHTM 06-01
4.9	Is there a strategy for distribution?	• Floor plans with containment distribution routing (horizontal and vertical).
4.10	Is there evidence of the Health Board developing electrical commissioning proposals?	• Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient do the meet the requirements of the project, guidance and the design of the system? • Has sufficient time been allocated for a full commissioning program?
4.11	Has the Health Board starting on its early thinking for the electrical governance arrangements for the operational phase?	• Has the Health Board commenced its planning and recorded how it will ensure appropriate trained staff and appointment of AE for the project and is it clear how this project will interface with the Health Board existing arrangements for management of the electrical installations, inclusive of third party providers?

No.	Areas to probe	Evidence expected
4.12	Evaluation of the Health Boards planned preventative maintenance (PPM) proposals.	• Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes, inclusive of third party providers?

Medical Gases

No.	Areas to probe	Evidence expected
5.1	Has the Health Board completed competency checks on the medical gases consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards. • Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the consultant designers? • Recorded evidence that input from the Health Boards Authorising Engineer for Medical Gases (AE(MG)) has been requested. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
5.2	How does the Health Board assure itself that all variations / derogations' which may be required to medical gas systems are being investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their medical gases management group, clinical, Estates, infection control and FM teams.
5.3	How does the Health Board ensure that medical gas services are designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future?	• Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board. • Evidence that the designer has presented each of the main service runs to the Board's FM team.
5.4	Is there evidence of the Health Board developing medical gases commissioning proposals?	• Evaluation of the suitability of the proposed plans in the context of the FBC are these sufficient do the meet the requirements of the project, guidance and the design of the system?

No.	Areas to probe	Evidence expected
5.5	Has the Health Board started developing its medical gases governance arrangements for the operational phase?	• Is the Health Board considering how it will ensure appropriate numbers of trained staff (AP and CP) and AE(V) for the project? And is it clear how this project will interface with the Board existing arrangements for management of the medical gases installations?
5.6	Is there recorded evidence of a strategy for bulk gas and bottle gas storage?	• Floor plans with vacuum insulated evaporator (VIE) locations highlighted plus simple schematic of strategy. • Confirmation that the medical gas strategy is adequate. • Floor plans with pipework distribution routing and manifold locations.
5.7	Evaluation of the Health Boards planned preventative maintenance (PPM) proposals	• Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes?

No.	Areas to probe	Evidence expected
6.1	Has the Health Board completed competency checks on the Fire Engineering consultant designers?	• Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards applicable to healthcare premises. • Recorded evidence that input from the Health Boards Fire Advisors has been requested. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
6.2	Has a written fire strategy been completed and does it provide evidence, where there is a variance from statutory and mandatory guidance, that an equivalent level of safety has been achieved by alternative means?	• Is there documented evidence that fire suppression systems have been considered for life safety and property protection? • Is progressive horizontal evacuation available for all patient areas that continuously moves away from the fire area? • Does the design considerations of the fire and detection system, for in-patient facilities, provide L1 coverage including voids? • Does the design provide for a compliant emergency lighting system? • Are free swing arm self-closers fitted to all leafs of doors serving sleeping accommodation? • Have escape lifts been considered for the evacuation of patients and others with mobility issues? • Are multi sensor fire detectors installed to reduce the occurrence of unwanted fire alarm signals? • Are there adequate storage facilities to ensure escape routes are not used for this purpose? • Are measures in place to provide safe charging of electrical and personal electronic equipment? • In addition to the prescribed list in the Building Standards Technical Handbook have fire hazard rooms been designated based on fire load? • Where there is a mechanical ventilation system - have all compartments, sub-compartments and corridors serving sleeping

No.	Areas to probe	Evidence expected
		accommodation been designed to be fitted with fire and smoke dampers?
6.3	How does the Health Board assure itself that all variations / derogations which may be required to fire systems are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation and any fire engineering proposals are being referred to the Board and agreed with their fire safety advisors, NDAP group, clinical, engineering, Infection Prevention and Control, FM teams and regulatory authorities.
6.4	How does the Health Board assure itself that all fire dampers and fire/smoke dampers are designed to allow for inspection, resetting and maintenance?	• Safe and adequate access has been allocated on both sides of all fire dampers for maintenance.
6.5	How does the Health Board assure itself that any smoke control and/or clearance systems are fit for purpose?	• Evidence that the smoke system is being designed by an accredited Fire Engineer. • Evidence that Building Control are being consulted. • Confirmation that the Health Boards fire advisors and NDAP team are satisfied with the design proposal.
6.6	Has the Health Board started the development of the fire system outline commissioning proposals?	• Is there an established fire management group that will ensure the fire strategy is adhered to?
6.7	Has the Health Board started its early thinking for the Fire Safety arrangements for the operational phase?	• Has the Health Board commenced its planning and recorded how it will ensure appropriate trained staff and appointment of Fire Officers for the project in the operational phase and is it clear how this project will interface with the

No.	Areas to probe	Evidence expected
		Health Boards existing arrangements for management of the Fire Safety?

No.	Areas to probe	Evidence expected
7.1	How does the Health Board demonstrate that there is an effective infection prevention and control management structure in place? How does the Board demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation and that there is an effective IPC structure in place; inputting into the design process?	• The Health Board provides evidence that there is an IPC Management Structure with the necessary expertise and leadership skills to support the design work ○ The Health Board provides evidence that there is an IPC Management Team with the necessary expertise and leadership skills to support the project. ○ Executive board reports or minutes. Risk registers or equivalent, Minutes from operational and governance groups, (and action points). ○ Structure of infection prevention and control team (IPCT) and qualifications held, previous experience supporting new build projects. ○ Evidence IPC and clinical teams have been involved with any derogation through the design process and are satisfied this will not impact on patient safety. This can be meeting minutes, risk assessments, and risk registers. There is IPC evidence of escalation through the agreed NHS board governance process. ○ Evidence the Executive Board Member assigned to lead on IPCT has been kept informed of IPC risks identified and associated with the project this can be demonstrated by the board. ○ Evidence that fixtures fitting and equipment have not been proposed for the project that would represent an identified IPC risk. ○ Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
7.2	How does the Health Board demonstrate implementation of evidence based infection prevention and control	• The Health Board provides evidence ○ The board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this

No.	Areas to probe	Evidence expected
	measures during the design process?	and it is being referred to during the design process. ○ The board can demonstrate IPC advisors have been included within the design phase and development of HAISCRIBE.
7.3	How does the Health Board assure itself that the designers have a proper understanding of the infection prevention and control procedures required?	• The Health Board evidences that: ○ All relevant staff within the designers' organisation are provided with clear guidance on roles and responsibilities in relation to infection prevention and control. ○ The contractors' organisation will provide evidence of education in relation to infection prevention in the built environment for all staff involved in the project.
7.4	How does the Health Board assure itself that equipment being proposed meets the required IPC standards?	• The IPC Team are involved and IPC advice followed in all procurement decisions for new equipment prior to purchase. IPCT are satisfied that all equipment purchased can be decontaminated safely in line with National Guidance and manufacturers' instructions.
7.5	Evaluation of the Health Boards planned preventative maintenance (PPM) proposals for equipment issues and the Built Environment in relation to IPC issues.	• Has the Health Board considered how they will undertake assessment of and report cleanliness of the proposed facility and equipment within the healthcare environment, this is inclusive of planned programmes of maintenance? • Does the Health Board plan to seek feedback from patients, staff and visitors for their views? • Is it clear how the work for this project will interface with the Health Board existing arrangements for management of the IPC in the Built Environment in the wider estate?

Key Stage Assurance Review Workbook

Construction

June 2021

Version 1.0

A46676816

Contents

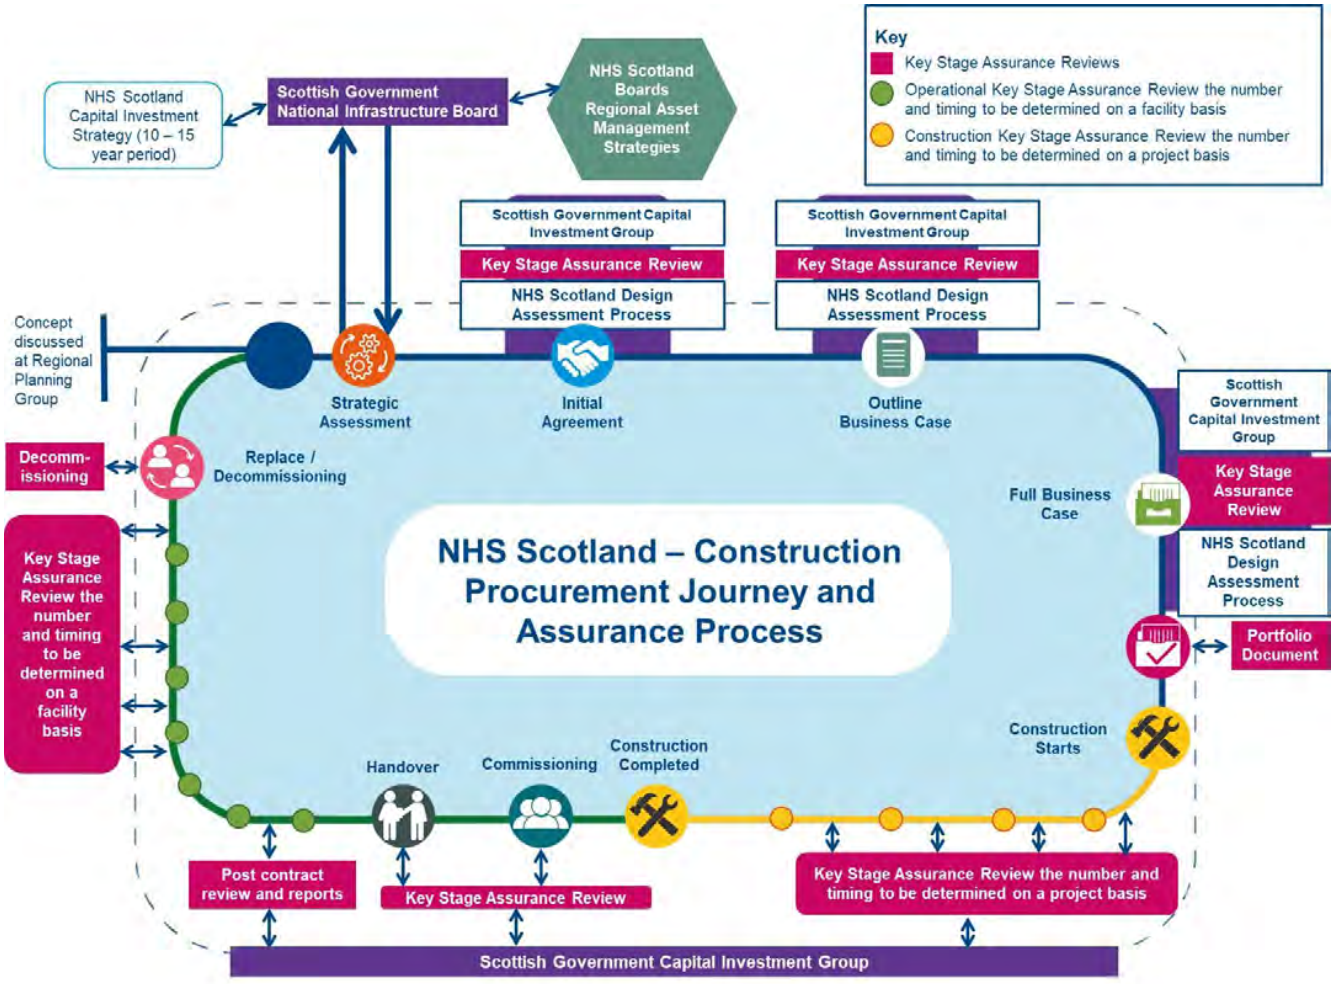
1. About this workbook

This workbook supports the Construction Key Stage Assurance Review (KSAR), delivered by the NHS Scotland Assure Assurance service.

Further information about the NHS Scotland Assure Assurance service and KSAR process is provided in section 2.

Figure 1. shows how the Construction stage in the procurement and construction journey commences following the Full Business Case. The timing and frequency of KSARs during this stage will vary dependent upon the facility. Specific workbooks have been developed for the other stages within this journey.

Figure 1: Construction Procurement Journey



KSARs are of a process ensuring facilities and the teams using them are able to deliver the standards required to provide the best and safest outcomes for patients, staff and visitors in the built environment.

KSARs deliver an independent peer review. NSS staff outside the project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility.

It is vital to receive feedback on the following elements of health facilities - Infection Prevention and Control (IPC), water, ventilation, electrical, plumbing, medical gases installations and fire. This ensures they are designed, installed and functioning from

initial commissioning of a new facility and throughout its lifetime. Health Boards are required to have appropriate governance in place at all stages of the construction procurement journey.

The KSAR workbook provides a transparent, structured framework for all clinical specialisms, facilities and operational management professionals to assess and manage a health care build or refurbishment. Allowing facilities to align with current standards as the assurance reviews are taking place, as well as aligning changes for patient cohort.

Using this workbook

The review investigates at various points during the Build / Construction Stage of the construction of the facility. The timing and number of Build / Construction Reviews will be determined during the design process and by agreement of the NHS Assessment Team and the Client Board.

The workbook is predominantly intended to be used by NHS Scotland Assure KSAR review teams, Health Boards are encouraged to use its content to support their own projects.

This workbook is predominantly intended to be used by NHS Scotland Assure KSAR review teams, Health Boards are encouraged to use its content to support their own projects. It provides guidance on the review structure and areas of investigation to be addressed by the review team and should be regarded as indicative and not prescriptive.

The review team will consider whether any emerging findings require additional topics to be addressed. If so, evidence relating to these areas, regarding the safety of the patients, staff and visitors should be provided.

2. Key Stage Assurance Review

Introduction to NHS Scotland Assure – Assurance Service

Good management effective control of projects is an essential element to the successful delivery and maintenance of healthcare facilities across NHS Scotland estates.

The initial delivery of the NHS Scotland Assure - Assurance Service will focus upon new builds and major refurbishments in the acute estate, submitted to the Scottish Government Capital Investment Group (CIG). In addition, a number of projects identified as being complex, primarily due to the needs of patients utilising the facilities, will be reviewed by this service. Whilst not an exhaustive list, these projects will cover oncology, maternity, theatre and critical care units, no matter of their financial value.

The NHS Scotland Assure - Assurance Service will deliver KSARs, designed to provide independent assurance to Scottish Government Health and Social Care Directorates (SGHSCD's).

It will assess if Health Boards Project Management teams (inclusive of clinicians, appointed construction consultants, and contractors) are briefed and following best practice procedures in the provision of facilities. We will review if projects are compliant in all aspects of safety, if specific engineering systems are designed, installed and commissioned, and for ongoing safety maintenance including IPC.

The KSAR process is applicable regardless of procurement route chosen

The KSAR Process

The KSAR process examines projects at key points in their lifecycle. It does not remove any legal or contractual obligations from the NHS Health Board, their designers or contractors. It provides assurance to progress successfully to the next review point and the process will be mandated for projects requiring CIG approval. KSARs focus on the assessment of the delivery approach, and will work with the Health Board's project team to ensure there is comprehensive understanding of the patient cohorts utilising the facility. KSARs also ensure relevant guidance is fully implemented and any technical derogations have been fully reasoned, transparently

discussed, the implications understood, recorded and signed off by the Health Board and their advisors.

With a focus on construction elements where previous reviews have demonstrated potential patient safety concerns, KSARs will concentrate on water; ventilation, electrical, plumbing, medical gases installations, fire, and associated IPC guidance. If further issues are raised with the review team, they will fully incorporate those issues into the reporting process.

Value of the KSAR Process

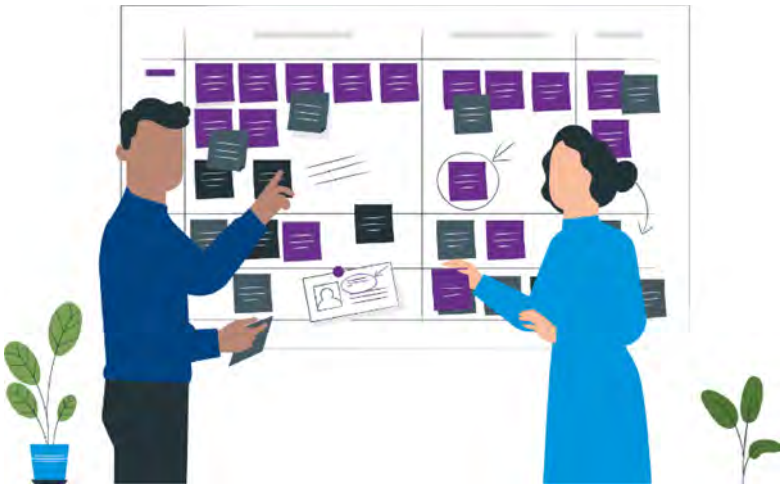
Key Stage Assurance Reviews (KSARs) deliver an independent peer review. NSS staff outside the Health Board's project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility. KSARs provide an external perspective and provide a challenge to the robustness of the Health Board's brief, plans and processes.

This includes work delivered by construction consultants, employed either directly or through construction contractors, and the work being delivered by the primary contractor, their sub-contractors and specialist suppliers.

The KSAR provides an independent report and action plan, which is shared with the Health Board to ensure:

- Appropriate skills and experience are deployed on the project by the Health Board, consultants, primary contractor and all sub-contractors.
- The clinicians and wider stakeholders covered by the project fully understand the project status, aims and the issues involved.
- Appropriate management structures put in place to ensure appropriate infection prevention and control measures are designed into the project to reduce the risk of transmission of infectious agent.
- There is assurance the project can progress to the next stage of development or implementation with particular emphasis on the safety of the patients, staff and visitors utilising the facility.
- Provision of advice and guidance to programme and project teams by fellow Practitioners.

The KSAR report and the Health Board's response and action plan is submitted to CIG along with a recommendation from the NHS Scotland Assure - Assurance Service regarding the projects' progression to the next stage of the construction procurement journey.



KSAR as part of the overall assurance framework

Each NHS Health Board will be fully responsible for the delivery of all projects, and its own internal process and resources for carrying out internal reviews and audits of its activities. The KSAR is seen as a complementary independent review, and not as a replacement for the responsibilities of the Health Board.

NHS Health Boards should have in place an effective framework to provide a suitable level of assurance for their programmes and projects. Health Boards are encouraged and expected to ensure adequate and timely coordination and sharing of information, including plans, between the various internal reviews and functions.

The KSAR process is not a substitute for a rigorous governance framework in the Board to manage key processes including business planning, investment appraisal, business case management, risk management and service and contract management.

The KSAR Process relationship with NHS Scotland Design Assessment Process (NDAP)

The Scottish Government's ambition for NHS Scotland's estate and the need for well-designed healthcare environments is articulated in the Policy on Design Quality for NHS Scotland. Good design in the built environment encompasses a wide range of inter-related factors such as, sustainability, engineering, architecture, fire safety, energy, environment, decontamination, space utilisation, landscaping, security, technology, lighting, access for visitors and mobility impaired persons.

The NDAP process is overseen by Health Facilities Scotland and Architecture and Design Scotland and holistically considers all of the above. It sets the principles for the resolution of potential conflicts of statutory or mandatory compliance to ensure the specific facility provides; the best balance of the technical requirements, meets clinical needs and fulfils the conceptual aims of the policy on Design Quality. The NDAP process begins at the initial agreement stage of a project and provides advice through to the Full Business Case. There is no change to either SCIM or NDAP processes.

The Scottish Government is progressing policy to improve the safety of the healthcare environment in relation to the built environment risk. The Assurance Service delivered through NHS Scotland Assure is a response to this policy and the KSARs are integral to the compliance work. The aspiration is not to duplicate any of the work included in the NDAP process, but to provide assurance regarding the critical components highlighted throughout this workbook.

Integral to the KSARs will be a review of the balance between sustainability issues and patient safety.

The NDAP, working with Health Boards, will set the principles of the design solution, whereas the KSAR will provide a detailed technical review of the specifics of the design solution. Where possible the two reviews will be aligned to avoid duplication of work. For example, in instances where the NDAP has reviewed detail at a technical level, this will be used by the KSAR team rather than being separately requested and reviewed.

Sustainability

The review will provide assurance that the proposals for the project provide an effective balance in terms of patient, staff and visitors safety, whilst meeting required sustainability outcomes and complying with the guidance standards.

Construction KSAR

KSAR reviews are designed to provide independent assessment to Scottish Government Health and Social Care Directorates (SGHSCD's) so that:

- The construction phase is fully defined, and effectively utilises national guidance and construction techniques required to deliver a building which comply with relevant national guidelines and meet the needs of patients who will be using the facility.
- The construction and commissioning teams are skilled in the necessary construction methods and understand the required outcomes.
- The facility complies with:
    - NHS Scotland current guidance; e.g. NHS Scotland policy letters
    - Scottish Health Planning Notes (SHPN)
    - Scottish Health Facilities Notes (SHFN)
    - Scottish Health Technical Memoranda (SHTM)
    - Scottish Fire Practice Notes (SFPN)
    - Health Building Notes (HBN)
    - Health Technical Memoranda (HTM)
    - Health Facilities Notes (HFN)
    - UK construction industry bodies best practice or design guidance publications e.g. HSE, CIBSE, BRE, IHEEM, IET, BRE, BSRIA, sustainability, dementia and equality.
    - Incident Reporting and Investigation Centre (IRIC) Alerts
    - Relevant British Standards
    - Fire Safety

Also, including but not limited to:

- Other Statutory requirements: Planning permission; Building Regulations compliance; Equality Act compliance; Health and Safety Executive (HSE) compliance; Construction (Design and Management) Regulations compliance. Fire Scotland Act
- Other mandatory NHS Scotland requirements – use of:
- Activity Data Base (ADB);
- Achieving Excellence Design Evaluation Tool;
- BREEAM Healthcare or equivalent (BRE environmental & sustainability tools);
- Scottish Government BIM Policy (SPPN 1/2017; implementation of building information modelling within construction projects: March 2017).
- The implementation of NHS Scotland Soft Landings (SL) guidance.
- Confirm that there are plans in place for risk management, issue management and that these plans are being shared with suppliers and delivery partners.

- Evaluation of actions taken to implement recommendations made in earlier assessment of deliverability.

- There are plans in place for the requirements of the NHS Scotland National Infection Prevention and Control Manual for Scotland to be incorporated into the development in a manner to allow the staff allocated to the role to deliver the services to the patients.
- There are plans in place for risk management, issue management and these plans are being shared with suppliers and delivery partners.
- Action taken to implement recommendations made in earlier assessment of deliverability.

At this stage in the facility lifecycle the review will be site based. The review teams will consist of experienced operational estates professionals and experienced Infection Prevention Control clinicians. This team will work with the Health Board's project team, inclusive of their clinicians and their appointed consultants and contractor. Each review will result in a report being prepared for the Programme Director at the Health Board and a copy of the report will be provided to the Scottish Government Capital Investment Group.

The appendix is provided indicates the typical question set for Construction the review Team use as the basis of evidence finding for the KSAR. The review team amend this as necessary depending on the project and areas of particular interest. The Health Board, their designers and contractors should be aware this is the information expected and the design should effectively be completed at Construction at the time of the KSAR to ensure the accuracy of the report.

3. Assessment of Delivery Approach

General approach to the Governance of Quality on the Project

No.	Areas to probe	Evidence expected
1.1	Has suitable plans and documentation been put in place for the project to manage and monitor Quality Management and Assurance?	• Project Quality Plan. • Inspection and Test Plans. • Inspection and Test Schedule / Register.
1.2	Has suitable arrangements been implemented on the project for document control processes for Quality Assurance and Management?	• Process for ensuring latest drawings approved and used. • Processes for ensuring latest specification and details approved and used. • Approach to management of non-conformances. • Approach to change management control. • Document management recording and structure.
1.3	How has the Health Board approached Quality Assurance on the project to ensure processes and procedures are being adhered?	• Evidence of regular Quality Assurance audits / reports undertaken on the project.
1.4	How does the Health Board assure itself that Testing and Commissioning of services and systems have / are being developed and put in place to meet the project needs?	• Evidence of Testing and Commissioning monitoring / witness of tests. • Evidence of Testing and Commissioning review of results. • Evidence of Testing and Commissioning acceptance of results. • Testing and Commissioning programme. • Plans have / are being developed for collating information and documents. • Have additional checks (external parties) been carried out to review the Contractors T&C's proposed plans.
1.5	How does the Health Board assure itself that the management of defects have / are being developed and put in	• Systems and process for recording and management defects. • Process for the rectification and close out of defects prior to handover. • Plans have / are being developed for collating information and documents.

No.	Areas to probe	Evidence expected
	place to meet the project needs?	
1.6	How does the Health Board assure itself that the management of the Handover process have / are being developed and put in place to meet the project needs?	• Soft Landings process. • Plans have / are being developed for collating as installed information and documents.
1.7	How does the Health Board assure itself that the works are following the procedures as laid out in HAISCRIBE?	• Evidence that the Contractor in charge of the works has read, understood and signed the HAISCRIBE. • Evidence that Infection Control have carried out interim site inspections at points where setting out of the rooms are underway to pick up implications of any Contractor's onsite adjustments. • For works inside of or adjacent to healthcare spaces which are in use, evidence that a task specific HAISCRIBE has been produced and that compliance is monitored by the Board.
1.8	How does the Health Board continue to assure itself that the clinical needs of the facility are clearly understood by each section of the client organisation?	• Updated description of each department of the facility review process evidenced. • All specifications are being related back to the Portfolio Document (PD). • An updated and live Derogation document.
1.9	Are the Principal Designers regularly carrying out site inspections and providing reports to the Board and Principal Contractor?	• Regular (fortnightly) reports being provided to the clients' project management team, certifying installation is being provided in accordance with the CD. • Regular comment on each of the installing contractors' quality safety plan and work delivered. • If the Principal Designer is not employed to carry out site inspections, evidence that the Board has alternative, adequate means of design / construction quality control in place.

No.	Areas to probe	Evidence expected
1.10	The Health Boards approach on the procurement journey with evidence of the plans on how the Board will provide assurance, particularly emphasis on the critical system identified earlier.	• Evidence on how this requirement is being managed and how it fits with the project governance arrangements • Plans to identify any gaps in the procurement approach that may require to be addressed. • Evidence on how Infection Prevention and Control are involved with the procurement approach to future plans for project. • Evidence that the Health Boards selected procurement route has gone through the Board's Governance channels.
1.11	Evaluation of the Health Boards commissioning plan.	• Evidence that the Health Board has recorded plans that are comprehensive and adequate to address the needs of the project and that they are fully resourced. • Evidence that the Board has had all pre-commissioning checks audited and approved by an independent organisation.
1.12	Evaluation of the Health Boards duty holder matrix.	• Evidence that the Health Board have a fully recorded matrix of the required roles and responsibilities and have a clear governance structure that is fully resourced together with plans in place for the implementation. • Evidence that Health Boards have appropriate number of competent, qualified staff to carry out specific duties throughout the life cycle of the project e.g., IPC, Engineers, Estates staff etc. The number of competent, qualified staff will depend on the type and size of the Build Project.

Water and Plumbing / Drainage Systems

No.	Areas to probe	Evidence expected
2.1	How does the Health Board assure itself that all plumbers are trained to understand the needs (including special requirements) for the installation of water and plumbing/drainage systems in the healthcare environment?	• Evidence of a vetted list of site plumbers which confirms qualifications and healthcare experience. • Evidence that the site induction with respect to working on water and plumbing/drainage services has been developed, implemented and agreed with the Board. • Where anyone does not have previous healthcare experience, evidence should be provided of the relevant onsite training which was provided to them before they commence work on site. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
2.2	How does the Health Board assure itself that the plumbing contracting company have the relevant experience to direct and manage their staff on the site for a healthcare environment?	• Evidence of similar, previous healthcare projects by the contractor. • Evidence of site management structure. • Evidence of HAI and SHPN 30 training.
2.3	How does the Health Board ensure that the water and plumbing / drainage systems are being installed to the correct standard and reflect the agreed design?	• Written and photographic, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms compliance of the works to date.
2.4	How does the Health Board ensure that precautions are taken throughout the works to avoid open pipe ends for a period beyond the time needed to make a joint on that pipe end?	• Photographic and written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).
2.5	How does the Health Board ensure that water services are installed in a fashion which will provide ease of access for future maintenance?	• Evidence that the contractor has presented their co-ordination drawings (BIM model) to the Board. • Evidence that the contractor has presented their co-ordination drawings (BIM model) to

No.	Areas to probe	Evidence expected
		the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Board's FM team. • Evidence that the plant access strategy is being adhered too.
2.6	How does the Health Board ensure that water and plumbing / drainage services are installed in a fashion which will retain space for minor additions and modifications to services in the future?	• Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Board. • Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Board's FM team, to highlight space for future flexibility. • Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant/tank rooms, IPS sections, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance?
2.7	How does the Health Board assure itself that all plumbers materials are stored on site in an environment which protects them from deterioration and from the entry of contaminants into the parts of the component which will be in contact with the water?	• Written, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms inspection of the site storage of materials. • Photographic evidence of the site storage of materials produced by a body which is independent of the contractor (on a monthly basis).
2.8	How does the Health Board assure itself that all pre-commissioning	• Evidence that adequate pre-commissioning check sheets (SHTM 04-01

No.	Areas to probe	Evidence expected
	inspections are completed and recorded before commissioning can commence?	Part A) have been completed and signed off. • Evidence that the Health Board has had all pre-commissioning checks audited and approved by an independent organisation.
2.9	How does the Health Board assure itself that all variations which may be required to water and plumbing and drainage systems after tender are investigated and agreed by all parties before they are instigated?	Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their water management group, clinical, Estates, infection control and FM teams.

Ventilation

No.	Areas to probe	Evidence expected
3.1	How does the Health Board assure itself that all duct and plant installers are trained to understand the needs (including special requirements) for the installation of ventilation systems in the healthcare environment?	• Evidence of a vetted list of duct and plant installers which confirms qualifications and healthcare experience. • Evidence that the site induction with respect to working on ducts and plant services has been developed, implemented and agreed with the Board. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
3.2	How does the Health Board assure itself that the ventilation contracting company and their plant installers have the relevant experience to direct and manage their staff on the site for a healthcare environment?	• Evidence of similar, previous healthcare projects by the contractor. • Evidence of site management structure.
3.3	How does the Health Board ensure that the ventilation systems are being installed to the correct standard and reflect the agreed design?	• Written, monthly evidence for the progress of work (including photographs) produced by a body which is independent of the contractor and which confirms compliance of the works to date.
3.4	How does the Health Board ensure that precautions are taken throughout the works to avoid open duct or plant ends for a period beyond the time needed to make a joint on that duct / plant end?	• Photographic and written evidence for the progress of work produced by a body which is independent of the Contractor (on a monthly basis).
3.5	How does the Health Board ensure that ventilation services are installed in a fashion which will provide ease of access for future maintenance?	• Evidence that the Contractor has presented their co-ordination drawings (BIM model) to the Board. • Evidence that the Contractor has presented their co-ordination drawings (BIM model) to the Design Consultant and that they have agreed them for construction. • Evidence that the Contractor has presented each of the main service runs plus plant rooms to the Board's FM team.

No.	Areas to probe	Evidence expected
		• Safe and adequate access has been provided.
3.6	How does the Health Board ensure that ventilation services are installed in a fashion which will retain space for minor additions and modifications to services in the future?	• Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Board. • Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Board's Estates team and / or, to highlight space for future flexibility. • Evidence that the ventilation solution has been agreed with clinical and IPC colleagues. • Evidence that the Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design. • Are plant rooms, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance?
3.7	How does the Health Board assure itself that all ventilation materials are stored on site in an environment which protects them from deterioration and from the entry of contaminants into the parts of the component which will be in contact with the air flow?	• Written and photographic, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms inspection of the site storage of materials. • Photographic evidence of the site storage of materials produced by a body which is independent of the contractor (on a monthly basis).
3.8	How does the Health Board assure itself that all pre-commissioning inspections are completed and	• Evidence that adequate pre-commissioning check sheets (CIBSE, BSRIA) have been completed and signed off.

No.	Areas to probe	Evidence expected
	recorded before commissioning can commence?	• Evidence that the Board has had all pre-commissioning checks audited and approved by an independent organisation.
3.9	How does the Health Board assure itself that all variations which may be required to ventilation systems after tender are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their clinical, Estates, infection control and FM teams.

Electrical

No.	Areas to probe	Evidence expected
4.1	How does the Health Board assure itself that all electricians are trained to understand the needs (including special requirements) for the installation of electrical systems in the healthcare environment?	• Evidence of a vetted list of site electricians which confirms qualifications and healthcare experience. • Evidence that the site induction with respect to working on electrical services has been developed, implemented and agreed with the Board. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
4.2	How does the Health Board assure itself that the electrical contracting company have the relevant experience to direct and manage their staff on the site for a healthcare environment?	• Evidence of similar, previous healthcare projects by the contractor. • Evidence of site management structure. • Electricians completed approved current BS 7671 training course. • Evidence that commissioning contractors have completed relevant test and commissioning courses. • Evidence of trained operatives (AP and CP) to SHTM 06-02.
4.3	How does the Health Board ensure that the electrical systems are being installed to the correct standard and reflect the agreed design?	• Written, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms compliance of the works to date. • Photographic and written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).
4.4	How does the Health Board ensure that electrical services are installed in a fashion which will provide ease of access for future maintenance?	• Evidence that the contractor has presented their co-ordination drawings (BIM model) to the Health Board. • Evidence that the contractor has presented their co-ordination drawings (BIM model) to the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Health Board's FM team.

No.	Areas to probe	Evidence expected
5.1	How does the Health Board assure itself that all medical gas installers are trained to understand the needs (including special requirements) for the installation of medical gas systems in the relevant healthcare environment?	• Evidence of a vetted list of site medical gas installers which confirms qualifications and healthcare experience. • Evidence that the site induction with respect to working on medical gas services has been developed, implemented and agreed with the Board. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
5.2	How does the Health Board assure itself that the medical gas contracting company have the relevant experience to direct and manage their staff on the site for the relevant healthcare environment?	• Evidence of similar, previous healthcare projects by the contractor. • Evidence of site management structure. • AP and CP training to SHTM 02-01 for operatives.
5.3	How does the Health Board ensure that the medical gas systems are being installed to the correct standard and reflect the agreed design?	• Written and photographic, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms compliance of the works to date.
5.4	How does the Health Board ensure that precautions are taken throughout the works to avoid open pipe ends for a period beyond the time needed to make a joint on that pipe end?	• Photographic and written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).
5.5	How does the Health Board ensure that medical gas services are installed in a fashion which will provide ease of access for future maintenance?	• Evidence that the contractor has presented their co-ordination drawings (BIM model) to the Board. • Evidence that the contractor has presented their co-ordination drawings (BIM model) to the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Health Board's FM team.

No.	Areas to probe	Evidence expected
5.6	How does the Health Board ensure that medical gas services are installed in a fashion which will retain space for minor additions and modifications to services in the future?	• Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Health Board. • Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations. • Evidence that the contractor has presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the design consultant and that they have agreed them for construction. • Evidence that the contractor has presented each of the main service runs plus plant rooms to the Health Board's FM team, to highlight space for future flexibility.
5.7	How does the Health Board assure itself that all medical gas materials are stored on site in an environment which protects them from deterioration and from the entry of contaminants into the parts of the component which will be in contact with the gas?	• Written, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms inspection of the site storage of materials. • Photographic evidence of the site storage of materials produced by a body which is independent of the contractor (on a monthly basis).
5.8	How does the Health Board assure itself that all pre-commissioning inspections are completed and recorded before commissioning can commence?	• Evidence that adequate pre-commissioning check sheets (e.g. SHTM 02-01 Part A) have been completed and signed off. • Evidence that the Health Board has had all pre-commissioning checks audited and approved by an independent organisation.
5.9	How does the Health Board assure itself that all variations which may be required to medical gas systems after tender are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their medical gas management group, clinical, Estates, infection control and FM teams.

No.	Areas to probe	Evidence expected
6.1	How does the Health Board assure itself that all fire stopping specialists are trained to understand the needs (including special requirements) for the installation of fire stopping systems in the healthcare environment?	• Evidence of a vetted list of site fire stopping specialists which confirms qualifications and healthcare experience. • Evidence that the site induction with respect to working on fire stopping services has been developed, implemented and agreed with Board. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
6.2	How does the Health Board assure itself that the fire stopping contracting company have the relevant experience to direct and manage their staff on the site for a healthcare environment?	• Evidence of similar, previous healthcare projects by the contractor. • Evidence of site management structure.
6.3	How does the Health Board ensure that the fire stopping systems are being installed to the correct standard and reflect the agreed design?	• Written, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms compliance of the works to date.
6.4	How does the Health Board ensure that precautions are taken throughout the works to avoid openings in fire barriers to occupied spaces during the works?	• Written and photographic evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).
6.5	How does the Health Board ensure that fire stopping systems are installed on ventilation, electrical, plumbing and drainage services where they penetrate fire barriers?	• Photographic and written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).
6.6	How does the Health Board ensure that fire stopping is installed in electrical containment (trunking / tray systems) systems where they penetrate fire barriers?	• Photographic and written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis).

No.	Areas to probe	Evidence expected
6.7	How does the Health Board assure itself that all fire stopping materials are stored on site in an environment which protects them from deterioration?	• Written, monthly evidence for the progress of work produced by a body which is independent of the contractor and which confirms inspection of the site storage of materials. • Photographic evidence of the site storage of materials produced by a body which is independent of the contractor (on a monthly basis).
6.8	How does the Health Board assure itself that all fire detection and alarm systems are installed in the correct locations and are easily maintained?	• Written evidence for the progress of work produced by a body which is independent of the contractor (on a monthly basis). • Demonstration by the contractor that any detectors which are above 3m from floor level or in ceiling voids, to the Board's FM team, have suitable access for maintenance.
6.9	How does the Health Board assure itself that all variations which may be required to fire stopping systems after tender are investigated and agreed by all parties before they are instigated?	• Evidence that the each variation has been referred to the Health Board and agreed with their clinical, engineering, infection control and FM teams.
6.10	How does the Health Board assure itself that all fire dampers and fire/smoke dampers can be accessed for inspection, resetting and maintenance?	• Evidence that the contractor has presented their co-ordination drawings (BIM model) to the Health Board. • Evidence that the contractor has presented their co-ordination drawings (BIM model) to the design consultant and that they have • agreed them for construction. • Evidence that the contractor has presented each of the fire dampers and smoke / fire dampers to the Health Board's FM team.
6.11	How does the Health Board assure itself that any fire rated ductwork is correctly installed?	• Evidence that the system is certificated and that the installation follows the installation details which were used for the certification. • Written confirmation from the design consultant.

No.	Areas to probe	Evidence expected
6.12	How does the Health Board assure itself that any smoke control and / or clearance systems are fit for purpose?	• Evidence that the smoke system has been designed by an accredited Fire Engineer. • Evidence that Building Control have accepted the solution. • Confirmation from the Building Services Design Consultant that the operating sequence for the smoke system has been agreed and integrated into the control of other building systems.
6.13	How does the Health Board assure itself that all pre-commissioning inspections are completed and recorded before commissioning can commence?	• Evidence that the Health Board has had all pre-commissioning checks audited and approved by an independent organisation.

No.	Areas to probe	Evidence expected
7.1	How does the Health Board demonstrate that there is an effective infection prevention and control management structure in place? How does the Health Board demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation and that there is an effective IPC structure in place?	**The Health Board provides evidence that there is an IPC Management Structure with the necessary expertise and leadership skills to support the organisation:** • The Health Board provides evidence that there is an IPC Management Team with the necessary expertise and leadership skills to support the project. The board are compliant with content of HDL (2008) role of the ICM / CNO 22.12.16. • Executive board reports or minutes. Risk registers or equivalent, Minutes from operational and governance groups, (and action points). • Structure of infection prevention and control team (IPCT) and qualifications held, previous experience supporting new build projects. • Evidence IPC and clinical teams have been involved with any derogation through the build process and are satisfied this will not impact on patient safety, evidence could be through meeting minutes, risk assessments, risk registers relating to IPC with evidence of escalation through the agreed NHS board governance process. • Evidence the Executive Board Member assigned to lead on IPCT has been kept informed of IPC risks identified and associated with the project this can be demonstrated by the board. • Evidence IPCT advice has been followed, such as IPCT walk round audits during the construction process. • Evidence that fixtures fitting and equipment have not been incorporated into the project that would represent an identified IPC risk. • Evidence that all contractors and sub-contractor competency checks have been completed and signed off.
7.2	How does the Health Board demonstrate implementation of evidence based infection prevention and control	**The Health Board provides evidence:** • The board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this

No.	Areas to probe	Evidence expected
	measures during the construction process?	and it is being referred to during the construction process. • IPC risks (actual or perceived) risks identified during the work programme or through the KSAR evidence review are provided. • Evidence of walk rounds during the construction process and these are being fed back to clinical staff and the executive team to provide assurance that the requirements of the CD are being adhered with.
7.3	How does the Health Board assure itself that the contractors have a proper understanding of the infection prevention and control procedures required by the CD and that the contractors work is being rigorously managed in this respect?	**The Health Board evidences that:** • All relevant staff within the contractors' organisation are provided with clear guidance on roles and responsibilities in relation to infection prevention and control. • The contractors' organisation provides an education programme that meets the need of staff which includes mandatory induction, training and updates on HAI guidance, policies and procedures.
7.4	How does the Health Board assure itself that equipment meets the required IPC standards?	• The IPC Team are involved and IPC advice followed in all procurement decisions for new equipment prior to purchase. IPCT are satisfied that all equipment purchased can be decontaminated safely in line with National Guidance and manufacturer's instructions.

Contents

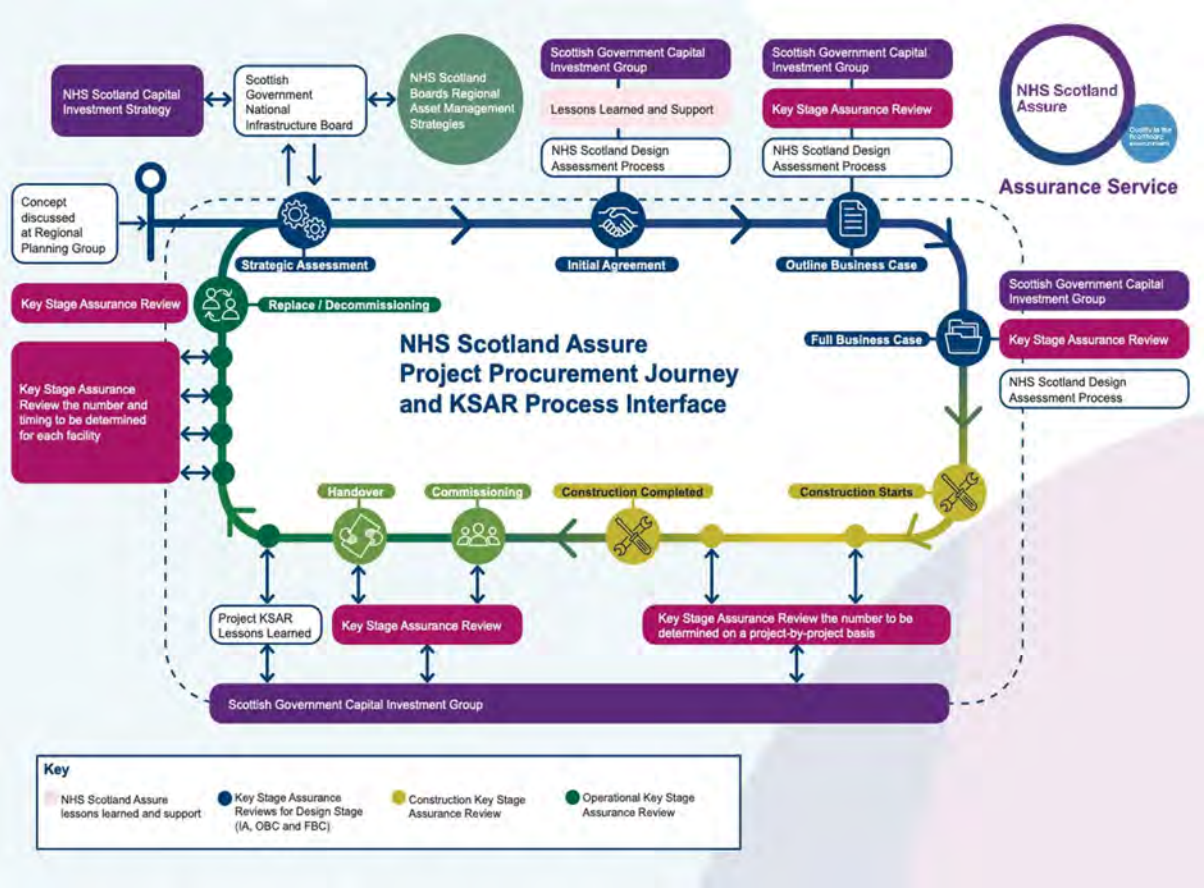
1. About this workbook

This workbook supports the Handover Key Stage Assurance Review (KSAR), delivered by the NHS Scotland Assure Assurance service.

Further information about the NHS Scotland Assure Assurance service and KSAR process is provided in Section 2.

Figure 1. shows how the Handover stage in the procurement and construction journey. The timing and frequency of KSARs during this stage will vary dependent upon the facility. Specific workbooks have been developed for the other stages within this journey.

Figure 1: Construction Procurement Journey



The KSAR process and workbooks provide a transparent, structured framework for all clinical specialisms, facilities and operational management professionals to assess and manage a healthcare build or refurbishment. In turn this assists health boards to provide the best and safest outcomes for patients, staff and visitors in the built environment.

KSARs deliver an independent peer review. NHS Scotland Assure staff, outside the project, use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility. KSARs also focus on how projects are able to demonstrate compliance with relevant guidance and standards.

It is vital to receive feedback on the following elements of health facilities - Infection Prevention and Control (IPC), water, ventilation, electrical, plumbing, medical gas installations and fire. This ensures they are designed, installed and functioning from the initial commissioning of a new facility and throughout its lifetime. Health boards are required to have appropriate governance in place at all stages of the construction procurement journey.

Using this workbook

The review at Handover stage investigates the approach taken by the health board and other stakeholders during this critical stage of the project to ensure that there continues to be an appropriate level of knowledge and awareness of the importance of the Handover stage on patient, staff and visitor safety.

The purpose of the KSAR at Handover stage is to confirm there is a continued good and comprehensive understanding of the category of patient who will use the proposed facility, and that the project team consider how appropriate quality and safety standards will influence the handover of the various systems. It looks to provide assurance that the project can proceed to the Operational phase.

Additionally, the KSAR at Handover will carry out an appropriate level of checking of the handover documentation. This level of checking will be set by the review team following their initial discussions on site.

The KSAR workbook is a tool for both NHS Scotland Assure to undertake project reviews and for health boards to support the development of their own projects. It provides guidance on the review structure and areas of investigation to be addressed by the review team and should be regarded as indicative and not prescriptive. The review team will consider whether any emerging findings require additional topics to be addressed. If so, evidence relating to these areas, regarding the safety of the patients, staff and visitors, should be provided.

2. Key Stage Assurance Review

Introduction to NHS Scotland Assure – Assurance Service

Good management and effective control of projects are essential elements to the successful delivery and maintenance of healthcare facilities across NHS Scotland estates.

The NHS Scotland Assure Assurance Service will deliver KSARs, designed to provide independent assurance to Scottish Government Health and Social Care Directorates (SGHSCDs).

It will assess if health board's project management teams (inclusive of clinicians, appointed construction consultants, and contractors) are briefed and following best practice procedures in the provision of facilities. We will review if projects are compliant in all aspects of safety, if specific engineering systems are designed, installed and commissioned, and for ongoing safe maintenance including IPC consideration.

The KSAR process is applicable regardless of procurement route chosen.

The KSAR Process

The KSAR process examines projects at key points in their lifecycle. It does not remove any legal or contractual obligations from the NHS health board, their designers or contractors. It provides assurance to progress successfully to the next review point. KSARs focus on the assessment of the delivery approach and the review team will work with the health board's project team to ensure there is comprehensive understanding of the patient cohorts utilising the facility. KSARs also ensure relevant guidance is fully implemented and any technical derogations have been fully reasoned, transparently discussed, the implications understood, recorded and signed-off by the health board and their advisors.

KSARs will concentrate on project governance related to the core review topics of water, ventilation, electrical, plumbing, medical gases installations, fire, and associated IPC guidance. If further issues are raised with the review team, they will fully incorporate those issues into the reporting process.

Value of the KSAR Process

Key Stage Assurance Reviews (KSARs) deliver an independent peer review. NSS staff outside the health board's project use their experience and expertise to examine the progress and likelihood of successful delivery, with a particular emphasis on the safety of the patients, staff and visitors using the facility. KSARs provide an external perspective and provide a challenge to the robustness of the health board's brief, plans and processes.

This includes work delivered by construction consultants, employed either directly or through construction contractors, and the work being delivered by the primary contractor, their sub-contractors and specialist suppliers.

The KSAR provides an independent report and recommended action plan, which is shared with the health board to ensure:

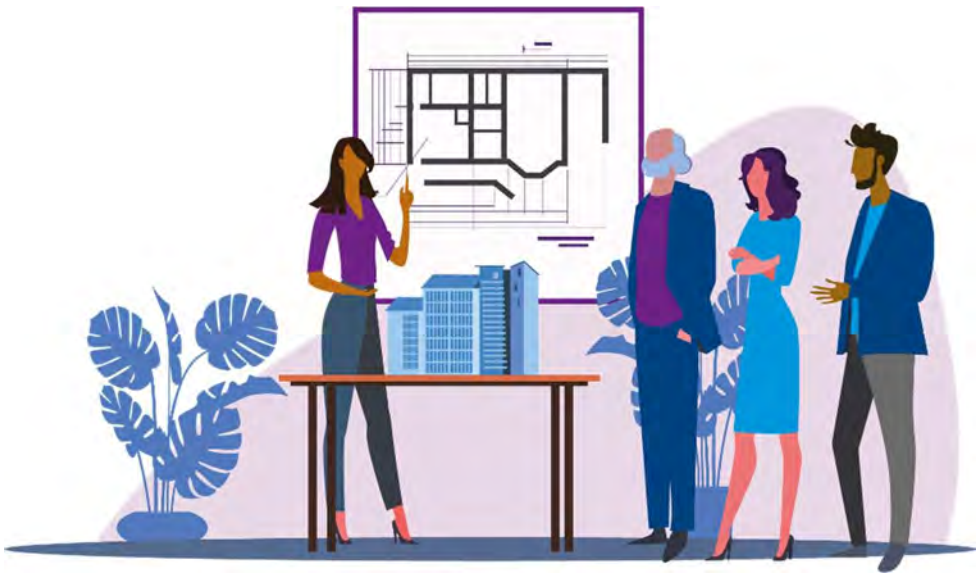
- Appropriate skills and experience are deployed on the project by the health board, consultants, primary contractor and all sub-contractors.
- The clinicians and wider stakeholders covered by the project fully understand the project status, aims and the issues involved.
- Appropriate management structures, put in place to ensure appropriate infection prevention and control measures, are designed into the project to reduce the risk of transmission of infectious agents.
- There is assurance the project can progress to the next stage of development or implementation, with particular emphasis on the safety of the patients, staff and visitors utilising the facility.
- Provision of advice and guidance to programme and project teams by fellow practitioners.

KSAR as part of the overall assurance framework

Each NHS health board will be fully responsible for the delivery of all projects, and its own internal process and resources for carrying out internal reviews and audits of its activities. The KSAR is seen as a complementary independent review, and not as a replacement for the responsibilities of the health board.

NHS health boards should have in place an effective framework to provide a suitable level of assurance for their programmes and projects. Health boards are encouraged and expected to ensure adequate and timely coordination and sharing of information, including plans, between the various internal reviews and functions.

The KSAR process is not a substitute for a rigorous governance framework being put place by the health board to manage key processes including business planning, investment appraisal, business case management, risk management and service and contract management.



The KSAR Process relationship with NHS Scotland Design Assessment Process (NDAP)

The Scottish Government's ambition for NHS Scotland's estate and the need for well-designed healthcare environments is articulated in the Policy on Design Quality for NHS Scotland. Good design in the built environment encompasses a wide range of inter-related factors such as:

- access for visitors and mobility impaired persons
- architecture
- decontamination
- energy
- engineering
- environment
- fire safety
- landscaping
- lighting
- security
- space utilisation
- sustainability
- technology.

The mandated NHS Scotland Design Assessment Process (NDAP) process is undertaken by NHS Scotland Assure, Architecture and Design Scotland, and considers all of the above. It sets the principles for the resolution of potential conflicts of statutory or mandatory compliance to ensure the specific facility provides; the best balance of the technical requirements, meets clinical needs and fulfils the conceptual aims of the policy on Design Quality. The NDAP process begins at the Initial Agreement stage of a project and provides advice through to the Full Business Case (FBC). There is no change to either Scottish Capital Investment Manual (SCIM) or NDAP processes.

The Scottish Government is progressing policy to improve the safety of the healthcare environment in relation to the built environment risk. The Assurance Service delivered through NHS Scotland Assure is a response to this policy and the KSARs are integral to the compliance work. The aspiration is not to duplicate any of the work included in the NDAP process but to provide assurance regarding the critical components highlighted throughout this workbook.

Integral to the KSARs will be a review of the balance between sustainability issues and patient safety.

Where possible the two reviews will be aligned to avoid duplication of work. For example, in instances where the NDAP has reviewed detail at a technical level, this will be used by the KSAR team rather than being separately requested and reviewed.

Sustainability

The review will provide assurance that the proposals for the project provide an effective balance in terms of patient, staff and visitors safety, whilst meeting required sustainability outcomes and complying with the guidance standards.

Handover KSAR

The Handover KSAR will be an independent “peer review” in which NHS Scotland Assure (NHS SA) subject matter experts, independent of the project, use their experience and expertise to review and assess the proposed pre-Handover and Handover stage documentation. It is anticipated that the implementation of the Handover KSAR will differ from other reviews, as it will predominately take the form of a site-based audit of the processes and documentation associated with the Handover phase.

Any areas of concern found during this KSAR will be immediately raised with the NHS health board.

The Handover KSAR will consider (particularly with respect to IPC measures):

- Water systems.
- Ventilation systems.
- Plumbing and drainage.
- Fire safety.
- Electrical systems.
- Medical gases.
- Any other building or engineering component critical to the safety and welfare of a particular patient cohort (defined by the review team).
- The requirements of Infection Prevention & Control Guidance have been incorporated and implemented, including the NHS Scotland National Infection Prevention and Control Manual, to allow staff to deliver the health services in a safe and comprehensive manner.

At all stages of the Handover phase, knowledge of compliance in design and implementation will need to encompass (but is not limited to) the following:

- NHS Scotland policy letters (DLs, CELs, CMOs).
- Scottish Health Planning Notes (SHPN).
- Scottish Health Facilities Notes (SHFN).
- Scottish Health Technical Memoranda (SHTM).
- Scottish Fire Practice Notes (SFPN).
- Health Building Notes (HBN).
- Health Technical Memoranda (HTM).
- Health Facilities Notes (HFN).
- Incident Reporting and Investigation Centre (IRIC) Alerts.
- Relevant British Standards.
- UK construction industry bodies best practice or design guidance publications e.g., HSE, CIBSE, BRE, IHEEM, IET, BRE, BSRIA, sustainability, dementia and equality.
- Incident Reporting and Investigation Centre (IRIC) Alerts.
- The implementation of NHS Scotland Soft Landings (SL) guidance.
- Confirm that there are plans in place for risk management, issue management and that these plans are being shared with suppliers and delivery partners.
- Evaluation of actions taken to implement recommendations made in earlier assessment of deliverability.
- Confirm there are plans in place to ensure the requirements of IPC Guidance, including the NHS Scotland National Infection Prevention and Control Manual for Scotland, are being incorporated into the development in a manner which will allow the staff allocated to the role to deliver the services to the patients.
- Other statutory requirements: Planning permission; Building Regulations compliance; Equality Act compliance; Health and Safety Executive (HSE) compliance; Construction (Design and Management) Regulations compliance. Fire Scotland Act.
- Other mandatory NHS Scotland use of:
  - Activity Data Base (ADB).
  - Achieving Excellence Design Evaluation Tool.
  - Sustainable Design and Construction (SDaC).
  - Scottish Government BIM Policy (SPPN 1/2017; implementation of building information modelling within construction projects: March 2017).

Additionally, the Handover KSAR will carry out an appropriate level of checking of the commissioning results, as-installed drawings, health and safety documents, manufacturers' literature and solutions adopted.

This level of checking will be set by the review team following their initial discussions on site. One impact of this work may be that the review will take longer than the initial programme, dependant on the conclusions / findings from this assessment of the design.

The review teams consist of experienced professionals and Infection Control clinicians. The team will work with the health board's project team, inclusive of their clinicians and their appointed facility management consultants and contractor. Each review will result in a report being prepared for the Programme Director at the Board and a copy of the report will also be provided to Scottish Government Capital Investment Group.

Section 3 below provides the typical question sets for each discipline that the review team will use as the basis for the Handover KSAR review process. The team will amend this as necessary depending on the project and areas of particular interest. The health board, their designers and contractors should be aware that this is the information which will be expected, and the project should effectively be completed and ready for acceptance at the time of the KSAR to ensure the accuracy of the report.

3. Assessment of Delivery Approach

It is anticipated that Project Handover may be phased as determined by the scale and complexity of the building and systems.

The review should focus on Governance, management, planning, resources, risk assessments, method statements, validation and health board acceptance of Commissioning results. Those responsible for Project Handover should have the appropriate level of competency to undertake the receipt of the systems which they are responsible for. The Handover process should be carried out in accordance with the Board Contract Requirements (BCR).

A suite of documents should be specified for handover to include health and safety files and operations and maintenance manuals. Further, project handover plan checklist should be completed by all relevant parties confirming system completion, system acceptance, training, certification and as installed document handover.

Project Governance and General Arrangements

No.	Areas to probe	Evidence expected
1.1	How does the health board assure itself that actions from the previous Key Stage Assurance Review have been appropriately closed out?	• Evidence of a completed action plan, with reference to evidence, to demonstrate appropriate close out of actions.
1.2	How does the health board ensure that all Commissioning activities have been completed successfully, appropriately validated (including witnessing) and documented, prior to handover?	• Evidence that commissioning / validation processes are complete, and that the Contractor has issued a verification letter to confirm that the systems have been installed and commissioned in line with specification and guidance. • Evidence of commissioning and witnessing activities, including any independent 3rd party validation. • Completed commissioning and validation records for all mechanical, electrical and public health (MEP) systems. • Completed commissioning and validation records for all fire safety systems. • Completed commissioning and validation records for all MEP plant, including plant associated with incoming utilities.

No.	Areas to probe	Evidence expected
1.3	How does the health board ensure that all relevant information from the Commissioning and Handover phases has been collated, appropriately documented and reviewed prior to Handover?	• Evidence of the completed, final Commissioning records which demonstrate design conditions and actual commissioned conditions. • Evidence of completed O&M information in line with the requirements of guidance, the BCRs and BSRIA BG 79. • Evidence of record drawings. • Evidence of the completed Health and Safety file. • Evidence of digital information exchange in line with Employers Information Requirements (EIRs). (Graphical and non-graphical data, e.g. Federated BIM model, COBie data, asset lists etc.). • Evidence of an updated access and maintenance strategy. • Evidence that any derogations from standards have been agreed by the health board and signed-off prior to Handover. • Evidence of processes in place to allow stakeholders to review and comment on Handover documentation prior to Handover. • Completed handover checklists. • Evidence that testing commissioning and validation processes are complete, and documentation has been received and reviewed by key stakeholders from the health board (e.g. WSG/VSG/ESG, AEs, IPC etc.) in line with their governance processes.
1.4	How does the health board ensure that the works have been completed to the required safety and quality standards?	• Evidence of a quality monitoring role having been undertaken with associated supporting documentation e.g. actioned observation trackers. • Evidence there is a process in place to track the close out of any observations / defects prior to handover, including review by key health board stakeholders. • Evidence of contractor/designer approvals of completed works.

No.	Areas to probe	Evidence expected
1.5	How does the health board assure itself that key stakeholders have been involved in the handover process?	• Evidence of a roles and responsibilities document for all individuals involved in the handover process. • Evidence of how the health board assures themselves that relevant stakeholders (e.g., IPC / AE / AP) are available for handover activities as required. • Evidence that maintenance procedures and operational processes have been completed with clinical and IPC stakeholders (to consider access requirements etc).
1.6	How does the health board ensure that there is sufficient resource allocated to manage the accommodation post-handover?	• Evidence that health boards (and/or their appointed FM provider) have appropriate number of competent, qualified staff appointed to carry out specific duties during operation e.g., IPC, Estates staff, APs, CPs etc. • Evidence that the health board (and/or their appointed FM provider) has a fully recorded duty holder matrix, stating the required roles and responsibilities. • Evidence there is a Handover plan in place for staff assuming responsibility for ongoing maintenance and operation of the systems.
1.7	How does the health board ensure that adequate site familiarisation training has been provided?	• Evidence of processes in place to deliver relevant site training / familiarisation sessions to key stakeholders (including end users, IPC, Estates, Hard FM / Soft FM). • Evidence of site visits and walk-rounds by end users.
1.8	How does the health board ensure that adequate technical training has been provided?	• Evidence of demonstrations/ training of system operation for those who will operate and maintain the installed systems, including routine planned preventive maintenance activities. • Evidence that dedicated training has been provided to clinical staff on the operation of technical systems (for example theatre control panels, magnehelic gauges, staff call systems, etc). • Evidence of attendance at training sessions / demonstrations. • Evidence of any training resources / materials provided. • Evidence that all required tools, spares and consumables have been received, along with an inventory. • Evidence of maintenance processes in place.

No.	Areas to probe	Evidence expected
1.9	How does the health board ensure that knowledge of the project is transferred to operational teams? How does the health board ensure that Soft Landings processes are being implemented?	• Evidence of a detailed Handover programme encompassing all Handover activities, as agreed with the health board. • Evidence of PPM activities undertaken in the period between commissioning and handover. • Evidence of Soft Landings review meetings. • Evidence of user guides provided for systems. • Evidence of an aftercare team in place, with delivery plan for in-use support and monitoring. • Evidence of Post Occupancy Evaluation plan. • Evidence of a process for fine tuning, measuring performance and capturing lessons learned from the building operation following Handover.
1.10	How does the health board ensure that there is a process in place for managing Statutory Compliance (including use of the NHS Scotland SCART system)	• Evidence of SCART question review. • Evidence of personnel allocated to compliance. • Evidence of policies and procedures in place for managing and operating engineering systems. • Evidence of process for storing and managing documentation and statutory maintenance records associated with the project.

IPC Built Environment

No.	Areas to probe	Evidence expected
2.1	How does the health board assure itself that IPC specialists have been fully involved in the handover process?	• Evidence of Executive Board reports. • Evidence of Board Minutes. • Evidence of Minutes and actions from Governance and Operational Groups relevant to the project, including IPCC. • Evidence of completed Stage 4 HAI-SCRIBE.
2.2	How does the health board assure itself that those IPC specialists involved in the Handover process are appropriately qualified and experienced?	• Evidence of the structure of IPCT with details of qualifications held and previous experience in commissioning new builds, refurbishments, or special projects. • Evidence that this has been reviewed and recorded by the health board.
2.3	How has the health board ensured that the IPC specialists engaged in the handover process have access to all relevant Commissioning completion documentation for all water, ventilation, and decontamination equipment?	• Evidence that the respective technical commissioning experts have liaised with IPC on final commissioning results, including consideration of any residual IPC risks. Evidence of minutes and actions from governance and operational groups relevant to the project, including IPCC and Water / Ventilation Safety Groups.
2.4	How has the health board assured itself that staff in the facility will be able to comply with the requirements of IPC guidance including the National Infection Prevention and Control Manual?	• Evidence of HAI-SCRIBE documentation. • Evidence of minutes and actions from governance and operational groups relevant to the project, including IPCC. • Evidence of a process in place for access to NIPCM across the facility/organisation.
2.5	How has the health board assured itself that proposed cleaning schedules will meet the requirements of the National Cleaning Specification?	• Evidence that proposed cleaning schedules have been matched against the National Cleaning Specification. • Details of facilities, clinical and IPC teams' involvement in drawing up proposed cleaning schedules.

Fire

No.	Areas to probe	Evidence expected
3.1	Have there been any changes to the fire strategy since the previous Key Stage Assurance Review?	• Evidence of written confirmation of any changes that have been made to the fire strategy.
3.2	Has a Fire Risk Assessment been carried out in accordance with SHTM 86?	• Evidence of Fire Risk Assessment Documentation.
3.3	Have the findings of the Fire Risk Assessment generated a significant findings report?	• Evidence of significant findings Action Plan. • Evidence of the timeline for completion of actions has been documented.
3.4	Are appropriate members of the management team including the Nominated Officer (fire) aware of their responsibility for fire safety management procedures?	• Written documentation and verbal verification from responsible persons. • Evidence of the Board Fire Safety Policy. • Evidence of the Board fire safety procedures.
3.5	Has an Emergency Fire Action Plan (EFAP) been produced in accordance with SHTM 83?	• Evidence of the Emergency Fire Action Plan (EFAP) documentation. • Evidence that this is available to staff. • Details of Emergency response team and their expected actions in response to fire.
3.6	Is there a fire safety induction-training programme in place in line with SHTM 83 Part 2: Fire Safety Training?	• Evidence of the training syllabus. • Evidence of all training programmes and materials. • Evidence of training records.
3.7	Are commissioning documents such as completed for all passive and active fire safety measures?	• Evidence of documentation such as OEM manuals, testing/inspection reports, as-installed information and certificates for all passive and active fire safety measures? • Evidence that the documents are available to relevant staff.
3.8	Has a Fire Safety Manual been produced?	• Evidence of Fire Safety Manual documentation. • Evidence that the document is available to relevant staff.

Scottish Health Technical Memorandum 2025

(Part 1 of 4)

Overview and management responsibilities

Ventilation in healthcare premises

The production of this document was jointly funded by the Scottish Executive Health Department and the NHSScotland Property and Environment Forum.

NHSScotland, P&EFEx, June 2001

Contents

1. Introduction

General

1.1 Ventilation is used extensively in healthcare premises for primary patient treatment eg. in operating departments, intensive treatment units and isolation suites. It is also installed to ensure compliance with quality assurance of manufactured items in pharmacy and sterile supply departments and to protect staff from harmful organisms and toxic substances for example in laboratories.

1.2 This edition of Scottish Health Technical Memorandum 2025; *Ventilation in healthcare premises* is published in four separate parts. It is equally applicable to both new and existing sites. It gives comprehensive advice and guidance to healthcare management, design engineers, estates' managers and operations' managers on the legal requirements, design implications, maintenance and operation of specialist ventilation in all types of healthcare premises.

1.3 Current statutory legislation requires both "management" and "staff" to be aware of their collective responsibility.

1.4 "Ventilation" is provided in healthcare premises for the comfort of the occupants of buildings. More specialised ventilation will also provide comfort but its prime function will be to closely control the environment and air movement in the space that it serves in order to contain, control and reduce hazards to patients and staff from airborne contaminants, dust and harmful micro-organisms.

1.5 Ventilation systems, in themselves, present little danger to patients or staff; however, they do possess the ability to transmit hazards arising from other sources to large numbers of people. The danger may not become apparent until many patients and staff have been affected.

1.6 The sophistication of ventilation systems in healthcare premises is increasing. Patients and staff have a right to expect that the systems will be designed, installed, operated and maintained to standards that will enable them to fulfil their desired functions reliably and safely.

2. Management responsibilities

Statutory requirements

2.1 The Health and Safety at Work etc Act 1974 (HSW Act 1974) is the core legislation that applies to ventilation installations. As these installations are intended to prevent contamination, closely control the environment, dilute contaminants or contain hazards, their very presence indicates that risks to health have been identified.

2.2 The Control of Substances Hazardous to Health (COSHH) Regulations 1999 regulations place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialist ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and safety cabinets.

2.3 The existing requirements to provide ventilation, implicit under HSW Act 1974 and COSHH, have been made explicit by the Management of Health and Safety at Work Regulations 1999, the Workplace (Health, Safety and Welfare) Regulations 1992 and the Provision and Use of Work Equipment Regulations 1998, all issued as a result of European Directives.

2.4 Where specialist ventilation plant is provided as part of the protection measures there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of the COSHH regulations requires that the plant be inspected and tested at least every 14 months by an independent organisation and that management maintains comprehensive records of its performance, repair and maintenance.

2.5 Certain substances have Occupational Exposure Limits (OEL) set out in Guidance Note EH 40 published annually by the Health and Safety Executive. If special ventilation systems are provided to meet these standards they will also be subject to the COSHH regulations as above.

2.6 All ventilation systems should conform to the principles set out in the *Approved Code of Practice on the Prevention and Control of Legionellosis* published by the Health and Safety Commission and Scottish Health Technical Memorandum SHTM 2040;*The control of legionellae in healthcare premises – a code of practice*.

2.7 Special ventilation plants installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified organisms, may be subject to particular legislation with regard to their operation in addition to that mentioned above. Further information is given by the Health and Safety Commission Health Services Advisory Committee in:

a. safe working and prevention of infection in clinical laboratories;

b. safe working and prevention of infection in clinical laboratories: model rules for staff and visitors;

c. safe working and prevention of infection in clinical laboratories in the mortuary and post-mortem room.

2.8 Plants installed in units manufacturing medicinal products to the standards set out in the current European Guide to Good Manufacturing Practice may also be subject to particular legislation with regard to their operation in addition to that mentioned above.

2.9 Records and log books should be kept of the commissioning information, operational management, monitoring and maintenance of the equipment. The Health and Safety Executive, Medicines Inspectorate and other interested bodies have a statutory right to inspect them at any time. All records should be kept for at least five years.

2.10 The fire regulations require that if ventilation ductwork penetrates the fabric of a building it should be designed and installed so as to contain the spread of fire. It is a management responsibility to ensure that the standards applied during the design and installation are not reduced during the operation and maintenance of the equipment.

2.11 In the event of a reportable incident connected with ventilation equipment or any area that it serves, all records and plant log books will need to be collected as evidence. Proven breaches of the statutory requirements can result in prosecution and may also give rise to a civil suit against the operators.

Other responsibilities

2.12 Management has a general responsibility to ensure that ventilation systems are operated at a standard suitable for the purpose for which they were installed.

2.13 While ventilation plant itself has not been shown to pose a high risk to health, it does have the ability to transfer a hazard, originating from another source, to a large number of people, without them becoming immediately aware of it.

2.14 Increased health risks to patients will occur if the more specialised ventilation systems installed to supply high quality air to operating departments do not achieve and maintain the required standards. The link between post-operative infection and theatre air quality has been well established. Plants serving conventional operating departments, for instance, will be required to ensure the separation of areas within the suite by maintaining a specific direction of air flow between rooms, even when doors are opened. They will also maintain the selected operating department environmental conditions regardless of changes in the outside air conditions or activities within the space. In addition ultra-clean operating ventilation systems which are designed to provide an effectively particle-free zone around the patient while the operation is in progress have been shown to significantly reduce post-operative infection in patients undergoing deep wound surgery. Their use for similar forms of surgery may well be indicated.

2.15 Ventilation systems that can be shown to be inappropriate, inadequate or ineffective and that give rise to proven failures can result in a civil suit by the patient against the operators. The same may be true of other ventilation applications.

2.16 If the plant has been installed to dilute or contain harmful substances, its failure may expose people to unacceptable levels of contamination, again without their becoming immediately aware of it. Proven failures can give rise to a civil suit against the operators by the individuals who have been affected. This would be in addition to the actions brought as a result of breaching the statutory requirements.

Summary of requirements

Requirement	Reason	Location
Statutory	Health and Safety at Work etc Act	Operating departments. Laboratories. Pharmacies Post Mortem Rooms
	COSHH regulations (including Local exhaust ventilation requirements)	Areas containing identified biological or chemical hazards. Areas containing oxygen displacing gases. Enclosed work-spaces. Workshops.
	Building regulations	Any room which cannot be naturally ventilated.
Functional	Comfort	Situations where the quality of the environment for staff and patient is critical to their general performance and well-being.
Clinical	Post-operative infection reduction	Operating suites used for general surgery, casualty, obstetrics/gynaecological and maternity procedures.
	Reduction of deep wound sepsis	Ultra-clean operating suites for transplant, deep wound surgery, hip replacement, bone grafting and bone marrow transplant procedures.
	Control of infection	Isolation rooms Barrier nursing rooms Treatment rooms Plaster rooms

Operational management

2.17 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure.

2.18 Those required to monitor and/or maintain ventilation equipment will need to show that they are competent to do so. As a minimum they should have sufficient knowledge of its correct operation in order to be able to recognise and report faults. Training in the correct operation and routine maintenance of the equipment will be required as part of the handover procedure at the end of the commissioning period.

2.19 Routine maintenance procedures can cause risks to the health of staff carrying out the work and those receiving air from the plant. All those involved

should be made aware of the risks, safe systems of work should be agreed, and suitable safety equipment should be provided and training in its use given.

2.20 Staff engaged in the service and maintenance of ventilation extract systems from pathology departments or laboratories may be particularly at risk. In these cases the risk should be identified and assessed, the means by which the system can be rendered safe to work on should be determined, training in the exact procedures should be adopted and given to all staff involved and a permit-to-work scheme on the system should be implemented.

2.21 Regular tests, at intervals agreed with the local fire prevention officer, will need to be carried out in order to demonstrate the continuing efficiency of the fire detection and containment systems. Records of these tests should be kept.

2.22 A periodic review of the need for, and operational condition of, ventilation equipment will need to be undertaken.

2.23 Training in the use of safety equipment and a safe system of work will need to be repeated periodically in order to cater for changes in staff. Records of the training provided should be kept and maintenance procedures reviewed periodically to ensure that they remain appropriate.

Designated staff functions

2.24 A person intending to fulfil any of the staff functions specified below should be able to prove that they possess sufficient skills, knowledge and experience so as to be able to perform safely the designated tasks.

2.25 **Management** - management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the safe operation of premises.

2.26 **Authorised person** - a person appointed or contracted by the general manager to review and witness documentation on validation and provide auditing and advice on ventilation installations and their application.

2.27 **Test person** - a person or organisation contracted by the general manager to carry out commissioning, validation and routine testing of ventilation installations.

2.28 **Maintenance person** - a member of the maintenance staff, ventilation equipment manufacturer or maintenance organisation employed by the general manager to carry out maintenance duties on ventilation installations.

2.29 **Infection control officer** - or consultant microbiologist, if not the same person, nominated by the management to advise on monitoring infection control policy and microbiological performance of the systems. Major policy decisions should be made through an infection control committee.

2.30 **Plant operator** - any person who operates a ventilation installation.

2.31 **User** - the person responsible for the management of the unit in which the ventilation system is installed, for example, head of department, operating theatre manager, head of laboratory, production pharmacist, head of research or other responsible person.

2.32 **Contractor** - the person or organisation responsible for the supply of the ventilation equipment, its installation, commissioning and validation. This person may be a representative of a specialist ventilation organisation or a member of the general manager/chief executive's staff.

2.33 A record should be kept of those appointed to carry out the staff functions listed above. The record should clearly state the extent of the post holders duties and responsibilities and to whom they are to report.

2.34 Any training given should be recorded together with the date of delivery and topics covered.

2.35 Substitute or replacement staff should be designated in order to cover for sickness, holidays and staff transfers.

3. Functional overview

Terms in use

3.1 The terms “ventilation” and “air-conditioning” are often used interchangeably to describe the same equipment. A general explanation of the terms is given below.

Ventilation

3.2 Ventilation is a means of removing and replacing the air in a space. In its simplest form this may be achieved by opening windows and doors. Mechanical ventilation systems provide a more controllable method. Basic systems consist of a fan and collection or distribution ductwork; more complex systems may include the ability to heat and filter the air passing through them. Ventilating equipment may be required in order to remove smells, dilute contaminants and ensure that a supply of “fresh” air enters a space.

Air-conditioning

3.3 Air-conditioning is the ability to heat, cool, humidify, dehumidify and filter air. This means that the climate within a space being supplied by an air-conditioning plant can be maintained at a specific level within a specified range regardless of changes in the outside air conditions or the activities within the space. Air-conditioning equipment may be required in order to provide “comfort conditions” within a space.

Special ventilation

3.4 In healthcare premises, certain activities will necessitate the provision of ventilation equipment with additional special features in order to achieve and maintain specific conditions. These may be needed in order to assist with the treatment of patients or maintain the health and safety of staff. The precise reason for providing special ventilation will depend upon its intended application. The list below indicates some of the more typical reasons:

a. to provide “close” control of temperature;

b. to provide “close” control of humidity;

c. to remove, contain or dilute specific contaminants and fumes;

d. to ensure the isolation of one space from another;

e. to preserve a desired air flow path from a “clean” to a “less clean” area;

f. to provide control of the cleanliness of a space.

3.5 The following departments will usually have specialist ventilation requirements, either for a single room or throughout a suite:

a. an operating suite;
b. a laser surgery unit;
c. an intensive treatment unit;
d. an infectious diseases isolation unit;
e. a manufacturing pharmacy and cytotoxic drug units;
f. a specialist X-ray and scanning unit;
g. pathology department;
h. a mortuary and dissection suites;
i. research laboratories and associated animal houses;
j. sterilizing and disinfecting unit (SDU).

Equipment requirements

3.6 Ventilation may be provided in a wide variety of ways. These will include extensive purpose-built air-conditioning units housed in their own plantrooms, proprietary "packaged" systems often sited outside on a roof or wall-mounted electric fans located at the point of use.

3.7 Specialist ventilation systems utilising full air-conditioning are expensive so they are only used where there is a specific need to control closely the environment within a space, for example an operating department, intensive treatment suite or laboratory.

3.8 A fixed volume of air may be supplied, usually expressed as a number of air changes per hour (ac/h) or cubic metres per second (m^3/s) that the plant is set to deliver, or the volume of air supplied may be varied in order to maintain a specific pressure relationship between the area supplied by a special ventilation system and other surrounding areas.

3.9 An uncontaminated air supply to the plant is essential. In order to achieve this the air intake will be positioned so that air from extract systems or other dubious sources cannot be drawn in. The area surrounding the intake will need to be kept clean and free of waste material in order to reduce the possibility of bio-hazards or fire. The intake itself will be protected by a louvre and mesh screen to prevent rain water, vermin and insects etc from entering the system

3.10 Most modern plants are fitted with the means to recover energy from the extract air without causing contamination of the incoming supply air.

3.11 Ultra-clean systems use the same basic plant and equipment as standard air-conditioning but are in addition fitted with a terminal device that supplies the air in a uni-directional manner to the working area. Their standard of filtration

is also higher and is capable of delivering air with a very low particle count to the space that they serve.

3.12 Local exhaust ventilation (LEV) is a term used to describe systems installed to prevent hazardous substances from entering the general atmosphere of the room in which they are being used. Their primary function is to protect staff from the effects of their work activity.

3.13 Simple LEV systems comprise a capture hood, extract ductwork and fan. These are used to contain industrial types of hazard such as fumes from welding processes, gas discharges from standby battery banks and dust from woodworking machinery. The vapour given off when large quantities of chemicals are decanted into ready-use containers and fumes from X-ray film processing units are examples of chemical hazards often controlled by LEV systems.

3.14 In laboratories, pharmaceutical manufacturing facilities and operating suites, LEV systems usually take the form of semi-open fronted cabinets within which the hazardous substance is manipulated. These cabinets either have their own filtered air supply or are fed with air from the room. The air extracted from the cabinet is passed through a high-efficiency filter before being discharged either to the atmosphere or back into the room. Microbiological safety cabinets, laboratory fume cupboards, cytotoxic drug cabinets, and fixed or mobile glutaraldehyde disinfecting enclosures are all examples of this type of facility.

3.15 Mortuaries and dissection suites may have LEV systems incorporated within the dissection table, specimen bench and bone saw.

4. Management summary

4.1 The guidance contained in this SHTM should not be applied retrospectively; however, there is an obligation to review existing installations and ensure that they are of a safe standard. The guidance should be applied in full to new installations and major refurbishments of existing installations.

4.2 Ventilation will need to be provided:

a. as a requirement for patient care;

b. in order to fulfil a statutory duty.

In assessing the need for more specialist ventilation and the standards desired for patient care, managers will need to be guided by their medical colleagues and by information published by the Department of Health.

4.3 The statutory need for ventilation falls into two categories:

a. in the first, the need for specialist ventilation and the standards to be adopted are clearly set out in specific pieces of legislation. An excellent example of this is the current legislation surrounding the manufacture of medicinal products in the European Community. The managers of the departments affected by this type of legislative requirement should be aware of their needs and be able to advise on the standards to be achieved;

b. the second type of statutory requirement arises due to the interpretation of both the Health and Safety at Work etc Act and the Control of Substances Hazardous to Health (COSHH) regulations. The person tasked with conducting COSHH assessments will be able to advise as to the need for, and standard of, ventilation in each particular case.

4.4 It is a management responsibility to ensure that the standards applied during the design and installation of ventilation systems are not reduced during the operation and maintenance of the equipment.

4.5 Clear lines of managerial responsibility should be in place so that no doubt exists as to who is responsible for the safe operation and maintenance of the equipment. A periodic review of the management systems should take place in order to ensure that the agreed standards are being maintained.

4.6 These objectives will only be achievable if the personnel engaged have the necessary experience and training to undertake their designated tasks.

Appendix 1

Use and function of typical equipment used in ventilation plants

1. Typical equipment used in ventilation plants is listed below together with a brief description of both function and use.

General

2. The equipment built into the ductwork should be of a type that will neither cause nor sustain combustion.

3. No materials that could sustain biological activity should be used in the construction or assembly of the plant.

Air intake

4. As an uncontaminated air supply is essential, it is positioned so that air from extract systems or other dubious sources cannot be drawn in. The area surrounding the intake will be kept clean and free of waste material in order to reduce the possibility of bio-hazards or fire. The intake itself will be protected by a louvre and mesh screen to prevent rain water, vermin and insects etc entering the system.

Damper

5. Several types may be fitted:

   a. automatic dampers fitted immediately behind the air intake and extract louvres. They will automatically close when the plant is shut down in order to prevent an uncontrolled circulation of air;

   b. balance dampers are fitted into each branch of the air distribution ductwork system so that the design air flow rate can be set during the commissioning process;

   c. where ductwork passes through a fire compartment wall, ceiling or floor a fire and/or smoke damper may be required;

   d. plant isolating dampers are fitted so that the main plant can be isolated from its air distribution duct system. They are manually operated and enable cleaning and maintenance of the air-conditioning equipment to be carried out.

Ducting

6. The means by which air is conveyed from the intake to its point of use. Ducting is usually constructed of galvanised steel and will normally be insulated to reduce noise and conserve energy. Ducts can also be formed in concrete, brickwork, stainless steel or plastic and may be rigid or flexible.

Fan

7. A series of rotating blades that move the air in the direction required. Fans are usually powered by electric motors either directly connected to them or driven through belts and pulleys. A fan may be arranged to either force air into or draw air from a ductwork system.

Attenuator/silencer

8. A device that will contain and absorb the noise emitted by a fan. They may be required to reduce disturbance caused by noise breaking out through the air intake and also noise transmitted along the ductwork to the conditioned space.

Filter

9. A filter consists of a labyrinth of fibrous material contained in a frame. It is designed to capture and hold particles being carried in the airstream. Because of the size, range and number of particles that exist in air, no filter can remove them all. The purpose of filtration is to reduce their number, size and range to an acceptable level. Filters of progressively higher grades are fitted through the ventilation system:

   a. primary filters (coarse) are designed to collect the larger particles and are intended to keep the air conditioning plant clean;

   b. secondary filters (fine) will remove the staining particles from air and keep the conditioned space visibly clean;

   c. high efficiency particulate air filters (HEPA/absolute) will remove virtually all particles from air. These may be required in order to reduce contamination in the working area either biologically or in terms of particle count.

10. Filters may be fitted to extract systems in order to remove biological, radiation or chemical hazards. If so they are often contained in a “safe change” facility in order to protect those carrying out their maintenance.

11. Activated carbon filters will reduce odours in extracted or recirculated air.

Heater battery/heater coil

12. A series of coils with or without fins through which steam or hot water is circulated. Heat is given up to the air passing over the battery thus increasing its temperature. Heating is usually carried out in stages, the final battery being controlled by the end user. Small batteries may be electric.

Humidifier

13. A device for increasing the humidity of air by adding moisture. For ventilation in healthcare premises this is normally achieved by releasing “clean” steam into an air supply duct. The steam will be completely absorbed into the air, increasing its humidity. The level of humidity may be preset or controlled by the end user.

Cooler battery/cooling coil

14. A series of finned coils mounted in the air supply duct. Either chilled water or refrigerant is circulated through the coils causing heat to be removed from the air. This will reduce its temperature and may also condense moisture out of the air. As free moisture in a duct can be a source of contamination the coil will be fitted with an eliminator and drainage system.

Eliminator

15. A device for catching and removing water droplets from an air stream. It may form part of a cooling coil or be a separate device.

Drainage system

16. A means of removing water from ductwork and disposing of it safely. Typically it will consist of a tray mounted in the duct to catch moisture, a glass water seal trap, continuously falling drainage pipework and an air break in the drain run to prevent waste water returning and contaminating the duct.

Access and observation ports

17. Doors and removable panels providing access for routine maintenance and cleaning. The doors should be fitted with glazed ports and suitable lighting provided so that the correct operation of devices such as cooling coils, humidifiers and filters can be easily observed.

Energy recovery

18. Most modern plants are fitted with the means to recover energy from the extract air without causing contamination of the incoming supply air. These devices will be fitted with both an eliminator and a drainage system. Several types of energy recovery systems are available.

Typical plant

19. The layout of a typical plant designed to serve an operating suite is shown in Figure 1. It contains most of the equipment described above. Full details of the plant illustrated and its mode of operation are given in Part 2; 'Design considerations' of this SHTM.

Figure 1: A typical operating suite ventilation plant

Certificate of Practical Completion

Issued by:	Arcadis LLP (previously EC Harris LLP)
Address:	34 York Way, London, N1 9AB
Project Co:	IHS Lothian Limited
Address:	13 Queen's Road, Aberdeen, AB15 4YL
Board:	Lothian Health Board
Address:	Waverley Gate, 2-4 Waterloo Place, Edinburgh EH1 EG
Contractor:	Multiplex Construction Europe Limited (previously Brookfield Multiplex Construction Europe Limited)
Address:	99 Bishopsgate, Second floor, London EC2M 3XD
Issue date:	22nd February 2019
Works:	Re-provision of RHSC and DCN at Little France
Situated at:	Little France Crescent, Edinburgh EH16 4TJ

Under the terms of the above-mentioned Project Agreement and as subsequently amended and supplemented by the Settlement Agreement and Supplemental Agreement relating to the Project Agreement. (Concluded and implemented 22/02/2019)
We certify that the Actual Completion Date of the Works was achieved on 22nd February 2019.

To be signed by or for the issuer named above.

AHU Remedials Cover Sheet

The enclosed sheets represent the individual reviews of each Air Handling Unit (36 Total). Where items were deemed unsatisfactory at first visit this has been recorded at line 24 in the table. A sub table has then been included showing the items that were deemed deficient. If satisfactory at the second visit all items have been recorded as such. A third table contains the list of reviewers for sign off.

Additionally a summary sheet has been produced identifying maintenance items Bouygues need to continually be aware of when carrying out maintenance on the units.

As discussed and agreed between the Board and the AE's representing IOM and Turner PES and to satisfy board governance, could all participants in the AHU review process please sign each individual AHU sheet as well as in the table below recording that the unit meets the criteria set out in Section 8 of SHTM 03-01 and return a scanned copy. All reviewers will be given a complete copy once all signatures are received.

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

AHU 02-01

Item Number	Source of Reference	Description	Date of 1st Visit: 04.02.20 Satisfactory Y/N	Date of 2nd Visit: 24.03.20 Satisfactory Y/N
1	29	Cabling inside AHU's – All cabling run through the length of the AHU to be encapsulated in a cleanable metal finish to the same specification as the AHU sections. This to be sealed using a gasket and sealant that can also be cleaned. All materials selected should meet the requirements of SHTM 03-01, Part A, Clause 1.41		Y
2	30	Filter pleat orientation – All filters to be installed with pleats in vertical orientation to prevent collapse		Y
3	31	Pre filters showing signs of bypass – All filters to be correctly installed and any gaps to the frame sealed to prevent, or minimise to within acceptable limits, air bypass.		Y
4	39	Motorised dampers take a long time to close – Adjustments made by Schneider, item now closed		Y
5	40	Plant labelling incorrect – Labelling of AHU and main branch ducting to be clear and legible with agreed names and locations served indicated.		Y
6	43	Motors running 95% – Report provided demonstrating that AHU's are capable of overcoming dirty filter condition and remaining spare capacity, Item is closed.		Y
7	50	AHU Pressure controls – Reviewed by IOM and agreed closed.		Y
8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
02-01	Fresh air inlet plenum debris	24.03.20	Y
	Pre-filters & F7 final filters some panels wrong orientation top row		Y
	Pre-filter sliders & spaces missing on floor		Y
	Exposed cables at fans		Y
	Motorised damper not closing fully		Y
	Return filter door clashing with cable tray		Y
	Inaccessible channels for cleaning at metalwork		Y
	AHU not labelled to SHTM standard		Y
	Mud on inside face side of ductwork after final supply VCD non access door		Y
	Muddy footprint on inside top face of ductwork after final supply VC		Y

Date re-inspected - 24.03.20

Satisfactory Y/N - Y

8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
02-04	G4 fresh air inlet filters incorrect orientation	24.03.20	Y
	Misaligned backdraught damper blades		Y
	F7 final filter wrong orientation		Y
	Air leakage from ductwork access door on bend on the first section of ductwork immediately down-stream of the		Y
	Damaged & incomplete thermal insulation of fresh air intake ductwork, not full width of duct		Y
	Electrical conduit copex has air leak		Y
	Air leak from cooling coil drain connection		Y
	Filter gauge not marked up		Y

Date re-inspected - 24.03.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspecte	Corrected (Y/N)
02-10	Gaps in metalwork	24.03.20	Y
	Dust present on inner door faces, floor after frist coil. Unit not cleaned		Y
	F7 final filter wrong orientation		Y
	Tech screw spikes in fan inlet plenum as a result on additional metalwork neither cut or capped, hazard for someone in the unit		Y
	Water in trap not clean, milky appearance		Y
	Thermal insulation metal-cladding to be repaired after the new access door has been installed		Y
	Access door wont close at pre-filter catching door frame		Y

Date re-inspected - 24.03.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

AHU 02-11

Item Number	Source of Reference	Description	Date of 1st Visit: 04.02.20 Satisfactory Y/N	Date of 2nd Visit: 24.03.20 Satisfactory Y/N
1	29	Cabling inside AHU's – All cabling run through the length of the AHU to be encapsulated in a cleanable metal finish to the same specification as the AHU sections. This to be sealed using a gasket and sealant that can also be cleaned. All materials selected should meet the requirements of SHTM 03-01, Part A, Clause 1.41		Y
2	30	Filter pleat orientation – All filters to be installed with pleats in vertical orientation to prevent collapse		Y
3	31	Pre filters showing signs of bypass – All filters to be correctly installed and any gaps to the frame sealed to prevent, or minimise to within acceptable limits, air bypass.		Y
4	39	Motorised dampers take a long time to close – Adjustments made by Schneider, item now closed		Y
5	40	Plant labelling incorrect – Labelling of AHU and main branch ducting to be clear and legible with agreed names and locations served indicated.		Y
6	43	Motors running 95% – Report provided demonstrating that AHU's are capable of overcoming dirty filter condition and remaining spare capacity, Item is closed.		Y
7	50	AHU Pressure controls – Reviewed by IOM and agreed closed.		Y
8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y

12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
02-16	Filter orientation incorrect	10.03.20	Y
	Pre filters incorrectly positioned on slider rail		Y
	Top slider rain on pre filters missing		Y
	Debris and swarf in cooling coil drip tray		Y
	Glass trap empty		Y
	Unit generally not clean		Y
	Labelling to test point should be permanent and include duct size		Y

Date re-inspected - 10.03.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

AHU 02-17

Item Number	Source of Reference	Description	Date of 1st Visit: 14.01.20 Satisfactory Y/N	Date of 2nd Visit: Satisfactory Y/N
1	29	Cabling inside AHU's – All cabling run through the length of the AHU to be encapsulated in a cleanable metal finish to the same specification as the AHU sections. This to be sealed using a gasket and sealant that can also be cleaned. All materials selected should meet the requirements of SHTM 03-01, Part A, Clause 1.41		Y
2	30	Filter pleat orientation – All filters to be installed with pleats in vertical orientation to prevent collapse		Y
3	31	Pre filters showing signs of bypass – All filters to be correctly installed and any gaps to the frame sealed to prevent, or minimise to within acceptable limits, air bypass.		Y
4	39	Motorised dampers take a long time to close – Adjustments made by Schneider, item now closed		Y
5	40	Plant labelling incorrect – Labelling of AHU and main branch ducting to be clear and legible with agreed names and locations served indicated.		Y
6	43	Motors running 95% – Report provided demonstrating that AHU's are capable of overcoming dirty filter condition and remaining spare capacity, item is closed.		Y
7	50	AHU Pressure controls – Reviewed by IOM and agreed closed.		Y
8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y

17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y
General		BMS set point for dirty filter condition to be adjusted and set point advised.		

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
02-22	Glass trap to be provided to inlet drain	10.03.20	Y
	Hatch size to inlet section too small (BYES to identify other locations by survey)		Y
	Labelling to test point should be permanent and include duct size		Y

Date re-inspected- 10.03.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
04-01	Screw spikes upto 5cm long in supply ductwork down stream of AHU discharge after manual damper.	02.04.20	Y
	Pre-filters slider plates missing		Y
	Plant labelling font too small		Y
	Tech screw spikes in fan inlet plenum as a result on additional metalwork		Y

Date re-inspected - 02.04.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

AHU 04-02

Item Number	Source of Reference	Description	Date of 1st Visit: 25.02.20 Satisfactory Y/N	Date of 2nd Visit: 02.04.20 Satisfactory Y/N
1	29	Cabling inside AHU's – All cabling run through the length of the AHU to be encapsulated in a cleanable metal finish to the same specification as the AHU sections. This to be sealed using a gasket and sealant that can also be cleaned. All materials selected should meet the requirements of SHTM 03-01, Part A, Clause 1.41		Y
2	30	Filter pleat orientation – All filters to be installed with pleats in vertical orientation to prevent collapse		Y
3	31	Pre filters showing signs of bypass – All filters to be correctly installed and any gaps to the frame sealed to prevent, or minimise to within acceptable limits, air bypass.		Y
4	39	Motorised dampers take a long time to close – Adjustments made by Schneider, item now closed		Y
5	40	Plant labelling incorrect – Labelling of AHU and main branch ducting to be clear and legible with agreed names and locations served indicated.		Y
6	43	Motors running 95% – Report provided demonstrating that AHU's are capable of overcoming dirty filter condition and remaining spare capacity, Item is closed.		Y
7	50	AHU Pressure controls – Reviewed by IOM and agreed closed.		Y
8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y

17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
23	I	Air flow test points – Appropriate and correctly labelled airflow test points should be available on major branches to main ducts		Y
24	N/A	**OVERALL ASSESSMENT OF UNIT AT INSPECTION VISIT**	N	Y

AHU	ISSUES IDENTIFIED AT FIRST INSPECTION	Date RE-Inspected	Corrected (Y/N)
04-07	F7 final filter bag trapped in front of frame	02.04.20	Y
	Pre-filter slider tabs missing		Y
	Tech screw spikes in fan inet plenum as a result of additional metalwork neither cut or capped, hazard for someone in the unit		Y
	Return filter door wont open fullt as manometer hitting pipework		Y
	Difficult to clean channels at metalwork in thermal wheel section		Y
	Air leakage at reheat coil pipework		Y

Date re-inspected - 02.04.20

Satisfactory Y/N - Y

The signatories below confirm that the AHU meets the definition contained in section 8 of SHTM 03-01 as follows:
"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."

AHU 04-08

Item Number	Source of Reference	Description	Date of 1st Visit: 04.02.20 Satisfactory Y/N	Date of 2nd Visit: 02.04.20 Satisfactory Y/N
1	29	Cabling inside AHU's – All cabling run through the length of the AHU to be encapsulated in a cleanable metal finish to the same specification as the AHU sections. This to be sealed using a gasket and sealant that can also be cleaned. All materials selected should meet the requirements of SHTM 03-01, Part A, Clause 1.41		Y
2	30	Filter pleat orientation – All filters to be installed with pleats in vertical orientation to prevent collapse		Y
3	31	Pre filters showing signs of bypass – All filters to be correctly installed and any gaps to the frame sealed to prevent, or minimise to within acceptable limits, air bypass.		Y
4	39	Motorised dampers take a long time to close – Adjustments made by Schneider, item now closed		Y
5	40	Plant labelling incorrect – Labelling of AHU and main branch ducting to be clear and legible with agreed names and locations served indicated.		Y
6	43	Motors running 95% – Report provided demonstrating that AHU's are capable of overcoming dirty filter condition and remaining spare capacity, Item is closed.		Y
7	50	AHU Pressure controls – Reviewed by IOM and agreed closed.		Y
8	52	Temperature control – Temperature log received and reviewed by NHSL and IOM and agreed closed.		Y
9	57	Inverters – All inverters currently installed within the AHU to be removed		Y
10	58	Dampers (backdraught) – Damaged blades of backdraught dampers to be repaired		Y
11	60	Cleaning – Evidence of bird droppings and fouling of AHU 04-01 and associated pipework and cable tray, this to be fully cleaned		Y
12	61	Cleaning – Evidence of dead bird or rodent in inlet section of AHU 04-05, this to be removed and section fully cleaned		Y
13	62	Cleaning – Internals of all AHU's to be fully cleaned		Y
14	64	Inlet section – Appropriate means of draining AHU inlet section to be installed		Y
15	A	Air tightness – All penetrations for pipework, cables hoses etc should be sealed to prevent air leakage		Y
16	B	AHU access – NHSL require confirmation that all access doors to AHU's are free from opening restrictions		Y
17	C	Position of light switches – NHSL requires that light switches installed at high level are re-positioned to a convenient height from floor level. Bouygues have confirmed that they have a safe system of work for the switches in their current location, all agreed item closed		Y
18	D	Ductwork section changes – These may give rise to turbulence, however, provided this is not transferred to the area served all agreed that this item can now be closed.		Y
19	E	AHU Intake Louvres – Appropriate access is required for cleaning and after survey some hatches have been resized or relocated. Bouygues have confirmed that they have a safe system of work for this activity with the hatches in their current size and location. All agreed item closed.		Y
20	F	AHU Drainage – All AHU drainage traps to be clean. Bouygues to confirm that a PPM regime is in place to ensure they are maintained and kept in a clean condition		Y
21	G	AHU Drainage – AHU drainage to have appropriate fall to drain and that there is a minimum air gap of 15mm		Y
22	H	AHU 04-07 drainage – Brackets and impediments to be removed to allow correct installation of drainage pipework. Inspection of this unit showed satisfactory resolution and this item is now closed		Y
