New	Trans	Total					
1		1	PEG002	PEGS; equipment; medium; 2; wide spacing; wall mounted.		1	
3		3	PEN002	PENDANT; Anaesthetic; medical & power supply unit; vertical movement; ceiling mounted; outlets comprising.		1	
1		1	PEN006A	PENDANT SURGICAL; touch screen monitor; medical and power supply unit; tandem; lateral and vertical movement; ceiling mounted; outlets comprising.		1	
3		3	PLA002	PLATFORM; step-stand; stackable; portable. 130H 480W 330D		3	
1		1	PRI015	PRINTER; label; portable		3	
1		1	SCA012	SCALE; swab; includes Mains adaptor		3	
2		2	STA101	STAND; lotion bowl; single; stainless steel; (Bowls not included)		3	
2		2	STA142	STAND; infusion; twin hook; breaks; mobile		3	
2		2	STA2509	STAND; sharps bin, mobile, 30 litre		3	
3		3	STO006	STOOL, surgeon/anaesthetist, height adjustable, includes anti-static seat pads		3	
2		2	SUC002	SUCTION UNIT; pipeline; high pressure; theatre		3	
2		2	SUP2500	SUPPORT LEG; for 920 high worktop		1	
1		1	SUR971	Swab bucket		3	
2		2	SWC025	SWITCH, light		1	
3		3	SYR004	SYRINGE pump; anaesthetic use; with diprifusor; 115H 400W 180D		3	
1		1	TAB071	TABLE operating patient, powered with 250mm transverse top, complete with specialty accessories, 715H 600W 2102D		3	
2		2	TEL2500	TELEPHONE; handset, wall mounted.		2	
1		1	TRF002	AUTOTRANSFUSION cell separator; mobile; built in air and foam detector; 1620H 270W 585D		3	
2		2	TRO021	TROLLEY; 4 sets of runners; 850H 600W 600D		3	
4		4	TRO131	TROLLEY, dressing/instrument, stainless steel, buffered, 870H 450W 450D		3	
2		2	TRO133	TROLLEY, dressing/instrument, stainless steel, buffered, 870H 750W 450D		3	
2		2	TRO201	TROLLEY, instruments, stainless steel, buffered, 870H 920W 620D		3	
1		1	TRO204	TROLLEY instrument tray MAYO, 650W 450D		3	
1		1	TRU1000	TRUNKING; Power and Data trunking; length as drawn.		1	
1		1	UPS003	Uninterrupted power supply (UPS).		1	
1		1	WAR053	WARMER, blood/fluid, maintains temperature between 36 and 43 deg.C at flow rates up to 500 ml/min, 35H 235W 273D		3	
1		1	WAR901	Blanket Warmer		3	
1		1	WKT1006H	WORKTOP; 920 high 800 deep 40mm thick; with 50mm upstand; length as drawn.		1

1		1	DIS011	DISPENSER, barrier cream, disposable single cartridge, wall mounted		2	
1		1	DIS013	DISPENSER, paper towel, wall mounted		2	
1		1	DIS030	DISPENSER, soap, disposable single cartridge, lever action, wall mounted		2	
2		2	HOL005	HOLDER; bin; medium; capacity 70 litres; freestanding.		3	
7		7	HOO024	HOOK; hat and coat; 1.		1	
2		2	LAB400	FREEZER; Laboratory, under bench		3	
1		1	MIC040	MICROSCOPE: Conventional		3	
1		1	OUT005	SOCKET outlet, switched, 13amp, single		1	
7		7	OUT006	SOCKET outlet unswitched 13amp single; wall mounted.		1	
22		22	OUT010	SOCKET outlet, switched, 13amp, twin.		1	
7		7	OUT052	CONNECTION UNIT; switched, 13 amp		1	
3		3	OUT121	SOCKET outlet; computer data; double.		1	
1		1	OUT131	SOCKET outlet double data/voice; wall/trunking mounted.		1	
1		1	OUT315	OUTLET, drinking water for equipment		1	
1		1	OUT341	OUTLET, drainage, anti-syphon		1	
3		3	OUT452	OUTLET; 4 kPa compressed air medical; trunking mounted.		1	
3		3	OUT476	OUTLET; vacuum medical; trunking mounted.		1	
1		1	PCR010	PCR MACHINE		3	
1		1	REF032	FREEZER upright -20 deg.C; Panasonic MDF-U700VX-PE; 2010H 1010W 870D		3	
1		1	REF105	ICE MACHINE: under bench, plumbed in		2	
1		1	SHE902	SHELF, with supports from island units, 2no each side		1	
2		2	SHE903	SHELF, 2no, with supports		1	
1		1	SIG900	SIGN; door; vacant/engaged & names slot		1	
2		2	SNS753	SINKTOP; single bowl; no tap holes; no overflow; right hand integral ribbed drainer; stainless steel; 1200W 600D. HTM64STA		1	
1		1	SPI301	RADIATION SPILL KIT		3

2		2	DIS2500	DISPENSER; danicentre; combined glove/apron.		2
1		1	DIS2503	DISPENSER; alcohol gel; disposable single cartridge; wall mounted.		2
4		4	HOL005	HOLDER; bin; medium; capacity 70 litres; freestanding.		3
2		2	INF001	INFUSION volumetric pump; 356H 178W 178D		3
1		1	LIG074	ILLUMINATED SIGN DO NOT ENTER		1
1		1	LIG074	ILLUMINATED SIGN DO NOT ENTER		1
2		2	LIG081	LUMINAIRE fitted with single fluorescent lamp with switch; below drug cupboard; 8watt; 400mm.		1
2		2	MON904	MONITOR; High end multi-functionality for ITU/Theatre/High Acuity		3
2		2	MON906	MONITOR; Clinical slave		2
2		2	MSC127	CABINET top; 600mm facing; (600x400 inserts); with formed plastic liners; 1 door hinged right; wall mounted.		1
2		2	MSC128	CABINET top; 600mm facing; (600x400 inserts); with formed plastic liners; 1 door hinged left; wall mounted.		1
4		4	MSC981	CABINET base; 600mm facing; (600x400 inserts); with formed plastic liners; vertical tambour front; on plinth; o/a height 880		1
4		4	MST001	TROLLEY; single open frame; with handle; up to 5 sets of runners; 600mm facing; approx 850H 730W 450D		3
4		4	MST005	TROLLEY; half size open frame; up to 5 sets of runners; 400mm facing; approx 850H 450W 350D		3
2		2	OUT005	SOCKET outlet, switched, 13amp, single		1
2		2	OUT006	SOCKET outlet unswitched 13amp single; wall mounted.		1
13		13	OUT010	SOCKET outlet, switched, 13amp, twin		1
16		16	OUT012	SOCKET outlet switched 13amp twin; trunking/pendant mounted.		1
2		2	OUT050	OUTLET, controlled drugs cupboard		1
2		2	OUT059	CONNECTION UNIT switched 13amp, indicator light		1

8		8	OUT121	SOCKET outlet; computer data; double.		1
8		8	OUT131	SOCKET outlet double data/voice; wall/trunking mounted.		1
2		2	OUT210	SOCKET outlet two-way communication system (intercom), wall mounted		1
4		4	OUT453	OUTLET, 4kPa compressed air, medical		1
4		4	OUT461	OUTLET, nitrous oxide, medical		1
8		8	OUT470	OUTLET, oxygen, medical		1
4		4	OUT475	OUTLET, vacuum, medical		1
4		4	OUT480	OUTLET, gas scavenging (AGS), medical		1
4		4	PEN900	PENDANT RESUSCITATION, medical gases and power supply unit, fixed location, ceiling mounted, medical gases and power outlets comprising:		1
2		2	PRI015	PRINTER; label; portable		3
1		1	RAC196	RACK, x-ray lead apron, 5 hangers hinged, wall mounted		2
2		2	REF062	REFRIGERATOR, capacity 82 litres, external temperature gauge, lockable, 660H 500W 510D		3
2		2	RSU010	DEFIBRILLATOR; Manual		3
3		3	SCR066	SCREEN shielding; radiation protection; lead sheets; mobile; 1140H 1070L; lead equivalent 0.8 mm Pb @ 110 keV.		5
2		2	STA142	STAND; infusion; twin hook; breaks; mobile		3
2		2	STA2504	STAND; Roll stand for monitor		3
2		2	STF290	STORAGE UNIT; upper; cupboard; controlled drugs; 1 door; lockable; with inner lockable cupboard and warning light; 550H 600W 300D		1
2		2	STO006	STOOL, surgeon/anaesthetist, height adjustable, includes anti-static seat pads		3
1		1	SWC025	SWITCH, light		1
1		1	SWC062	EMERGENCY STOP switch button, wall mounted		1
4		4	SYR004	SYRINGE pump; anaesthetic use; with diprifusor; 115H 400W 180D		3
2		2	TAP894	TAP bib; hospital pattern; integral thermostatic mixer; HTM64		1
2		2	TEL2500	TELEPHONE; handset, wall mounted.		2
2		2	TRO2507	TROLLEY; control; including PC		3
2		2	TRO282	TROLLEY PATIENT; accident; image top; with tilt and brakes; 540-1000H 740W 2110D		3
1		1	UPS003	Uninterrupted power supply (UPS).		1
1		1	WAR053	WARMER, blood/fluid, maintains temperature between 36 and 43 deg.C at flow rates up to 500 ml/min, 35H 235W 273D		3
2		2	WAS100	WASTE, unslotted flush-grated, metal, 1.1/4 in		1
2		2	WAS1000	TRAP; concealed waste; for back outlet basins.		1
2		2	WKT1003H	WORKTOP; 920 high 600 deep 40mm thick; with 50mm upstand; length as drawn.		1
1		1	XRA010	X-RAY CS; ceiling suspensions; with telescopic tube of column and rotating/tilting arm		5
4		4	XRA015	X-RAY CS RAIL; ceiling suspensions; 6280mm; (Part of XRA010)		5
1		1	XRA040	X-RAY Resus equipment		5

AIR	Requirements	Notes
Winter Temperature (DegC):		Permissible space temperature range (dry bulb) (degC): 18 - 28
Summer Temperature (DegC):		
Mechanical Ventilation (Supply ac/hr):	3.0	Ventilation Type: Central Supply and Extract
Mechanical Ventilation (Extract ac/hr):	3.0	
Pressure Relative to Adjoining Space:	Balanced	
Filtration (%DSE and % Arrestance):	/	G4 - minimum
Humidity (%RH):		

**General Notes:** Heating Type: Radiant Panels with TRV Remote Head Adj. Cooling: Comfort Cooled Fresh Air

LIGHTING	Requirements	Notes
Service Illumination (Lux):	300	
Service Illumination Night (Lux):		Not Applicable
Local Illumination (Lux):	1,000.0	@ Bed/Trolley 1450 AFFL
Colour Rendering Required:	Y	Colour rendering characteristics (Ra) 80
Standby Lighting Grade:	A	Lighting of the level and quality equal or nearly equal to that provided by normal lighting

**General Notes:** Control: Switch

NOISE	Requirements	Notes
Privacy Factor Required (dB):		
Mechanical Services (NR):	35	Intrusive Noise: SHTM 08-01 noise intrusion from external noise sources is not given in NR values but instead in LAeq,1hr and LAmax,1
Intrusive Noise (NR Eq):		40:daytime (LAeq,1hr)
*Acceptable Sound Level [L10dB(A)]:		
*Speech Privacy Required:	Y	
*Quality Which Cannot Be Tolerated: (* alternative format)		

**General Notes:** Refer to HLM 252 series of drawings for partition types and Acoustic Report (PCP 4.13)

SAFETY	Requirements	Notes
Hot Surface Max. Temp (DegC):	43	
Hot Water Max. Temp (DegC):	41	

**General Notes:** Maximum cold water discharge temperature (degC): 20

FIRE
Enclosure:
Automatic Detection:
Refer to HLM 572 series of drawings and Fire Strategy Report (PCP 4.12)

M1- M4	DCN Support Space
N1	DCN Out Patient Departments
P1	Combined Theatres
Q1	Combined Radiology
R1 - R2	Office / Admin Support Services
S1 - S7	Combined Facilities / Infrastructure Support Services
T1	Plant
U1	Shelled Space

Rev	By	Description	Date

**Environmental Matrix - Guidance Notes**

- 1 This workbook is prepared for the Financial Close Stage as an easier reference tool to replace ADB RDS M&E Sheets for the Environmental Criteria elements as described on these sheets.
- 2 The services matrices are produced from the Schedule of Accommodation Sheets.
- 3 The design of the HVAC systems to the theatres shall be in accordance with SHTM 03-01.
- 4 Where radiant panels are indicated in any room in these matrices, detailed design development may remove the need for these without detriment to environmental temperature. This design development is dependant on actual room layout - i.e. whether a room is located adjacent to an external wall, ground bearing floor, roof surface or is internal.
- 5 Ventilation air change rates and the use of natural ventilation in Patient Areas shall be reviewed throughout the detail design process to ensure a maximum internal temperature of 25°C (dry bulb) is not exceeded during normal occupancy. This criteria shall also apply to cellular and open plan office spaces.
- 6 Maximum internal temperatures listed relate to normal occupancy and Summer Design Conditions ; External Summer Conditions for Cooling Plant Selection as per SHTM2025.Enthalpy 54kJ/kgda.26deg°Cdb,19deg°C wb. External Winter Conditions as per CIBSE Guide A Table A 2.2 for locality = - 6°C for Heat Losses, and as SHTM 2025 for locality = -10°C for AHU Ventilation Plant design.
- 7 Examination lamp notes where listed are provisional. Detailed requirements (fixed, mobile, illumination) will be detailed on C sheets as agreed from signed off 1:50 RDS, which shall take precedence over this schedule.
- 8 All lighting levels are derived from CIBSE Lighting Guide LG2.
- 9 Colour rendering refers to CIBSE Lighting Design Guide and will be applied throughout.  
"80" : Normal  
"90" - Enhanced to provide close as possible match to natural light for clinical purposes
- 10 Thermostatic Mixing Devices - SHTM 04-01 Guidance shall be employed for specific TRV Type versus listed Area/Activity.
- 11 Standby Lighting to be Grade A throughout .
- 12 The internal temperature in naturally or mechanically ventilated rooms shall not exceed the maximum temperature as listed on these Environmental Matrices provided external summer design criteria is not exceeded .
- 13 Local Radiant Panel PICV's shall have adjustable sensors.
- 14 Local Control BMS Temperature Sensors for ducted reheat zones and chilled water cassettes for hotspots shall be provided with local range adjustment to +/- 2°C of BMS Set Point. BMS set point shall be adjustable via operator/user dialogue through formal FM
- 15 **Typical bedroom** - Design Criteria - SHTM 03-01 Clause 2.11 - internal temperatures in patient areas should not exceed 28°C db for more than 50 hrs per year. Appendix 1 SHTM 03-01 gives 18°C to 28°C float range. NHSL however require that the maximum internal design temperature should not exceed 25°C for more than 50 hrs per year.  
**HDU bed areas** - Design Criteria - HBN 57 gives specific guidance as well as SHTM 03-01 - Appendix 1 for air change rates - 10ac/hr Supply, 18°C to 25°C control range. ( Capability shall be provided but not at the summer and winter external ambient design extremes against the internal maximum and minimum range conditions ).  
The department will be comfort cooled and controlled on a zonal basis.  
Central AHU to be provided with blank section for future provision of humidification.  
**Post theatre recovery areas** - Design Criteria - SHTM 03-01 - Appendix 1 for air change rates - 15ac/hr S&E , 18°C to 25°C control range.( Capability shall be provided but not at the summer and winter external ambient design extremes against the maximum and minimum range conditions ).  
**Critical Care areas** - Design Criteria - SHTM 03-01 - Appendix 1 for air change rates - 10ac/hr Supply , 18°C to 25°C control range.( Capability shall be provided but not at the summer and winter external ambient design extremes against the maximum and minimum range conditions). NHSL may require specific rooms to have a control range up to 28°C.  
Central AHU to be provided with blank section for future provision of humidification.
- 16 **Corridor** ventilation may be either mechanical or where the opportunity exists natural. To be determined during detailed design with due regard to clinical functionality.
- 17 **Single Room WC** - SHTM 03-01 Appendix 1 suggests 3ac/hr extract air change rate only. We have applied 10ac/hr extract rate to provide a more robust rate of extract.
- 18 **Diagnostic Rooms** - ( X Ray, CT Scanner, MRI Scanners, Gamma Camera ) - air change rates listed at 8ac/hr. Actual air change rate must be derived through room heat gain analysis and actual equipment guidance.
- 19 **Operating Theatre Laminar Flow/UCV Requirements** - Refer to Operational Policy Documents for specific theatres which require Laminar Flow/UCV canopy style ventilation solution.
- 20 **Small workshop Areas** - Local Extract Ventilation (LEV) unit requirement to be determined from room equipment schedules.
- 21 **Note that Isolation Suite ventilation solutions for this project shall follow HBN 4 Supplement 1 Section 4 Item 4.8 Guidance i.e.**  
A common departmental AHU shall be employed to provide supply air ventilation ( and shall therefore employ duty & standby motors ).  
Isolation Rooms En Suite Extracts shall be provided with an independent Isolation Room toilet extract ventilation system.  
Isolation Rooms En Suite Extracts shall be provided with either externally located 3 mtr high discharge stack in a safe location or with extract filters ( H14 ) within a safe change housing outside the building on the suction side of the fan.  
Heating & Cooling Isolation Suites shall be provided via the ventilation system.
- 22 **Retail Provision** - Service provisions listed are Infrastructure only for future fit-out by retailer. ( Fire detection shall be provided to assist completion).
- 23 **Comfort Cooled Fresh Air** - Where noted as such on the matrices, this means as provided via departmental air handling plant via chilled water cooling coils.
- 24 **Body View Room** to be provided with ceiling cassette incorporating specialist refrigeration based cooling unit to reduce room temperature to 8°C minimum +/- 2°C. Room temperature will be achieved within two hours of plant operation.  
This room will have dual function capability, normally at 28°C design max temperature and when required go to 8°C for storage and viewing of body.
- 25 Anti ligature rooms (5no. off ) will be treated as sealed rooms with Supply at 6ac/hr and Extract to match to achieve a balanced pressure.
- 26 **Single Bedroom** - The design philosophy for ventilation is for a mixed mode operation where natural vent is encouraged which has benefits both physiological with users being partly in control, and from an energy stand point where mechanical vent loading is partly reduced (2/3rds). This strategy results in zero pressure differential regime within the room where supply and extract is balanced.

Room Function Reference Sheet.

The following table details reference templates which are used to populate cells within the environmental matrix. Refer to individual department sheets for individual room environmental conditions

Room Function	Temperature		Heating		Cooling Present	Cooling Type	Ventilation				Safety temperatures		Safety Notes	Lighting						Notes	Medical Location Group

### About Scottish Health Technical Memoranda

Engineering Scottish Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Scottish Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.

Healthcare providers have a duty of care to ensure that appropriate engineering governance arrangements are in place and are managed effectively. The Engineering Scottish Health Technical Memorandum series provides best practice engineering standards and policy to enable management of this duty of care.

It is not the intention within this suite of documents to repeat unnecessarily international or European standards, industry standards or UK Government legislation. Where appropriate, these will be referenced.

Healthcare-specific technical engineering guidance is a vital tool in the safe and efficient operation of healthcare facilities. Scottish Health Technical Memorandum guidance is the main source of specific healthcare-related guidance for estates and facilities professionals.

The core suite of eight subject areas provides access to guidance which:

- is more streamlined and accessible;
- encapsulates the latest standards and best practice in healthcare engineering;
- provides a structured reference for healthcare engineering.

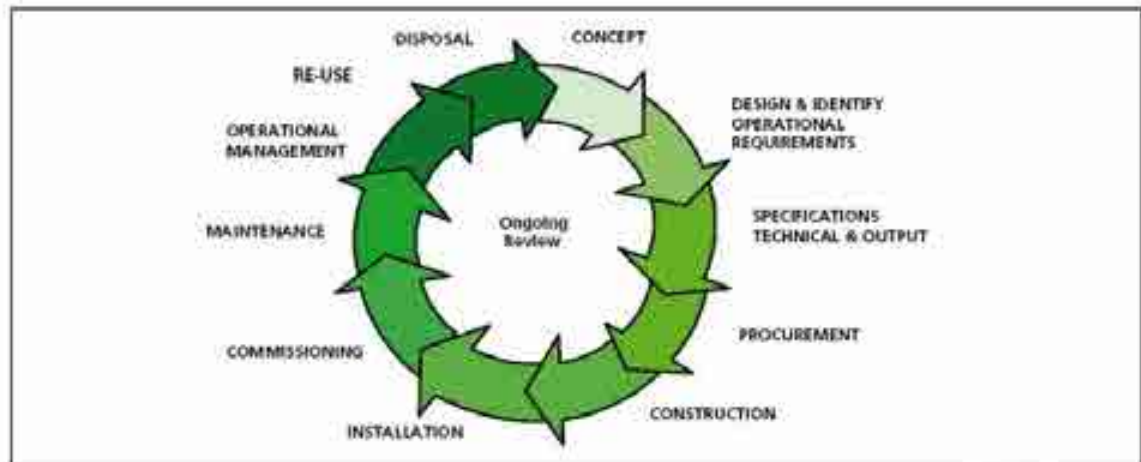

Figure 1: Healthcare building lifecycle

## Structure of the Scottish Health Technical Memorandum suite

The series of engineering-specific guidance contains a suite of eight core subjects:

Scottish Health Technical Memorandum 00 - Policies and principles (applicable to all Scottish Health Technical Memoranda in this series).

Scottish Health Technical Memorandum 01 - Decontamination.

Scottish Health Technical Memorandum 02 - Medical gases.

Scottish Health Technical Memorandum 03 - Heating and ventilation systems.

Scottish Health Technical Memorandum 04 - Water systems.

Scottish Health Technical Memorandum 05 - Reserved for future use.

Scottish Health Technical Memorandum 06 - Electrical services.

Scottish Health Technical Memorandum 07 - Environment and sustainability.

Scottish Health Technical Memorandum 08 - Specialist services.

Some subject areas may be further developed into topics shown as -01, -02 etc and further referenced into Parts A, B etc.

Example: Scottish Health Technical Memorandum 06-02 Part A will represent: Electrical Services – Electrical safety guidance for low voltage systems.

In a similar way Scottish Health Technical Memorandum 07-02 will simply represent:

Environment and Sustainability – EnCO<sub>2</sub>de.

All Scottish Health Technical Memoranda are supported by the initial document Scottish Health Technical Memorandum 00 which embraces the management and operational policies from previous documents and explores risk management issues.

Some variation in style and structure is reflected by the topic and approach of the different review working groups.

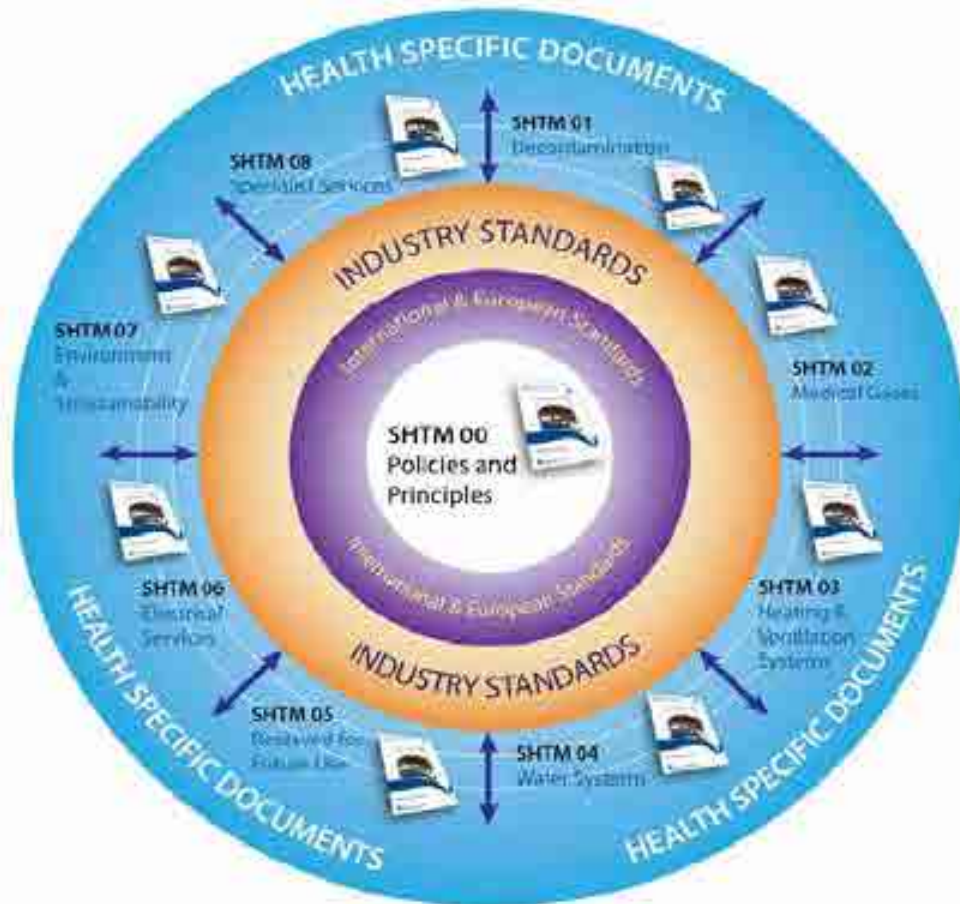

Figure 2: Engineering guidance

## 1. Introduction

---

- 1.1 Ventilation is used extensively in healthcare premises for primary patient treatment in operating departments, high dependency units and isolation facilities. It is also installed to ensure compliance with quality assurance of processed items in pharmacy and sterile supply departments and to protect staff from harmful organisms and toxic substances, for example, in laboratories.
- 1.2 This edition of Scottish Health Technical Memorandum 03 'Ventilation in healthcare premises' is published in two sections. It is equally applicable to both new and existing sites. It gives comprehensive advice and guidance to healthcare management, design engineers, estate managers and operations managers on the legal requirements, design implications, maintenance and operation of general and specialised ventilation in all types of healthcare premises.
- 1.3 Current statutory legislation requires both 'management' and 'staff' to be aware of their collective responsibility.
- 1.4 'Ventilation' is also provided in healthcare premises for the comfort of the occupants of buildings. More specialised ventilation will also provide comfort but its prime function will be to control closely the environment and air movement of the space that it serves in order to contain, control and reduce hazards to patients and staff from airborne contaminants, dust and harmful micro-organisms.
- 1.5 Ventilation systems in themselves present little danger to patients or staff. However, they do possess the ability to transmit hazards arising from other sources to large numbers of people. The danger may not become apparent until many patients and staff have been affected.
- 1.6 The sophistication of ventilation systems in healthcare premises is increasing. Patients and staff have a right to expect that it will be designed, installed, operated and maintained to standards that will enable it to fulfil its desired functions reliably and safely.
- 1.7 The Health and Safety at Work etc Act 1974 (HSW Act 1974) is the core legislation that applies to ventilation installations. As these installations are intended to prevent contamination, control closely the environment, dilute contaminants or contain hazards. Their very presence indicates that risks to health have been

### Statutory requirements

- 1.8 The Control of Substances Hazardous to Health (COSHH) regulations place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised

ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and safety cabinets.

- 1.9 The existing requirements to provide ventilation, implicit under HSW Act 1974 and COSHH, have been made explicit by the Management of Health and Safety at Work Regulations 1999, the Workplace (Health, Safety and Welfare) Regulations 1992 and the Provision and Use of Work Equipment Regulations 1998, all issued as a result of European Directives.
- 1.10 Where specialised ventilation plant is provided as part of the protection measures there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of the COSHH regulations requires that the plant be inspected and tested at least every 14 months by an independent organisation and that management maintain comprehensive records of its performance, repair and maintenance.
- 1.11 Certain substances have Occupational Exposure Limits (OEL) set out in Guidance Note EH 40 published annually by the Health and Safety Executive. If special ventilation systems are provided in order to achieve these standards they will be subject to the COSHH regulations as above.
- 1.12 All ventilation systems should conform to the principles set out in the 'Approved Code of Practice on the Prevention or Control of Legionellosis' published by the Health and Safety Commission and Scottish Health Technical Memorandum SHTM 04-01 – The control of *Legionella*, hygiene, "safe" hot water, cold water and drinking water systems.
- 1.13 Special ventilation plants installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified organisms, may be subject to particular legislation with regard to their operation in addition to that mentioned above. Further information is given by the Health and Safety Commission Health Services Advisory Committee in:
- safe working and prevention of infection in clinical laboratories;
  - safe working and prevention of infection in clinical laboratories: model rules for staff and visitors;
  - safe working and prevention of infection in clinical laboratories in the mortuary and post-mortem room.
- 1.14 Plants installed in units manufacturing medicinal products to the standards set out in the current European Guide to Good Manufacturing Practice may also be subject to particular legislation with regard to their operation in addition to that mentioned above.
- 1.15 Records should be kept of equipment design and commissioning information. The Health and Safety Executive, Medicines Inspectorate and other interested bodies have a statutory right to inspect them at any time. All records should be kept for at least five years.

- 1.16 The fire regulations require that if ventilation ductwork penetrates the fabric of a building it should be designed and installed so as to contain the spread of fire.
- 1.17 Increased health risks to patients will occur if the more specialised ventilation systems installed to supply high quality air to operating departments do not achieve and maintain the required standards. The link between post-operative infection and theatre air quality has been well established. Plants serving conventional operating departments, for instance, will be required to ensure the separation of areas within the suite by maintaining a specific direction of air flow between rooms, even when doors are opened. They will also maintain the selected operating department environmental conditions regardless of changes in the outside air conditions or activities within the space. In addition ultra-clean operating ventilation systems that are designed to provide an effectively particle-free zone around the patient while the operation is in progress, have been shown to reduce significantly post-operative infection in patients undergoing deep wound surgery. Their use for other forms of surgery may well be indicated.
- 1.18 Ventilation systems that can be shown to be inappropriate, inadequate or ineffective and that give rise to proven failures can result in a civil suit by the patient against the operators.
- 1.19 If the plant has been installed to dilute, extract or contain harmful substances, its failure may expose people to unacceptable levels of hazard. Proven failures can give rise to a civil suit against the designers and operators by the individuals who have been affected. This would be in addition to the actions brought as a result of breaching the statutory requirements.
- 1.20 There is a statutory requirement to provide ventilation in all enclosed workspaces. It may be provided by either natural or mechanical means. The following are some of the factors that determine the ventilation requirements of a workspace:
- human habitation (minimum fresh air requirement);
  - the activities of the department, that is, extraction of odours, aerosols, gases, vapours, fumes and dust – some of which may be toxic, infectious, corrosive, flammable, or otherwise hazardous (see Control of Substances Hazardous to Health (COSHH) regulations);
  - dilution and control of airborne pathogenic material;
  - thermal comfort;
  - the removal of heat generated by equipment (e.g. catering, wash-up, sterilising areas, electrical switch rooms, Uninterruptible Power Supply (UPS) cupboards and some laboratory areas);
  - the reduction of the effects of solar heat gains where other forms of reducing the solar effect is not available or practical, i.e. solar blinds;
  - the reduction of excessive moisture levels to prevent condensation (for example Hydrotherapy pools);

- combustion requirements for fuel burning appliances (see BS5376, BS5410 and BS5440);
- 'make-up' supply air where local exhaust ventilation (LEV) etc., is installed.

Mechanical ventilation systems are expensive in terms of capital and running costs, and planning solutions should be sought which take advantage of natural ventilation either where the use of the area in question is not critical to airflow patterns or pressures, or where backup systems are available when natural ventilation cannot be achieved.

- 1.21 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure.

Requirement	Reason	Application
Statutory	Health and Safety at Work etc Act	Operating department Laboratories Pharmacy
	COSHH regulations	Areas containing identified biological or chemical hazards Areas containing oxygen displacing gases
	Local Exhaust Ventilation (LEV)	Enclosed work-spaces Workshops
Functional	Comfort	Situations where the quality of the environment for staff and patients is critical to their general performance and well-being
Clinical	Post-operative infection reduction	Operating suites used for general surgery, casualty, obstetrics/gynaecological and maternity procedures
	Reduction of deep wound sepsis	Ultra-clean operating suites for transplant, deep wound surgery, hip replacement, bone grafting and bone marrow transplant procedures
	Isolation from contact with bio hazards	Isolation units for patients who present a biological, chemical or radiation hazard to others. Isolation units for patients with a reduced immune system

Table 1: Reasons for providing ventilation

### Functional overview – Terms in use

- 1.22 The terms 'ventilation' and 'air-conditioning' are often incorrectly used to describe the same equipment. A general explanation of the terms is given below:

## Ventilation

- 1.23 Ventilation is a means of removing and replacing the air in a space. In its simplest form this may be achieved by opening windows and doors. Mechanical ventilation systems provide a more controllable method. Basic systems consist of a fan and either collection, (extraction) or distribution (supply) ductwork. More complex systems may include the ability to heat and filter the air passing through them. Ventilating equipment may be required in order to remove smells, dilute contaminants and ensure that a supply of 'fresh' air enters a space.

## Air-conditioning and mechanical cooling

- 1.24 Air-conditioning is the ability to heat, cool, dehumidify and filter air. For full air-conditioning, humidification may also be provided. This means that the climate within a space being supplied by an air-conditioning plant can be maintained at a specific level regardless of changes in the outside air conditions or the activities within the space. Mechanical cooling may be provided where close control of 'comfort conditions' within a space is required but humidity control is not needed.

## Special ventilation

- 1.25 In healthcare premises, certain activities will necessitate the provision of ventilation equipment with additional special features in order to achieve and maintain specific conditions. These may be needed in order to assist with the treatment of patients or maintain the health and safety of staff. The precise reason for providing special ventilation will depend upon the intended application. The list below indicates some of the more typical reasons:
- to remove, contain or dilute specific contaminants and fumes;
  - to ensure the isolation of one space from another;
  - to preserve a desired air flow path from a 'clean' to a 'less clean' area;
  - to provide control of the cleanliness of a space;
  - to provide 'close' control of temperature;
  - to provide 'close' control of humidity.
- 1.26 The following departments will usually have specialised ventilation requirements, either for a single room or throughout a suite of rooms:
- operating department;
  - laser surgery unit;
  - intensive treatment unit;
  - infectious diseases isolation unit;
  - manufacturing pharmacy;
  - specialised imaging, X-ray and scanning unit;

- pathology containment laboratories;
- mortuary and dissection suite;
- research laboratory;
- sterilising and disinfecting unit (SDU);
- endoscopy unit;
- renal dialysis suite;
- ultrasound facilities;
- audiology room.

1.27 Ventilation may be provided in a wide variety of ways. These will include:

- extensive purpose-built air-conditioning units housed in their own plant rooms;
- proprietary 'packaged' systems often sited outside on a roof or;
- wall-mounted electric fans located at the point of use.

1.28 A fixed volume of air may be supplied, often expressed in terms of the resulting number of air changes per hour (ac/h) within the space being ventilated. It may also be expressed in terms of litres/second/person. Alternatively the volume of air supplied may be varied in order to maintain a specific pressure relationship between the area supplied and other surrounding areas. In some situations a combination of both methods may be adopted.

1.29 Modern plants are fitted with the means to recover energy from the extract air where this can be justified without causing contamination of the incoming supply air.

1.30 Ultra-clean systems use the same basic plant and equipment as standard air-conditioning but are in addition fitted with a terminal device that supplies the air in a unidirectional manner to the working area. Their standard of filtration will be capable of delivering air with a very low particle count to the space that they serve.

### Local exhaust ventilation

1.31 Local exhaust ventilation (LEV) is a term used to describe systems installed to prevent hazardous substances from entering the general atmosphere of the room in which they are being used. Their primary function is to protect staff from the effects of their work activity.

1.32 Simple LEV systems comprise a capture hood, extract ductwork and fan. These are used to contain industrial types of hazard such as fumes from welding processes, gas discharges from standby battery banks and dust from woodworking machinery. The vapour given off when large quantities of chemicals are decanted into ready-use containers and fumes from X-ray film processing units are further examples of chemical hazards often controlled by LEV systems.

- 1.33 In laboratories, pharmaceutical manufacturing facilities and operating suites, LEV systems usually take the form of semi-open fronted cabinets within which the hazardous substance is manipulated. These cabinets either have their own filtered air supply or are fed with air from the room. The air extracted from the cabinet is passed through a high-efficiency filter before being discharged either to the atmosphere or back into the room. Microbiological safety cabinets, laboratory fume cupboards, cytotoxic drug cabinets and fixed or mobile disinfection enclosures are all examples of this type of facility.
- 1.34 Mortuaries and dissection suites may have LEV systems incorporated within the dissection table, specimen bench and bone saw.

### Management action

- 1.35 The guidance contained in this SHTM should be applied in full to new installations and major refurbishments of existing installations.
- 1.36 Ventilation will need to be provided:
- as a requirement for patient care;
  - in order to fulfil a statutory duty.
- 1.37 In assessing the need for more specialised ventilation and the standards desired for patient care, managers will need to be guided by their medical colleagues and by information published by Health Facilities Scotland.
- 1.38 The statutory need for ventilation falls into two categories:
- in the first, the need for specialised ventilation and the standards to be adopted are clearly set out in specific pieces of legislation. An excellent example of this is the current legislation surrounding the manufacture of medicinal products in the European Community. The managers of the departments affected by this type of legislative requirement should be aware of their needs and be able to advise on the standards to be achieved;
  - the second type of statutory requirement arises due to the interpretation of both the Health and Safety at Work etc Act and the Control of Substances Hazardous to Health (COSHH) regulations. The person tasked with conducting COSHH assessments will be able to advise as to the need for, and standard of, ventilation in each particular case.

### Design and validation process

- 1.39 It is essential when undertaking the design of a specialised ventilation system that the project be considered as a whole. The process model set out below should ensure that all relevant factors are considered.

Step	Question	Design statement and information required	Comment
1	Why is the system required?	Healthcare applications Statutory elements Non-healthcare applications	
2	What is the required system performance?	Room air flow pattern Air change rate Differential pressures Air quality Room air condition Noise limits	
3	What are the constraints on the distribution system?	Location, Size, Materials Dampers, Access, Insulation Fire considerations Room terminals	
4	What are the minimum requirements for the AHU(s)?	Intake / Discharge positions <i>Legionella</i> , Health and Safety Access, Fire, Electrical safety Leaks, Insulation, Cleanliness Filtration, Drainage	
5	What control functions are required?	User control requirements Estates control functions Energy management Environmental conditions Control sequence logic Run, Set back, Off philosophy	
6	How will the system performance be validated?	Validation methodology Instruments used Design information required <i>[Design air flow rates Design air velocities Pressure differentials Noise levels Air quality Installation standard]</i>	
7	The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.		
8	Handover to client	Basic design information Commissioning results Validation report	

Table 2: Design and Validation process model

## Use and function of typical equipment used in ventilation plant

- 1.40 Typical equipment used in ventilation systems is listed below together with a brief description of both function and use.

### General

- 1.41 The equipment built into the ventilation system and its ductwork should be of a type that will neither cause nor sustain combustion. No materials that could sustain biological activity should be used in the construction or assembly of the system.

### Air Intake

- 1.42 An uncontaminated air supply to the system is essential. In order to achieve this, the air intake will be positioned so that air discharged from extract systems or other dubious sources cannot be drawn in. Exhaust fumes from vehicles can present particular problems. The area surrounding the intake will need to be kept clean and free of vegetation and waste material in order to reduce the possibility of biohazards or fire. The intake itself will be protected by a louvre and mesh screen to prevent rainwater, vermin and insects etc from entering the system.

### Damper

- 1.43 Several types may be fitted:
- automatic dampers fitted immediately behind the air intake and extract louvres. They will automatically close when the system is shut down in order to prevent an uncontrolled circulation of air;
  - balancing dampers are fitted into each branch of the air distribution ductwork system so that the design air flow rate can be set during the commissioning process;
  - where ductwork passes through a fire compartment wall, ceiling or floor a fire and/or smoke damper may be required;
  - plant isolating dampers are fitted so that the main plant can be isolated from its air distribution duct system. They are manually operated and enable cleaning and maintenance of the air-conditioning equipment to be carried out.

### Ducting

- 1.44 The means by which air is conveyed from the intake to its point of use. Ducting is usually constructed of galvanised steel and will normally be insulated to reduce noise and conserve energy. Ducts can also be formed in concrete, brickwork, stainless steel or plastic and may be rigid or flexible.

## Fan

- 1.45 A series of rotating blades that move the air in the direction required. Fans are usually powered by electric motors either directly connected to them or driven through belts and pulleys. A fan may be arranged either to force air into or draw air from a ductwork system.

## Attenuator / silencer

- 1.46 A device that will contain and absorb the noise emitted by a fan. They may be required to reduce disturbance caused by noise breaking out through the air intake and also noise transmitted along the ductwork to the conditioned space.

## Filter

- 1.47 A filter consists of a labyrinth of fibrous material contained in a frame. It is designed to capture and hold particles being carried in the airstream. Because of the size range and number of particles that exist in air no filter can remove them all. The purpose of filtration is to reduce their number and size range to an acceptable level. Filters of progressively higher grades are fitted through the ventilation system:

- primary filters (coarse) are designed to collect the larger particles and are intended to keep the air-conditioning plant clean;
- secondary filters (fine) will remove the staining particles from air and keep the conditioned space visibly clean;
- high efficiency particulate air filters (HEPA/absolute) will remove virtually all particles from air. These may be required in order to reduce contamination in the working area either biologically or in terms of particle count.

Filters may be fitted to extract systems to protect energy recovery devices. They may also be fitted to remove biological, radiation or chemical hazards and if so, are often contained in a 'safe change' facility in order to protect those carrying out maintenance.

Activated carbon filters will reduce odours in extracted or recirculated air.

## Heater battery / heater coils

- 1.48 A series of heater batteries or heating coils with or without fins through which steam or hot water is circulated. Heat is given up to the air passing over the battery thus increasing its temperature. Heating is usually carried out in stages, the final battery being controlled by the end user. Small batteries may be electric.

## Humidifier

- 1.49 A device for increasing the humidity of air by adding moisture. For ventilation in healthcare premises this is normally achieved by releasing 'clean' steam into an

air supply duct. The steam will be completely absorbed into the air, increasing its humidity. The level of humidity may be preset or controlled by the end user.

#### Cooler battery / cooling coil

- 1.50 A series of finned coils mounted in the air supply duct. Either chilled water or refrigerant is circulated through the coils causing heat to be removed from the air. This will reduce its temperature and may also condense moisture out of the air. As free moisture in a duct can be a source of contamination the coil will be fitted with an eliminator and drainage system.

#### Eliminator

- 1.51 A device for catching and removing water droplets from an air stream. It may form part of a cooling coil or be a separate device.

#### Drainage system

- 1.52 A means of removing water from ductwork and disposing of it safely. Typically it will consist of a tray mounted in the duct to catch moisture, a glass water seal trap, continuously falling drainage pipework and an air break in the drain run to prevent waste water returning and contaminating the duct.

#### Access doors and observation ports

- 1.53 Doors and removable panels providing access for routine maintenance and cleaning. The doors should be fitted with glazed ports and suitable lighting provided so that the correct operation of devices such as cooling coils, humidifiers and filters can be easily observed without needing to switch off the plant.

#### Energy recovery

- 1.54 Many plants are fitted with the means to recover energy from the extract air without causing contamination of the incoming supply air. These devices will be fitted with a drainage system and may incorporate an eliminator. Several types of energy recovery systems are available.
- 1.55 Precise definitions of ventilation and air-conditioning terms are given in the CIBSE Guide B.

#### Typical plant

- 1.56 The layout of a typical plant that conforms to the requirements for healthcare applications is shown in Figure 3 below. It contains most of the equipment described above.

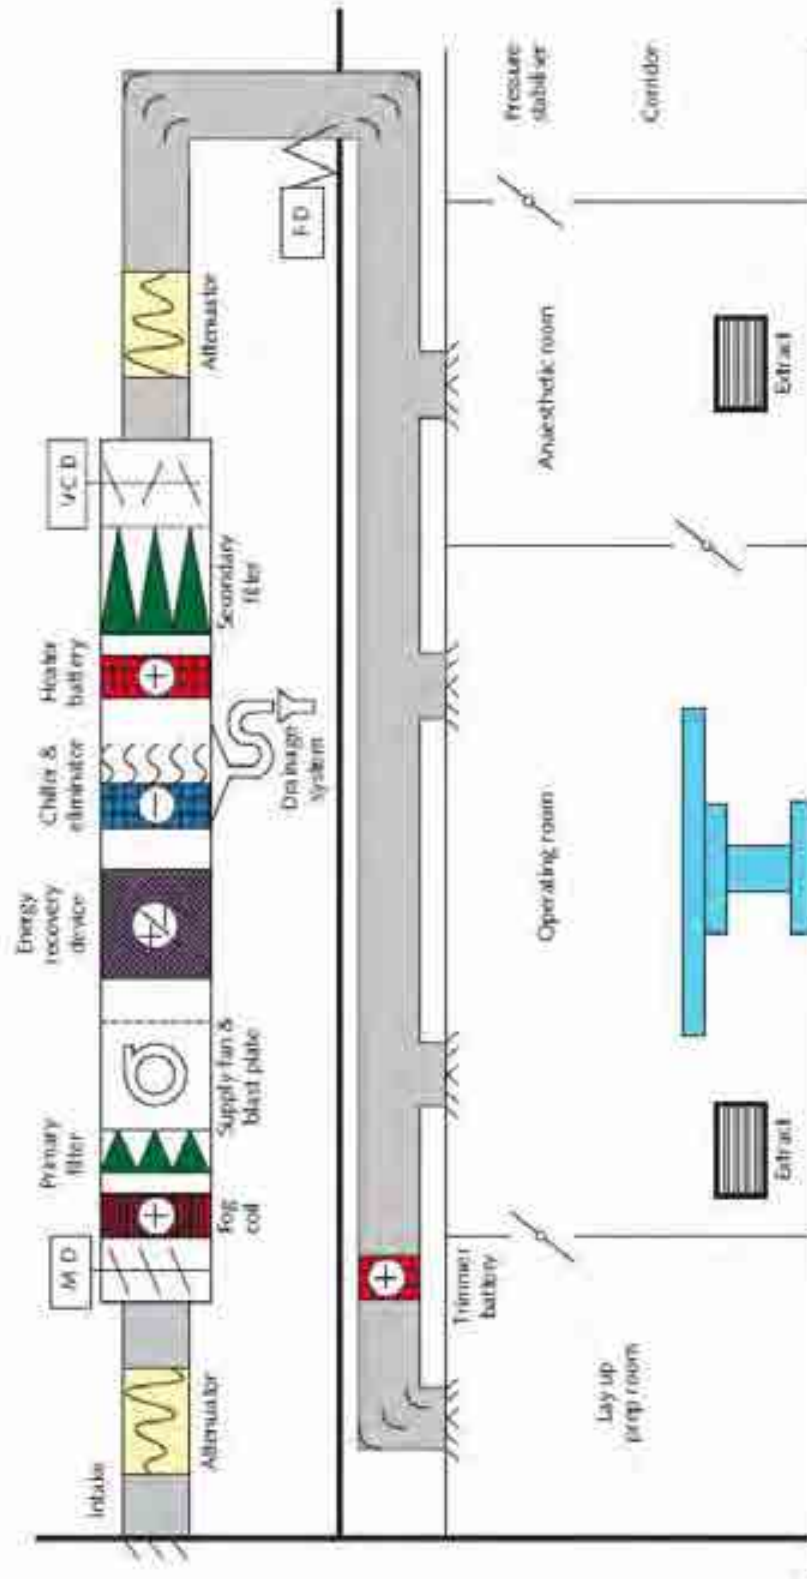

Figure 3: Design and Validation process model

## 2. Provision of ventilation in healthcare buildings

- 2.1 It is acknowledged that planning constraints imposed by the building shape and/or functional relationships of specific areas will invariably result in some measure of deep planning thus reducing the opportunity for natural ventilation. However, ventilation costs can be minimised by ensuring that where practicable, core areas are reserved for rooms that have a functional requirement for mechanical ventilation. Examples are sanitary facilities, dirty utilities and those rooms where clinical or functional requirements have specific environmental needs; and where for reasons of privacy, absence of solar gain etc., windowless accommodation is acceptable. Other spaces appropriate to core areas are those that have only transient occupation and therefore require little or no mechanical ventilation, for example circulation and storage areas.

### Natural ventilation

- 2.2 Natural ventilation is usually created by the effects of wind pressure. It will also occur if there is a temperature difference between the inside and the outside of the building. The thermo-convective effect frequently predominates when the wind speed is low and will be enhanced if there is a difference in height between inlet and outlet openings. Ventilation induced by wind pressures can induce high air change rates through a building provided air is allowed to move freely within the space from the windward to the leeward side.
- 2.3 As the motivating influences of natural ventilation are variable, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. This variability is normally acceptable for general areas including office accommodation, general wards, staff areas, libraries rooms, dining rooms and similar areas which should, where possible, be provided with opening windows of a design that facilitates natural ventilation.
- 2.4 Current guidance restricts the amount windows can be opened for safety reasons and as many designs are top-hung, their ability to permit natural ventilation is limited. It may therefore be necessary to provide dedicated ventilation openings in the fabric of the building to allow a sufficient natural flow of air into and out of the space. Paragraph 2.20 also refers.
- 2.5 In all cases, excessive heat gain, indoor air quality requirements or external noise may limit or preclude the use of natural ventilation.

### Extract ventilation systems

- 2.6 Separate extract ventilation will be required for sanitary facilities, lavage areas, dirty utilities and in rooms where odorous, but non-toxic fumes are likely, in order to ensure air movement into the space. 10 air changes per hour have been found necessary, particularly in geriatric and psycho geriatric

accommodation. This will assist with control of infection procedures. A single fan/motor unit can be suitable for individual rooms, but multi-room systems should be provided with duty and standby fans or motors to meet this need.

- 2.7 Toilets should have an extract rate as set out in the building regulations. Where WC's are located in shower and bathroom spaces, the ventilation required for the WC will normally be adequate for the whole space.

### Supply only ventilation

- 2.8 Mechanical supply ventilation will be required in areas where it is important to maintain a positive pressure in order to prevent the ingress of less clean air, e.g. in pharmacy aseptic suites, sterile supply packing rooms, operating theatres and their preparation rooms (air change rates are given in Table A1 within Appendix 1).

### Supply and extract ventilation

- 2.9 Mechanical supply and extract ventilation should be provided in rooms where there is a need to control room pressure in relation to adjacent spaces. ICU, isolation suites and treatment areas are typical applications.

### Mechanical or comfort cooling

- 2.10 Cooling is very expensive in terms of energy costs and should be provided only where necessary to maintain a comfortable environment for staff and patient, or to ensure satisfactory operation of equipment. The imaging department in particular may require cooling to offset the equipment load.
- 2.11 Calculations and thermal modelling should be undertaken to ensure that during the summertime, internal temperatures in patient areas do not exceed 28°C (dry bulb) for more than 50 hours per year taking into account the level of design risk for the application.
- 2.12 Certain non-patient areas may also require cooling and will typically include some laboratories, central wash-up and other areas that are subject to high equipment heat gains.
- 2.13 Where deep planning of other continuously occupied spaces, for example offices, is unavoidable, there will also be occasions when acceptable levels of comfort can only be maintained by cooling. Planning solutions of this type however will be exceptional.
- 2.14 Refrigeration plant should be of sufficient capacity to offset heat gains and maintain areas at a temperature that does not exceed the external design shade temperatures by more than about 3°C taking into account the level of design risk for the application.

## Air-conditioning

- 2.15 Full air-conditioning is only required in a very small number of areas within healthcare buildings and due to the capital and running cost its inclusion should be kept to a minimum. Paragraphs 3.14, 3.15 and 4.91-4.93 also refer.
- 2.16 Areas whose functions may warrant the installation of air-conditioning include operating departments, intensive therapy units, manufacturing pharmacies and areas with particularly sensitive equipment.

## Specialised ventilation

- 2.17 Due to the nature and extent of activities carried out in healthcare buildings, there will be a need for a wide range of specialised ventilation systems. The types of system which are generally required in individual departments and typical arrangements are given in Section 7.
- 2.18 The activities within some departments will require the provision of local exhaust ventilation (LEV). This is a statutory requirement under COSHH wherever the escape of chemicals, toxic fumes, biological material or quantities of dust into the general area would present a hazard to the occupants.

## Ventilation for general areas

- 2.19 Table A1 in Appendix 1 provides recommended air change rates, temperatures and pressures for general areas that require mechanical ventilation in healthcare buildings.

## Use of natural ventilation

- 2.20 The air tightness of new buildings has improved to the point that infiltration through building leakage can no longer be relied upon to provide sufficient air-flow. Attention must therefore be given to the provision of purpose made ventilation openings to achieve the necessary flow rates. The air entering the openings may need to be controlled by motorised dampers linked to temperature and / or occupancy sensors in the ventilated space.
- 2.21 Internal partitions, fire compartment walls and closed doorways can often impede the flow path, and when this happens, the process will be more dependent on single-sided ventilation. Nevertheless, even with this degree of compartmentation, acceptable ventilation may still be achieved without window openings that would prejudice safety, security or comfort.
- 2.22 Some types of window, for example, vertical sliding, can enhance single sided air change by temperature difference, and these will improve the overall rate of natural ventilation in protected or sheltered areas where the effect of wind pressure is likely to be minimal.

- 2.23 It is generally considered that natural cross-flow ventilation is able to give reasonable air distribution for a distance of up to 6 metres inwards from the external facade, provided that reasonably clear air paths are maintained. Beyond this distance in areas where clear air paths cannot be maintained and in areas where high minimum air change rates are specified, mechanical ventilation should be provided.
- 2.24 Further information can be found in SHTM 55 'Windows', BS5925 'Code of practice for ventilation principles and designing for natural ventilation' and CIBSE Applications Manual AM10: 'Natural ventilation in non-domestic buildings'.

### Mixed mode ventilation

- 2.25 This comprises an assisted form of natural ventilation. Fans are fitted in the purpose made damper-controlled ventilation openings. Alternatively a separate ventilation unit may be installed. In both cases the dampers and fans are controlled under the dictates of temperature and occupancy sensors to ensure a minimum air flow rate while taking advantage of natural ventilation effects when present.
- 2.26 Where natural or mixed mode ventilation is adopted with complex air paths, the designer should produce an air flow diagram in order to ensure correct provision of air transfer devices. CIBSE Applications Manual AM13: 'Mixed mode ventilation in non-domestic buildings' gives guidance.

### Mechanical extract ventilation

- 2.27 General extract systems can vary in complexity from a single wall-mounted fan to a ducted air system with dual extract fans.
- 2.28 Replacement air is generally provided by a central supply system (as described below). Unless special precautions are taken, the latter may result in an unacceptable level of draughts occurring in winter, and possible risk of unacceptable levels of noise transmission.
- 2.29 If individual systems are used, the ventilation can be operated intermittently, provided it continues to run for at least 15 minutes after the room is vacated, as with light switch-operated fans in individual toilets.
- 2.30 If general exhaust systems are used; it is recommended that filtered and tempered replacement air is provided via a central supply plant to adjoining lobbies or corridors, to prevent the risk of discomfort caused by the ingress of cold air. Fire compartmentation requirements must be maintained.
- 2.31 Information on specialised extract systems is given in Section 7.

## Mechanical supply systems

- 2.32 Where mechanical supply systems are required, the fresh air should be tempered and filtered before being delivered to the space, to avoid discomfort.
- 2.33 The air should be heated using a constant or variable temperature source, but generally only to the space air temperature. In most instances, the low-pressure hot water heating (LPHW) should offset any fabric loss, so that setback room temperatures can be maintained during unoccupied periods without the need for the ventilation system to operate.

## Balanced ventilation

- 2.34 Balanced ventilation systems are merely a combination of a supply and extract systems of equal volume; and either a single space or a whole building may be considered to be balanced. A balanced system is necessary in instances where it is essential to maintain consistent air movement within an area, for example, treatment rooms.

## Cascade ventilation

- 2.35 In operating departments it is normal practice to supply air to the operating room, and allow it to pass through less clean areas – corridors, utility rooms etc. (from where it is eventually extracted).

## Recirculation systems

- 2.36 Due to the nature of the use of mechanical ventilation systems within healthcare buildings, there are few opportunities for the application of recirculation air systems. They are however normally used for HEPA filtered clean room applications where the extract air is significantly cleaner than the outside supply. Recirculation is also routinely used in the canopy section of Ultra Clean Operating theatre ventilation systems.
- 2.37 Where the designer is considering the installation of a recirculation air system, due account must be taken of:
- minimum fresh air supply volume required by the Building Regulations (currently 20%);
  - prevention of contamination of supply air from vitiated air in extract systems;
  - prevention of stratification occurring within plenum chambers and mixing boxes which may result in freezing of downstream coils;
  - ensuring sufficient velocities through control dampers (ideally 5-6 m/s) to provide suitable authority; and good shut-off;
  - modulating control of mixing to provide optimum on-plant conditions;

- use of 'free cooling' by cycling the dampers to minimum fresh air when the enthalpy of the outside air is above that of the extract air under conditions when cooling is required.

### Chilled beams

- 2.38 The use of chilled beams for the provision of heating, cooling and ventilation is increasingly common in healthcare premises. The use of Active Chilled Beams providing tempered filtered air to a heating / cooling device within the room can provide effective local control of environmental conditions.
- 2.39 Care should be taken in positioning chilled beams to ensure the avoidance of cold draughts particularly when used in the cooling mode. The control settings should ensure that the external elements of the beam are always above dewpoint.
- 2.40 Consideration should be given to the ease with which specific types of chilled beam units can be accessed for cleaning having regard to the need to control the infection risk. The impact of maintenance requirements on room availability should also be considered.

### Split comfort air-conditioners

- 2.41 Split comfort air-conditioners, room conditioners or cassette units are used increasingly where there is a small local requirement for cooling for operational purposes. They can provide an effective economic solution to cooling needs, where a central refrigeration system is not practicable.
- 2.42 The units re-circulate room air so provision for a fresh air make up, either by natural or mechanical means, to the standard required by the Building Regulations must be provided.
- 2.43 The recirculation of room air presents problems with indoor air quality (IAQ) and may increase the risk of healthcare associated infection (HAI). Split units should not therefore be used in critical patient areas.
- 2.44 Split units may be used for single room applications or as multiple linked units that can independently provide either heating or cooling, all served by a single outdoor unit. These systems enable good temperature control of a number of rooms with maximum energy efficiency.
- 2.45 Whether single or multiple systems are used, it is essential that the designer gives due consideration to the source of electrical supply, location of the heat rejection unit, environmental effects to the refrigerant used and drainage provision for the cooling coil condensate.
- 2.46 The units will require routine maintenance for filter change and cleaning; they should therefore be installed in an accessible position.

## Dilution ventilation and clean air flow paths

- 2.47 Dilution ventilation has in the past been used to control levels of hazardous substances in a space. This approach is no longer considered acceptable. The COSHH Regulations require that known hazardous substances should be substituted by safe alternatives. If this is not possible then they should be controlled at source by the use of closed systems such as anaesthetic gas scavenging units or exhaust protective enclosures such as fume cupboards.
- 2.48 The exposure of staff to casual spillages of substances such as medical gases in anaesthetic rooms should in the first instance be dealt with by establishing a clean airflow path. Air should be supplied at high level and extracted at low level directly behind the anaesthetic equipment position. The philosophy of establishing a clean air-flow path from the supply point, to the staff; on to the patient and out via a low level extract would also apply in recovery rooms and maternity delivery rooms including labour, delivery, recovery & post partum (LDRP) Rooms. A suitable air change rate will provide dilution ventilation as an additional safeguard; see Table A1 in Appendix 1 and Table A2 in Appendix 2, Note c.
- 2.49 In operating theatres the patient will be on a closed breathing circuit in a room with a high air change rate. Under these circumstances the dilution effect would be considered sufficient to control any casual exposure to anaesthetic gases.

## Mechanical ventilation systems

### System selection

- 2.50 Natural ventilation is always the preferred solution for a space, provided that the quantity and quality of air required, and the consistency of control of ventilation to suit the requirements of the space, are achievable with this method. If this is not the case, a mechanical ventilation system will be required.

### Choice of central/local plant

- 2.51 Mechanical ventilation is expensive to operate, and as such, should be controlled to operate when the space being served requires to be ventilated. In addition, loads on refrigeration plant are rarely constant owing to changes in solar gain, occupancy and use of heat-generating equipment and lights, therefore control of temperature is critical.
- 2.53 If the ventilation loads throughout a department or building are in phase, or are not significant, a central plant with single zone control can be adopted. However, this is rarely the case, and elsewhere, the condition or quantity of supply air to different areas or zones of the building must be varied accordingly. This can be done by providing either individual plants to each zone, or separate zone terminal control. Where there is a high density of rooms with similar ventilation requirements in an area of a building or department, it is usually economical to combine them into a central system.

- 2.54 In large buildings, a choice between a single distribution system and multiple smaller systems may arise. Large distribution systems and their plant can have the advantage of lower operating costs, but require more space for vertical shafts. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage, and difficulties in balancing during commissioning. As the pressure losses in the long runs will be greater and a higher initial static pressure will be required, this will lead to a more expensive class of ductwork. Multiple smaller distribution systems may be more expensive in capital and operating costs but they avoid long runs, large ducts and vertical shafts, and this may reduce overall building costs. They also provide a more robust service as the failure of an individual system does not prevent the use of the rest of the building.

### Zoning of the building

- 2.55 The efficiency and effectiveness of any ventilation or air-conditioning installation depends largely on the zoning and control of the installation. The factors to consider when determining the zoning of a ventilation system for a building or department are:
- periods of occupancy;
  - fresh air/ventilation requirements;
  - smoke control.
- 2.56 Where the ventilation system is not merely tempering the air, but also providing the heating and/or cooling requirements, the following additional factors will need to be considered:
- internal or peripheral location;
  - orientation of windows;
  - variation in internal loads;
  - level of control required.
- 2.57 For single zone plant in staff areas, local control (with a run-on timer if required) is recommended, as this can be turned off when the space is not in use, thus saving both thermal and electrical energy. Most supply and extract systems, conversely, are required to operate continuously while the department is occupied, thus some form of time or use control is necessary.
- 2.58 The control of individual plant items is covered in Section 4, with examples of typical control strategies in Section 6. For control of particular specialised ventilation and air-conditioning systems refer to Section 7 of this document.
- 2.59 On very rare occasions a duplicate standby air handling plant may be justified. If installed it must be provided with a gas-tight damper at its junction with the supply distribution duct, so that no back-flow can occur. Standby plants can become sources of contamination if warm moist air is allowed to dwell within them. Their design and control system must ensure that this cannot happen.

## Specific requirements for hospital departments

- 2.60 Specific requirements for individual spaces and departments are included in the Health Building Notes (HBNs) and Activity Database (ADB) A-Sheets, or Scottish Health Planning Notes (SHPNs).

Draft for consultation

## 3. Assessment of service requirement

---

### Selection of design criteria

#### External design conditions

- 3.1 The most accurate data that is available for the summer and winter conditions at the site should be used. The Metrological office can supply data for the United Kingdom.
- 3.2 Healthcare mechanical ventilation systems will normally be 'full fresh air'.
- 3.3 Local adjustments such as for height above sea level, exposure factor, or other climate peculiarities, should be made as appropriate.

#### Internal design conditions

- 3.4 The design conditions selected within patient areas must strike a balance between the comfort requirements of staff and patients, who often have very different levels of clothing and activity.
- 3.5 Recommendations for the dry resultant temperature and humidity of individual spaces are shown on Activity Database (ADB) A-Sheets. Appendix 1 Table A1 gives a summary.

#### Minimum fresh air requirements

- 3.6 For most applications involving human occupancy, the dilution of body odours is the critical factor in determining ventilation requirements. Where natural ventilation or mechanical full fresh-air systems are used, all ventilation air will be fresh.
- 3.7 Where odour dilution is the overriding factor, it is recommended that 10 litres/second/person should be taken as the minimum ventilation rate.
- 3.8 Smoking is not permitted in healthcare premises. If permitted for example in residential care, it will be confined to designated areas. It therefore follows that these areas will contain a high percentage of smokers so the ventilation rate would be at least 36 litres/second/person for these applications (CIBSE Guide A; Table 1.10 refers).
- 3.9 In non-standard applications such as laboratories, aseptic suites, operating departments, etc., the particular requirements for each area should be considered independently in order to determine the overriding minimum requirement for ventilation.

### Limiting supply air conditions

- 3.10 For most applications in healthcare buildings, it is the temperature differential between the supply and room air, rather than the actual temperature of the supply air which is the critical factor. The maximum recommended supply-to-room air temperature differential is:

summer cooling: - 7K

winter heating: + 10K

- 3.11 It is also necessary to keep supply air humidity below 70% during winter in order to minimise risks associated with condensation.

### Air purity

- 3.12 In healthcare premises, the standard of filtration will depend on the activities within the occupied spaces. With the exception of special areas, (for example manufacturing pharmacies), the requirement for aerobiological needs is not stringent and filtration is only required to:

- maintain hygienic conditions for the health and welfare of occupants, or for processes such as food preparation;
- protect finishes, fabrics and furnishings; to reduce redecoration costs;
- protect equipment either within the supply air system, that is, to prevent blocking of coils, or in the space itself to prevent dust collection.

- 3.13 Given that almost all viable particles will originate from the occupants of a space and not from the incoming air, dilution is the more important factor aerobiologically. Therefore, for general areas a G4 filter will be suitable. More critical areas will require a F7 filter. HEPA filters will only be required in Ultra Clean systems.

### Humidity control requirements

- 3.14 Providing humidification is expensive in terms of plant, running costs and maintenance, and therefore its use should be restricted to where it is necessary for physiological or operational reasons.
- 3.15 Humidification was originally required for some healthcare applications e.g. operating theatres, in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.

### Maximum noise levels

- 3.16 Noise will be generated in an air distribution system by the fan, ductwork fittings, dampers and grilles. The specified maximum noise level will depend on the activities within the occupied spaces.
- 3.17 The overall noise levels should not exceed the values given in Scottish Health Technical Memorandum 08-01 – 'Acoustics', although general requirements are given in Table 3.
- 3.18 Attenuation should be incorporated into the ductwork system or plant arrangement as necessary to reduce noise from fans and plant items in order to achieve the acceptable limits within the rooms at the design air flows.
- 3.19 Plant noise should not be greater than 80dB(A) within the plant room from the fans, coolers, heaters, humidifiers etc. when starting up or running, and should be reduced to lower noise levels where the plant is near to departments sensitive to noise.
- 3.20 Attention must be given to the reduction of tonal components. High tonal components from air diffusers etc. can seriously disturb concentration over longer periods even when the overall noise level is low. Broadband noise causes less annoyance. Reference should be made to SHTM 08-01 - 'Acoustics'.
- 3.21 The designer requires knowledge of the total hospital layout and operational policies, to assign acceptance magnitudes to all the possible noise sources, in order to arrive at the correct rating.

Room	Overall noise level - NR	Ventilation plant commissioning - NR	Ventilation plant design - NR
Operating department	50 (55)	45	40
Ward areas	33	30	30
Sanitary facilities	45	40	35
Industrial areas	50	45	40
Circulation areas	50	45	40

Table 3: Interior noise level

- 3.22 In Table 3 the overall noise level takes account of all internal and external noise sources. The commissioning noise level is the level measured with a sound level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use, this commissioning level will constitute a continuous background noise which will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise that must be considered in the overall design, that is, in specifying the attenuation of walls, partitions, ceilings, etc.

- 3.23 The recommended criterion is measured as the "A" weighted sound pressure level expressed in decibels, which should not be exceeded for more than 10% of the time.
- 3.24 The designer must also consider noise escaping to the external environment and this must not be unacceptable to occupants of adjacent buildings.

## Calculation of building loads

### Air infiltration

- 3.25 Air infiltration occurs due to a complex combination of wind pressure, thermal effects, location relative to other features and the construction standard of the building. The infiltration rate is governed by the size and number of openings in the building envelope and the complexity of internal air paths.
- 3.26 CIBSE Guide A (2006) Section 4 provides information and formulae for the calculation of air infiltration and natural ventilation of buildings. In all cases the requirements of the appropriate section of the Scottish Building Regulations must be met.

### Summertime temperatures

- 3.27 The calculation method for determining the summertime temperature is described CIBSE Guide A (2006) Section 5. However, it is very important to select the time of day and time of year of peak loadings for the calculations. These will be dependent on the orientation and proportion of solar to total heat gain. In establishing outside design values, the design risk having regard to the function and occupancy of the building should be considered.
- 3.28 Where calculations indicate that internal temperatures will frequently exceed the selected design external shade temperature by more than 3K for a period that exceeds the building design risk, methods of reducing temperature rise should be implemented. Options include: - reducing solar and casual gains, the use of chilled beams or ceilings, increasing ventilation rates or providing mechanical cooling. In some situations it may be possible to alter the thermal mass of the structure to 'move' the peak temperature event time so that it occurs outside of the occupancy period. Calculations and thermal modelling should be undertaken to ensure that during the summertime internal temperatures in patient areas do not exceed 28°C dry bulb for more than 50 hours per year. It has been found that there is a relationship between preferred indoor temperatures and mean outside temperature. Fig A2 in CIBSE Guide A indicates this relationship.

### Peak heating load

- 3.29 Peak heating local calculations are necessary on all mechanical supply systems to establish the size of heater batteries and subsequently the central plant.

- 3.30 Where ventilation systems provide tempered air to spaces that have supplementary LPHW to offset the building fabric losses, the plant heating load should be calculated based on the external winter design temperature, the design internal air temperature, and the calculated total air volume (including a suitable allowance for leakage).
- 3.31 Where the ventilation system is the only means of heating a space, an increase in load equivalent to the calculated fabric heat losses from the space should be added to the ventilation load. A check of supply temperature difference should be made. If it exceeds 10K the ventilation supply volume should be increased to suit.

#### Condensation risk

- 3.32 A check should be made to ensure that the selected air condition will not lead to surface condensation on low-temperature elements of the ventilated space.
- 3.33 Where there are local sources of moisture that would require excessive levels of ventilation to avoid condensation, the designer should consider the capture and removal of moisture at the source of the evaporation via an exhaust hood or similar device.
- 3.34 In intermittently heated buildings, it is necessary to consider the condensation risk at night setback conditions as well as during normal operation. Calculation methods for this assessment are given in CIBSE Guide A.

#### Peak cooling load

- 3.35 In addition to the base data of airflow rates and temperatures, when calculating cooling loads, the designer must take into account:
- solar cooling loads;
  - surface conduction cooling loads;
  - internal gain cooling loads;
  - cooling loads due to high-level humidity control;
  - method of control of internal conditions;
  - fluctuations in internal temperatures.
- 3.36 When the peak internal loads have been assessed and a suitable allowance made for non-coincidence, the supply temperature can be calculated.
- 3.37 Once the lowest required supply temperature of the air handling unit has been established, and an allowance made for temperature rise through the fan and ductwork (usually 1K for low pressure systems), the off-plant enthalpy can be established from a psychrometric chart or table.
- 3.38 The cooling loads for all plants on the chilled water system should be calculated at each of the individual peak times in order to establish accurately the required (diversified) capacity of the chiller.

## Annual energy consumption

- 3.39 Annual energy consumptions of heating-only ventilation systems are simple to calculate based on supply-to-external air temperature rise, and frequency of occurrence of external temperatures as given in CIBSE Guide A.
- 3.40 Minimum air volumes are usually fixed by the room loads or fresh air requirements. However, the designer may increase airflow to some rooms or zones in order to balance loads, as detailed in the following paragraphs on "Calculation of plant requirements."
- 3.41 The method of zoning and control can significantly influence energy consumption.
- 3.42 The nature of air-conditioning operation, comprising cooling and reheating for humidity or zonal temperature control, makes prediction of energy consumption very complex. It is imperative that these calculations are performed to ensure optimum energy efficiency.
- 3.43 The concept of load and plant operation charts is outlined in the CIBSE Guide A. The method requires the designer to establish the minimum and maximum loads on all zones across the range of external temperatures between winter and summer design conditions. Once the load chart is complete, the plant chart converts the loads to supply temperatures, which are then superimposed on external air temperatures.
- 3.44 When all temperatures for all zones are plotted on the plant operation chart, set points and resetting schedules can be established. From this information, the outputs of individual heaters, coolers and humidifiers can be established at any given external temperature. When those loads are computed against annual frequency of occurrence of external temperatures as given in CIBSE Guide A, the annual energy consumption of individual elements, and thus the air-conditioning system, can be established.
- 3.45 In order to prevent surface condensation occurring, it is necessary to provide sufficient ventilation to maintain the maximum and ambient dew-point temperature below the lowest surface temperature, the coldest usually being the glazing. Paragraphs 3.33 and 3.34 also refer.

## Calculation of plant requirements

### Air supply volumes

- 3.46 The minimum air supply volume for a room is determined by the greatest of these three criteria:
- the minimum fresh-air requirement;
  - the minimum supply volume for the room load as determined by the maximum heating or cooling supply temperature differential;
  - the desired/required air change rate.

## Plant sizing

- 3.47 Once the design airflow has been established the cross-sectional area of the air-handling unit can be calculated based on a maximum coil face velocity of 2.0 m/s.
- 3.48 In order to establish the length of the air-handling unit, it will be necessary to refer to manufacturers' literature, ensuring all necessary access panels and components are included as detailed in Chapter 4.
- 3.49 The fan duty should be calculated by adding the resistances of all elements that contribute to the pressure drop of the index circuit.
- 3.50 The main elements that must be considered are:
- inlet or discharge louvres;
  - plant entry and discharge;
  - attenuators;
  - components within the air-handling unit;
  - duct-mounted heaters and filters (including a dust allowance);
  - ductwork distribution;
  - ductwork fittings, including: fire dampers, volume control dampers, bends and sets, tees, changes of section;
  - air terminal device;
  - discharge velocity.
- 3.51 Where packaged air-handling units are installed, the fan pressure drop is usually quoted as external plant resistance, and thus the designer does not need to calculate the resistances of individual plant items. The designer should, however, ensure that an allowance has been made for filter clogging; and confirm whether the fan pressure quoted is fan total or static pressure.
- 3.52 Resistances of ductwork and fittings may be obtained from the CIBSE Guide A. However, the designer should exercise some care when using tabulated pressure loss information for fittings that are relatively close together.
- 3.53 Upon completion of the resistance calculation exercise, the designer should make allowances for calculation and construction tolerances as indicated in Table 4.

Criteria	Low pressure systems	Medium/high pressure systems
Volume flow rate margin for leaking and balancing requirements	+5%	+5%
Total pressure loss margin		
A. for increase in volume flow rate (above)	+5%	+5%
B. for uncertainties in calculation	+5%	+10%
Combined total pressure loss margin	+10%	+15%

Table 4: Typical fan volume and pressure margins

### Plantroom size and location

- 3.54 The ventilation plant and associated equipment should be positioned to give maximum reduction of noise and vibration transmitted to sensitive departments; while at the same time, achieve an economic solution for the distribution of services.
- 3.55 It is not recommended that noise and vibration generating plant be housed either directly above or below sensitive areas (for example, operating or anaesthetic rooms) unless there is no alternative, in which case, additional care and attention must be given to the control measures.
- 3.56 The plant must also be located so that it is remote from possible sources of contamination, heat gains and adverse weather conditions. The design should ensure that wind speed and direction have a minimal effect on plant throughput.
- 3.57 Safe access to and around plant is essential to facilitate inspection, routine maintenance, repair and plant replacement.

### Provision of primary services

- 3.58 Where more than one air-handling plant requires cooling, remote central cooling plants with piped chilled water are preferred. In the case of a single plant, a multi-stage direct-expansion cooling coil with refrigerant piped from an adjacent compressor/condensing plant could be considered. If this option is selected, a refrigerant gas detector mounted in the base of the duct and an alarm system audible to the end-user will also need to be provided (as dictated by COSHH Regulations).
- 3.59 Clean dry steam is preferred for humidification, provided that the boiler water treatment does not render the steam unusable for direct humidification.
- 3.60 If a suitable supply of steam cannot be obtained from the steam main, a steam generator should be provided locally, or a self-generating humidifier installed. Electric humidifiers require considerable electrical loads and if a gas supply can

be derived, this would be preferable. The location of a local steam generator is critical if condensate is to drain back into it.

### Inlet and discharge sizing and location

- 3.61 Air intakes and discharge points should preferably be located at high level, to minimise the risks of noise nuisance to surrounding buildings, contamination and vandalism.
- 3.62 Intakes and discharges should be designed and located so that wind speed and direction have a minimal effect on the plant throughput.
- 3.63 Helicopter landing pads in the vicinity of ventilation intakes and discharges can result in large short-term pressure changes. This can cause pressure surges in supply systems and reverse airflows in extracts. Exhaust fumes from the helicopter may also be drawn into intakes.
- 3.64 Intake points should be situated away from cooling towers, boiler flues, vents from oil storage tanks, fume cupboards and other discharges of contaminated air, vapours and gases, and places where vehicle exhaust gases may be drawn in.
- 3.65 Where intakes have necessarily to be sited at or near ground level, the area around them should be paved or concreted to prevent soil or vegetation being drawn in. They should also be caged or located within a compound to prevent rubbish being left in the vicinity. The likely proximity of vehicle exhausts should also be taken into account when determining the protected area around the intake.
- 3.66 The discharge from an extract system must be located so that vitiated air cannot be drawn back into the supply air intake or any other fresh-air inlet. Ideally, the extract discharge will be located on a different face of the building from the supply intake(s). In any event, there must be a minimum separation of 4 metres between them, with the discharge mounted at a higher level than the intake.
- 3.67 Discharges from LEV systems should preferably be vertical and usually not less than 3m above roof level. They should not be fitted with a cowl that could cause the discharge to be deflected downwards.
- 3.68 Each intake and discharge point should be fitted with corrosion-resistant weatherproof louvres or cowls to protect the system from driving rain. Louvres should be sized based on a maximum face velocity of 2 m/s in order to prevent excessive noise generation and pressure loss.
- 3.69 The inside of the louvres should be fitted with a mesh of not less than 6 mm and not more than 12 mm to prevent leaves being drawn in and infestation by vermin.
- 3.70 The duct behind louvres should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system.

- 3.71 Cleaning access must be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a common plenum is provided, cleaning access should be via a walk-in door.

### Heat rejection devices

- 3.72 The design conditions given in Chapter 2 make no allowance for the elevated temperatures that can occur on the roof of buildings. Refrigeration condensers and cooling towers should, if practicable, be shaded from direct solar radiation, or the design adjusted to take account of the gain.
- 3.73 Air-cooled condensers must always be the first choice for heat rejection from any refrigeration plant. Evaporative cooling systems must not be used in healthcare premises unless limitations of space mean that they are the only way that the cooling load can be met. If they are used, national guidance on preventing and controlling *legionella* must be closely followed.
- 3.74 Reference should be made to Scottish Health Technical Memorandum 04-01: 'The Control of *Legionella*, hygiene, 'Safe' hot water, cold water and drinking water systems, Part A: Design, Installation and Testing, and Part B: Operational Management, published by Health Facilities Scotland, 2010.

## 4. Air handling unit design and specification guidance

### General requirements

#### Location and access

- 4.1 Air-handling units should be located in an accessible area secured from unauthorised entry. Siting units in ceiling voids above occupied spaces is not appropriate.
- 4.2 Units located on roofs must have a safe means of access together with suitable precautions to prevent personnel or equipment falling or being blown off during maintenance activities.
- 4.3 Units located at ground level should be secured within a locked compound to prevent unauthorised access. Measures should be taken to exclude vehicles from the vicinity to ensure that exhaust fumes will not be drawn into intakes.
- 4.4 Units may have a working life of approximately 20 years. It can be anticipated that over this period there will be a need to access every element within the unit for deep cleaning. It is also quite possible that the main fan and individual heater and chiller batteries will need replacement. Suitably positioned service connection joints and adequate spacing should permit these items to be withdrawn without the need to dismantle other installed plant or equipment. Batteries that are significantly wider than 1metre should be split to permit withdrawal from both sides.
- 4.5 It is essential that air-handling units are positioned so that all parts are easily and safely accessible for routine inspection and service. If a unit is located against a wall or backs onto another unit then access to all parts must be available from the front. Units greater than 1 metre wide should preferably have access from both sides or access doors large enough to permit the full and safe entry of maintenance personnel.
- 4.6 Water may be used during routine cleaning or spilt when maintenance is being undertaken. The area around the unit should be tanked to prevent water penetration to adjacent areas and adequately drained.
- 4.7 Fire precautions should be incorporated in accordance with Firecode. Guidance is available in BS5588: Part 9 and Sections 5 & 6 of this document.
- 4.8 Combustion equipment must not be located in a fire compartment that houses air-handling equipment.

## Technical requirements

- 4.9 The basic technical requirements of the whole of the ventilation system should meet the relevant clauses of the Health Technical Specification. It should be noted that the Specification contains a menu of clauses that cover a wide range of applications, so it is important to select only those that are relevant to the specific application.

**Note 1:** At the time of writing, Health Technical Specification C04 was due for revision in order to bring it into line with the revised standards as set out in this Scottish Health Technical Memorandum. Where conflicts in specification arise, the Scottish Health Technical Memorandum takes precedence.

- 4.10 It is essential that the main plant/ductwork is located far enough above the floor to permit the correct installation of drainage systems for cooling coils, humidifiers and heat recovery systems. Easy access for maintenance of drainage systems and their associated pipework must be provided.
- 4.11 Organic materials or substances that can support the growth of microorganisms must not be used in the construction of the plant or its distribution system. The water fittings and materials directory lists suitable materials for sealants and gaskets.
- 4.12 The plant and its distribution system must not contain any material or substance that could cause or support combustion.
- 4.13 Plants should have a high standard of air-tightness. The double-skin method of construction with insulation sandwiched between two metal faces is recommended. The panels may be available in a variety of colours at no additional cost. This can aid identification by colour coding of units in a plant room (for example green for general ventilation; blue for theatres; red for laboratories and isolation facilities; grey for extract etc).
- 4.14 The inside of the plant should be as smooth as possible. Channels, rolled angles or formed sections that could trap or hold moisture should be kept to a minimum. If stiffeners are required, they should be fitted externally. If internal bracing has to be fitted it must be of a design that will not trap or hold moisture.
- 4.15 Airflow across air treatment components such as filters, heat exchangers and humidifiers will be influenced by the pattern of the approaching airstream. If unsatisfactory conditions are created, the performance of the component will be reduced.
- 4.16 Access to items that require routine service such as filters, frost batteries and chiller batteries should be via hinged doors. The doors should be large enough (for example 500 mm minimum) to allow easy access. Items requiring infrequent access such as attenuators may be via bolted-on, lift-off panels. All doors and panels should be close-fitting and without leaks.

- 4.17 Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access.
- 4.18 It can be difficult to turn off AHUs in order to inspect filters and drainage trays. Viewing ports and internal illumination will therefore facilitate routine inspection of such items. Viewing ports should be at a convenient height so that temporary ladders are not required. Internal illumination should be provided by fittings to at least IP55 rating. Fittings should be positioned so that they provide both illumination for inspection and task lighting. All of the lights in a unit should be operated by a single switch.
- 4.19 Access to AHUs and items in the distribution system such as filters or heater / chiller batteries should be via fixed ladders and platforms or pulpit-style moveable steps. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow the pulpit steps to be easily wheeled into position.

#### AHU drainage system

- 4.20 All items of plant that could produce moisture must be provided with a drainage system. The system will comprise a drip tray, glass trap, air break and associated drainage pipework.
- 4.21 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent 'pooling', it is essential that the drain connection should not have an upstand; and that a slope of approximately 1 in 20 in all directions should be incorporated to the drain outlet position. The tray must be completely accessible or, for smaller units, easily removable for inspection and cleaning.
- 4.22 Each drip tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed thus giving an early indication of corrosion, biological activity or contamination within the duct. The trap should have a means for filling and incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting it to the drainage tray should have a continuous fall of not less than 1 in 20.
- 4.23 Traps fitted to plant located outside or in unheated plant rooms may need to be trace-heated in winter. The trace-heating must not raise the temperature of water in the trap above 5°C.
- 4.24 Water from each trap must discharge via a clear air gap of at least 15mm above the unrestricted spill-over level of either an open tundish connected to a foul drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish providing each has its own air break.

- 4.25 Drainage pipework may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22 mm and a fall of at least 1 in 60 in the direction of flow. It should be well supported and located so as not to inhibit access to the AHU.

#### Layout of air handling unit

- 4.26 The AHU should be arranged so that the majority of items are under positive pressure. Any item of plant requiring a drain should be on the positive pressure side of the fan. A recommended layout is given in schematic form in Figure 3.
- 4.27 A separate extract unit will generally be required for the area served by each supply unit.
- 4.28 An energy recovery system will normally be fitted between the supply and extract units.

#### Provision of dampers

- 4.29 Fire- or smoke-actuated dampers shall be provided at the locations required by Firecode. (See paragraphs 5.17 to 5.21).
- 4.30 Motorised low-leakage shut-off dampers should be located immediately behind the intake and discharge of each supply and extract system respectively. They should be of the opposed-blade type, opening through a full 90° and must close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow.
- 4.31 The quality of motorised dampers is critical. They should be rigid, with square connections fitted with end and edge seals of a flexible material and with minimal play in linkages. The leakage on shut-off should be less than 2%.
- 4.32 A manually operated isolating damper should be installed between the main AHU and its distribution system to enable the unit to be isolated when cleaning is in progress.
- 4.33 Good practice will require the fitting of a main volume control damper so that the design airflow rate can be set at commissioning. The damper should be lockable in any position. If it will also be used for plant isolation, it should be capable of being reset to give the design airflow without the need for re-measurement.
- 4.34 Internal plant isolating dampers or provision for the fitting of shut-off plates between items within a unit are not required.

#### Vibration

- 4.35 Vibration from a remote plantroom can be transmitted by the structure of the building, may be regenerated and may sometimes be magnified many times. Units should be selected to have the minimum vibration generation and installed on suitable anti-vibration mounts. Pipe and ductwork should incorporate anti-

vibration couplings, preferably in two planes at right angles, as close to the vibration source as possible. Consideration should be given to the use of anti-vibration pipe hangers and supports.

### Sequence of components

4.36 The following arrangement of plant components is typical although in many instances not all elements will be required:

- fresh air intake;
- motorised isolation damper;
- frost / fog coil;
- pre-filter;
- energy-recovery device;
- attenuator;
- fan;
- blast plate;
- attenuator;
- chiller battery;
- eliminator;
- heater battery;
- humidifier;
- final filter;
- isolation / volume control damper.

**Note 2:** Attenuators may be located in the intake and discharge duct if they are of a suitable type (See clause paragraphs 4.159 to 4.162)

There may be instances where the above arrangement is not appropriate and the plant arrangement should be planned accordingly.

## Fans

### General requirements

4.37 The fan should be selected for good efficiency and minimum noise level, but the overriding factor should be the selection of a fan characteristic such that the air quantity is not greatly affected by system pressure changes due to filters becoming dirty or external wind effects.

### Acceptable types

- 4.38 Fans can be of the axial, centrifugal, cross-flow, mixed-flow or propeller type, depending upon the requirements of the system.
- 4.39 Where used, centrifugal fans should preferably be of the backward-blade type. Alternatively, where noise levels are more critical and pressure requirements are lower, forward-curved blade fans are acceptable. For high-power applications, aerofoil-blade fans may be appropriate.

### Selection

- 4.40 Generally, large ventilation systems will use centrifugal fans due to their efficiency, non-overloading characteristics, and developed pressures.
- 4.41 Forward curved centrifugal fans can overload if allowed to handle more air than they are designed for.
- 4.42 Alternatively, it may be appropriate to use mixed flow fans in high-pressure systems.
- 4.43 Axial flow or propeller fans are generally only used in local through-the-wall systems, or systems with very low pressure requirements.
- 4.44 Cross-flow fans have very low operating efficiencies, and thus their use is restricted to applications such as fan coil units.

### Location and connection

- 4.45 Fans are normally positioned to 'blow through' the central plant so that the cooling coil and humidifier drains will be under positive pressure.
- 4.46 The fan performance figures given by manufacturers in their catalogue data are based on tests carried out under ideal conditions, which include long uniform ducts on the fan inlet/outlet. These standard test connections are unlikely to occur in practice, the designer should therefore ensure as far as is practical that the fan performance will not be significantly de-rated by the system. This objective can be approached by ensuring that the fan inlet flow conditions comprise uniform axial flow velocities with low levels of turbulence.
- 4.47 Where the outlet duct is larger than the fan discharge connections, there should be a gradual transition, with a following section of straight duct, having a length equivalent to three duct diameters.
- 4.48 The design of the fan intake connection must be carefully considered to avoid swirl in the airstream. When the air spins in the same direction as the impeller, the performance and power consumption of the fan are reduced. When the air spins in the opposite direction to the impeller the power consumption and noise will increase with hardly any pressure increase. Airstream swirl is usually induced by large variations across the fan intake caused by the air passing round a tight bend immediately before the intake.

- 4.49 Where a centrifugal fan is located with an open intake, the clear distance between the suction opening and the nearest wall should be not less than half the diameter of the inlet. If two fans with free inlets are positioned within the same chamber, their adjacent suction openings should be at least 1 diameter apart.
- 4.50 Airtight flexible joints should be provided at fan inlet and outlet connections. They should be equal in cross-section to the points of connection and be neither longer than 200 mm nor shorter than 100 mm.
- 4.51 For centrifugal fans, a diffuser screen / blast plate should be fitted immediately downstream of their discharge.

#### Supply fan drive arrangements

- 4.52 Where the fan drive is via a motor-driven belt and pulley, it should be external to the air stream. This arrangement has the following advantages:
- the fire risk is reduced;
  - the drive is visible so it is simple to check that the belt is still there;
  - particles shed from the drive belt are outside of the air stream;
  - if the belt slips, the “burning rubber smell” is not transmitted down into occupied areas of the premises;
  - noise generated by the motor and drive will not be transmitted along the ductwork;
  - waste heat is excluded from the system;
  - the drive may be through a vee or toothed belt and pulley. The latter have the advantage of eliminating belt squeal on start up and have a longer service life. They are particularly suitable where the fan drive motor is fitted with a soft start and should be located external to the air stream.
- 4.53 The drive train should be easily visible without the need to remove access covers. Protecting the drive train with a mesh guard is the preferred option. For weatherproof units designed to be located outside, the fan drive will be external to the duct but enclosed. It should be easily visible through a viewing port with internal illumination and access via a lockable hinged door.
- 4.54 For direct-coupled fan and motor units, the motor should be out of the air stream.
- 4.55 For induction drive ‘plug’ motor arrangements (where the motor is fitted within the fan and is integral to it) and in line axial fans with a pod motor; the fan / motor combination may be within the air stream provided the motor windings are protected from over temperature by a thermister and lockout relay.

### Extract fan drive arrangements

- 4.56 The preferred method where the fan drive is via a motor driven belt and pulley arrangement will be to locate it external to the air stream.
- 4.57 The fan drive and motor may be located inside the duct within the air stream provided the motor windings are protected from over-temperature by a thermister and lockout. The drive train should be easily visible through a viewing port, have internal illumination and access via a lockable hinged door.
- 4.58 Where the system air is explosive, aggressive or has high moisture content, the extract fan motor must be located outside the air stream. This is generally achieved with axial fans by using a bifurcated unit.

### Control

- 4.59 Fans in healthcare applications are normally either single or two-speed. Where there is a requirement for two-speed operation, this is generally via a local user control (for example, in a hood extract system to provide a boost facility) or via a time schedule for energy saving during unoccupied periods.
- 4.60 Normally only a single motor is required with a standby motor available for fitting as necessary or fitted but not belted. Twin, run and standby motors - with the standby being jockeyed around - are not required.
- 4.61 Where there is a specified requirement for standby fans, the system should incorporate an automatic changeover facility activated via an airflow sensor. Fault indication should be provided.
- 4.62 The control of fans in terms of start-up and run is increasingly being vested in computer software. Inverter-drive, variable-speed, soft-start systems are becoming a standard approach. It should be remembered that most healthcare applications require known amounts of air to be delivered while the system is in use. Constant volume systems that deliver specified air-change rates are therefore the norm. Duct- or room-pressure-controlled, variable-speed systems have a very limited application in healthcare.
- 4.63 It is necessary to ensure that - should the computer control system or its software develop a fault - then the fan can be switched to a direct-start, fixed-speed, manual operation. This is particularly important for critical care systems serving operating suites, high-dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites. Off-site software support is no substitute for the ability of on site staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff.

## Heater batteries / heater coils

### General requirements

- 4.64 Frost batteries are installed to protect the downstream filters from low-temperature, high-humidity intake air conditions. As they handle unfiltered air they should be constructed of plain tubing without fins and be as near to the outside as possible to minimise condensation during cold weather. Access for cleaning will need to be provided to both sides of the coil.
- 4.65 Where steam coils are used for a frost battery, they may be constructed using spiral-finned copper tube. As they will be prone to fouling the tube layout and spacing should permit easy access for regular cleaning.
- 4.66 Main and branch heater-batteries should be constructed of solid-drawn copper-tube coils with copper fins, generally connected in parallel.
- 4.67 Where there is a wet heating system in the areas served, the main heater-battery should be sized for the ventilation requirements only, and not for the fabric loss.
- 4.68 Access for cleaning must be provided to both sides of all frost batteries and heater-batteries.

### Acceptable types

- 4.69 Electric, water or steam heater-batteries may be considered. However, electric heater-batteries are expensive to operate and where there are alternatives, their use should be restricted to low-power use (for example trimming control).
- 4.70 Where steam-supplied heater-batteries are used, their control, venting and trapping systems should be designed so that a vacuum cannot occur within the coil. The condensate drainage arrangements should not allow pressure to build in the main resulting in a back-up of condensate in the coil.

### Location

- 4.71 Where possible, wet-trimmer heater-batteries should be located in plant areas.
- 4.72 Where it is necessary to locate heater-batteries in false ceilings etc, consideration should be given to the use of electric heaters. If this is not practicable, drip-trays should be installed under both the battery and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.
- 4.73 Auxiliary fan coil units should not be installed in the ceiling above an occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the department that they serve.

## Control

- 4.74 LPHW frost coils should be controlled by an off-coil temperature sensor operating a motorised valve to provide a minimum plant “on temperature” of between 2°C and 5°C. The off-coil temperature of the frost coil is generally sensed by a serpentine thermostat downstream of the coil or upstream of the next plant item. This thermostat will shut the fan down if any part of the air stream is below the minimum set-point.
- 4.75 Steam-supplied frost coils should be fitted with an on/off control operated by a temperature sensor mounted upstream of the battery. These are normally set to open the control valve fully when the outside temperature drops to +1°C. This will ensure that there is no standing condensate in the base of the coil.
- 4.76 The main heater-battery should be controlled in the same manner under the dictates of either an off-coil temperature sensor, or a room temperature sensor, depending on the plant configuration and method of control. Trimmer heater-batteries are generally controlled by one or more averaging temperature sensors within the room or rooms in the zone.
- 4.77 Heater-battery control valves should drive closed on system shutdown or fan failure. The control system should then automatically set to provide frost protection.

## Cooling coils

### General requirements

- 4.78 Cooling coils will need to be decontaminated periodically. They must have good access both up and downstream. Hinged access doors with viewing ports and illumination inside the duct should be provided both sides of the coil.
- 4.79 An eliminator will be required downstream of all cooling coils. The eliminator may take the form of an extension of the coil fins or be a separate device. If a separate device it should be removable as a unit to permit cleaning of the coil face.
- 4.80 All cooling coils must be fitted with their own independent drainage system as specified above. A baffle or similar device must be provided in the drip tray to prevent air bypassing the coil. The tray should be large enough to capture the moisture from the eliminator, bends and headers.
- 4.81 Where coils are greater than 1m high, intermediate drip-trays will be required.

### Selection

- 4.82 Cooling coils supplied with chilled water are the preferred option. For small loads or where chilled water is not available, direct expansion coils may be used.

- 4.83 Care must be taken in selection to minimise electrolytic action resulting from condensation on the airside. Coils constructed from copper tubes with copper fins extended on the downstream side in the form of an eliminator, and electro-tinned after manufacture are preferred. Aluminium fins should only be used if vinyl-coated.
- 4.84 All parts of the coil and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Pressed steel coil headers, even if treated, have been shown to be prone to corrosion over time and should not be used. Steel mounting frames and casings present similar problems so stainless steel is preferred.

### Location

- 4.85 Micro-organisms that multiply in moisture cannot be avoided when the coil is dehumidifying. However, locating the final filter downstream of the coils will reduce the risk of infection.
- 4.86 Cooling coils in AHUs should be located upstream of the final filter.
- 4.87 Where any cooling coil has to be located above a ceiling, drip-trays should be installed under both the coil and the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. To facilitate maintenance access, they should be located above corridors or other non-critical areas and never above patient occupied spaces.

### Control

- 4.88 There are two basic methods of control for cooling coils:
- off-coil control – used in multi-zone systems or single-zone systems where close humidity control is required, to provide a constant maximum off-plant condition which satisfies the temperature and high humidity requirements of the zone with the highest load;
  - sequential control – used in single-zone systems, or multi-zone systems with averaging sensors where close control is not required. A room or duct temperature sensor controls the cooling coil and heater battery in sequence to maintain constant room conditions.
- 4.89 The advantage of off-coil control is that accurate humidity control can be provided without relying on humidity sensors, which are prone to inaccuracy and drift. Off-coil control is however, expensive to operate in terms of energy consumption, due to the fact that there is no feedback of room loads, and thus at low loads and in systems where there are large zonal variations, significant over-cooling and reheating will occur.
- 4.90 On systems with two-speed operating, it is usual to isolate the cooling coil upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the cooling coil must be isolated.

## Humidifiers

### Design need

- 4.91 Humidification was originally required for some healthcare applications in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement.
- 4.92 Operating-theatre AHUs do not generally require humidifiers but provision for their retrofitting in terms of space provision and a capped drainage system should be provided.
- 4.93 Where humidification is required, it will be subject to the specific requirements set out below. These are intended to ensure that the unit will operate safely and not become a source of contamination.

### General requirements

- 4.94 The most important requirement for a humidifier is to create complete mixing of the steam with the air. The manufacturers' instructions should be followed regarding minimum distances which should be allowed before bends or other components. This is particularly important with respect to a filter mounted downstream. If it becomes saturated by the humidifier, organisms can grow through the filter and be released into the duct. These may then be carried on the airstream into an occupied space.
- 4.95 The section of ductwork containing the humidifier may need to be periodically decontaminated. Hinged access doors with viewing ports and internal illumination should be provided. A label warning that the device emits live steam and should be isolated prior to opening should be affixed to the access door.
- 4.96 All parts of the humidifier and its associated ductwork in contact with moisture must be manufactured from corrosion-resistant materials. Stainless steel is preferred.
- 4.97 The electrodes of self-generating electrode-boiler type humidifiers should be stainless steel.
- 4.98 All humidifiers must be fitted with their own independent drainage systems as detailed in paragraphs 4.72 and 4.87 or 4.20 to 4.25.
- 4.99 For self- and locally-generated steam humidifiers, the cleanliness of the water supply is essential for their safe operation. Provision should be made for draining down supply pipework and break tanks for periodic disinfection and cleaning during periods when they are not required in service.
- 4.100 The addition of treatment chemicals for continuous control of water quality for humidifier/air handling units should be avoided. Consideration could be given to installing a UV system to control microbiological growth. Given the limitations of

UV systems, however, this will require filtration to high quality to ensure the effectiveness of exposure of organisms to the UV irradiation. As with all water treatment systems the unit should be of proven efficacy and incorporate UV monitors so that any loss of transmission can be detected.

### Acceptable types

- 4.101 Only steam-injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. Water humidifiers of any type should not be used.
- 4.102 Steam may be derived from the central steam supply provided that it does not contain any treatment carry-over, or generated locally either within or adjacent to the humidifier.
- 4.103 The introduction of steam should be by an appliance specially designed to discharge dry steam into the air-conditioning system without objectionable noise or carry-over of moisture.
- 4.104 During the design stage, consideration should be given to the proposed methods for the regular cleansing of the humidifier(s) and their components.

### Selection

- 4.105 The number and length of steam-injection manifolds to be used is dependent on various factors such as duct cross-sectional area, air velocity, dry-bulb temperature and manifold design. Guidance from the manufacturer should be followed closely.
- 4.106 A mains steam humidifier can be noisy and will be difficult to control if it is operated at an excessive steam pressure. It should be sized for an operating pressure of approximately 1 bar. The pipework supplying it should be provided with a dirt pocket, pressure reducing valve and steam trap installed as close as practicable to the humidifier, so that the steam condition at entry is as dry as possible. A temperature switch on the condensate line (or equivalent design provision by the humidifier manufacturer) should be incorporated to prevent 'spitting' on start-up.
- 4.107 Most operational problems with mains steam humidifiers arise because of back-pressure in the condensate discharge line which will result in flooding into the duct. Unless the condensate from the device can be discharged and collected at atmospheric pressure, it should be discharged directly to drain.
- 4.108 A local steam generator, where used, must be fed with potable quality water. Additional water treatment to the standard set out above may be required. If the humidifier is unused for a period exceeding 48 hours, it must automatically drain its water content, including that contained in the supply pipework, right back to the running main and leave itself empty.
- 4.109 Some steam generators are of a type that requires regular cleaning and descaling. The design must allow for them to be installed such that they can be

physically isolated from the air duct in order to prevent contamination of the supply by cleaning agents while this is taking place.

### Location

- 4.110 Careful siting of the humidifier injection manifold is required to prevent the steam impinging onto the side(s) of the duct, condensing and generating excess moisture.

### Control

- 4.111 Accurate humidity control can only be provided on single-zone systems, or multi-zone systems with zonal humidifiers. In the above systems, humidity sensors control the humidifier for low-level humidity control, and override the temperature controls to open the cooling coil valve for high-limit humidity control.
- 4.112 Multi-zone systems are more usually controlled by a minimum humidity sensor located in the supply duct(s) following the last heater-battery.
- 4.113 Overriding controls separate from the normal plant humidistat should be installed. Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay should be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/plant start-up. In addition, a high-limit humidistat should be installed to limit the output of the humidifier so that the saturation in the duct does not exceed 70%. This humidistat is to control the added moisture. It is not necessary to install a de-humidifier to reduce the humidity of the incoming air if it already exceeds 70%. The humidifier control system should ensure that the humidifier is switched off when the fan is not running.
- 4.114 On systems with two-speed operating, it is usual to isolate the humidifier upon selection of low speed. In addition, on system shutdown, low airflow or fan failure, the humidifier should be isolated.

## Filtration

### General requirements

- 4.115 The purpose of filtration is to reduce the level of airborne contamination in an air stream. It is generally carried out in stages.
- 4.116 Filters must be securely housed and sealed in well-fitting frames that minimise air by pass. Air by pass significantly reduces filter efficiency, the higher the filter grade the greater the effect. Mounting frames should be designed so that the air flow pushes the filter into its housing to help minimise air bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred.

- 4.117 Neither the filter media, nor any material used in the construction of the filters, should be capable of sustaining combustion. The filter media should be such that particles of it do not detach and become carried away by the airflow.
- 4.118 Filters need to be readily accessible for replacement so a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.
- 4.119 All filters should be provided with a means of visually checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred.
- 4.120 A complete spare set of filters must be provided at handover.

**Definition of filter terms**

- 4.121 Particulate air filters are divided into four categories:
  - general ventilation filters grades G1 to G4;
  - fine filters grades F5 to F9;
  - high efficiency particulate filters (HEPA) graded H10 to H14;
  - ultra-low particulate air filters (ULPA) graded U15 to U17.
- 4.122 General filters are graded in terms of their 'Synthetic dust weight 'Arrestance'. This represents the percentage of a test dust captured by a filter. 'Arrestance' provides a good indication of a filter's ability to remove the larger, heavier particles found in outdoor air. These are of a size to block finned batteries and large enough to settle out in the air distribution system.

BSEN 779 grade (Eurovent grade)	% Arrestance	Notes and typical healthcare application
G1 - (EU1)	< 65	Metal mesh grease filter
G2 - (EU2)	65 to < 80	Coarse primary filter
G3 - (EU3)	80 to < 90	Primary air intake; return air; energy recovery device protection
G4 - (EU4)	> 90	General purpose tempered air supply

**Table 4a: General Filters**

- 4.123 Fine filters are graded in terms of their 'Atmospheric dust spot Efficiency'. This is a measure of the filter's ability to remove the very fine staining particles found in outdoor air. It will indicate how 'visibly' clean a filter will keep a ventilated space. The staining particles are approximately the same size as most common bacteria so it is also a rough measure of the filter's ability to remove microorganisms.

BSEN 779 grade (Eurovent grade)	% Efficiency	Notes and typical healthcare applications
F5 - (EU5)	40 to 60	General purpose panel / bag filter
F6 - (EU6)	60 to < 80	Basic grade bag filter
F7 - (EU7)	80 to < 90	Medium grade bag or pleated paper Conventional operating theatre supply air
F8 - (EU8)	90 to < 95	High grade bag or pleated paper
F9 - (EU9)	> 95	Basic HEPA filter – Level 8 clean rooms

Table 5: Fine Filters

- 4.124 High efficiency filters (HEPA and ULPA) are graded in terms of their ability to capture their 'Most Penetrating Particle Size' (MPPS). High-efficiency filters self-select the particle that they are least able to trap, hence the MPPS. They are then tested against that size of particle. These filters are designed to provide very high-efficiency filtration of particles in the sub-micron size range.

BSEN 1822 grade (Eurovent grade)	% Efficiency @ MPPS	Notes and typical healthcare application
H10 - (EU10)	85	Ultra-clean theatre terminal
H11 - (EU11)	95	
H12 - (EU12)	99.5	
H13 - (EU13)	99.95	
H14 - (EU14)	99.995	Pharmacy aseptic suite Category 3 room extract
U15 – U17	-	Not generally used in healthcare

Table 6: High Efficiency (HEPA) Particulate Filters

#### Selection primary filters

- 4.125 All filters should be of the dry type. Panel filters are cheap and disposable with relatively low dust-holding capacity. They are generally used as pre-filters to eliminate large particles that would otherwise clog or cause damage to the fan and finned heating and cooling batteries. Stainless steel frames that hold disposable pre-cut filter pads are preferred.
- 4.126 General ventilation supply plant should incorporate primary air filters of grade G3, sized for a maximum face velocity of 2.0 m/s. Additional coarse pre-filters may be justified where the intake air is exceptionally polluted. They are sometimes fitted as a temporary measure when building work is being carried out in the vicinity of the air intake.

#### Secondary filters

- 4.127 Where a higher standard of filtration is required, secondary bag or pleated paper panel filters would be used. Rigid frame filters incorporating pleated paper elements are preferred over bag filters for critical care applications such as operating theatres.

- 4.128 In urban or other areas of high atmospheric pollution, a higher standard of filtration may be justified to reduce the level of staining to internal finishes.

#### Extract air filters

- 4.129 Extract filtration will generally only be required where heat-recovery devices are installed. There are a very limited number of specialised applications (microbiological safety cabinets and similar LEV systems) where contaminated air is required to be filtered prior to discharge to atmosphere. If it is safe for staff to work in a room without wearing respiratory protective equipment, it is safe to discharge the room air to atmosphere without filtration.

#### Return-air filters

- 4.130 They are used to reduce the load on HEPA filters in recirculating applications such as Ultra Clean operating suite ventilation canopies and pharmacy aseptic suites.

#### High-efficiency filters – HEPA and ULPA

- 4.131 HEPA filters are expensive so their use should be kept to a minimum. Applications requiring HEPA filters include the air supply to aseptic suites in manufacturing pharmacies, the discharges from microbiological safety cabinets and isolation facilities.
- 4.132 If used, HEPA filters should be of the replaceable panel type with leak-proof seals. They should be installed in a manner that permits on-site validation of the filter and its housing. This may involve the release of a Dispersed Oil Particle (DOP) challenge smoke through an injection point upstream of the filter and a measurement of the DOP penetration across the downstream face. Alternatively a particle-counting method may be used.
- 4.133 HEPA filters are sometimes fitted in extract systems to capture hazardous substances or organisms. Design provision must be made for the subsequent safe handling of contaminated filters by maintenance staff. This may be achieved by:
- sealing the hazardous substance into the filter before it is removed;
  - providing a system to fumigate the filter to kill any organisms;
  - housing it in a "safe change" unit that permits the filter to be ejected into a bag and sealed without staff having to come into direct contact with it.
- 4.134 In view of the costs and problems associated with placing HEPA filters in extracts, it is recommended that a full risk assessment be carried out at the design stage. This should include defining the true need for HEPA filters in an extract; validation of its performance at installation; the method of safely changing a contaminated filter; and its subsequent disposal.

- 4.135 ULPA filters are very expensive and are designed to remove particles below a size that are either surgically or aerobiologically significant. There would have to be exceptional circumstances in order to justify their use in healthcare ventilation systems.

#### Activated carbon filters

- 4.136 Activated carbon filters are able to remove gases and vapours from an air stream and are graded according to the range of substances they can remove. They are not normally fitted in air-conditioning supply systems.
- 4.137 They are occasionally fitted retrospectively because the main air intake has been poorly sited and is drawing in traffic fumes. Where used they must be protected by a particulate air filter.
- 4.138 Activated carbon filters are more commonly used in specialised fume extraction systems when the location of the discharge means that dilution cannot be relied upon to disperse noxious fumes.

#### Location

- 4.139 The primary filter should be positioned on the inlet side of the supply fan, downstream of the frost coil. The secondary filter, when fitted, should be on the positive-pressure side of the fan. This will prevent air being drawn into the system after the filter and capture any particles shed by items of equipment within the AHU.
- 4.140 The filter installation must be arranged to provide easy access to filter media for cleaning, removal or replacement, with side or front withdrawal as required.

#### Control

- 4.141 Differential-pressure transducers should be provided to monitor and alarm remotely on excessive filter pressure drop. In critical areas dirty-filter indication lights should be provided at the point of use.

### Energy-recovery

#### General requirements

- 4.142 Energy recovery will normally be fitted to all healthcare ventilation systems. It may be omitted only where it would clearly be uneconomic. Where the economic case is marginal, space should be allowed for the retrofitting of an energy recovery system.
- 4.143 For systems in healthcare premises, a plate heat exchanger or 'run-around coil' system is suitable. Thermal wheels may be used providing they are fitted with a purge sector. The small amounts of air leakage across those devices are not considered significant. Other systems such as heat pumps or heat pipes are also suitable. Selection should be based on relative locations of the supply and

extract units, ease of maintenance and practicality. Cleaning access will be required to both sides of any energy-recovery device.

- 4.144 The following are the minimum energy transfer efficiencies required for devices handling equal air volumes:
- run-around coil – 45%;
  - plate heat exchanger – 50%;
  - thermal wheel – 65%;
  - any other energy-recovery device – 50%.
- 4.145 If a plate heat exchanger is chosen, the plates should be constructed of metal. Plastic should not be used for internal bypass dampers and drive gears.
- 4.146 Whichever energy-recovery device is chosen the extract side will need to be protected by a G3 filter and provided with a drainage system as described in Section 4; Paragraphs 4.20 to 4.25, to remove condensate.

#### Location

- 4.147 Energy-recovery devices should be located downstream of the frost battery and pre-filter, prior to the cooling coil or main heater battery on the supply side.

#### Control

- 4.148 It is essential to consider the control of both the energy recovery device and the frost battery when assessing the economics of recovery, as all energy provided by the frost battery will directly reduce the heat exchange of the recovery device. To this end, the off-coil setting of the frost coil should be the minimum possible to protect the primary filter (for example +2°C).
- 4.149 The energy-recovery device should be controlled in sequence with the main heater battery, and should incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the required plant set point.
- 4.150 In instances where the plant is cooling the air, it may be possible to remove heat from the supply air at high ambient conditions, under the dictates of enthalpy sensors in the intake and extract ducts.

### Attenuation

#### General requirements

- 4.151 Noise will be generated in an air distribution system by the fan, plant items and airflow. The ductwork is a very effective transmitter of this noise hence there is generally a need to limit the noise transmission to meet the requirements of the

building. This normally involves the provision of sound attenuation treatment as part of the overall ductwork system design.

- 4.152 A thorough assessment of the design should be made to assess the noise impact. This should take into account the following primary factors:
- fan- and plant-noise generation;
  - air-flow generated noise in ductwork fittings and dampers;
  - noise generated at grilles, diffusers and other terminals;
  - noise break-in and break-out of ductwork;
  - cross-talk and similar interference;
  - the noise limitations for the building and surrounding areas;
  - external noise generation.
- 4.153 A method of assessment of these factors and the sound attenuation requirements of ductwork systems is given in CIBSE Guide B.
- 4.154 The fan is usually the main source of system noise. The sound power that it generates varies as the square of the fan pressure, and thus to limit the fan noise level the system resistance should be kept as low as economically possible. As a general rule the selected fan should operate close to its point of maximum efficiency to minimise its noise generation. Where there is disturbance to the airflow at the fan inlet, the manufacturer's stated fan noise levels should be increased by up to 5 dB(A). More precise guidance on this aspect may be available from the manufacturers.
- 4.155 Fans radiate noise through both the inlet and outlet connections and it may be necessary to provide attenuation to limit the noise from both of these connections. It is always preferable and more economic to control noise and vibration at source, or as close to source as possible. It should be noted that attenuators offer a resistance to airflow. The resistance must be included in the fan and ductwork calculations.
- 4.156 Provided care is taken in the design and construction of low-pressure systems to avoid significant noise generation in the ductwork, attenuation should only be needed to absorb fan noise.
- 4.157 Noise breakout from all equipment housed in the plantroom must be taken into consideration if control is to be satisfactory. Any ductwork within the plantroom after the silencer should be acoustically insulated to prevent noise break-in or the silencer relocated at the point of entry or exit of ductwork to and from the plant room.
- 4.158 There is no complete means of control over external noise generation from such as road traffic, aircraft, factory and community noise. Consideration must be given to this at the design and planning stage.

### Acceptable types and location

- 4.159 The noise levels produced by ventilation and other plant should be reduced by either lining the inside of the duct with sound-absorbing material or fitting bespoke attenuator units.
- 4.160 In supply systems, sound-absorbing material should not be applied to the inside surface of a duct system downstream of the final filter, owing to the risk of mechanical damage and the subsequent dispersal of the media into the ventilation system.
- 4.161 In supply and extract systems, sound-absorbing material must not be applied to the inside of a duct within 1 metre of a fire damper. The material should be non-particle-shedding and fire-resistant (further guidance can be found in SHTM Firecode suite of documents). Where sound-absorbing material is applied in a section of duct that will be routinely exposed during maintenance activities it should be protected from mechanical damage.
- 4.162 Bespoke attenuator units with a sound-absorbing infill suitable for the quality of air being handled and protected by a perforated sheet metal casing are the preferred option for critical systems. Absorption of moisture, dirt and corrosive substances into the 'in-fill' and the release of fibrous particles into the airstream should be prevented by the use of a membrane. The membrane material should have a declared service life of at least 25 years. If these conditions can be met then the attenuator may be located in the supply ductwork downstream of the final filter. When so located cleaning access should be provided at both ends of the attenuator unit.

## 5. Air distribution system

### Air distribution arrangements

#### Ductwork distribution systems

- 5.1 Ductwork systems for ventilating and air-conditioning applications are referred to by their velocity or pressure category, that is, as low, medium or high velocity (or pressure) systems. Heating & Ventilating Contractors Association (HVCA) limits are up to 10 m/s or 1,000 Pa; 20 m/s or 1,750 Pa; and 40 m/s or 3,250 Pa in the case of conventional low, medium and high pressure systems respectively. High-pressure systems are disappearing because of the constraints of the Building Regulations but existing systems may sometimes need to be altered or extended.
- 5.2 For normal applications in healthcare buildings, low velocity systems are recommended; and the use of higher velocities than those recommended is not likely to be economical. Future trends are likely to be towards even lower optimum duct velocities; however, velocities below 2 m/s are unlikely to be justified.
- 5.3 The site will often dictate the main routing of ductwork systems, but in general, the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid regulation and may reduce the number and variety of duct fittings that are needed.
- 5.4 Main distribution ductwork should not be routed above sleeping areas. Where there is no alternative route, additional acoustic insulation will be required.
- 5.5 Where auxiliary cooling units, fans, filters or trimming devices are installed in the distribution system, they must be independently supported and fitted with a suitable drainage system where appropriate. If they are a source of vibration they should be linked to the distribution ductwork via flexible connections.
- 5.6 The fan of a Local Exhaust Ventilation (LEV) system provided under the COSHH Regulations should be located outside of the building so that all of the ductwork within the building is under negative pressure. Where the fan has to be within the building it should be located as close as practicable to the outside with an absolute minimum run of discharge ductwork within the building. The discharge ductwork within the building will be under positive pressure so it must not be penetrated by test holes or inspection hatches.

#### Ductwork materials and construction

- 5.7 The choice of duct material should take account of the nature of the air or gas being conveyed and the environment in which the duct will be placed.

- 5.8 Galvanised-sheet-steel is generally suitable and most economical for normal ventilating and air-conditioning applications. Its inherent mechanical strength renders it resistant to casual damage both during the construction phase and throughout its service life when mechanical and electrical services around it are altered. It also readily withstands the impacts sustained when rotary equipment is used to clean it internally.
- 5.9 In instances where moisture levels and/or corrosive elements in the air being conveyed are very high, aluminium, stainless steel, PVC or GRP (glass-reinforced plastic) ducts should be used. Stainless or black steel are the only suitable materials for high-temperature ductwork.
- 5.10 In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in Section 4 Clauses 4.20 to 4.25.
- 5.11 Where builderwork plenum chambers or ducts are used, these may be constructed of various materials. However all such ducts must be rendered and sealed to prevent dust shedding. A greater allowance may need to be made for leakage.
- 5.12 Galvanised, black and stainless steel ductwork should be manufactured and installed to the current HVCA specification for sheet metal ductwork DW144, but excluding the use of bolt-through supports.
- 5.13 GRP and PVC ductwork should be manufactured and installed to the current HVCA specification for plastic ductwork DW154.
- 5.14 Where phenolic-board ductwork is considered, care should be taken to ensure that it is fabricated to a quality standard and installed strictly in accordance with the manufacturers' instructions. Its pressure rating and degree of support should be suitable for the application and ducts should be fitted with mechanical protection where required. Installers should be experienced having received training in the techniques required and certified to this effect by the manufacturers. Due consideration should be given to the impact on ductwork pressures created by the closing of dampers. Phenolic-board ducting should not be installed in plant rooms where it could be vulnerable to impact damage.
- 5.15 Flexible ductwork is unsuitable for air distribution in healthcare applications. It should only be used to make the final connection to a terminal (See clauses 5.54 and 5.55).
- 5.16 The inside of the ductwork should be free from structural projections and as smooth as possible. Flanged, gasketed joints are preferred.

### Fire aspects, damper types and locations

- 5.17 It is essential that all relevant fire aspects of ducting systems are agreed with the fire officer before the design is finalised.

- 5.18 Ductwork must be fire-stopped where it penetrates fire compartment walls, floors and enclosures, cavity barriers and sub-compartment walls or enclosures, and provided with weatherproof collars where roofs or external walls are penetrated.
- 5.19 Fire/smoke dampers shall be provided at the locations required by Firecode. The fire-damper mounting frame must be securely attached to the building fabric. Where a fire-damper is not mounted directly in a fire compartment wall, it must be correctly supported and the ductwork between it and the firewall must possess the same fire rating as the firewall that it penetrates. The fire-rated portion of ductwork must not be penetrated by test holes or inspection hatches. All fire/smoke dampers shall be capable of remote re-setting via the Building and Energy Management System or equivalent, after periodic testing procedures.
- 5.20 An access hatch shall be provided adjacent to each fire damper so that its correct operation can be directly observed.
- 5.21 Smoke-diverting dampers must be provided on recirculation air systems to divert automatically any smoke-contaminated return air to the outside of the building in the event of a fire; and arranged so that the normal open smoke-diverting damper on the return-air branch to the input unit closes and all the return air is exhausted through the extract fan. Guidance is available in SHTM 81 and BS5588: Part 9.

### Duct sections

- 5.22 Ducting is generally available in rectangular, circular and flat oval sections, although other sections may be made for special situations.
- 5.23 Rectangular ducting is most common on low-pressure systems, for the following reasons:
- it can readily be adapted to fit into the space available;
  - fittings are cheaper than those for circular or flat oval ductwork;
  - it can readily be joined to such component items as heating and cooling coils, and filters.
- 5.24 When sizing ductwork, the designer should take into account:
- both installation and operating costs;
  - space limitations imposed by the structure and other services;
  - operating noise levels;
  - requirements of regulation at the commissioning stage.
- 5.25 For overall economy and performance, the aspect ratio should be close to 1:1, since high aspect ratios increase the pressure loss, heat gains or losses and overall cost (for example, changing the aspect ratio from 1:1 to 1:4 can typically

increase the installed cost of the ductwork by 40% and add 25% to the heat gains or losses).

- 5.26 Rectangular ducting should not be the first choice for high pressure systems, and should be avoided in systems operating at high negative pressures, because the strengthening of the flat sides and the sealing requirements necessary to make rectangular ducts suitable for these high pressures are costly.
- 5.27 Circular ducting is preferable for high-pressure systems, and for systems operating at high negative pressures. In the case of the latter, additional stiffening rings may be necessary. Machine-formed spirally-wound ducting and a standard range of pressed and fabricated fittings can sometimes make circular ducting more economical, particularly in low pressure systems having a relatively low proportion of fittings.
- 5.28 Flat oval ducting provides an alternative to circular ducting, principally where there is a limitation on one of the dimensions in the space available for the duct run.
- 5.29 Other sections may be used, such as triangular sections to pass through roof trusses. Such sections present difficulties in the provision of fittings, and connections to standard plant items, and are likely to be more expensive than traditional sections.

#### Standard ductwork fittings

- 5.30 All fittings should conform to current HVCA specification DW144. Wherever possible, long radius bends, large radius main branches, not more than 45° angle sub-branches and long-taper transformations should be used.
- 5.31 Fittings should be arranged with vanes in sub-branches connected directly to grilles and diffusers, and turning vanes in square bends (when used). When vanes are used, additional cleaning access will be required.
- 5.32 The number of duct fittings should be kept to a minimum and there should be a conscious attempt to achieve some standardisation of types and sizes. Increasing the number and variety of fittings in a system can markedly raise its overall cost.
- 5.33 Bad design in relation to air flow can lead to vibration of flat duct surfaces, increases duct-generated noise and pressure loss, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of installed plant items (such as trimmer batteries).

#### Branches

- 5.34 There are many designs of branches and junctions in use. The important features are that the flow should be divided (or combined) with the minimum interference and disturbance. Changes in duct sizes should not be made at the branch but a short distance downstream (or upstream). A good dividing branch

design cannot be effective if the flow entering the branch is not uniform across the section.

### Changes of section

- 5.35 The expansion of a duct section should be formed with sides having a total included angle of no more than  $30^{\circ}$ , and preferably less than  $20^{\circ}$ . If the angle of expansion is greater, the flow is not likely to remain attached to the walls of the duct and large eddies will be formed with flow reversal at the walls. This leads not only to a high-pressure loss, but also to non-uniform velocity pattern at the outlet. Where there is insufficient space for a gentle expansion and a greater angle is necessary, internal splitters should be used.
- 5.36 A contraction in a duct section is less critical, but the total included angle of the taper should not exceed  $40^{\circ}$  (or  $20^{\circ}$  where the contraction is made on one side of the duct only)
- 5.37 The most economical way to change the section of a rectangular duct is to restrict the change of duct size to one side only. If the calculated reduction or increase to the side dimension is 50 mm or less, it is usually not economical to change the size at the position. The minimum size of a rectangular duct should usually be 150 mm x 100 mm.

### Other fittings

- 5.38 As a general rule, fittings should avoid abrupt changes in direction and also sharp edges that cause the flow to separate and form eddies, thus limiting pressure loss and causing noise generation. If the fitting leads to the flow preferentially attaching to one side of the outlet, then a significant length of straight downstream duct is necessary before the next branch or fitting; this length should be greater than five equivalent diameters.

### Thermal insulation

- 5.39 Thermal insulation is applied to ductwork to reduce heat exchange, and to prevent condensation.
- 5.40 In a duct system, the air temperature changes can be significant, especially when passing through untreated space, and these have the effect of reducing the heating or cooling capacity of the air and of increasing the energy input to the system. The heat transmission to and from the surrounding space can be reduced by effective insulation of the ducts.
- 5.41 Condensation can arise in ductwork systems conveying cooled air and, apart from creating conditions conducive to corrosion of ductwork, condensation affects the heat and vapour-resisting properties of insulating materials themselves which may induce further condensation.
- 5.42 In normal circumstances, the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the

insulation thickness for vapour resistance may be greater than that for heat resistance. When cold ducts pass through areas of high dew-point, carefully selected vapour barriers should be applied externally to the insulation.

### Noise generation within the ductwork

- 5.43 Noise is generated in ductwork at sharp edges, by tie rods, damper blades, duct obstructions and sharp bends etc. This air-flow-generated noise becomes an important factor if it is about the same or greater level than the upstream noise level. (Air-flow-generated noise is often referred to as “regenerated noise”).
- 5.44 The noise level generated by airflow in ductwork is very sensitive to the velocity. The sound power of this noise is approximately proportional to the sixth power of the velocity; that is, a doubling of the duct velocity will increase the sound power by a factor of 64. The duct velocities should therefore be kept as low as possible. In general, duct fittings that have lower pressure loss factors in similar flow conditions will generate less noise.
- 5.45 Ductwork serving quiet areas should not be routed through noisy areas where noise break-in can occur and increase the noise level in the ductwork.
- 5.46 Grille, register and louvre noise should be kept to the minimum by selecting types having low noise-producing characteristics, without high tonal noise, and should be fitted with acoustically treated external inlet and outlet louvres.
- 5.47 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. They will normally be of the ‘through-the-ceiling, ‘up-and-over’ type and may include a fire damper if required.

### Volume control damper locations

- 5.48 Manually operated balancing dampers are needed generally:
- in the main duct downstream of the fan;
  - in branches of zone ducts;
  - in sub-branch ducts serving four or more terminals;
  - at terminals not covered by the previous item.
- 5.49 Dampers integral with terminals should only be used for final trimming of air volumes, otherwise noise and air distribution problems may ensue.
- 5.50 Dampers in rectangular ducts should be single-bladed when the longer side is up to 450 mm but be of the opposed-blade multi-leaf type above this size. In circular ducts, iris-type dampers are recommended. Dampers must be accessible, incorporate a position indicator and means of locking in the commissioned position. Dampers should be located as far away as possible from adjacent branches or plant items.

### Cleaning and access door locations

- 5.51 Cleaning and access doors are required to facilitate access to plant items and ductwork components for inspection, maintenance, cleaning and replacement, and must be of sufficient size to permit safe access for the required functions. Consideration should also be given to the number of doors to be provided.
- 5.52 Recommended locations for access doors are given in the current HVCA specification DW144 and are generally provided to give access to:
- every regulating damper;
  - every fire and motorised damper;
  - filter (to facilitate filter withdrawal);
  - both sides of cooling/heating coils;
  - humidifiers;
  - fans and
  - motors and impellers.
- 5.53 Care should be taken when siting access doors to ensure that no other services to be installed will prevent reasonable access.

### Flexible ducting

- 5.54 Flexible ductwork may be used for final connections to grilles and diffusers provided it is constructed to meet the fire precautions recommended in BS8313. It must not pass through fire compartment walls, floors or enclosures of sub-compartment walls or enclosures, or through cavity barriers.
- 5.55 Flexible ducting will cause a significant frictional loss and may be difficult to clean and should never be used in lieu of a bend. Where installed it should take the most direct route and be as short as possible, never exceeding 1 metre in length.

### Diffuser and grille selection and sizing

- 5.56 The effectiveness of all ventilation and air-conditioning systems depends on the methods by which air is introduced to, and vitiated air is removed from, the space. The usual results of poor air-terminal selection and/or positioning are: - draughts, stagnation, poor air quality, large temperature gradients and excessive noise.
- 5.57 Air can be supplied to a space in a number of ways, although any device can be broadly placed into one of two categories: that producing a diffused supply, or that producing a perpendicular jet. Diffusers may be radial or linear, and normally utilise the Coanda effect (that is, adhesion of the air stream to an adjacent surface), to reduce the risk of excessive room-air movement. A

perpendicular jet is formed by discharging air through grilles, louvres or nozzles, which are generally adjustable.

- 5.58 Air-flow patterns produced by both types of terminal are dependent to a large extent on the presence of the Coanda effect.
- 5.59 Supply air terminals can be incorporated into any room surface, for example, floors, walls (high or low level), desktop etc.
- 5.60 As they operate on the jet principle, the use of sidewall and linear grilles is restricted to areas where air change rates are low, that is, less than 10 per hour. Perforated rectangular diffusers can provide acceptable conditions within the occupied zone at up to 15 air changes per hour. In areas where a higher air change rate is required, square or circular ceiling mounted diffusers should be used.
- 5.61 The performance of supply air terminal devices is provided, based on three criteria: throw, spread and drop. **Throw** is defined as perpendicular or parallel distance from the terminal to the point at which the air velocity is 0.5 m/s isovel. **Spread** is defined as the width of the 0.5 m/s isovel; and **drop** is defined as the vertical distance from the centre line of the terminal to the bottom edge of the 0.25 m/s isovel.
- 5.62 It is necessary to consider each of these parameters in both summer and winter conditions to ensure satisfactory operation of the air-terminal device, as warm jets behave very differently from cold jets.
- 5.63 A warm jet tends to rise until it attaches itself to a horizontal surface, while a cold jet falls. Care must be taken to ensure that this does not lead to unacceptable temperature gradients in winter or excessive air velocities in the occupied zone in summer.
- 5.64 In order to ensure satisfactory air movement within a space, it is necessary to consider interaction between air movement from adjacent terminals, and ceiling mounted fixtures (light fittings etc), as well as interaction between air movement and room surfaces.
- 5.65 If the supply and extract terminals are too close, short-circuiting may occur, while if they are too far apart, stagnant zones may be formed. Where two opposing air streams meet, the individual velocities must not be greater than 0.25 m/s.
- 5.66 Supply and extract grilles and diffusers should be fitted with opposed-blade dampers for fine balancing purposes.
- 5.67 Further guidance on the selection of grilles and diffusers is given in the CIBSE Guide B.
- 5.68 In operating theatres, the supply terminals must be able to produce a down-flow movement of air in the operating zone 1 metre above floor level. Ceiling mounted diffusers with fixed directional vanes that provide a downward turbulent airflow are the preferred option. Plenum boxes fitted with perforated

screens to produce a parallel downward flow are also acceptable. Nozzles or jets of any type are not acceptable. Sidewall-mounted linear diffusers that utilise the Coanda effect to send air across the ceiling and 'drop' it into the operating zone are also not suitable. However linear ceiling mounted diffusers that provide a direct downward airflow around the operating zone may be used.

### Transfer grille - size and location

- 5.69 Air-transfer grilles in walls, partitions or doors form an integral part of the building's air distribution system. Modern doorsets have very low leakage rates so cannot be relied upon to permit even quite small airflows. Failure to make adequate provision for air to move from room to room will result in excessive pressure differentials and 'door whistle'.
- 5.70 Transfer grilles are required in locations where there is a significant imbalance between the supply and extract rates in a room. They will relieve any pressure differentials that may affect the operation of the spaces and/or the ventilation system and permit airflow in a known direction. However, transfer grilles are vulnerable to damage and, in many instances, as long as the equivalent free area is provided, they can be substituted with undercut door.
- 5.71 Care needs to be taken to ensure that the positioning of transfer grilles does not interfere with the fire or smoke integrity of the building. In general, the air-transfer grilles should not be installed within fire-resisting boundaries, although if this is unavoidable, they should be fitted with fire- or smoke-dampers.
- 5.72 Where installed, transfer grilles should be of the non-vision type, sized for a maximum face velocity of 1.5 m/s.
- 5.73 In photographic dark rooms, lightproof transfer grilles will be required.
- 5.74 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. (See also paragraphs 5.43 to 5.47).

### Pressure stabilisers - size and location

- 5.75 Pressure stabilisers are required in lieu of air-transfer grilles in areas where it is necessary to maintain pressure differentials between adjacent rooms to prevent reversal of airflows for example, in operating suites, isolation facilities and clean rooms. (See also Section 7 paragraphs 7.24–7.28).
- 5.76 Fire precautions for pressure stabilisers are the same as for transfer grilles. For sizing criteria, refer to Section 7 paragraph 7.23
- 5.77 Pressure stabilisers should be of the balanced-blade type, with the facility to make fine adjustment of the pressure setting. They should be silent in operation and give a seal as tight as practicable when closed. The materials of construction and method of assembly should allow for cleaning and disinfection.

- 5.78 Pressure stabilisers should be installed in a visible location so that their operation can be readily observed.
- 5.79 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where confidentiality is required. In these cases, the pressure stabiliser and cross-talk attenuator should be mounted in a short length of ductwork within the ceiling void.
- 5.80 Pressure stabilisers may need to be fitted with a stand-off baffle on their discharge side to prevent a sight line in situations where a laser will be used. Baffles may also be required to preserve privacy or prevent discharge air causing draughts or disturbing the air distribution pattern in the adjoining room. They are also useful in low-level locations to prevent the airflow path being obstructed by portable equipment.

## 6. Automatic controls

- 6.1 Various options for control of single and multi-zone air-conditioning systems are given in CIBSE Guide B.

### General requirements

- 6.2 The basic requirements for an automatic control system are as follows:

- facilities to start, set-back and stop the plant;
- facilities to control the volumetric air-flow;
- facilities to control the system or room pressure;
- temperature control and indication;
- humidity control and indication;
- devices to monitor and indicate the plant's operating state;
- alarms to indicate plant failure, low air-flow, and filter state.

The control functions actually provided will depend on the purpose of the ventilation system.

- 6.3 There will also be a need to determine the control strategy in the event of a fire either within the zone being served or within an adjoining zone.
- 6.4 The designer should consider whether it is necessary for the supply and extract fans to be interlocked, either so that the supply fan will not operate unless air-flow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served.
- 6.5 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratory and pharmacy areas that also contain fume cupboards, safety cabinets and other LEV systems.
- 6.6 Alarms should be provided to show 'filter fault' and 'low air-flow'. The "filter fault" alarm should be initiated by a predetermined increase of pressure differentials across the filter. The 'low air-flow' alarm should be initiated when the supply air quantity falls to 80% of the design value.

### Objectives of control system

- 6.7 The primary objective of ventilation plant control system is to maintain the space served within the required environmental control limits, at the appropriate times, regardless of external conditions or internal loads and with the minimum energy consumption.

- 6.8 Often, it is not possible to predict accurately building load variation at the design stage, and thus optimum set points cannot be assessed. Information provided by monitoring the operation of the plant via a Building and Energy Management System (BEMS) will enable optimum set points to be established and energy consumption reduced. Control of most systems will be via a BEMS. This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system together with that recovered by the energy-recovery device. This will provide a useful check on overall operating efficiency and provide evidence that energy targets are being achieved.
- 6.9 BEMS incorporating self-adaptive control algorithms that automatically adjust the set-point to the suit the usage and load are preferred. The provision of movement sensors within the controlled space in order to determine the actual occupancy will facilitate this process.
- 6.10 The failure of specialised ventilation systems can have grave consequences for the delivery of healthcare. Control systems should therefore be simple, robust and reliable.
- 6.11 Computer-software-driven control systems are becoming the norm in building services. However, it should be remembered that healthcare ventilation systems need to be available to operate outside of normal working periods when software support is not available. Should the software fail, it will be left to site staff, who may have little knowledge of the control algorithms to restart the ventilation system. It is therefore essential to ensure that a simple means of re-starting critical systems in the event of a software failure is provided (see also paragraphs 4.62 - 4.63)

### Location of controls

- 6.12 Whether within the plant, duct or room, sensors should be located to provide accurate measurement of the condition of the air being monitored.
- 6.13 Sensors and control items such as control valves should be located close to the element being sensed or plant item being controlled, in order to minimise time lags within the system which may create over-shoot of conditions beyond the design envelope and result in additional energy consumption.
- 6.14 There are practical advantages in locating all control valves for an air-handling unit in a bank (at a convenient height) at one end of the unit. (This will not normally result in an undue additional control lag.)
- 6.15 Some applications require intermittent mechanical ventilation, frequently at a high air-change rate, (for example, in bathrooms and treatment rooms.) Local controls to facilitate this mode of operation should be placed in a prominent position to encourage economical use.
- 6.16 Local controls that enable the user to select more than one mode of operation should be clearly labelled to identify the particular mode selected. Where the system allows different room pressures to be selected then a direct-reading

pressure gauge should be fitted within the eye line of the users to provide an independent confirmation of the resultant mode of operation. A clear description of the selectable modes of operation should be mounted adjacent to the control switch.

## Fire aspects

- 6.17 A fire control panel should be mounted at the entrance of the area that the ventilation serves. The panel should have restricted access for the fire officer and include independent on/off controls and indication of the supply and extract systems.
- 6.18 In certain critical care departments it is preferable to maintain the supply ventilation in case of a fire within the area. For example, in an operating department, while undergoing surgery the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department, or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. This will allow time for the patient to be stabilised so that he/she can be safely evacuated if necessary. A similar situation occurs for patients in ITU and other critical care units. In all of these cases the ventilation to the critical area should continue to operate unless the AHU starts to draw in smoke. For these departments, a notice should be affixed to the fire control panel drawing attention for the need to liaise with departmental staff before switching off fan units.
- 6.19 All supply AHUs should have a smoke sensor mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the supply air fire damper to close and shut down the AHU.

## Time switching

- 6.20 Facilities to start, set-back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location, for example, at the reception or staff base or, in theatres, within the Surgeon's Panel.
- 6.21 Many ventilation systems may be completely shut down when the area served is not in active use. Alternatively, where there is a need to maintain a background condition, the ventilation output can be reduced by "setting back" the system. This will significantly reduce energy consumption and extend the life of filters and other system components.

## Start-up control

- 6.22 The plant's start control should contain a control logic that will start the plant in the sequence set out in the following algorithms, Figures 4-7.

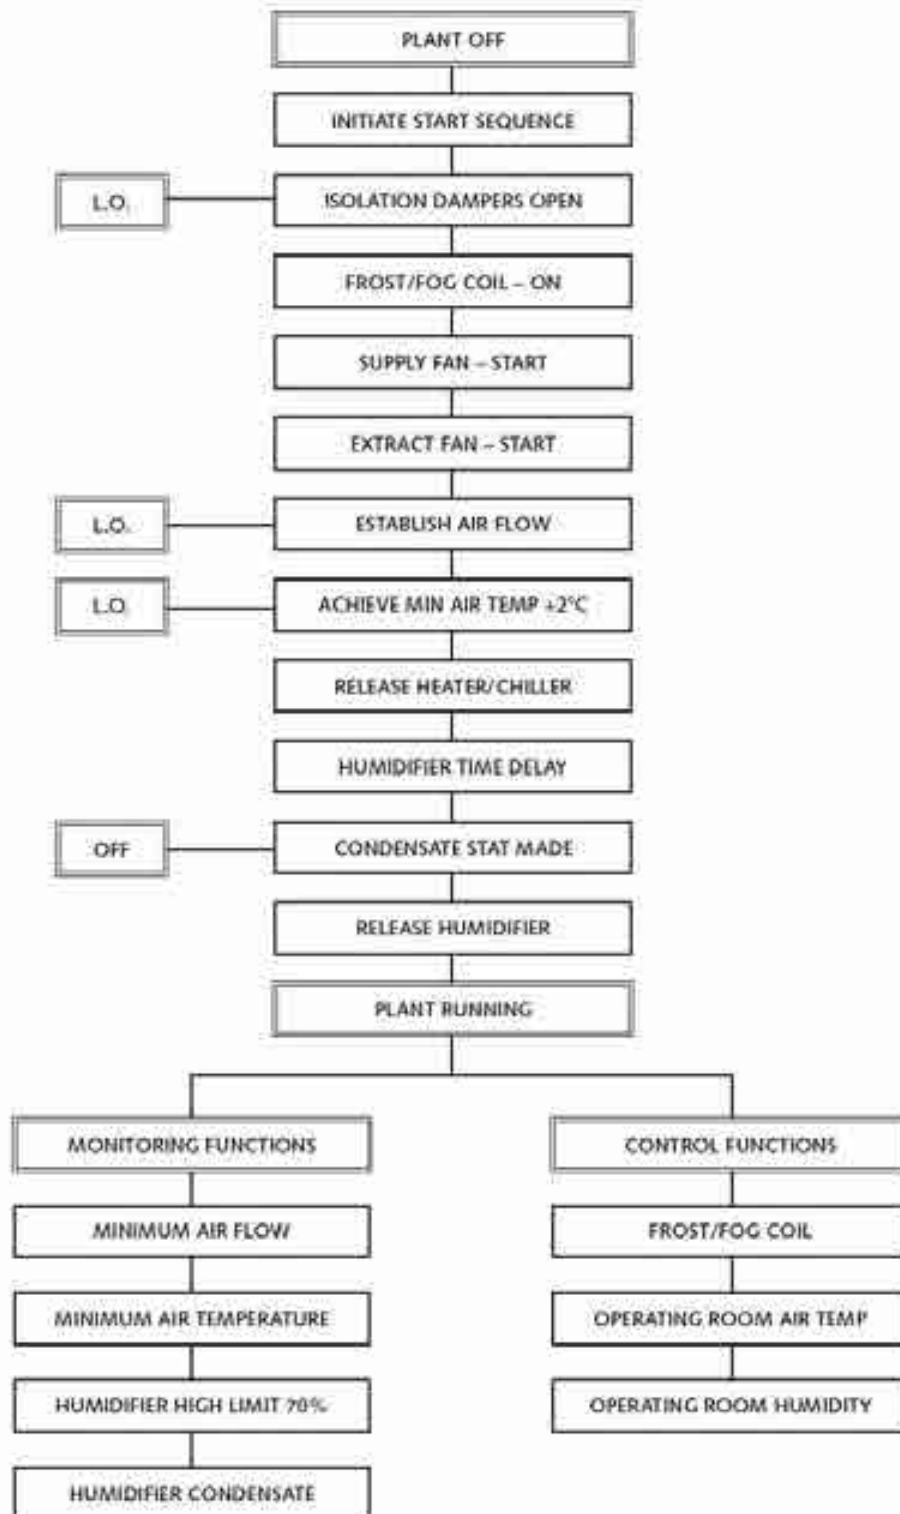

Figure 4: Typical plant control algorithm – normal start-up sequence

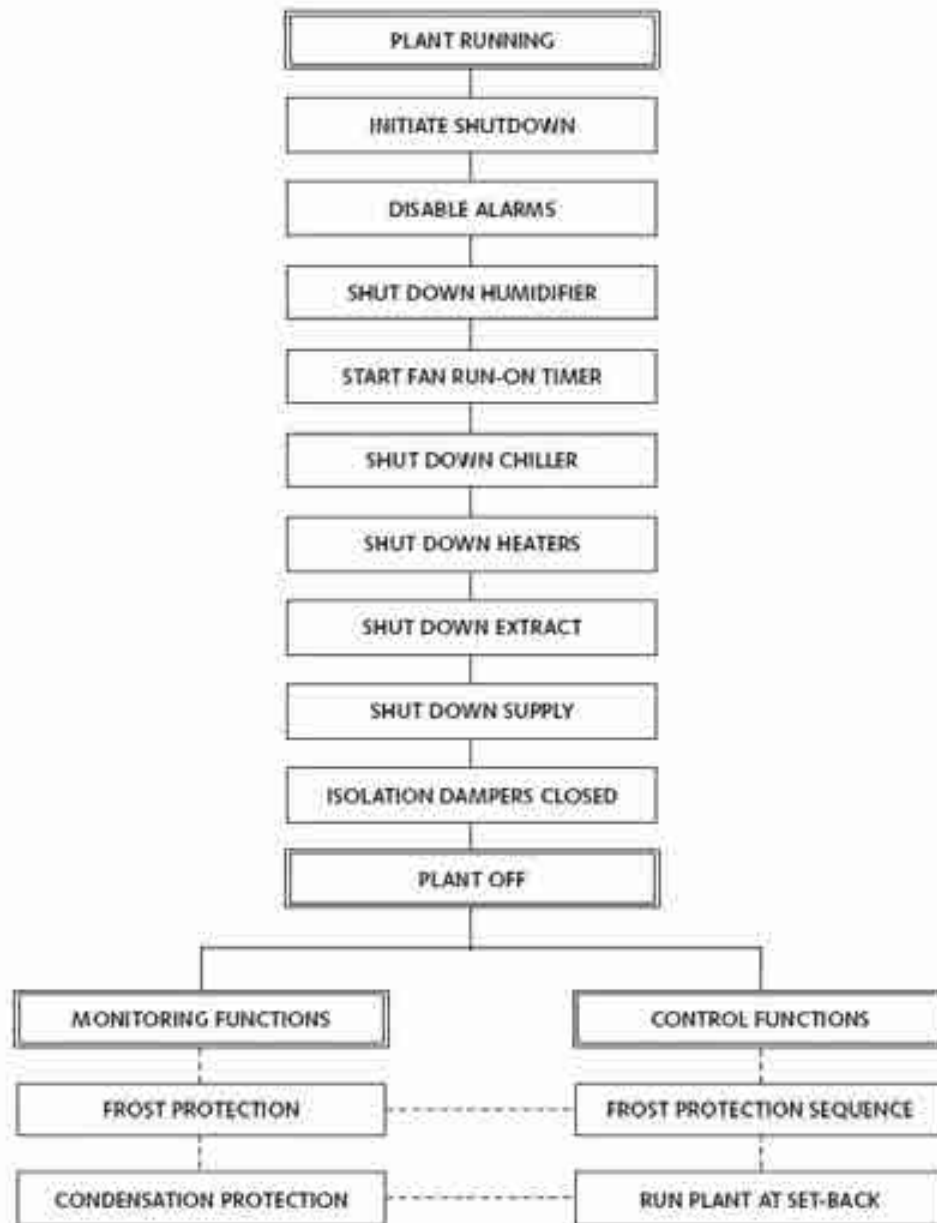

Figure 5: Plant control algorithm – normal shutdown sequence

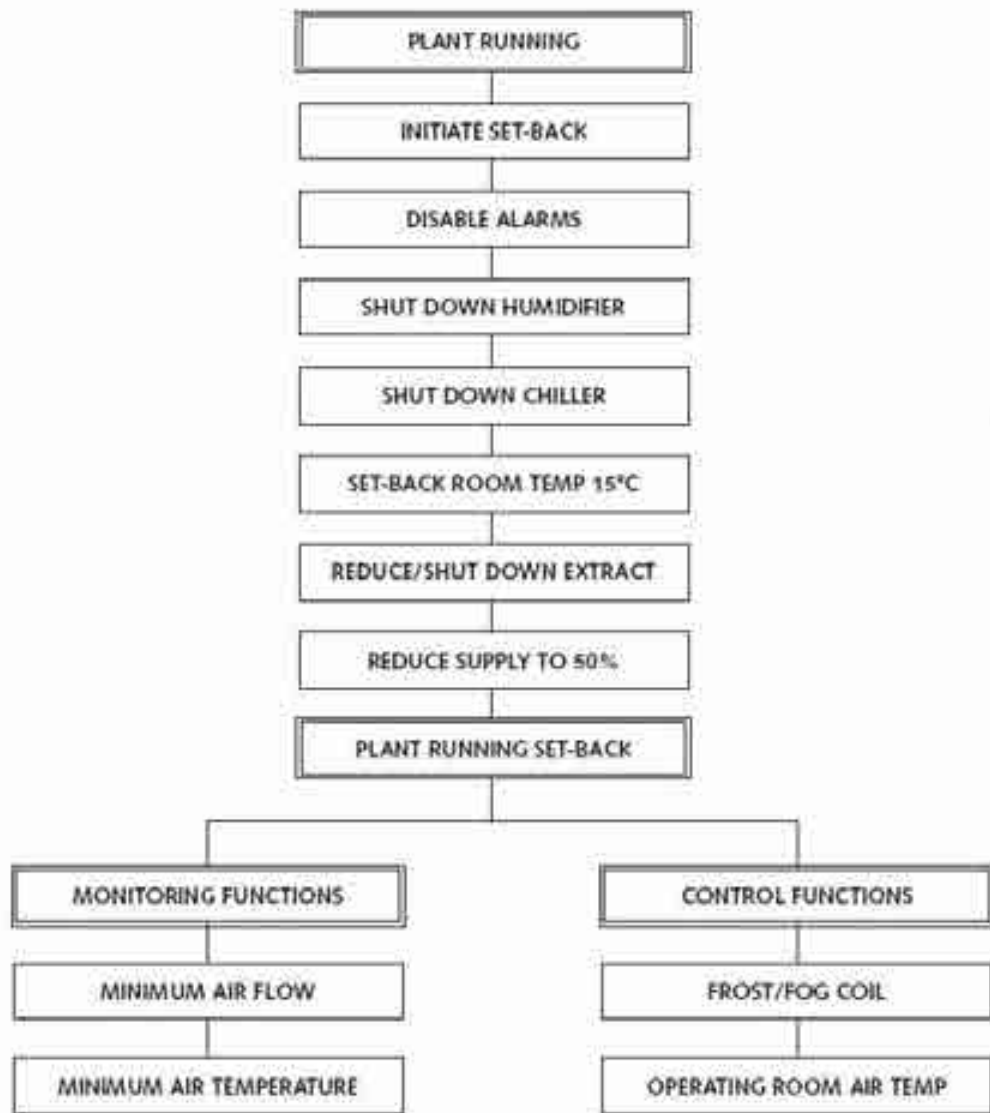

Figure 6: Plant control algorithm – set back sequence

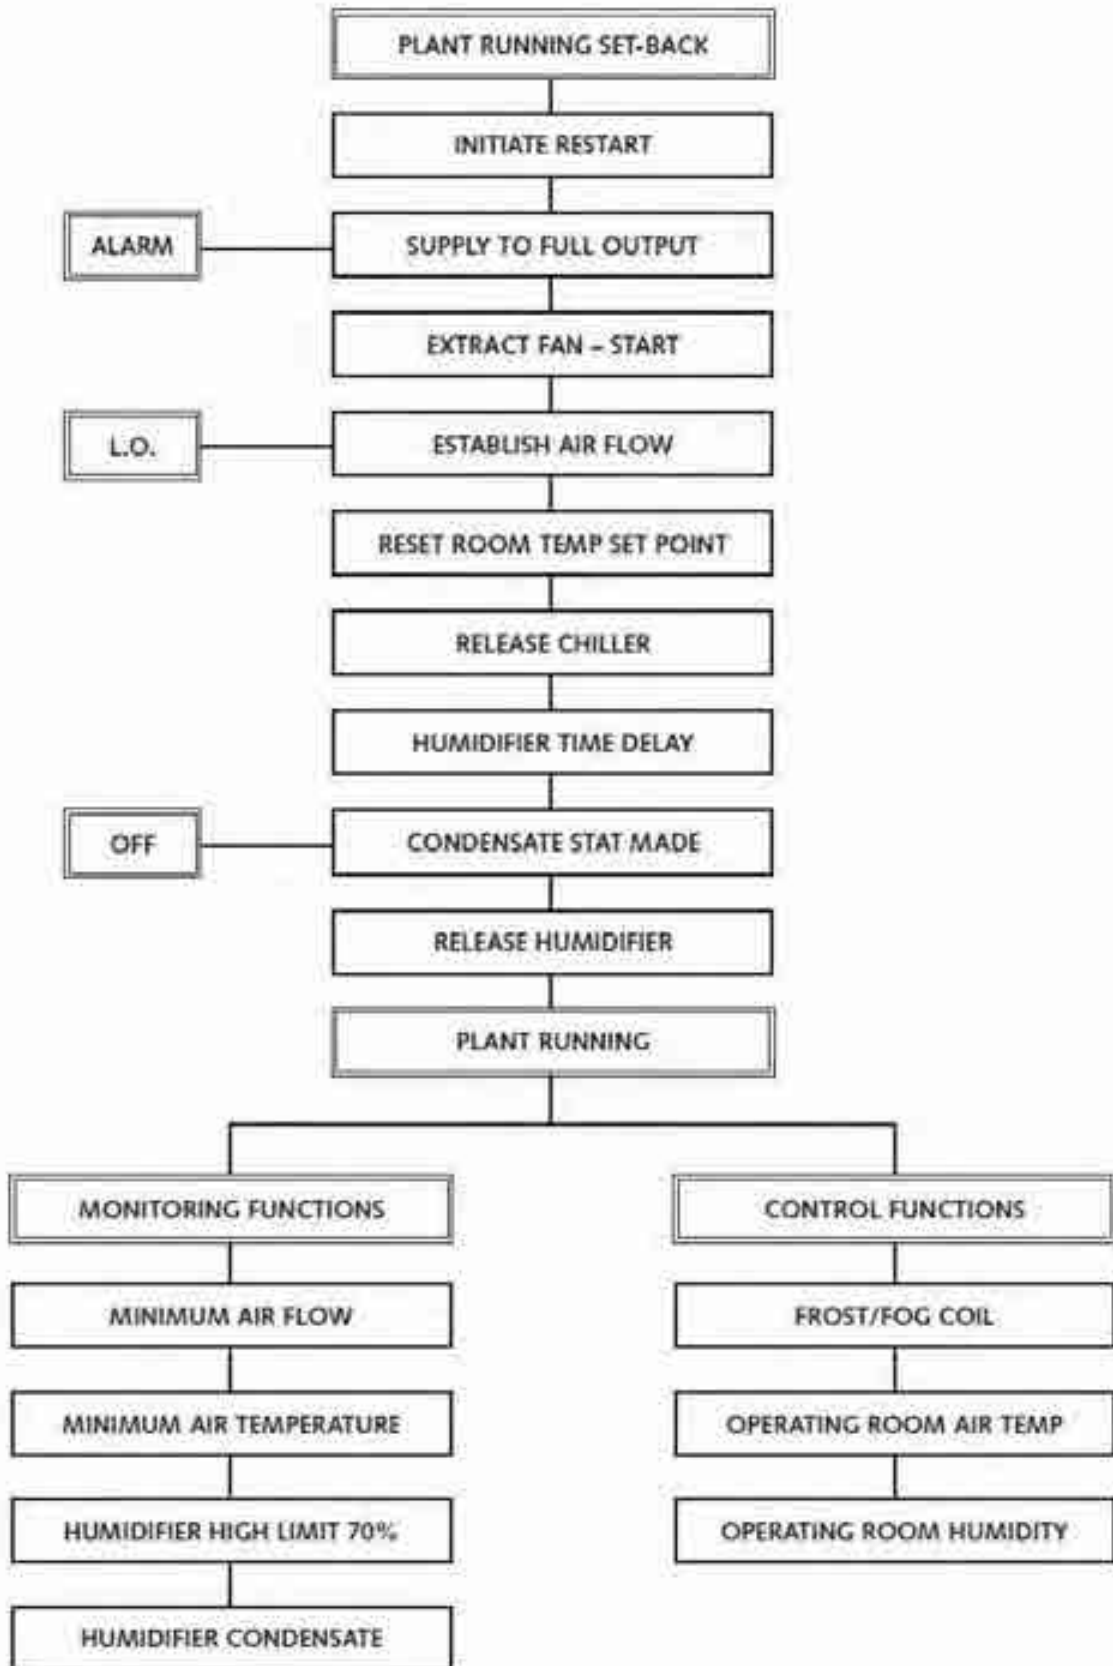

Figure 7: Plant control algorithm – restart from set-back

## Set-back control

- 6.23 Where variable speed controls are installed, the setback facility for each plant should depress the control temperature to around 15°C; exclude any humidification and cooling from the system; and reduce the supply and extract air volumes to around 50%. The extract fan can also be turned off as long as the desired direction of air movement from clean to less clean will be maintained (See also figures 4-7).

## Use control

- 6.24 The installation of movement detectors allows for "use control" of ventilation systems. A simple control logic that reduces the system to a "set-back" condition if there has been no movement detected in the space for, say, 30 minutes and that switches the system "off" if no movement is detected for one hour is recommended for many applications, including operating suites.
- 6.25 A variation on this can be provided by linking ventilation controls to lighting. For example, in an operating theatre, the system may be off outside of working hours, could run at set-back when the general lighting was switched on and increase to full speed when the operating lamp is switched on. As with movement detection, a 30-minute run-on should be provided at each stage when the lights are turned off.
- 6.26 Either of the above control strategies may be refined by linking to the BEMS to provide a control logic related to normal working hours and associated 'real-time' movement within the zone being controlled. This should result in significant energy savings.

## Environmental control

### Temperature control methods and application

#### General

- 6.27 All control valves must fail safe, that is, close in the event of power or air-flow failure, with the exception of the fog/frost battery control valve, which should open upon power or airflow failure.
- 6.28 Control valves should be located in an accessible position. Isolation valves should be provided to enable the control valve to be removed for service without the need to drain-down the system.
- 6.29 Care should be taken to ensure that the installation of control valves and their associated pipework do not obstruct access to the AHU inspection doors and hatches.

### Room temperature control

- 6.30 The limits for room temperature set point are generally between 16°C and 25°C depending on the particular application, and in some specialised instances (for example, operating departments) are adjustable within a predetermined range by the user.
- 6.31 The selection of temperature set point for each room or zone, may be by a control facility in the room / zone, or remotely at the control panel or BEMS. Where the control device is mounted within the room / zone and adjustable by the user, it should be marked either 'raise' and 'lower' or '+' and '-'. It should control within a specified temperature range to suit the user requirement with a control tolerance of  $\pm 1\text{K}$ . All other control set-points should be selectable either on the control panel or at the BEMS interface.
- 6.32 Where local control is provided, an indication of temperature will be required locally, or at a staff base (if appropriate), using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example, at the operating table in a theatre). This may be mounted in a supervisory or, "surgeon's" control panel, with the signal repeated on the main system control panel or BEMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.
- 6.33 Where the supply and extraction systems are designed for ventilation only and there is a wet heating system to provide background heating, care must be taken to avoid one system trying to heat the space while the other system is trying to cool the area.

### Frost battery control

- 6.34 Steam-supplied frost batteries must be operated as on/off devices with their sensor mounted upstream of the battery. This will give 'open loop' control. A set point of  $+1^{\circ}\text{C}$  is recommended.
- 6.35 Low pressure hot water (LPHW)-supplied frost batteries should be controlled using the proportional mode. Their sensor should be located downstream of the battery to give 'closed loop' control. A set point of between  $2^{\circ}\text{C}$  and  $5^{\circ}\text{C}$  is recommended.
- 6.36 If the temperature downstream of the frost battery, as sensed by a serpentine thermostat, falls below the required set point over any part of the coil, the plant must automatically shut down in order to prevent damage to the other batteries. The serpentine thermostat must not be in direct contact with the coil.

### Off-plant control

- 6.37 The control logic must prevent the chiller and pre-heater being on at the same time.

### Humidity control methods and application

- 6.38 In order to prevent excessive condensation when starting up from a total plant shut-down, a time delay should be incorporated into the control system such that the humidifier does not start until 30 minutes after the ventilation plant starts up.
- 6.39 Irrespective of the method of control, a high-limit humidistat should be installed to ensure that when the humidifier operates, the condition of the air in the duct does not exceed 70% saturated, particularly during plant start-up.
- 6.40 With certain types of steam humidifiers, it may be necessary to install a thermostat in the condensate line from the humidifier's steam supply, to ensure that the steam at the control valve is as dry as possible before it is injected into the air supply.
- 6.41 The humidifier and cooling-coil control must be interlocked so that they cannot be on at the same time.
- 6.42 The humidifier control system should ensure that it is switched off with the fan. It is preferable to design the control system so that the humidifier is isolated for an adequate time before the fan is turned off so as to purge humid air from the system.
- 6.43 All control valves must fail safe (that is, close in the event of power failure) and the humidifier must be interlocked with the low airflow switch.

### Multi-zone control methods and application.

- 6.44 Close control of all air-conditioning parameters may be difficult to achieve with multi-zone systems, since each zone will in theory require a re-heater and humidifier to give total control of humidity if that is what is required. In reality such close control is rarely required in practice. It is therefore usual with multi-zone systems to provide control of zonal temperature only, with humidity control where fitted being based on average conditions within all zones, or minimum conditions within one zone.
- 6.45 Where there is a requirement for close control of air-conditioning parameters in a number of zones (e.g. an operating department) separate plants should be provided for each zone in order to avoid the need for expensive over-cooling and reheating of individual zones.
- 6.46 Most multi-zone systems within healthcare premises are controlled based on off-coil control within the central plant, with trimmer heater batteries on individual zones.

### Alarms and indication

- 6.47 Supply and extract systems should include indicator lamps on the control panels to confirm the operational status of each system. Where the usage is on

a regular daily pattern, time control with a user-operated timed manual over-ride should be provided.

- 6.48 Where a system is provided for a particular space, the indicator should be in, or immediately adjacent to, that space and local controls should be provided with labels clearly defining their function (eg. isolation suites.)
- 6.49 The 'plant failure' and 'low air-flow' alarms should be initiated by a paddle switch or other device located in the main air supply duct. This should operate when the air quantity fails to reach or falls to around 80% of the design value and will give indication of fan failure, damper closed, access door left open, or any other eventuality that could cause a reduction of air quantity. Monitoring the current drawn by the fan motor is not a substitute for a sensing device that is directly affected by the air-flow.
- 6.50 The 'filter fault alarm' should be initiated by a predetermined increase of pressure differential across the filters, thereby indicating a dirty filter.
- 6.51 Direct-reading gauges or manometers should be installed across filters to give maintenance staff an indication of their condition.
- 6.52 Visual indication should be provided at a manned staff location (for example, the reception or staff base) and on the main control panel and BEMS to show 'plant failure' and 'low air flow'.

### BEMS

- 6.53 Control of most systems will be via a Building Energy Management System. This will enable the operating conditions and control tolerances to be set and monitored. The BEMS may also be set to log the actual energy consumed by the system and recovered by the energy recovery system. This will provide a useful check on the overall operating efficiency and provide evidence that energy targets are being achieved.

## 7. Specialised ventilation systems

- 7.1 This section contains design information for a range of healthcare ventilation applications.
- 7.2 The following departments will require a degree of specialised ventilation:
- the Operating department;
    - treatment rooms;
    - endoscopy, day case and minimum invasive suites;
    - cardiology and operative imaging suites;
    - conventional operating theatres;
    - Ultra Clean Ventilation (UCV) operating theatres;
    - barn theatres;
    - recovery and ancillary areas.
  - Obstetrics;
    - maternity theatres;
    - birthing rooms;
    - LDRP Rooms;
    - SCBU.
  - critical areas and high-dependency units of any type;
  - Isolation facilities;
    - infectious diseases units;
    - bone marrow and other transplant units;
    - chemotherapy and oncology units.
  - Sterile Supply and Decontamination Units;
    - wash rooms;
    - inspection and packing rooms;
    - sterile pack stores.
  - the Pharmacy departments;
    - aseptic suites;
    - extemporaneous preparation areas;
    - radio pharmacies.
  - the Pathology department;
    - laboratories;

- cat 3 and 4 rooms.
- the Mortuary and Post mortem suite;
  - mortuaries;
  - post-mortem rooms;
  - specimen stores.
- Hydrotherapy units;
- Burns units;
  - burns theatres;
  - treatment rooms;
  - isolation rooms;
  - tissue banks.
- Emerging specialties;
  - gene therapy units;
  - stem-cell laboratories.
- Infrastructure;
  - plant rooms housing combustion equipment;
  - welding facilities;
  - wood working workshops;
  - electric vehicle charging areas.

7.3 Design information for many of these applications is given in Appendix 1 Table A1, Appendix 2 and in the following Chapters within this section.

7.4 It is not possible within this existing document to give definitive guidance for every healthcare specific ventilation application. Additional detailed guidance may be issued in due course in the form of supplements.

### General information

7.5 The section on operating theatres is the most extensive and contains much information that is common to other applications. Where no specific guidance is given then the principles set out below should be followed:

- the foregoing sections of the document contain general information on healthcare-specific aspects of ventilation system design and specification;
- a set of standard solutions for the design of general operating theatre suites to conform to past and new standards is given in new standard layouts Nos 1, 3, 5 and 7 and those for UCV theatres in new standard layouts Nos 2, 4, 6 and 8 within Appendix 3;
- the CIBSE Guides A & B contain basic information on ventilation design that can be applied to most applications;

- where a British or European standard exists that is specific to the application (for example, a clean room) it should be used as the basis of the design requirement;
- air should always move from clean to less clean areas. A hierarchy of room cleanliness is given in Appendix 2 Table A2;
- differential pressure will prevent contamination between areas when doors are closed. Information on air leakage through closed doors and hatches for a range of differential pressures is given in Appendix 2 Table A3;
- the flow of air will prevent contamination between areas when doors are open. Information on air leakage through open doors and hatches for a range of differential pressures is given in Appendix 2 Table A4;
- if anaesthetic gases are used, 15 air changes per hour will be required;
- a methodology for calculating a design solution for a non-standard suite of operating rooms is given in Appendix 4. This may be adapted as necessary to suit other less complex applications where air is required to cascade from clean to less clean areas.

7.6 The supply of air to a room has four main functions:

- to dilute airborne contamination;
- to control air movement within such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
- to control the temperature and if necessary the humidity of the space;
- to assist the removal of and dilute waste gases where used.

7.7 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied will be determined by the number of doors and desired air-change rate.

7.8 There are four routes whereby airborne contaminants may appear in a room:-

- through the supply air;
- shed directly by the room occupants;
- arising as a result of the work activities;
- transferred from adjacent spaces.

7.9 Particles entering with the supply air can be controlled by the selection of suitable filter grades.

7.10 Particles shed directly by the room occupants can be controlled by:

- restricting access to essential persons only;
- the choice of the occupants' clothing;

- the room's air-change rate.

7.11 Particles arising as a result of the work activity can be controlled by:

- enclosing, semi-enclosing or otherwise controlling the work-based source;
- the room air-change rate.

7.12 The transfer of particles from adjacent spaces can be controlled by:

- differential pressure;
- air-flow paths.

7.13 Air change rates are given in Appendix 1 Table A1. These figures have been found to give sufficient dilution of airborne contaminants, provided the mixing of room air is reasonably uniform.

7.14 A downward-displacement turbulent air distribution is generally preferred. The supply and extract diffusers should be positioned to ensure that all parts of the room are actively ventilated and that where necessary the staff will be in a clean air-flow path. (See Section 5 for additional guidance on supply terminals).

7.15 Horizontal-flow room-air distribution with or without a Coanda effect can be a source of draughts and difficult to set up correctly. Its use should be confined to non-critical areas.

#### Air movement control

7.16 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room pressure differentials. When closed they prevent significant reverse air-flow.

7.17 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic airflow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less clean areas. Failure to provide such devices will lead to uncontrolled air flows when personnel move between rooms. They may also result in doors being held partially open by air pressure.

#### Temperature and humidity control

7.18 To achieve the required room conditions, supply flow rates are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the base heating load will be provided by a heating system. In critical systems the room or suite being considered will be within the

heated building envelope so the ventilation will be sized to suit the casual gains or losses.

- 7.19 Temperature differences of up to 10 K for winter heating and 7 K for summer cooling must not be exceeded.
- 7.20 It is acceptable for the humidity to swing uncontrolled between 35% and 70% saturation.

#### Removal and dilution of waste anaesthetic gases

- 7.21 Anaesthetic gases are subject to occupational exposure limits. Waste anaesthetic gas must be contained and removed by a suitable gas-scavenging system. Some leakage from the anaesthetic equipment and the patient's breathing circuit will occur with all systems, particularly during connection and disconnection; and from the interface with the patient. The air movement scheme should ensure that this leakage is diluted and removed from the room. Anaesthetic agents are heavier than air so placing the supply terminal at high level with an extract at low level, adjacent to the anaesthetic gas terminal units will ensure that staff are in a clean air-flow path.
- 7.22 In LDRP and delivery rooms the use of anaesthetic gas is controlled on demand by the patient. This may result in significant leakage which, in order to reduce staff exposure, will need to be controlled by establishing a clean airflow path. A supply at high level at the foot-end of the bed with extract at low level at the head-end will provide such a path.

#### Fire aspects

- 7.23 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire.

#### Door protection

- 7.24 Air should flow from the cleaner to the less clean areas as shown in Appendix 2 Table A2. There are several factors that affect the likelihood of a reverse air-flow through doorways:
  - when a person passes through a doorway, both the passage of the person and the movement of the door flap cause a transfer of air between the areas separated by the door;
  - when a door is left open there is a transfer of air between the two areas separated by the doorway. This is caused by air turbulence, but is greatly increased by any temperature differential between the areas (a 1.4 m wide doorway may allow the transfer of 0.19 m<sup>3</sup>/s of air in each direction when there is no temperature difference, but when the temperature differential increases to say 2 K, the volume transferred may increase to 0.24 m<sup>3</sup>/s).

- 7.25 Two methods of door protection are used in order to reduce the likelihood of contamination of clean area by a reverse air-flow from a less clean area:
- closed door protection – a pressure differential is created across a closed door so that any air leakage is from the clean to the less clean area. Appendix 2 Table A3 gives details of closed door leakage rates for a range of differential pressures;
  - open door protection – the pressure differential drops (See Appendix 2 Table A5) and is effectively replaced by a flow of air through the doorway from the clean to the less clean area. The flow of air needs to be sufficiently large to ensure that significant reverse airflow cannot occur and will be related to the relative cleanliness of the areas being considered. Appendix 2 Table A4 gives air-flow rates for open door protection related to door / opening size and classification of the adjoining areas.
- 7.26 Pressure stabilisers enable the room differential pressure to be set when the doors are shut, thus providing closed-door protection. When a door is opened the stabilisers will close, forcing air to be directed through the doorway thus providing open-door protection.
- 7.27 The recommended air-flow rates to achieve this are given in Appendix 2 Table A3. Provided that the dilution criteria in Appendix 1 Table A1 are met, the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.
- 7.28 In applications where it is critical to maintain a specific airflow and /or pressure regime (for example isolation rooms) all windows in the zone should be locked shut or sealed. Trickle vents, if fitted, will also need to be sealed.

### Systems design

- 7.29 The design of the ventilation system for an area depends on the overall configuration of the department. Where the department is served by more than one AHU, the control of the units may need to be interlocked so that reverse air-flow patterns do not occur.
- 7.30 Dual-duct high velocity systems have advantages, but are noisy, costly and may give rise to unacceptable values of humidity. Single-duct, low velocity/pressure systems are preferred.
- 7.31 Extract grilles should be sited and balanced to promote air movement in the desired direction.

## 7.0 (a) Operating department ventilation systems

- 7.32 The information given in this section relates to general operating suites. It will be applicable to other types of theatre suite such as maternity, burns, cardiac, etc. The standard values given may need to be adjusted to reflect non-standard room sizes, pressure regimes and air change rates.

- 7.33 A method of obtaining a design solution for non-standard theatres is given in Appendix 4.
- 7.34 Additional information for UCV theatres is given in Section 7.0 (b).

### General

- 7.35 The supply of air to an operating room has four main functions:
- to dilute airborne contamination;
  - to control air movement within the suite such that the transfer of airborne contaminants from less clean to cleaner areas is minimized;
  - to control the temperature and if necessary the humidity of the space;
  - to assist the removal of, and dilute, waste anaesthetic gases.
- 7.36 Because of the complexities of controlling air-movement patterns, much design effort will be required for this aspect. It is important that the design makes the best possible use of the air available, as excessive supply airflows for the control of air movement should not be used. The amount of air supplied to the operating room will be determined by the number of doors and desired air-change rate.
- 7.37 The detailed considerations upon which the supply air-flow rate is based are as follows.

### Dilution of airborne bacterial contaminants

- 7.38 There are four routes that airborne contaminants may appear in an operating room:
- through the supply air;
  - shed by operating staff;
  - produced by the surgical activities;
  - transferred from adjacent spaces.
- 7.39 Supply flow rates for the main rooms of the operating suite are given in Appendix 3. For the other areas where room sizes and activities vary from site to site, air-change rates are given in Appendix 1; Table A1. These figures have been found to give sufficient dilution of airborne bacterial contaminants, provided the mixing of room air is reasonably uniform.
- 7.40 A downward-displacement air distribution is preferred; it may be either turbulent or laminar flow. For turbulent flow the supply-air diffusers should be positioned either in the centre of each quadrant of the ceiling or along a line between the centres of each quadrant. This should ensure that all parts of the room are actively ventilated and that there will be adequate air movement at the operating table. Laminar flow would be provided by a perforated plenum terminal centred

above the operating table. (See Section 5 for additional guidance on supply terminals).

- 7.41 Suspended articulated equipment is usually fitted in theatres. These require significant structural steelwork in the ceiling void to cater for the loads imposed by the resulting bending moments. It is important to ensure that the void is deep enough to accommodate both the steelwork and the ventilation ducts. The location of the steelwork must not prevent a suitable layout of the ventilation ductwork and correct positioning of the supply air terminals. It needs to be recognised that the correct ventilation of an operating theatre plays a significant part in controlling healthcare acquired infections and is not subordinate to the desire to make equipment easy to move.
- 7.42 Horizontal flow distribution with or without a Coanda effect can be difficult to set up correctly and are unlikely to be as effective in Theatre applications. It should not be used in new installations. However space constraints may force its retention or replacement when refurbishing existing installations. Where fitted, the supply grilles will require a means of directional adjustment.
- 7.43 For general operating theatres, the air supply would be filtered in the AHU. Terminal HEPA filters are not generally required.

#### Control of air movement within the suite

- 7.44 The design of the system should seek to minimise the movement of contaminated air from less clean to cleaner areas. Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. In older designs suitably dimensioned door undercuts were often used in lieu of transfer grilles. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room-pressure differentials.
- 7.45 The relative locations of supply and extract terminals and their design air-volume rates will determine the basic air-flow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces ensuring a flow from the clean to less clean areas of the suite. Failure to provide such devices will lead to uncontrolled airflows when personnel move between rooms and doors being held partially open by air pressure.

#### Temperature and humidity control

- 7.46 Supply flow rates to achieve the required room conditions, are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the room being considered will be within the heated building envelope.
- 7.47 Temperature differences of up to 10 K for winter heating and 7 K for summer cooling must not be exceeded.

- 7.48 It is acceptable for the humidity to swing uncontrolled between 35% and 60% saturation.

### Removal and dilution of waste anaesthetic gases

- 7.49 Anaesthetic gases are subject to occupational exposure limits. The air-movement scheme should ensure that staff are in a clean air-flow path. (See Section 7 paragraph 7.21).
- 7.50 Air extracted from operating suites should not be re-circulated, as it may contain malodorous contaminants. However an energy recovery system should be fitted in the extract in order to reduce the plant energy consumption. (See Section 4 paragraphs 4.142 - 4.147).

### Fire aspects

- 7.51 When considering the overall air-flow movement, careful thought needs to be given to the operation of the ventilation system, to limit smoke spread in the event of a fire. However, this is a highly staffed department with a low fire risk/load status and these factors need to be recognised when developing the fire strategy. It is considered satisfactory to treat the complete operating department as a single fire compartment providing there are at least two exits from it. Over-compartmentalisation can lead to difficulties in establishing clean air-flow paths and room-air dilution rates. This will lead to an increased risk of healthcare-associated infections. Staff areas within the department should be treated as a sub-compartment. (See Section 6 paragraph 6.18).

### Door protection

- 7.52 Air should flow from the cleaner to the less clean areas as shown in Appendix 2 Table A2. The factors that affect the likelihood of a reverse airflow through doorways are discussed in Section 7 paragraphs 7.24 - 7.26.
- 7.53 It is not possible to design an air-movement scheme, within the restraints of the amount of air available that will protect the operating room when two doors are simultaneously opened. The design process that has been used considers that each door is opened in turn and ensures that the direction and rate of air-flow through any open doorway is sufficient to prevent any serious back-flow of air to a cleaner area.
- 7.54 Provided that the air-change rates in Appendix 1 Table A1 are met, dilution will be sufficient to ensure that the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.
- 7.55 The following general points should be taken into consideration during the design of operating suites:

- Number of exits – the fewer the number of rooms (and therefore doorways) leading from the operating room the better, as traffic is reduced and less complicated air-movement control schemes are required.
- Scrub and hand-wash facilities – these may be a part of the operating room, often in a bay. The bay would count as part of the operating room volume and should have a low-level active or passive extract to remove the moisture-laden air. Should a separate room be required for the scrub area, a door between the scrub-up room and the operating room is an inconvenience to scrubbed staff, and could be replaced by an opening. This opening should be larger than a normal single doorway, but the scrub would not, in these circumstances, be considered part of the operating room volume.
- If an alcohol scrub regime is employed, individual theatre scrubs may not be required and would be replaced by a common departmental pre-/post-operation scrub position in the corridor. This would require local extract to prevent a build-up of moisture.
- Preparation 'Sterile Pack Store' (SPS) – if it is intended to 'lay-up' instruments in the operating room, the preparation room is then used simply as a sterile pack store. The nominal room pressure can therefore be the same as that of the operating room and the airflow between the two rooms in either direction. Air supplied to the preparation room may be directed into the operating room either through a door mounted transfer grille or if no door is fitted, through the opening. Alternatively, stock ready-use sterile items can be located in a bay within the theatre. In this case, a portion of the total theatre supply air should be provided in the bay to ensure it is actively ventilated.
- Preparation room 'lay-up' – when the preparation room is used as an instrument 'lay-up' room, it should be regarded as being of greater cleanliness than the operating room, and the design should minimise the transfer of air from the operating room to the preparation room. Air supplied to the room may be directed to the operating room through a pressure stabiliser taking care not to compromise the airflow pattern in the operating room. The air may also be directed into a corridor;
- Service corridor – if materials to be disposed of are placed in impervious material for transportation, it is not necessary to have a separate corridor for this purpose. However, a service corridor has many operational advantages in terms of the flow of materials through the theatre suite. It also permits routine service and maintenance access without compromising the use of adjacent theatre suites.

### Standard air-movement control schemes

- 7.56 In the previous versions of this guidance standard air movement control schemes were given that provided a range of design solutions to typical operating suite layouts. These were satisfactory design solutions for 'standard' sized rooms within the suite but were never intended to be universal for any sized room or suite. Guidance on operating suites contained in HBN 26 (2004) has increased the recommended size of operating room from approximately

35m<sup>2</sup> to 55m<sup>2</sup>. Associated room sizes and air change rates have also increased. This means that the original standard solutions are no longer appropriate for new-build installations.

- 7.57 Because of the resulting increase in the volume of air supplied to the theatre, provision needs to be made either to actively remove it or allow it to escape passively through pressure stabilisers. The increase in room size has also made the number and position of air-supply terminals critical to the effective ventilation of the room.
- 7.58 Four new standard solutions have been developed to reflect the current guidance on theatre suite layout and room sizes given in HBN 26 (2004) as well as the general increase in air-change rates.
- 7.59 The most commonly used original standard solutions have been revised and updated. They have been retained in this guidance, as they will remain applicable to older theatre suites that are being refurbished to their original performance standards. They will also be applicable in existing departments where space constrains do not permit the upgrading of suites to the latest standard of performance or where a pre-built "shell" is being fitted out.
- 7.60 It is important to recognise that in any situation where a "non-standard" room size or theatre suite layout is being considered, the designer must return to first principles when developing a solution. Examples of non-standard configurations would be:
- cardiac theatres that typically have an operating room half as big again as normal, a perfusion laboratory and no anaesthetic room;
  - operating departments served by a central instrument lay-up preparation area rather than individual prep rooms;
  - balanced-flow theatres for infectious cases.

Appendix 4 contains a methodology for assisting the designer to arrive at a suitable solution.

- 7.61 The new and revised standard design solutions are as follows:
- No 1 – Typical Conventional theatre – room sizes as HBN 26;
- No 2 – Typical UCV theatre – room sizes as HBN 26;
- No 3 – HBN 26 illustrated Conventional theatre;
- No 4 – HBN 26 illustrated theatre with UCV terminal fitted;
- No 5 – Pre-2006 Conventional theatre, single corridor (SHTM 2025; 1b);
- No 6 – Pre-2006 UCV theatre, single corridor (SHTM 2025; 1a);
- No 7 – Pre-2006 Conventional theatre, two corridor (SHTM 2025; 5b);

No 8 – Pre-2006 UCV theatre, two corridor (SHTM 2025; 5a).

7.62 Details of these standard solutions are given in Appendix 3. They contain diagrams that show the relationship of rooms and the various doors and transfer devices between them, **but should not be regarded as architectural layouts**. The schemes have been developed using the calculation procedure described in Appendix 4. Important features of the solutions are:

- Zone trimmer heaters – a trimmer heater battery is advocated when calculations indicate that the temperature differential between rooms may be greater than 2 K. Generally this will only be the case in the preparation room when designated as a lay-up.
- The preparation room (sterile pack store)/operating room interface – these rooms are deemed to be of equal cleanliness, and thus a transfer grille is required between these rooms or the door can be replaced with an opening wider than a standard door.
- Preparation (lay-up)/disposal room interface – pressure relief dampers are recommended here to provide an air path when doors are closed, while preventing back-flow when a door is opened elsewhere.
- Operating room/anaesthetic room interface – pressure stabilisers, or in some cases, carefully sized transfer grilles are recommended here, and between the anaesthetic room and corridor, and between the operating room and corridor.
- Operating room/scrub room interface – an opening is provided between these rooms. The flow of air through the opening provides protection, and gives bacterial dilution within the scrub room; the air is then exhausted to the corridor via a pressure stabiliser.

7.63 No mechanical supply or extract ventilation is provided in the scrub room, and thus when a door is opened elsewhere in the suite, the stabiliser will close, allowing the air to be re-directed to help protect the doorway. If the scrub is a bay within the theatre then a suitably positioned pressure stabiliser and / or active extract should be provided to ensure air movement and prevent a local build-up of moisture.

7.64 Any other scheme may be used and the standard solutions applied, if the following conditions are met:

- room relationships in air network terms are as shown in the plans;
- door-gap measurements approximate to those given in Scottish Health Technical Memorandum 58 – ‘Internal doorsets’, (but see also Appendix 2 Table A3 and the comment below);
- casual heat gains are accounted for;
- a trimmer battery is installed in the air supply system to the preparation room;
- leakage through the structure is kept to a minimum.

**Note 3:** It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design door leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

- 7.65 It is recommended that every effort should be made to adopt one of the schemes described above.

#### Air terminals and air distribution within rooms

- 7.66 The selection and sighting of air diffusers will be critical in establishing an efficient pattern of mixing. To this end the diffusers selected must be fit for purpose. Ceiling mounted circular 'air master' style, square 'four-way blow' or similar diffuser designs that provide a downward displacement, turbulent airflow are the preferred option. (See Section 5 paragraph 5.68).
- 7.67 Plenum-type 'laminar'-flow-style diffusers with a footprint that encompasses the operating site are acceptable but may be prone to buoyancy effects as a result of temperature difference. Manufacturers' type-test data should be consulted to ensure that the terminal will achieve the required performance envelope. Note that these are not true laminar-flow systems in the strict sense of the word but produce a downward-displacement parallel-flow style of air distribution.
- 7.68 The diffuser equipment chosen should not cause 'dumping' and it should provide a velocity 1 metre above floor level at the operating position of between 0.2 m/s and 0.3 m/s.
- 7.69 In the operating room, the supply air terminals must be at high level, and should all be adjustable for rate of flow as well as being easily cleaned and silent in operation.
- 7.70 In order to ensure that all parts of the operating room are actively ventilated, there should be an air-out path on each face or in each corner of the theatre. This may be provided by a pressure stabiliser, transfer grille, active or passive extract terminal. A minimum of three, but preferably four, air-out paths - approximately equally spaced - should be provided.

#### Automatic control

- 7.71 The automatic control of ventilation in operating suites needs to be simple and robust. Over-reliance on complex room pressure and flow relationships linked to automatic fan speed control are unnecessary and in the long term have been shown to be unreliable. Complex software algorithms that can only be accessed and interpreted by off-site specialists should not be used. Whichever control strategy is chosen it is important that on-site staff have the facility to override the control system and keep the ventilation operating at least until the surgical procedure is complete. (See also Section 6; paragraph 6.11)

- 7.72 Theatre air-conditioning control sensors should be actively ventilated. They would typically be located in a sampling extract duct mounted in the surgeon's panel, positioned at normal working height (1.8 m above finished floor level) and be accessible for cleaning and the removal of fluff and lint.
- 7.73 Wall-mounted passive-temperature and humidity sensors are not recommended.
- 7.74 Controls should be provided to enable operating department ventilation plants to be closed down when the operating suites are unoccupied. (See also Section 6 paragraphs 6.24 - 6.26)
- 7.75 When in the 'off' mode, the control system should ensure that the ventilation plant is automatically reinstated if the space temperature falls below 15°C.
- 7.76 The theatre control panel should include plant status indication; clearly-readable temperature and humidity indicating gauges; and means of adjusting the set point for temperature. Theatre ventilation plant status indication should be located at the staff control base.
- 7.77 Where it is considered necessary to fit a humidifier, it should be selected to humidify to 40% saturation at 20°C during the design winter outside conditions. The cooling coil should be able to remove sufficient moisture so that 60% saturation at 20°C is not exceeded during the design summer outside conditions.
- 7.78 Each operating suite should be served by an independent supply and extract plant.

## Ventilation of operating department ancillary areas

### General

- 7.79 There are advantages in providing mechanical ventilation to all areas of the department. Maintaining operating suite airflow patterns is simpler and grilles and diffusers can be sited to eliminate condensation on windows. Where radiators or embedded wall or ceiling panels are installed they should be confined to the corridors and staff-only areas of the department.

### Ventilation requirements

- 7.80 Appendix 2 Table A2 gives guidance on the operating department areas in descending order of cleanliness, and this should be considered in the overall design of the department ventilation systems. The specified flow rates of air through doors given in Appendix 2 Table A4 for the operating suite are not necessary for other areas of the department. However, the air-flow directions must be maintained from the clean to the less clean areas.
- 7.81 All windows in the department should be double-glazed and hermetically-sealed in order to ensure that the desired airflow pattern is maintained under all

external environmental conditions and to avoid infestation. Trickle vents if fitted will need to be sealed.

### Systems design

- 7.82 The design of the ventilation system for the ancillary rooms depends on the overall configuration of the department. The plant for the ancillary rooms may need to be interlocked to the theatre suite plants so that reverse air-flow patterns do not occur.
- 7.83 Extract grilles should be sited and balanced to promote air movement along the clean and access corridors towards the reception/transfer areas. This should not affect the air distribution in the operating suite(s).

### Reception

- 7.84 The aim in these areas is to provide comfortable conditions having regard to the movement control requirements of the department as a whole. The number of air changes will depend on the particular design.

### Sterile pack bulk store

- 7.85 The store needs to be maintained at a positive pressure in order to preserve the cleanliness of the outside of the packs; 6 air changes are recommended.

### Recovery

- 7.86 The air-change rate in the recovery room will be rather higher than that needed merely to provide clean, comfortable conditions, as it is necessary to control the level of anaesthetic gas pollution; 15 air changes are recommended, with a balanced air flow.
- 7.87 The supply air terminals should be ceiling mounted above the foot-end of the recovery bed positions. Extract should be at low (bed height or below) level behind the bed head positions or in the corners. This will establish a clean airflow path so that staff do not inhale anaesthetic gases exhaled by recovering patients.

## 7.0 (b) Ultra-clean ventilation systems

### General requirements

- 7.88 The design philosophy of a conventionally ventilated operating suite is based on the need to dilute contaminants and control both the condition and movement of air in an operating suite. Ultra-clean ventilation (UCV) is a means of significantly increasing the dilution effect by providing a large volume of clean filtered air to the zone in which an operation is performed and sterile items are exposed. Air is discharged above the operating zone and while not truly laminar, its downward displacement purges the clean zone of contaminants and

particles generated by the activities within it. The airflow in and around the clean zone also serves to prevent particles originating outside the zone from entering it. The resulting reduction in contaminants has been shown to reduce significantly post-operative sepsis following certain orthopaedic procedures.

- 7.89 The number of bacteria that are present in the air at the wound site and exposed surgical items is dependent on the operating team, their procedural discipline, choice of clothing and the type of UCV system. Ultra-Clean air is defined as that containing not more than 10 CFU/m<sup>3</sup>.
- 7.90 UCV systems are very successful in reducing contaminants at the wound site so it is often considered that there is no need for complex air movement control schemes in the rest of the suite. However when designing the ventilation scheme it should be noted that the users may switch the UCV terminal to "set-back" when non-orthopaedic surgery is taking place. This is because the high airflow rates can cause increased moisture evaporation of exposed tissue that may be detrimental to the surgical outcome. In recognition of this, the ventilation scheme should be capable of providing operating conditions to at least a "conventional" theatre standard throughout the suite with the UCV in set-back mode. It should also be remembered that suitable levels of ventilation will always be required in the peripheral rooms.
- 7.91 UCV systems can be designed and built from first principles or a range of bespoke modular units of varying shapes and sizes are available with each manufacturer having a slightly different approach to UCV design. Some systems are fitted with partial or full walls to delineate the clean zone and direct a laminar or exponential downflow of air within it. Other designs utilise slotted linear supply terminals to produce an air curtain around the clean zone together with laminar-flow diffusers to provide a downward-displacement supply within it. **Notwithstanding any variation in the design philosophy, all UCV systems will be required to achieve completely the performance standard set out in the "Validation" section of this document.** (Section 8)
- 7.92 As with conventional theatres, each UCV operating suite should have its own dedicated air handling unit (AHU) to the standard set out in Section 4 of this document. To ensure operational flexibility and permit routine maintenance, air handling units should not be shared between suites.
- 7.93 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances an AHU may be shared between not more than two operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre so that the primary air volume to each UCV canopy can be determined. In addition the branch supply and extract should be capable of being physically isolated and the main air-flow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.
- 7.94 An inherent feature of a UCV system is its large airflow so it is essential to re-circulate the air supplied to the operating theatre and/or to recover its energy in order to optimise operating costs.

- 7.95 The primary fresh-air volume supplied to a UCV suite will be the same as in a conventional suite and it should be dispersed to the rooms in the suite in the same manner. This is an important aspect of the design and requests by UCV suppliers for increased primary air-supply volumes should be resisted.
- 7.96 Laying-up in the clean zone is preferable for infection control reasons. Where a Sterile Pack Store (SPS) Preparation room is provided a transfer grille will be required in the preparation room / theatre door.
- 7.97 If the Preparation room is intended to be used for laying-up instruments, a pressure stabiliser will be required between the prep room and theatre. It should be fitted with a stand-off baffle to prevent air transfer interfering with the ultra-clean airflow distribution.
- 7.98 Separate scrub-up or disposal facilities are not necessary for air cleanliness although operational policy may prefer such a provision. A separate anaesthetic room should, however, be provided.
- 7.99 There is no aerobiological reason why two or more UCV systems should not be installed in a common area as long as adequate spacing is provided. These are known as "barn theatres" and require special design considerations and operational discipline. The relative positions of the UCV units, temperature control range and location of doors and openings to other areas will all significantly affect the airflow at the operating positions.

## Types of UCV system

### Remote plant systems

- 7.100 In a remote plant system, all the air-conditioning equipment is located outside of the operating room, except for the unidirectional air-flow terminal, terminal filter, air diffuser and the return-air grilles (see Figure 8).

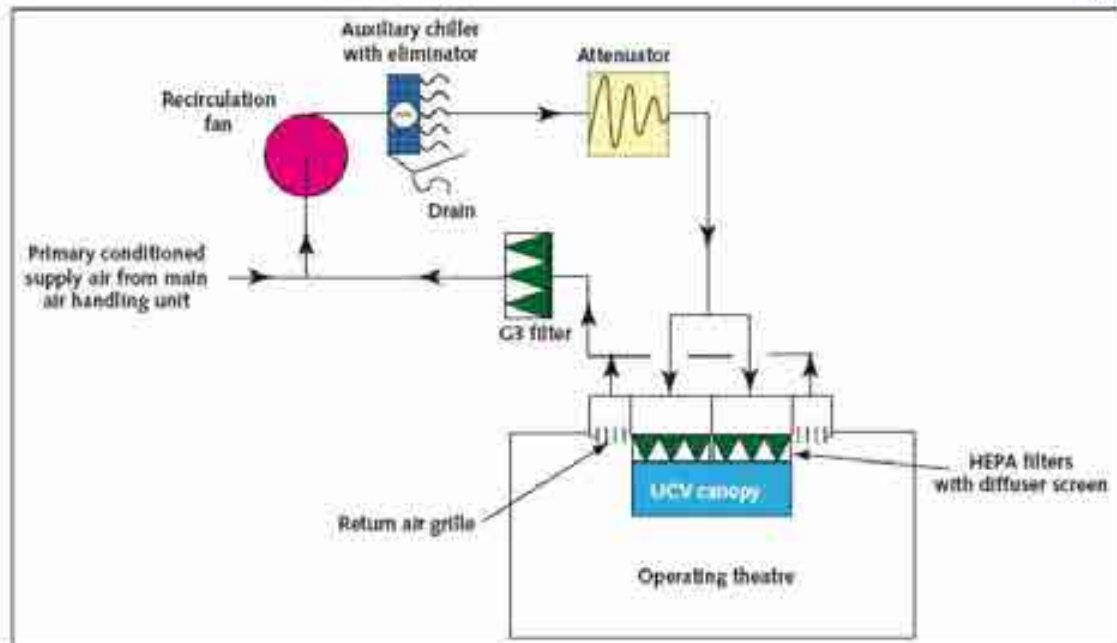

Figure 8: UCV theatre with remote air recirculation

7.101 This arrangement is the preferred option for new installations as it has the following advantages:

- the recirculation fans are out of the theatre thus reducing noise. Multiple recirculation fans can be replaced by a single fan unit with its drive out of the air stream;
- casual heat gains from recirculation fan(s), canopy lights, equipment and people within the theatre can be removed by a chiller battery in the return air stream. This will prevent heat build-up in the theatre;
- the return-air filters can be changed without needing access to the theatre making routine maintenance more feasible;
- the opportunity exists to locate the HEPA filter in the primary supply duct rather than the theatre terminal. This will reduce the number of filters required and allow them to be changed without entering the theatre.

### Modular systems

7.102 Modular systems are frequently used in retrofit applications. Vertical or horizontal units are available.

7.103 Vertical-flow modular units comprise a ceiling-mounted air-terminal module containing return-air filters, return-air fans, final filter and air diffuser. Primary air is supplied by a remote air-conditioning unit at the volume and to the standard required for a conventional operating suite. (see Figure 9)

Figure 9: UCV theatre with modular system

- 7.104 Horizontal or cross-flow modular units comprise a wall-mounted air-terminal module standing vertically to produce a horizontal flow of air and containing final filter/diffuser, return-air filters and fans. The module may incorporate a cooling unit or be supplied with 'fresh air' from a separate primary cooling system.

#### Vertical flow UCV systems

- 7.105 Vertical-flow systems have a superior performance and are more effective at reducing infection risks. Air-curtain or partial-wall systems are acceptable, but are known to be more susceptible to problems arising from performance deterioration, poor operating-team discipline and high occupancy rates than is the case with full-wall systems. A full-wall is considered to be any wall terminating not more than one metre above the finished floor level.
- 7.106 Because of the large volume of air being moved in a relatively small space, the siting of the return-air grilles can cause short-circuiting of the air discharged through the UCV terminal. If the return-air grilles are positioned at high level, partial walls should be provided to control short-circuiting. The partial-walls shall be not less than 1m from the operating room walls and terminate at least 2m above floor level. The clearance should be increased proportionally for larger terminals (that is, 1.15m for 3.2m x 3.2m units and 1.25m for 3.5m x 3.5m units). In all cases, the sidewalls should terminate at 2m above floor level.
- 7.107 Siting the return-air grilles around the periphery of the theatre at low level will eliminate short-circuiting, remove the need for partial walls and give an improved airflow path. In any event there should be an air-out path on each face or in each corner of the theatre. These may be provided by combination of pressure stabilisers and passive or active low level extract grilles. Failure to provide air-out paths on all faces of the theatre may result in the surplus air causing entrainment into the clean zone.
- 7.108 Vertical systems should have a clean zone large enough to encompass the operating site and all of the instrument trays likely to be needed for the surgical

procedures to be undertaken. Ophthalmic and minor hand surgery would typically require a 1.4m circular or rectangular terminal. For major orthopaedic procedures a minimum size of 2.8m x 2.8m will be required. This is the area projected on the floor under the supply air terminal within the partial walls, full walls or air curtain. Any air outside this zone cannot be guaranteed to be ultra-clean although given the dilution factor the level of microbiological contamination will be much lower than the general level in a conventional operating room. The use of lines or a coloured area on the floor delineating the extent of the clean zone will assist staff and is therefore essential.

- 7.109 When upgrading an existing conventional theatre to an ultra-clean standard the only solution may be the installation of a modular system. In these units, the heat gains from the return-air fans and terminal lights may warrant the inclusion of supplementary cooling within the module although modern luminaries contribute substantially less unwanted heat. However issues of cooling coil drainage, condensate removal and maintenance access within the space constraints of the module may make this option impracticable. The additional cooling load should then be catered for by conditioning the primary air to compensate.
- 7.110 If an existing AHU is to be retained, it may require modification to ensure that it achieves the minimum standards set out in Section 4 of this document. The fan may need re-rating to accommodate the change in system resistance. The cooling coil may also need to be upgraded to cater for the increased load resulting from the return air fans and terminal lights. Failure to make adequate provision for this may make the theatre unusable during prolonged warm spells.
- 7.111 A factor affecting the air-flow pattern is the supply or room air temperature difference. When the supply-air temperature is significantly above room temperature, buoyancy effects will reduce the volume of air reaching the operating zone. If it is anticipated at design stage that this will be a regular occurrence, then a system incorporating full-walls should be used. Demountable extensions that convert a partial-wall to a full-wall unit are available.
- 7.112 Convection up-currents from the surgical team and operating lamp tend to counter the movement of clean air towards the operating site, hence the air velocity reaching the operating level is critical. The minimum velocity given below has been selected to take account of these factors and is greater than the theoretical minimum value.
- 7.113 For all vertical UCV systems the design discharge velocities will be as follows:
- Air velocity 2 metres above floor level:
- partial-wall system = 0.38 m/s average;
  - full-wall system = 0.30 m/s average.
- Air velocity 1 metre above floor level:
- all systems = 0.2m/s minimum within the operating zone.

The validation Section 8 paragraphs 8.75 – 8.86 gives details of the method of measurement.

- 7.114 Variable-speed recirculation fans with differential pressure control may be the most suitable solution for maintaining consistent performance and energy saving.

### Horizontal UCV systems

- 7.115 Horizontal UCV air-flow systems have been shown to be less effective than vertical systems and are not the preferred solution. There may be occasions, however, where architectural, engineering, economic or workload considerations prevent the installation of a vertical-flow system and only a horizontal-flow system can be installed.
- 7.116 Horizontal- or cross-flow modular units comprise a wall-mounted air terminal standing vertically to produce a horizontal flow of air across the operating field. The terminal module contains the final filters, air diffuser, return-air grilles, filters and fans. The module may incorporate a full air-conditioning unit or be supplied with 'fresh-air' from a separate primary air-conditioning system. In the latter case the return-air fan power may warrant the inclusion of a supplementary cooling coil within the module.
- 7.117 The system should have sidewall panels at least 2.4m apart. The panels may fold to facilitate cleaning of the theatre. The minimum height of the terminal should be 2.1m and a deflector at the top of the filter/diffuser will be acceptable as an alternative to a full roof. These dimensions reflect currently available equipment and may impose operational constraints in addition to a lower level of performance common to these systems.
- 7.118 In the horizontal flow systems, personnel working between the filter and surgical wound will disperse bacteria that are more likely to contaminate exposed surgical instruments and enter the wound. This may be minimised by the use of improved clothing and operating procedure to reduce dispersion of bacteria. The use of lines on the floor delineating the extent of the clean zone and hatching or colour coding the 'no-entry' zone between the air diffuser and patient will serve to prompt staff and are therefore essential.
- 7.119 The air discharge velocity as measured 1m from the diffuser face should have a mean value of 0.4 m/s. The validation Section 8 gives details of the method of measurement.

### Filters

- 7.120 The main plant primary and secondary filters should be to the standards and in the location set out in Section 4.
- 7.121 Terminal filters should be provided within the airflow terminal or in the air supply to it. High efficiency particulate air (HEPA) filters grade H10 as specified in BS EN 1822 will be required as a minimum. There is no aerobiological benefit in

fitting filters of a higher grade than this, although for practical reasons most UCV manufacturer recommend the fitting of H12-grade filters.

- 7.122 In some modular UCV units, the terminal filter is used as a pressure equaliser to balance airflow and filters of a higher grade with a greater pressure drop may be recommended by their manufacturer. The increased resistance may affect the velocity of air reaching the operating level and there will be penalties in terms of installed fan power and higher noise levels.
- 7.123 The final filters should be installed in a leak-proof housing in a manner that allows the terminal unit, filters and their seals to be validated. A challenge test will be carried out during commissioning to prove the effectiveness of the complete installation.
- 7.124 Where UCV units are constructed in sections, a means of measuring the pressure drop across the terminal filters in each section should be provided. The pressure test-points should be located outside of the partial wall, capped to prevent air leakage and accessible within the theatre without the need to open the unit inspection panels. Alternatively direct-reading pressure gauges should be fitted.
- 7.125 The UCV system will require a return-air filter to capture the relatively coarse particles that would otherwise significantly reduce the life of the final filter. This should be at least a G3 grade to BS EN 779. In remote recirculation systems there may be advantages in fitting a higher grade return air filter, as it will reduce the load on the terminal HEPA filters and extend their life.

#### Noise level

- 7.126 If sound-attenuating material is used to line any portion of the inside of the UCV unit it should be non-particle-shedding and fire-resistant. (Further guidance can be found in SHTM Firecode suite of documents).
- 7.127 The maximum noise level in an operating room fitted with a UCV terminal of any type shall not exceed 50 NR. The validation section gives details of the method of measurement.

#### Lighting and operating lights

- 7.128 CIBSE lighting guide LG2 and BS EN 12464-1 give detailed information of lighting requirements. Operating luminaires should comply with the photometric requirements detailed in relevant sections of BS EN 60601.
- 7.129 The position of the UCV light fittings and style of partial walls, where fitted, should neither adversely disturb the airflow nor result in significant spatial variations in illuminance levels.
- 7.130 In vertical units, specialised task lighting should be provided by toroidal, cruciform or small multiple dome-shaped luminaires as they have good aerodynamic properties. The ideal luminaire will have a minimal effect on the airflow regardless of where it is positioned. Large-diameter saucer-shaped

luminaires should not be used in vertical-flow systems as they will occlude the airflow in the critical central zone. It is important to consider the suitability of existing luminaires when retrofitting UCV systems.

- 7.131 In vertical UCV installations a minimum of 2.75 m from floor to underside of the diffuser is required to allow for supporting mechanisms and lamp articulation. When upgrading existing systems this dimension may not be achievable. However, when parked, the lowest point of the central light stem, luminaire and articulation arms should never be less than 2 m above floor level.
- 7.132 The traditional means of light support is a central column that passes through the UCV terminal and is rigidly fixed to the building structure. The position of the support therefore prevents air being supplied at the centre of the terminal. Separate supports displaced from the centre of the clean zone would lead to improved airflow. This approach was advocated in the 1994 version of HTM 2025 but at the time of writing no UK manufacturer has chosen to adopt this solution.
- 7.133 In horizontal units the size or shape of the specialised task luminaire has little effect on the air-flow pattern.

#### Controls and Instrumentation

- 7.134 The functions of the supply AHU and extract ventilation should be continuously monitored by a BEMS control unit. The controls and instrumentation for the main plant are set out in Section 6.
- 7.135 UCV systems will additionally require:
- a set-back facility that can reduce the air supplied through the UCV terminal to a volume that equates to not less than 25 air changes per hour of the operating room gross volume whilst still leaving the supply AHU operating at full speed;
  - a facility to turn the entire system, supply AHU and UCV terminal, off. (an emergency stop is not required);
  - a read-out sufficiently large to be clearly visible from the operating table that shows the temperature of the air being supplied by the UCV terminal;
  - a read-out sufficiently large to be clearly visible from the operating table that shows the relative humidity of the air being supplied by the UCV terminal;
  - a red indicator light that will illuminate when either the supply AHU or the UCV terminal fails, either or both are switched off or are at set-back;
  - an amber indicator light that will illuminate when the UCV terminal is at set-back and the supply AHU is running;
  - a green indicator light that will illuminate when both the supply AHU and UCV terminal are operating at full speed;
  - a blue indicator light that will illuminate when the UCV terminal air flow, as detected by a differential pressure sensor, falls below 80% of the design flow rate.

AHU	UVC terminal	Indicator light	Comment
Off or Fault	Off or Fault		
Off or Fault	On (set-back)		
Off or Fault	On (full speed)	Red	Ventilation not operating at a suitable level to commence surgical procedures
On (set-back)	Off or Fault		
On (full speed)	Off or Fault		
On (set-back)	On (set-back)		
On (full speed)	On (set-back)	Amber	Ventilation provided to at least conventional theatre standard
On (full speed)	On (full speed)	Green	Full UCV standard conditions
–	–	Blue	HEPA-filter resistance causing low air flow

Table 7: Indicator light logic table

- 7.136 The switching devices and indicators should be incorporated in the surgeon's panel and their functions clearly labelled. In retrofit installations an auxiliary panel for the UCV may be the most practical option. If fitted it should be mounted adjacent to the surgeon's panel and their control functions interlocked as necessary.
- 7.137 When a system is designed to have partial walls with full-wall extensions, a volume control facility may be incorporated to allow the system to be run with reduced velocity when the demountable full-walls are in place. It would be the responsibility of the user to ensure correct operation of the system. To assist the user an explanatory notice should be included on the theatre control panel.
- 7.138 A direct-reading gauge should be fitted in the theatre to show a representative pressure drop across the final filters. If the UCV control box is located out of the theatre and has a means of manually adjusting the return air-fan speed then it should also be fitted with a direct-reading differential pressure gauge. The means of adjusting the return-air fan speed should be lockable to prevent casual adjustment. The direct-reading gauges should be fitted with a means of indicating the correct operating pressure range.
- 7.139 The UCV-unit manufacturer's control box should be located in an accessible position preferably in the operating department adjacent to the operating theatre that it serves. A service corridor, if provided, is an ideal location. The control box should be clearly labelled with the identity of the operating theatre that it serves.

### 7.0 (c) Extract systems

- 7.140 Extracts may be provided for a variety of reasons including:
- simple odour control (for example in a WC or mortuary);
  - to receive and remove moisture-laden air (for example, in a kitchen);
  - as part of a combined supply/extract balanced system (for example, in an operating suite);
  - to capture a hazardous substance at source (for example a safety cabinet).

- 7.141 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations.
- 7.142 An LEV system may comprise a self-contained unit incorporating its own carbon filter such as a simple bench-top fume cupboard. Alternatively it may be a complete “ventilation system” comprising a make-up air supply, multiple-exhaust-protected work stations, branch and central extract ductwork, duplex extract fans and a high-level discharge terminal. It may also incorporate a special filtration system appropriate to the hazardous substance being controlled. Such systems could be required for workshops containing woodworking machinery or large centralised pathology laboratories housing multiple safety cabinets, dissection benches, fume cupboards and specimen stores.
- 7.143 It is important to recognise at the design stage whether an extract is being provided for comfort or as an LEV system. Typical systems in healthcare include:
- microbiological safety cabinets and Category 3 containment rooms;
  - fume cupboards;
  - welding-fume extracts;
  - woodworking machinery duct collectors;
  - battery-charging bay extracts;
  - powered plaster and bone saws;
  - pharmaceutical preparation cabinets and tablet machines;
  - dissection benches, cut-up tables and some specimen stores;
  - medium- and high-risk infectious disease isolation facilities;
  - decontamination facilities;
  - dental furnaces, grinders and polishers.
- 7.144 General design information and guidance for LEV systems is produced by the Health and Safety Executive (HSE) as HS(G)37. Information on the design and installation of microbiological safety cabinets is given in BS5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.
- 7.145 LEV systems are statutory items that will be subject to an independent inspection every 14 months.

## Hood extract systems

### Special requirements

- 7.146 Extract canopies will be required over steam-and-heat-emitting appliances, for example sterilisers, catering and washing equipment; and for the extraction of toxic fumes over benches used for mixing, sifting and blending procedures.
- 7.147 Perimeter-drain gulley and corrosion-proof grease eliminators should be provided on kitchen hoods.

### Typical arrangements

- 7.148 The air-flow rate must be sufficient to ensure an adequate capture velocity in the vicinity of the process; typical values are as follows:
- evaporation of steam and like vapours 0.25 m/s to 0.5 m/s;
  - chemical and solvent releases 1.0 m/s;
  - vapour of gases 5 m/s to 6 m/s;
  - light dusts 7 m/s to 10.0 m/s.

Excessive velocities will be wasteful of power and generate noise.

- 7.149 The lowest edge of the canopy should be 2m above finished floor level, with a minimum of 300mm overhang beyond the edge of the equipment on all sides.
- 7.150 A compact arrangement of equipment (but with access for maintenance) will minimise the canopy area, and hence reduce the air volume necessary to achieve the optimum capture velocity.
- 7.151 Hoods required for the control of heat gain and vapours may be connected to the general extract system when it is convenient to do so, but where non-corrosive ductwork materials are necessary, a separate discharge is preferred.
- 7.152 Lighting and internal divider plates are often required to be built into the perimeter of large canopies. However, built-in shelving systems are not recommended, as they interfere with the air-flow, and constitute a maintenance problem.

### Control of hood extracts

- 7.153 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the hood extract and any associated supply can be shut down. To this end, local control should be provided.

## Bench extract systems

### Special requirements

- 7.154 Bench extract ventilation is required in departments such as pathology and mortuary, where activities involve the release of malodorous or toxic fumes that should not be inhaled. Where hazardous substances are being controlled, the system should be designated an LEV.

### Typical arrangements

- 7.155 Each ventilated position will usually be accommodated in a continuous run of benching, which should not be more than 650 mm from front to rear and which should be provided with a continuous upstand at the rear. Each position should have a 1200mm x 150mm linear extract grille mounted on a purpose-designed plenum box (incorporating guide vanes as necessary), with its face flush with the upstand. The bottom of the grille should be as close as practicable to the level of the working surface (usually 75mm above, to allow for cleaning). The minimum velocity across any part of the grille should be 1 m/s. The grille should be readily demountable to allow for cleaning.

### Control of bench extract systems

- 7.156 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the bench extract and any associated make-up supply can be shut down. However, a run-on timer with a minimum setting of 30 minutes must be provided. To this end, local or automatic-use control should be provided.
- 7.157 Processes that produce hazardous vapours, fumes, dusts or noxious vapours should be enclosed or semi-enclosed in a suitable cabinet or exhaust protected workstation.

### Safety cabinet and fume-cupboard extract systems

- 7.158 Safety cabinets and fume cupboards are devices that use an inflow of air to control exposure of staff to hazardous substances. The units, their exhaust systems, filters, fans and discharge terminals are all classified as Local Exhaust Ventilation (LEV) systems under the COSHH Regulations. The make-up air system to a room that contains an LEV system should also be considered as an essential part of the system and be included in the LEV classification. Information on the design and installation of microbiological safety cabinets is given in BS 5726 and that for fume cupboards is given in BS EN 14175. Their recommendations should be closely followed.
- 7.159 The Advisory Committee on Dangerous Pathogens (ACDP) publishes 'The Management, Design and Operation of Microbiological Containment Laboratories' covering the general environment in which they are used and operational considerations.

### Special requirements

- 7.160 The supply-air system should not distort the unidirectional and stable air pattern required for fume cupboards and microbiological safety cabinets. In general, supply-air ceiling diffusers should not discharge directly towards fume cupboards or safety cabinets, unless the terminal velocity is such that the air-flow pattern of the cabinet is unaffected. The design should ensure that high air-change rates, and/or the opening and closing of doors do not have any adverse effect on the performance of safety cabinets or fume cupboards. A damped door-closure mechanism may help.
- 7.161 In order to safeguard the user, all safety cabinets and fume cupboards must be fitted with a clear indication that they are operating correctly. Direct-reading gauges or falling-ball indicators are preferred (in addition to electronic pressure indicators). The system should be set to alarm audibly if the face velocity falls below the minimum safe operating level.

### Arrangements for safety cabinet installations

- 7.162 The manufacture and installation of microbiological safety cabinets must be in accordance with the relevant national standards and guidance issued by the Advisory Committee on Dangerous Pathogens (ACDP).
- 7.163 A Class 1 microbiological safety cabinet must be specified for routine work involving Group 3 pathogens. It should be housed in a Category 3 containment room. Specific design information on containment rooms is issued by ACDP in conjunction with the Health and Safety Commission.
- 7.164 Siting and installation of microbiological safety cabinets are of particular importance because:
- the protection afforded to the operator by the cabinet depends on a specific and stable unidirectional air flow through the open front;
  - the protection to the environment by the cabinet depends on the high efficiency particulate air (HEPA) filters. The exhaust air should never be considered as totally free from microbiological hazard.
- 7.165 Microbiological safety cabinet is HEPA filtered prior to being discharged to outside. The extract ductwork should as far as practicable be kept under negative pressure while inside the building.
- 7.166 Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2m); such an installation however, is likely to be noisy and is not recommended for use in new buildings.
- 7.167 The discharge from the cabinet should be fitted with a back-draft damper. In multiple installations where several cabinets discharge into a common extract and discharge duct, it must be possible to isolate each cabinet from the system when not in use.

7.168 Roof-level discharge, wherever practicable, is preferred since it removes much of the uncertainty over air re-entering the building through ventilation inlets and/or windows. In such an installation, the extract fan should be situated separately from the cabinet and close to the discharge outlet, to maintain the duct within the building under negative pressure. The discharge point on a flat roof should be through a 3 metre high terminal. This is required to safeguard staff who may need to access the roof periodically for maintenance. This requirement will also be applicable to fume-cupboard discharges.

7.169 Where this is impracticable, discharge into the room via a double HEPA filter has been accepted. The preferred method, however, is to discharge 3 meters above the roofline in line with the similar standard for fume cupboard designs.

### Arrangements for fume cupboard installations

7.170 The manufacture and installation of fume cupboards must be in accordance with the relevant national standards and associated guidance.

7.171 The primary factors that contribute to the effective performance of fume cupboards include:

- an adequate volume of supply air;
- an effective exhaust system to promote the safe dispersal of waste products to atmosphere.

7.172 The air velocities through sash openings must be sufficient to prevent hazardous materials from entering the laboratory while avoiding excess flow rates that interfere with the investigation process. Average face velocities should be between 0.5 and 1.0 m/s, with a minimum at any point within 20% of the average, the upper end of the range being applicable to the containment of materials of high toxicity. The design velocity must be maintained irrespective of whether the sash opening is varied, or whether doors or windows are open or closed. Variable Air Volume (VAV) cupboards are available which offer a reduction in energy use.

7.173 The possibility of a fire or explosion that may not be contained by a fume cupboard must always be considered. A fume cupboard should not, therefore, be sited in a position where exit to an escape route will necessitate passing directly in front of it.

7.174 Fume-cupboard fans should be installed as near as possible to the termination of the duct, thus maintaining the maximum amount of ductwork at negative pressure.

7.175 Where there are adjacent buildings with opening windows, or where downdraughts occur, it may be necessary to increase the height of discharge ducts in order to achieve adequate dispersal. In complex locations, airflow modelling or wind tunnel tests may be required to determine the optimum height of the stack (see also paragraph 7.167).

- 7.176 Fume-cupboards for certain processes must have separate extract systems. However, where appropriate, individual fume-cupboard exhaust systems may discharge via non-returning dampers into a single collection duct rather than having a large number of separate stacks. The collection duct should have a large cross-sectional area to minimise its effect on the individual exhaust systems; be open to atmosphere upstream of the first connection; and be designed to discharge a total air volume at least equal to the combined individual extract systems.
- 7.177 Individual fume-cupboard extract systems, discharging either directly to atmosphere or into a collection duct, do not require duplex fans. However, a collection duct designed to provide dispersal of effluent from a number of individual extracts, should have duplex fans with automatic changeover.
- 7.178 Some fumes are particularly corrosive, so the choice of material for the ductwork, and type of extract fan fitted should reflect the nature of the fume being conveyed.

#### Control of extract systems

- 7.179 It is desirable to provide local control of safety cabinets in order to maximise the life of the HEPA filter, and to permit the sealing of the cabinet and room for fumigation if spillage occurs.
- 7.180 To cope with the risk of an accident or spillage outside safety cabinets, a 'panic button' should be provided to switch off the supply to that area; and discharge all extracted air to atmosphere.
- 7.181 In pathology departments, it will be necessary to have one or more microbiological safety cabinets and one or more fume cupboards available for use at all times, including weekends, therefore, local overriding controls for all these items and any associated ventilation plant will be necessary.

### 7.0(d) Plantroom ventilation

#### General requirements

- 7.182 Plant rooms are required to be ventilated in order to maintain acceptable temperatures for satisfactory operation of the plant and controls, and for maintenance activities. In the case of plant rooms housing combustion equipment, a secondary function of the ventilation is to provide make-up air for the combustion process.
- 7.183 The air required for these purposes should be introduced into the space through inlets positioned to minimise the discomfort to occupants; they should be unlikely to be blocked, closed deliberately (except in the case of fire shutters if required), or rendered inoperative by prevailing winds.

- 7.184 Plantroom ventilation air should not be used for any other purposes, such as make-up air for extract; and where the plantroom contains combustion equipment, the appliance pressure must not fall below the outside air pressure.
- 7.185 Specialised healthcare air handling equipment must not be located in a fire compartment that houses combustion equipment.
- 7.186 Statutory regulations for plantroom ventilation are contained in the Scottish Building Regulations, and further guidance is given in CIBSE Guides A & B.

#### Assessment of ventilation levels

- 7.187 Ventilation requirements must take into account all heat sources within a plantroom, and where there are large glazing areas, solar gains. The ventilation rate should limit the maximum temperature within the plantroom to 32°C.
- 7.188 As the level of equipment operating during mid-season and summer is often lower than the winter condition, and the cooling effect of the outside air is reduced, it is necessary to calculate the minimum volume for each season of operation, and the inlet and outlet grilles or fan sizes should be chosen to cater for the largest seasonal air volume.
- 7.189 Replacement air should not be drawn through pipe trenches or fuel service ducts. Where metal ducts penetrate walls and floors, effective sealing should be provided to confine the ventilation to the boiler room and to meet fire protection requirements. Penetration of fire barrier walls by ventilation ducts should be avoided if possible.
- 7.190 Fire dampers in plant room ventilation ducts should be electrically interlocked with the boiler plant.
- 7.191 Care must be taken to prevent any noise generated in the boiler room emerging from natural or mechanical ventilation openings to the detriment of the surrounding environment. Particular care is necessary with mechanical flue draughts and fan-diluted flue systems.
- 7.192 Information on required air volumes is contained in the CIBSE Guide A & B.
- 7.193 Where combustion plant is installed, the high-level (outlet) openings should be sized to cater for the total ventilating air quantity; and the low-level (supply) openings sized to cater for the total combined ventilating and combustion air quantity.

#### Choice of ventilation system

- 7.194 Ventilation air may be introduced and exhausted by either natural or mechanical means or a combination of both. However, where possible, natural systems are preferred.

- 7.195 Generally, small installations at or above ground level should have their combustion and ventilation air provided by natural means, employing both high- and low-level openings.
- 7.196 Basement, internal and large installations at or above ground level will usually require a combination of natural and mechanical ventilation. If the airflow rate is difficult, both supply and extract may require mechanical means.
- 7.197 Whether natural or mechanical, the system should be designed to avoid both horizontal and vertical temperature gradients. Both inlet and outlet openings should be placed on opposite or adjacent sites of the building to reduce the effect of wind forces.
- 7.198 Where mechanical air supply is employed, electrical interlocks with the boiler plant should be provided to prevent damage in the event of failure of the supply fan(s) once the air volume is established.
- 7.199 The necessary free opening areas for a naturally ventilated plantroom may be calculated using either the method in A4 of the CIBSE Guide A or the table in section B13 of CIBSE Guide B.
- 7.200 A combined natural and mechanical ventilation system should allow for natural extract at high level, to take advantage of convective forces in the room, with mechanical supply at low level. The high level natural ventilators should be sized to cope with the total quantity of ventilation air, as above.
- 7.201 To prevent leakage of flue gases and to ensure that the flue draught is not impeded at any time, the air pressure in the boiler room must not exceed the prevailing outside pressure. Therefore, the fan duty should exceed the calculated total combined combustion and ventilation air quantity by at least 25%. Fan-powered inlets should be arranged to flow outside air into the space at a point where cross-ventilation will ensure pick-up of heat without causing discomfort to occupiers.
- 7.202 Where it is impractical to provide sufficient natural ventilation to remove the heat emitted by the plant, both mechanical supply and extract will be required.
- 7.203 The high-level extract should be sized to cater for the total ventilating air quantity and the low-level supply should exceed the total combined combustion and ventilating air quantity by at least 25%, as above.

## 7.0(e) Ventilation of hydrotherapy suites

### General requirements

- 7.204 In a hydrotherapy suite heat recovery should be via heat pump.
- 7.205 The quantity of supply air should be calculated as 25 litres/sec/m<sup>2</sup> wetted surface, with the wetted surface taken as 110% of the pool water surface area.
- 7.206 A re-circulation plant is recommended, with a minimum of 20% fresh air.

- 7.207 As far as practicable, re-circulated pool air should be provided to the ancillary changing and recover accommodation, with the only extract from the toilets, laundry/utility room and pool hall.
- 7.208 Supply air to the pool hall should be introduced at high level and directed towards the perimeter to mitigate condensation, with extract air taken from directly over the pool. Dampers should not be located over the pool water.

#### Control of hydrotherapy pool installations

- 7.209 The supply and extract fans should be interlocked so that the supply fan does not operate until flow is established within the extract system.
- 7.210 Time-clock control should be provided, with a local override switch to extend the normal operating period as required.
- 7.211 Night setback temperature (in the range of 21-25°C) and high humidity control (in the range of 60-75% sat) should be provided to override the time clock in order to prevent condensation. The exact set points should be ascertained post-installation.
- 7.212 A remote indication panel should be provided in the pool hall, giving a visual display of the pool water and pool air temperature.

## 8. Validation of specialised ventilation systems

### Definitions

**Commissioning** - Commissioning is the process of advancing a system from physical completion to an operating condition. It will normally be carried out by specialist commissioning contractors working in conjunction with equipment suppliers. Commissioning will normally be the responsibility of the main or mechanical contractor.

**Validation** - A process of proving that the system is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that *"The system will be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."*

Commissioning is often sub divided into sections e.g. air handling unit, automatic controls, airside balance, building fabric and fittings. Each section may be commissioned by its specialist installer and they are often accepted in isolation. Validation differs from commissioning in that its purpose is to look at the complete installation from air intake to extract discharge and assess its fitness for purpose as a whole. This involves examining the fabric of the building being served by the system and inspecting the ventilation equipment fitted as well as measuring the actual ventilation performance.

It is unlikely that 'in house' staff will possess the knowledge or equipment necessary to validate critical ventilation systems such as those serving operating suites, pharmacy clean rooms and local exhaust ventilation systems. Validation of these systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the Health Board.

It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.

### Commissioning general

- 8.1 Commissioning is an essential process for ventilation systems. It is therefore important that adequate provision for the process be made at the design stage of the project. Procedures for commissioning air-handling systems are given in CIBSE Commissioning Codes and BSRIA Application Guide Set COMPAK 1.
- 8.2 The duct-sizing procedure should take into account the requirements of system balancing, and the position and number of regulating dampers included in the design should be sufficient for this purpose.

## Location of dampers and test holes

- 8.3 Balancing/commissioning dampers will be required in each branch of the distribution ductwork.
- 8.4 Test holes for the measurement of air-flow will be required at carefully selected points in main and all branch ducts. The number and spacing of holes are given in the BSRIA Application Guide Set COMPAK 1. Their positions must be identified at the design stage.
- 8.5 The test positions need to be accessible for commissioning to take place. They may also be required for subsequent annual verification of the system performance, so they should not be covered by permanent lagging.
- 8.6 The measurement point should be in a straight length of duct as far away as possible from any upstream bends, dampers or other elements that could cause disturbance to the airflow. The actual location should be:
- at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends;
  - if this is not possible, 10 diameters downstream of dampers, bends or tees, and 5 diameters downstream of eccentric reducers;
  - where there is enough space round the duct to insert the pitot tube and take readings;
  - where the duct has a constant cross-sectional area.
- 8.7 Test holes for measuring total airflow from a fan should be located either 4 diameters upstream or 10 diameters downstream of the fan. Provision should also be made for measuring the speed of rotation.

## Information to be provided

- 8.8 It is essential that the designer should pass on his intentions fully to the commissioning engineer by indicating which parts of the system are high, medium and low pressure, and by providing:
- relevant parts of the specification;
  - schematic drawings indicating performance data as indicated in Table 8;
  - equipment schedules;
  - controller and regulator schedule;
  - fan performance curves;
  - wiring diagrams for electrical equipment, including interlock details.

Items in system	Information to be provided
Fans	Fan total pressure Volume flow rate at high and low speed Maximum motor current
Plant items	Type and identification numbers from equipment schedules Fluid and air volume flow rates Fluid and air side pressure losses Dry bulb temperatures Wet bulb temperatures Humidity
Dampers, including motorised and fire dampers	Identification numbers from equipment schedules Location Identification number Volume flow rate
Main and branch ducts	Dimensions Volume flow rates and velocities Identification numbers from equipment schedules
Terminal	Location Identification number Grille or diffuser factor Volume flow rate and neck velocity Operating static pressure
Test holes and access panels	Location Identification number
Controllers	Set points

Table 8: Information to be provided on schematic drawings

**Notes:** For Table 8

1. Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet.
2. Where volume flow rates are variable, maximum and minimum values should be provided.

### Commissioning personnel

8.9 As one individual is unlikely to possess all of the required commissioning skills, a commissioning team is therefore usually needed. The objective of commissioning is to ensure that the necessary performance and safety requirements are met.

- 8.10 During the commissioning process a great deal of information will be generated which will form an invaluable future source of reference about the plant. It is essential to ensure that it is collected together in the form of a commissioning manual and handed over to the client on completion of the contract together with the 'as fitted' drawings. This information should be both in hard copy and electronic format.
- 8.11 In order to be successful the commissioning process must start before achieving practical completion as many parts of the system will become progressively less accessible. The correct installation of those parts will need to be witnessed and leak -rate tests carried out as construction proceeds. Failure to establish responsibility for commissioning early enough will delay the completion of the project or lead to unsatisfactory plant performance.

### Commissioning brief

- 8.12 The commissioning team will require a detailed brief from the system designer. This should include:
- a 'user' brief comprising a description of the installation and its intended mode of operation;
  - the precise design requirements with regard to the scheme of air movement, room static pressures, supply and extract air-flow rates and acceptable tolerances;
  - full details of the design conditions both inside and out, for winter and summer together with the control strategy;
  - equipment manufacturer's type test data, commissioning, operation and maintenance recommendations;
  - drawings showing the layout of the system, positions of air-flow measurement test points, dampers, regulating devices and filters within the duct runs, together with sizes of ducts and terminal fittings. It will save time if these drawings are annotated with the design volumes and static pressures required at each branch and outlet point;
  - wiring diagrams for all electrical equipment associated with the air handling systems including motor control circuit details and any interlocking and safety devices such as emergency-stop buttons adjacent to the item of plant.
- 8.13 The CIBSE Commissioning Code, Series 'A' – "Air Distribution", provides full guidance on the information that will be required by the commissioning team.
- 8.14 The designer should include in the contract document instructions on verifying the accuracy of test instruments that should be supported by reference to relevant calibration certificates.
- 8.15 The system, on completion, should be operated by the contractor as a whole and subject to performance tests in accordance with the contract requirements.

For critical systems, these may include independent validation of the system performance on behalf of the client.

- 8.16 Prior to dynamic commissioning, it is essential that builders' work in the area served by the system is complete, all rubbish and dust is removed, concealed plumbing (IPS-type) panels are in position and ceiling tiles are in place and clipped. Floors should be mopped and visible dust removed from all other surfaces.
- 8.17 Once the system is shown to meet the design intent the handover documentation should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract arrangements.

### Pre-commissioning checks

- 8.18 The pre-commissioning checks consist of visual inspection, manual operation of equipment, static measurements and functional tests of individual components. They should be carried out prior to setting the system to work and undertaking the dynamic commissioning process set out in paragraph 8.29 onwards of this guidance.

### Standard of installation

- 8.19 During the installation of the system the following must be witnessed:
- that the plant and installations have been provided and installed in accordance with the design specification and drawings;
  - that only approved sealants have been used in the installation;
  - that all components function correctly;
  - that the satisfactory sealing of access doors and viewing ports have been carried out;
  - that air pressure tests and air-leakage tests on ventilation ducting have been carried out in accordance with the methods set out in the HVCA's DW/143: Ductwork Leakage Testing. It is usual to carry out these tests, a section at a time, as the ductwork is installed and before its insulation is applied. The results must be recorded in the commissioning manual;
  - that gaps around doors and hatches are as specified in the design;
  - that the correct operation of pressure stabilisers, control dampers, isolating and non-return dampers have been checked and installed in the correct orientation for air-flow;
  - that test holes have been provided in their specified locations and are sealed with suitable grommets;
  - that control dampers are secured and their quadrants fitted correctly;
  - that any interlocks are operative and in accordance with specification;

- that the electric circuits are completed, tested and energised;
- that electric motors have been checked for correct direction of rotation both at full speed and set-back;
- that cooling and heating media are available at correct temperatures and pressures and in specified quantities;
- that the air-conditioning plant components and controls function correctly;
- that the air-conditioning plant interlocks and safety controls function correctly;
- that the plant is physically complete, insulation is applied and all ducts and pipework are identified as specified;
- that the building housing the ventilation plant is generally in a fit condition for commissioning and performance tests to commence, that is, windows, doors, partitions etc are completed, surfaces sealed and their final finish applied;
- that the areas containing the ventilation plant and those being served by it are clean;
- that access to all parts of the system is safe and satisfactory.

### Cleanliness of installation

- 8.20 During installation it must be established that ductwork is being installed to the 'advanced level' as defined in the HVCA (2005) 'TR/19 – Guide to good practice: internal cleanliness of ventilation systems'. This specifically includes ensuring that ductwork sections arrive on site and are stored with their open ends sealed and that open ends remain sealed during installation to prevent the ingress of builders' dust.
- 8.21 Should any doubt exist whether the guidance has been observed, the ducts must be cleaned internally to restore them to this standard before being taken into use.
- 8.22 "Builders work" ducts of brick or concrete must be surface sealed to prevent the release of dust before being taken into use.
- 8.23 The area around the supply air intake must be free of vegetation, waste, rubbish, builders' debris or any other possible source of contamination.

### Certification of equipment

- 8.24 The following test certificates should be assembled by the commissioning team and be available for inspection at any time during the contract period. They will form part of the handover information and should be placed in the commissioning manual:
- type-test performance certificates for fans;
  - pressure-test certificates for:

- heater-batteries;
- cooling coils;
- humidifiers (if appropriate);
- type-test certificates for attenuators;
- type-test certificates for primary and secondary filters;
- individual test certificates for high efficiency particulate air (HEPA) filters.

## Equipment tests

- 8.25 Prior to setting the system to work, the checks in paragraphs 8.26-8.28 should be witnessed, and proving tests should be carried out as detailed.

## Filters

- 8.26 The quality of filter housing and in particular, the seals is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter panels. Therefore, the following checks should be made:
- filter seals should be fitted and in good condition;
  - filters should be installed correctly with respect to air flow;
  - bag filters should be installed so that the bags are vertical and their pockets free;
  - HEPA filters should be installed in a sealed housing and their seals tested to DIN 1946 if specified;
  - all filters should be checked to ensure they are free of visible damage;
  - the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.

## Drainage arrangements

- 8.27 The drain should conform in all respects to the "Design considerations" of this SHTM. In addition the following must be proved:
- that the drain tray is easily removable;
  - that a clear trap is fitted and is easily removable;
  - that the drain has a clear air gap of at least 15mm;
  - that the pipework is supported so that the air break cannot be reduced;
  - that the drain system from each drain tray is independent up to the air break;
  - that the operation of the drainage system is proved by introducing water into the duct at the drain tray and observing that it completely drains out. This check is to be repeated both at normal speed and set back once the fans

have been commissioned. At this time the clear trap can be marked to indicate the normal water level with the fan running.

## Fire dampers

8.28 The following must be witnessed and proving tests should be carried out as detailed:

- the operation of all fire dampers;
- the access provided to enable the dampers' to be visually inspected and / or re-set should be sufficient for the purpose;
- indication should be provided of the dampers' position (open/tripped);
- indication of the fire dampers' location should be provided both on the ductwork and at a visible point on the building fabric if the ductwork is concealed.

## Dynamic commissioning

### Air-handling and distribution system

8.29 The fan drive, direction of rotation, speed and current drawn should be set in accordance with their manufacturer's instructions.

8.30 After the installation has been checked to ensure that it is in a satisfactory and safe condition for start-up, it should be set to work and regulated to enable the plant to meet its design specification. The proportional balancing method described in the CIBSE Commissioning Code "A" must be followed. The air-flow rates must be set within the tolerances laid down in the design brief. This will normally be the design airflow rate +10% -0%.

8.31 When combined supply and extract systems are to be balanced and the area that they serve is to be at or above atmospheric pressure then the supply should be balanced first with the extract fan switched off, and then the extract balanced with the supply fan(s) on.

8.32 For combined systems where the area that they serve is to be below atmospheric pressure then the extract should be balanced first with the supply fan switched off and then the supply balanced with the extract fan on.

8.33 On completion of the balance all volume air-flows in supply and extract ducts and from grilles and diffusers must be measured and recorded. The true air change rate can then be calculated from the data obtained.

8.34 The main supply and extract duct volume control dampers must be locked and their position marked.

8.35 All grille and diffuser volume control registers must be locked to prevent alteration and their final position marked.

### Room air distribution

- 8.36 The pressure-relief dampers and pressure stabilisers must be set to achieve the specified room static pressures and locked. The grille direction control vanes and diffuser cones must be set to give the specified air-movement pattern. Visualisation techniques may need to be employed in order to prove that the required air-flow pattern is being achieved. This may be a potential requirement when commissioning LEV systems or rooms that contain them.

### Air-conditioning plant

- 8.37 The specified flow rate and/or pressure drops must be set for all heater batteries, cooling coils and humidifiers. The methods described in the CIBSE Commissioning Codes "W" and "R" should be followed. On completion their regulating devices must be locked to prevent alteration.

### Control system

- 8.38 The control system should not be commissioned until both the air distribution system and air-conditioning equipment have been commissioned.
- 8.39 Because of the specialised nature of control systems and the fact that each manufacturer's system will contain its own specialist components and settings, the commissioning should be completed by the supplier and witnessed by a representative of the user.
- 8.40 The location of all control and monitoring sensors should be checked and their accuracy proved.
- 8.41 The control system's ability to carry out its specified functions must be proved.
- 8.42 If the plant is provided with a "user's" control panel in addition to the one located in the plantroom then the operation of both must be proved. This will typically apply to operating departments and laboratory systems.

## Specific performance standards

### Air movement

- 8.43 The performance of the system should be measured and compared with information provided by the designer.

### Plant capacity and control

- 8.44 When setting to work and proving the design, both the manufacturer of the air-handling plant and the control specialist should attend site together and jointly commission the system.
- 8.45 If any doubt exists as to the capacity of the installed system, then its ability to achieve the specified inside design conditions with the plant operating at winter

and summer outside design conditions must be proved. Artificial loads will be required in order to simulate the internal gains/losses and the outside design conditions.

- 8.46 On completion of the plant performance test, recording thermo-hygrographs should be placed in each room/area served by the plant and also the supply air duct upstream of the frost battery. The plant should be run for 24 hours with all doors closed. During this period the inside conditions must stay within the tolerances specified. The BEMS should be used to obtain the information required wherever possible. Periodic tests will be required during the defects liability period.

### Noise levels - general

- 8.47 The commissioning noise level is the level measured with a sound-level meter in the unoccupied room and taking account of the external noise together with the noise generated by the ventilation system. When occupied and in use this commissioning level will constitute a continuous background noise that will allow the overall noise level to be achieved. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise.
- 8.48 The noise levels apply at the maximum velocity for which the system is designed to operate. Acoustic commissioning tests should be carried out with all plant and machinery running normally and achieving the design conditions of airflow, temperature and humidity.
- 8.49 An industrial-grade sound-level meter to BS3489 or IEC 651 Type 2 will normally be sufficient to check the noise level.
- 8.50 The noise level readings are to be taken at typical normal listening position 1.5m above floor level and at least 1m from any surface and not on any line of symmetry. In critical rooms the noise should be measured at the centre of the room and at the centre of each quarter. The mean of the 5 readings should then be calculated.
- 8.51 In the event of a contractual deficiency, a Type 1 precision-grade sound-level meter should be used and the noise level determined by the procedure given in Scottish Health Technical Memorandum 08-01 (forthcoming).

### Filter challenge

#### General ventilation filters

- 8.52 In-situ performance tests will not normally be required for primary and secondary filters and their housings. However the filters should be visually inspected for grade, tears, orientation and fit within their housing. Filters should be clean and a replacement set available. Bag filters should be installed so that

their bags are vertical and spaced so that air can move through them freely. Any filter found to be wet should be replaced and the cause investigated.

### HEPA filters (for exhaust protective enclosures and laboratories)

- 8.53 Pathogenic material may be discharged through damaged or badly installed HEPA terminal filters. The complete installation must be tested using the method set out in BSEN: 14644 'Method of Testing for the Determination of Filter Installation Leaks'.
- 8.54 The challenge tests may be carried out using either of the following techniques:
- use DOP (Dispersed Oil Generator) to provide the challenge and a photometer to detect leaks;
  - use a Discrete Particle Counter (DPC) to detect leaks. (In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters).
- 8.55 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.
- 8.56 A challenge aerosol of inert particles of the type produced by a DOP generator should be introduced into the air, upstream of the HEPA filter. The downstream face of the filter, its mounting seal and housing would then be scanned for leakage using a photometer. A leak should be deemed to have occurred if a steady and repeatable reading on the photometer at any point exceeds 0.01% of the upstream reading.
- 8.57 Alternatively a Discrete Particle Counter (DPC) may be used. For the Discrete Particle Counter method the filter face is sampled at several points to establish the smallest non-penetrating particle size. If particles at or above this size are detected when subsequent scans of the filter face, its seal and housing are made, then there is deemed to be a significant leak at, or near, the test position.
- 8.58 Should the HEPA filter fail this test it must be replaced. Should the filter mounting seal or housing fail this test it may be repaired and the test repeated.

## Bacteriological sampling

### General ventilation systems

- 8.59 Bacteriological sampling will not normally be required for either general or local exhaust ventilation (LEV) systems unless otherwise specified.

### Conventional operating rooms

- 8.60 The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for 15 minutes. An active air sampler set to 1 cubic metre and mounted on the operating table should then be activated remotely. Aerobic cultures on non-selective media should not exceed 10 bacterial and/or fungal colony forming units per cubic metre (CFU/m<sup>3</sup>).
- 8.61 The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation. Precise guidance is inappropriate and will depend on local circumstances.
- 8.62 It may be appropriate to carry out a check of airborne bacteria during a surgical operation. If required this should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacterial and/or fungal CFU averaged over any five-minute period, would be unlikely to exceed 180 per cubic metre.
- 8.63 Information on the additional validation testing of UCV Operating suites is given in Section 8.0(a).

### Ventilation system commissioning/validation report

- 8.64 Following commissioning and/or validation a full report detailing the findings should be produced. The system will only be acceptable to the client if at the time of validation it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life.
- 8.65 The report shall conclude with a clear statement as to whether the ventilation system achieved or did not achieve the required standard. A copy of the report should be lodged with the following groups:
- the user department;
  - infection control (where required);
  - estates and facilities.

## 8.0(a) Validation of UCV operating suites

### General

- 8.66 Commissioning of a UCV terminal will normally be carried out by its supplier. Commissioning of the air-handling unit, fire dampers, distribution ductwork and control systems may be undertaken by different teams. It is therefore important to recognise that the UCV terminal is only one element of the specialised ventilation system serving the operating suite and it cannot be accepted in isolation.

- 8.67 In order to ensure that the complete system operates correctly it will be necessary to validate the system as a whole from the air intake through to the extract discharge. It is unlikely that “in house” staff will possess the knowledge or equipment necessary to undertake this process. Validation of Ultra-Clean operating theatre ventilation systems should therefore be carried out by a suitably qualified independent Authorised Person appointed by the client.
- 8.68 It is anticipated that training in the validation of specialised healthcare ventilation systems for independent Authorised Persons will become available during the life of this SHTM.
- 8.69 The following regime of inspection and testing should be applied to the validation of new installations designed to provide Ultra-Clean conditions in an Operating suite. The test regime has been devised to ensure that the system as installed fully achieves the design requirement for these systems as set out in Section 7.0 (b) of this document.

#### Basic requirement

- 8.70 The operating suite to be validated should be physically complete with final finishes applied. All ventilation systems serving it should be operating correctly and delivering the design air-flow rates.
- 8.71 In order to avoid pre-loading the UCV terminal’s recirculation ducts and HEPA filters, the Operating suite should be free of any obvious dust and at least “builders clean” before the recirculation fans are set to work.
- 8.72 The validation procedure for a conventional theatre suite should have been satisfactorily completed to the standard set out in Section 8 prior to attempting to validate the UCV unit. In particular:
- the supply AHU will have achieved the minimum standard;
  - the operation of all fire dampers will have been proved;
  - the supply and extract air-flow rates as measured in ducts and at room terminals will achieve their design values +10%; -0%;
  - room differential pressures will be correct.

Evidence of the satisfactory achievement of the foregoing standard should be available for inspection and independently measured as necessary prior to validating the UCV unit.

#### UCV unit validation procedure

- 8.73 Tests to validate the suitability and performance of an ultra-clean operating suite should be undertaken in the order that they appear below. Should an item fail to meet the required standard it should be rectified and successfully retested before passing on to the next test.

## Summary of test regime

- Challenge tests to ensure that:
  - the UCV terminal unit is correctly assembled and sealed so that no air will bypass the filters;
  - the terminal filters are correctly sealed in their housings;
  - the terminal filters are of the same grade, of uniform quality and undamaged.
- Air velocity measurements to ensure that
  - a sufficient quantity of air is being delivered by the terminal;
  - the terminal quadrants are in balance;
  - the air flow has sufficient velocity to reach the working plane.
- An entrainment test to ensure that contaminants arising outside of the UCV terminal footprint are not drawn into it.
- Visualisation techniques to gain an understanding of the overall system performance.
- Noise measurement to ensure that working conditions are satisfactory.
- Control system checks to ensure that the system operates as specified.
- Biological monitoring to determine how effective the system is in use.

## Test and measuring conditions

- 8.74 While validating the UCV terminal, the conditions in the Operating room shall be stable and within the given ranges.

temperature: – 19 - 23°C dry bulb.

humidity: – 30 – 65% relative humidity.

## Test and measuring equipment

- 8.75 Any test or measuring equipment used should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards.
- 8.76 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been validated within the previous 12 months at a calibration facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

## Test grid – vertical units

- 8.77 A test grid should be constructed on the floor within the ultra-clean terminal footprint as projected by the inside dimensions of the sidewalls or boundary air

curtain. A suitably marked test sheet will provide a consistent standard of test grid.

- 8.78 The test grid should comprise test squares of 280mm each side.
- 8.79 The test grid should be aligned along the centre lines of the terminal footprint with its centre under the centre point of the terminal.
- 8.80 Any test square with 80% of its area within the UCV footprint should be used as a test position.
- 8.81 An inner zone should be designated that is not less than 36% of the total footprint. It should be made up of a number of test squares distributed symmetrically about the terminal footprint centre line. Regardless of the shape of the terminal footprint, the inner zone should comprise a minimum grid of 6 x 6 test squares.
- 8.82 Unless specified otherwise, a test position should be in the geometric centre of a test square.
- 8.83 Test position 1 should be the leftmost test square in the row nearest to the operating room wall that houses the surgeon's panel.

(For an example of a grid for a 2.8 x 2.8 metre terminal see Figure 10)

Figure 10: EXAMPLE of a TEST GRID for a 2.8m x 2.8m UCV TERMINAL

**Test grid – horizontal units**

- 8.84 A line of test positions should be marked on the floor 1 m in front of the face of the UCV terminal.
- 8.85 A test position should be marked in the centre of the line. Additional test positions should be marked at 280mm spacing along the line either side of the centre position, up to the full-face width of the unit.

#### UCV terminal challenge tests (Vertical and horizontal systems)

- 8.86 The diffuser screen fitted below the face of the terminal HEPA filters should be lowered or removed while the challenge tests are being carried out.
- 8.87 The installed HEPA filters should be checked to ensure that their grade accords with the design specification and that their performance has been certified by the manufacturer.
- 8.88 The challenge tests may be carried out using either of the following techniques:
- use DOP to provide the challenge and a photometer to detect leaks;
  - use a Discrete Particle Counter (DPC) to detect leaks. In order to obtain a sufficient challenge it may be necessary to remove temporarily the supply AHU secondary filters.
- 8.89 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the HEPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.
- 8.90 For the DOP test this should be set as the reference level and a leak will be declared significant if penetration greater than 0.01% of the range is detected. (See paragraph 8.56 for details).
- 8.91 For the Discrete Particle Counter (DPC) method the filter face is scanned to establish the smallest non-penetrating particle size. If significant particles at or above this size are detected when subsequent scans are made then there is deemed to be a significant leak at, or near, the test position. (see paragraph 8.57 for details)

#### UCV terminal unit clean zone leak test

- 8.92 This test will confirm that there is no unfiltered air bypassing the HEPA filter.
- 8.93 The joints and service penetration points under the UCV terminal within its side walls or boundary air curtain should be scanned to prove that there are no leaks.
- 8.94 A leak is defined as a significant rise above the background level.

### Terminal HEPA filter seal leak test

- 8.95 The test will confirm that there is no unfiltered air bypassing the HEPA filter's seal.
- 8.96 Each HEPA filter's seal should be scanned to prove that there are no leaks.
- 8.97 A leak is defined as a significant rise above the background level.

### Terminal HEPA filter media leak test

- 8.98 The test will confirm that the HEPA filters have not sustained damage while being installed.
- 8.99 The face of each HEPA filter should be scanned to prove that there are no leaks.
- 8.100 A leak is defined as a significant rise above the background level.

## Vertical UCV terminal air velocity tests

### Test set up

- 8.101 The terminal face diffuser screen should be in place for these tests.
- 8.102 Take spot readings to establish that the room is within the specified temperature and humidity test conditions.
- 8.103 Set out the test grid as described previously.
- 8.104 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow, are perpendicular to the front edge of the test sheet and face the back edge. Any lamp and equipment heads should as far as practicable be outside of the UCV terminal footprint.

### Test instrument

- 8.105 The measuring instrument should be a hot-wire anemometer with a digital read-out. The instrument resolution should be at least 0.01m/s, have a tolerance of  $\pm 0.015\text{m/s}$  or 3% of that reading and be calibrated down to 0.15m/s or lower. An alternative instrument may be used providing it is of no lesser specification.

### Test method

- 8.106 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.
- 8.107 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively they could be downloaded to a computer or data logger at the end of the test.

- 8.108 The test stand to be positioned on each test point in turn and the reading taken when the instrument has stabilised.
- 8.109 When taking a reading the test person should not stand within the same quadrant as the test instrument.
- 8.110 Readings are to be taken at the test positions with the instrument probe facing the wall housing the surgeon's panel, commencing at the first test position. Readings are taken working along the row from left to right and back, or for all test positions in one quadrant at a time.
- 8.111 When all test positions under one half of the terminal have been covered, readings of temperature and humidity are then taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.
- 8.112 Having completed one half of the test grid, the operating lamp arms and any other stem arms should be swung round through 180° and the test stand reversed so that the wall housing the surgeon's panel is behind the test person. Readings are recommenced starting at the right of the test row and working from right to left a quadrant at a time, as above.

#### UCV high-level discharge velocity test

- 8.113 Measurements of air velocity are to be taken at every test position 2 m above floor level and the results averaged.
- 8.114 The average of the total readings taken is to be not less than:  
0.38 m/s for a partial-wall system;  
0.30 m/s for a full-wall system.
- The average air velocity for each quadrant should not exceed ±6% of the measured average velocity for the terminal

#### UCV low-level air velocity test

- 8.115 Measurements of air velocity are to be taken at each of the inner zone test position 1m above floor level.
- 8.116 The measured velocity at every test position in the inner (operating) zone shall be not less than 0.2 m/s.

#### Horizontal UCV terminal air velocity test

##### Test set up

- 8.117 Set out the line of test positions as described previously.

- 8.118 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to air flow and are perpendicular to the line of test positions.

#### Test instrument

- 8.119 See that specified for vertical systems (paragraph 8.105 refers).

#### Test method

- 8.120 The instrument should be mounted on a test stand and set to take a mean reading over a ten-second sample interval.
- 8.121 It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. Alternatively, they could be downloaded to a computer or data-logger at the end of the test.
- 8.122 The test stand should be positioned on each test point in turn and the reading taken when the instrument has stabilised.
- 8.123 When taking readings the test person should stand well downstream of the instrument.
- 8.124 Readings are to be taken at the test positions with the instrument probe facing the UCV terminal, commencing at the first test position on the left and working along the row from left to right at the specified height.
- 8.125 The instrument should be reset to the next specified height and the test repeated and so on.
- 8.126 Readings of temperature and humidity should be taken at the specified height in the centre of the terminal. The read-outs on the surgeon's panel should be recorded at the same time.

#### UCV discharge velocity test

- 8.127 Measurements of air velocity are to be taken at all test positions at 1 m, 1.5 m and 2 m above floor level.
- 8.128 The average of the total readings taken should be no less than 0.4 m/s.

#### UCV entrainment test (Vertical systems only)

##### Rationale for the entrainment test

- 8.129 The performance of UCV systems may be compromised by room air being drawn into the ultra-clean airflow, a phenomenon known as "entrainment." Significant levels of entrainment could lead to microbial contamination of items left exposed on instrument trolleys laid out beneath the canopy.

- 8.130 UCV systems having permanently fitted full sidewalls do not need to be tested, as the sidewalls physically prevent entrainment.

#### Principle of the test

- 8.131 A source of particles is produced outside of the UCV terminal and is used to challenge the system. A detector is placed within the ultra-clean airflow and used to determine the percentage penetration of the test particles at predefined locations under the UCV terminal footprint. The source and detector are moved in tandem around the UCV canopy and pairs of readings taken, from which the percentage penetration at specified locations is calculated. The degree of penetration should be below specified maximum limits if entrainment is to be declared not significant.
- 8.132 The entrainment test may be carried out using either of the following techniques:
- use DOPs to provide the challenge source at the specified release position and a photometer to measure the entrainment; or
  - duct non-HEPA-filtered air to the specified release position and use a DPC to measure the entrainment.

#### Test set-up

- 8.133 The terminal face diffuser screen should be in place for these tests.
- 8.134 The test should be performed without any equipment in place beneath or closely adjacent to the UCV terminal.
- 8.135 The theatre lights should be moved to a central position beneath the terminal and raised to 2m above floor level, so as not to interfere with the peripheral airflows.
- 8.136 Take spot readings at the centre of the canopy, one metre from floor level, to establish that the room is within the specified temperature and humidity test conditions.
- 8.137 Set out the test grid as described previously.
- 8.138 For either of the following entrainment tests, a measurement of particle penetration through a representative section of the HEPA filter media is to be taken and used as the reference background level.

#### Test equipment, challenge source, measuring instrument and detector head

- 8.139 The challenge and detector equipment should be chosen so that:
- the tracer particles are mainly within the size range 0.3 to 5 microns and thus capable of remaining airborne for a substantial time;

- the particles used should not be able to penetrate the terminal filters in sufficient numbers to cause a background count that is more than 0.1% of the challenge count;
- the choice of particle and detector will enable a minimum of a three-logarithm (1,000-fold) range of counts to be recorded between the highest (that is, source) and lowest (that is, background) readings expected. (A concentration of approximately  $10^5$  particles per cubic metre of source air has been shown to be adequate.)

#### Source – Dispersed Oil Particles (D.O.P.)

- 8.140 The DOP generator should be able to produce a cloud of test particles in the form of a visible smoke. The test smoke should be delivered via an aperture so that it flows vertically downward from the lowermost edge of the partial wall, on the outside of the UCV canopy.
- 8.141 The test smoke is to be delivered via an aperture.

**Note 4:** To prevent undue contamination of the theatre and filters with deposits of oil, DOP should only be released for the minimum amount of time necessary to complete the test.

#### Challenge source – natural particles

- 8.142 The source unit should be a fan/blower or other method that takes non-HEPA-filtered air and expels it via a delivery head at the specified release position to provide the particle challenge. The challenge air should be delivered vertically downwards from the lowermost edge of the partial wall, on the outside of the UCV canopy, parallel to the airflow coming from the diffusers. The challenge air velocity should be the same as the measured average velocity at 2 m from the terminal under test.

**Note 5:** The use of DOP for testing is gradually being phased out and replaced by a natural challenge measured with a DPC. At the time of writing research is under way to define more precisely a challenge source unit for natural particles. It is anticipated that such a unit, together with a matching test methodology, will become available during the life of this Scottish Health Technical Memorandum.

#### The detector (defined in terms of range and resolution)

- 8.143 This may be a photometer or a DPC. It is recommended that a printer be linked to the test instrument so that readings are recorded automatically. The instrument should be capable of sampling a minimum a 28.3 litres of air per minute and in the case of the DPC, provide readings for particle size ranges from 0.3 microns to 5.0 microns and greater. The instrument should be compliant with the requirements of BS EN ISO 14644-1. An alternative instrument may be used providing it is of no lesser specification.

### Test positions and orientation of source and detector

- 8.144 The test positions should be at the centre of each test square, as defined for the velocity test.
- 8.145 For rectangular UCV terminals, measurements of penetration are to be taken at the four corner test squares of the test grid and at intermediate positions along the line of test squares between the corners. The number of intermediate test positions will be as equally spaced as possible around the periphery with no fewer than 3 and no more than 5 complete test squares between test positions.
- 8.146 A further series of measurements are to be obtained around the periphery of the inner zone. Measurements of penetration are to be taken at the four corner test squares of the inner zone of the test grid and if necessary at intermediate positions along the line of test squares between the corners as equally spaced as possible, with no fewer than 3 and no more than 5 complete test squares between test positions.
- 8.147 A single measurement should be taken at the geometrical centre of the UCV terminal footprint. The centre measurement will be taken with the detector head mounted vertically upwards 1 metre above floor level.
- 8.148 The centre of the challenge particle source should be aligned with the centre of the designated test square, with its longer edge against the outer edge of the partial wall and delivering the challenge from the lower edge of the partial wall. The air containing challenge particles is directed vertically downwards from the lower edge of the partial wall, in a plane parallel to the adjacent partial wall. Where there is physical interference due to obstructions such as gas pendants, the source will be moved to the next available non-obstructed test-square location nearest to the stipulated sampling position. The detector should then also be moved to remain opposite the source.
- 8.149 In the case of non-rectangular terminals, an interpretation of the above strategy should be adopted that will yield a no less searching examination of the unit's ability to control entrainment.

### Test method

- 8.150 The sampling head of the detector instrument is mounted on a test stand with its sampling orifice facing outwards horizontally from the centre of the UCV canopy, 1m above floor level. The sampling head should be orientated at right angles to the partial wall when sampling along the sides of the test grid but will be set to bisect the angle when measuring at the corner test positions (Figure 8 in section 8, at paragraph 8.84 illustrates the challenge and detector orientations when evaluating a 2.8m x 2.8 m UCV terminal).
- 8.151 The test will commence at the first test position, this being designated the leftmost corner of the test grid when facing the wall housing the surgeon's panel. The penetration will also be measured at the corresponding test point on the inner zone commencing at the corner nearest to the first test position. When these tests have been completed, the source and detector equipment should be

moved to the next test positions, working around the test grid in a clockwise direction.

- 8.152 The test stand should be positioned on each test point in turn and a pair of readings (challenge, then penetration) taken when the instrument has stabilised. The detector should be set to take a reading over a 15 second sample interval.
- 8.153 When taking a reading the test person should stand within the UCV terminal footprint but not in the same quadrant as the detector head.

### Analysis and Interpretation

- 8.154 The following standard is to be achieved:
- penetration to be not greater than 10% of the challenge at each test position in the outer zone;
  - penetration to be no greater than 1% of the challenge at each test position in the inner zone;
  - penetration to be no greater than 0.1% of the challenge at the centre of the test grid.

If a result is close to, or above the given limits, then a further reading must be obtained using a longer time base (1 minute) and the penetration must not exceed the given limit.

### Basis of the test

- 8.155 Whyte W, Shaw BH, Freeman MAR. An evaluation of a partial-walled laminar-flow operating room. *J Hyg Camb* 1974; 73: 61 – 75.

Whyte W, Lidwell OM, Lowbury EJJ, Blowers R. Suggested bacteriological standards for air in ultraclean operating rooms. *J Hosp Infect* 1983; 4: 133 – 139.

### UCV visualisation

- 8.156 The use of smoke to gain an understanding of the overall performance of the system may prove useful at this stage in the validation process but cannot be relied on to produce a contractually definitive measure of performance.

### UCV noise level

- 8.157 An industrial-grade sound-level meter to BS EN 61672 Type 2 fitted with a muff should be used to check the noise level. The instrument should be calibrated using a matched sound source prior to each set of readings.

### Vertical systems

- 8.158 The noise level readings should be taken at typical normal listening positions 1.5 m above floor level and at least 1m from any surface and not on any line of symmetry. Measurements should be taken under the centre of each quadrant of the UCV terminal and the four readings averaged.

### Horizontal systems

- 8.159 The noise level readings are to be taken at typical normal listening positions 1.5m above floor level on the test line. The width of the unit should be divided in two and a measurement taken in the centre of each half but avoiding any line of symmetry. The two readings should be averaged.
- 8.160 Measurements should also be taken in each room of the suite.
- 8.161 In the event of a contractual deficiency a Type 1 precision-grade sound-level meter complying with BS EN 61672 should be used. Readings should be taken at the positions specified above and in each case the logarithmic mean of the results should be calculated in order to determine the noise level. (Further information can be found in SHTM08-01, forthcoming).
- 8.162 For vertical or horizontal systems, the noise level shall not exceed:
- 50NR [55dB(A)] – for UCV operating rooms and spaces without doors that open directly on to it (for example the scrub);
  - 40NR [45dB(A)] – for all other peripheral rooms of the suite.

### UCV control system checks

#### Temperature

- 8.163 The readings of temperature taken under or in front of the UCV unit should be within  $\pm 1$  K of each other and the read-out on the surgeon's panel.

#### Humidity

- 8.164 The readings of humidity taken under or in front of the UCV unit should be within  $\pm 5\%$  of each other and the read-out on the surgeon's panel.

#### Direct-reading differential pressure gauges

- 8.165 The differential pressure across the terminal filter(s) should be measured to confirm the accuracy of the indicated reading of any gauge.

#### Control functions

- 8.166 The operation of all control functions provided on the surgeon's panel should be proved for conformity with the design specification.

- 8.167 If an auxiliary panel has been fitted then its interlocking with the main surgeon's panel control functions must be proved to conform to the design specification.

#### Panel indicator lights

- 8.168 The panel indicator lights should illuminate as appropriate when the control functions are selected or warning levels are reached

#### BEMS interface

- 8.169 The operation, monitoring and alarm functions must be proved to conform to those set out in the design specification.

#### UCV theatre microbiological tests

- 8.170 There is little value in performing microbiological sampling in a new theatre supplied with ultra-clean ventilation. The foregoing filter challenge tests, air velocity measurements and entrainment test should have proved that the system operates satisfactorily and achieves the contracted level of performance. The HEPA filters will remove bacteria-sized particles from the air supplied through the UCV terminal. Therefore there will be an insignificant number of bacterial and/or fungal CFUs present until the Theatre is actually used.
- 8.171 Once the theatre has been taken into use, microbial sampling during a surgical procedure should help to confirm the satisfactory performance of the system and discipline of the users. Before commencing bacteriological testing, the room and its ventilation system should have achieved a steady state condition: (see also paragraph 8.74)
- 8.172 The installation should be tested during surgical procedure at intervals between the time of the first incision and final closure of the wound. On average, the air sampled within 300 mm of the wound should not contain more than 10 CFU/m<sup>3</sup>.

#### UCV validation report

- 8.173 Following validation a full report detailing the findings should be produced. The report shall conclude with a clear statement as to whether the UCV theatre suite achieved or did not achieve the standard set out above.
- 8.174 A copy of the report should be lodged with the following groups:
- operating department;
  - infection control;
  - estates and facilities.

## Appendix 1 - Table A1: Recommended air-change rates

Application	Ventilation	ac/Hour	Pressure (Pascals)	Supply Filter	Noise (NR)	Temp (°C)	Comments For further information see Section 6
General ward	S / N	6	-	G4	30	18-28

Table A1: continued

**Notes:** 18-22°C indicates the range over which the temperature may float

18-22°C indicates the range over which the temperature should be capable of being controlled

S = supply                      N = natural ventilation

E = extract    a – European guidelines on good manufacturing practice published by the Medicines and Healthcare products Regulatory Authority (MHRA)

## Appendix 2 - Hierarchy of cleanliness

			Air-flow rate for bacterial contaminant dilution	
Class	Room	Nominal pressure (Pa) a	Flow in or supply m <sup>3</sup> /s	Flow out or extract m <sup>3</sup> /s
Sterile	Preparation room		See standard schemes in Appendix 3 for recommended design values	
	(a) lay-up	35		
	(b) sterile pack store	25		
	Operating room	25		
	Scrub bay b	25		
Clean	Sterile pack bulk store	+ve	6 ac/h	-
	Anaesthetic room c	14 c	The greater of 15 ac/hr or 0.15	The greater of 15 ac/hr or 0.15
	Scrub room	14	-	0.10
Transitional	Recovery room	3	15 ac/hr d	15 ac/hr d
	Clean corridor	0	e	7 ac/hr
	General access corridor	0	e	7 ac/hr
	Changing rooms	3	7 ac/hr	7 ac/hr
	Plaster room	3	7 ac/hr	7 ac/hr
Dirty	Service corridor	0	-	f
	Disposal room	-5 or 0	-	0.41 or 0.10

Table A2

**Notes: (applicable to Table A2)**

- a. Nominal room pressures are given to facilitate setting up of pressure relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not critical, provided the desired airflow rates and movement are achieved.
- b. An open or semi-open bay is considered to be part of the operating room; provided air movement is satisfactory, no specific extract is required. However if the layout means that air movement is poor, a local extract may be required to control local condensation on the building surfaces, which can result in mould growth.
- c. For design purposes, anaesthetic should be assumed to be at 14 Pa. When commissioning 10 Pa is considered suitable.
- d. 15 ac/hr are considered necessary for the control of anaesthetic gas pollution.
- e. Supply airflow rate necessary to make up 7 ac/hr after taking into account secondary air from cleaner areas.
- f. No dilution requirement. Temperature control requirements only.

Type	Pressure difference - Pa						
	5	10	15	20	25	30	40
Single door (CDB Size 2.4.3.2.6.)	.03	.05	.06	.06	.07	.07	.08
Double door (CDB)	.04	.08	.10	.11	.12	.13	.14
High permanent length of 3mm gap	.004	.008	.010	.011	.012	.012	.013

Table A3: Leakage flows in m<sup>3</sup>/s through closed door gaps

**Note:** CDB = Component Data Base

It should be noted that many doors are now fitted with cold smoke seals as standard. These will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design leakage is factored into the sizing of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air gap whistles and doors being held partially open by air pressure.

Factory-assembled door-sets with a steel frame and pre-hung leaves have become common. There is effectively no leakage across these doors when closed. Therefore, when this type of door assembly is fitted, the door leakage can be ignored and the design airflow into the room reduced accordingly. The design airflow would then become that required either (i) for open door

protection, or (ii) to achieve the specified air-change rate - whichever is the greater.

Room class		Dirty	Transitional	Clean	Sterile
Sterile	Hatch	0.3	0.24	0.18	
	Single door	0.47	0.39	0.28	0 or 0.28 a
	Double door	0.95	0.75	0.57	0 or 0.57 a
Clean	Single door	0.39	0.28	0 or 0.28 a	
	Double door	0.75	0.57	0 or 0.57 a	
Transitional	Single door	0.28	0 or 0.28 a		
	Double door	0.57	0 or 0.57 a		
Dirty	Single door	0	Open single door = 0.80m x 2.01m high		
	Double door	0	Open double door = 1.80m x 2.01m high		

Table A4: Recommended air flow rates in m<sup>3</sup>/s through a doorway between rooms of different cleanliness to control cross-contamination

**Designer's Notes:**

- a The degree of protection required at an open doorway between rooms is dependent upon the degree of difference in cleanliness between them.
- b Flow rate required between rooms within the same class tends to zero as class reduces.
- c If two rooms are of equal cleanliness, no flow is required (in practice there will be an interchange in either direction) and the design of the air movement will assume zero air-flow. In certain cases, however, interchange is not permitted and a protection airflow of 0.28 is assumed in the design, for example, in the case of a preparation room used as a "lay up".

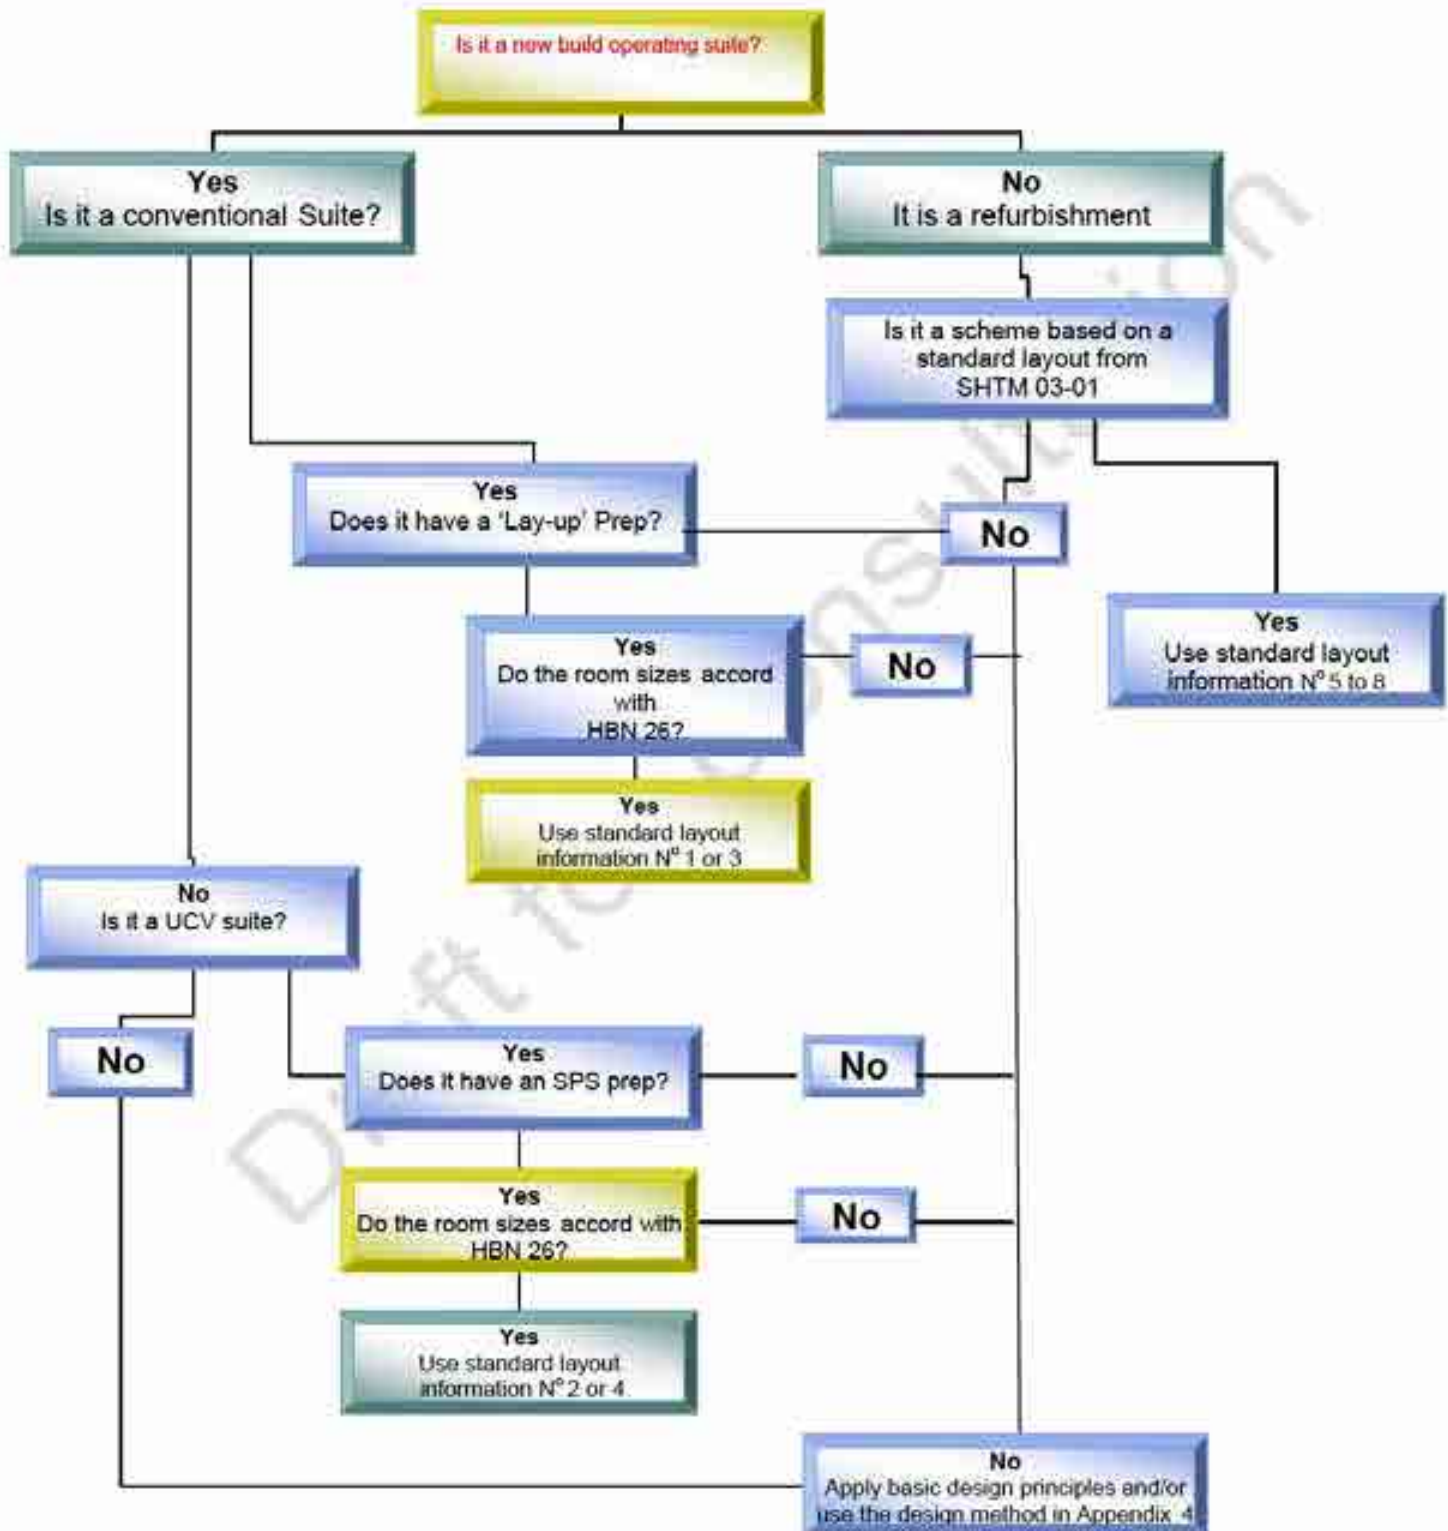

Door open between	Resultant pressure in these rooms (Pa)	Effect on other rooms	
		Room	Pressure (Pa)
Operating room and corridor or Scrub bay and corridor	0	Anaesthetic Preparation – lay up Disposal Preparation – sterile pack store	0 12 -6 5
Operating room and anaesthetic room (or other series room with double doors)	17	Preparation – lay up Disposal Preparation – sterile pack store	28 -9 22
Operating room and disposal room or Operating room and preparation room	25	No change	
Anaesthetic room and corridor (or other series room with double doors)	0	Preparation – lay-up Disposal Operating room Preparation – sterile pack store	30 -6 20 25
Preparation room – corridor Disposal room & corridor	0	No change	
Disposal room & outer corridor	0	No change	

Table A5: Typical pressures in an operating suite when a given door is open

**Notes:-**

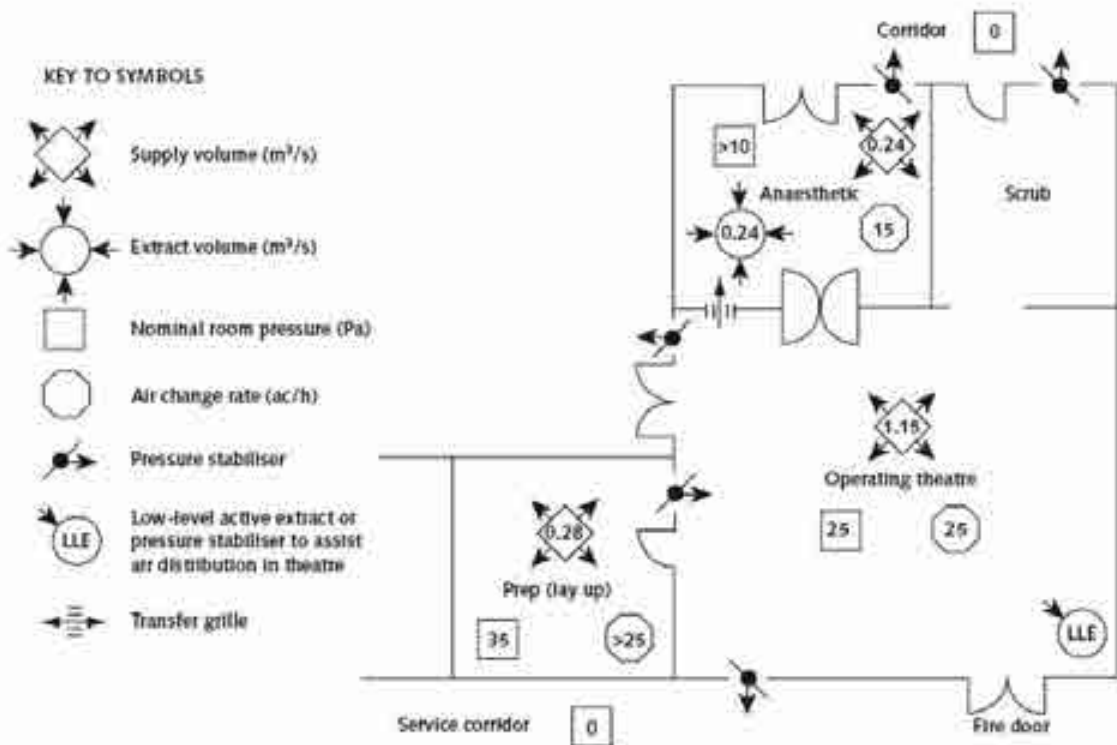

1. The room differential pressure protects against reverse flows when the door is closed.
2. The flow of air through a doorway protects against reverse airflow when the door is open.
3. Pressure stabilisers control flow and ensure a known air-flow path between rooms when doors are closed and reduce back-flow between rooms when doors to other rooms are open.

## Appendix 3 - Operating suite design logic

### New Standard Layout N<sup>o</sup> 1 - Suitable for a typical conventional theatre suite (Room sizes as specified in HBN 26)

Room	Size m <sup>3</sup> <small>Derived from HBN26</small>	Air-Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	165	25	25	1.15
Anaesthetic	57	15	>10	0.24
Lay-Up-Prep	36	>25	35	0.28**
Scrub	*	-	25	-

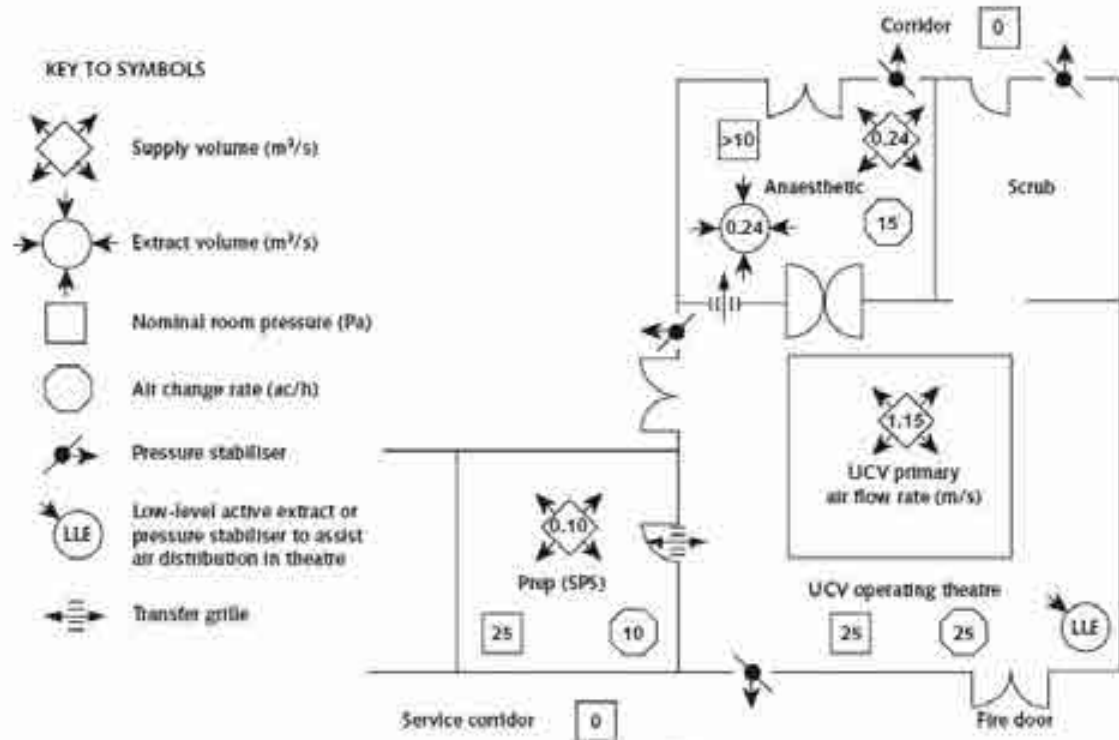

\*This is a separate scrub and is not considered as being part of the theatre volume.

\*\*Interchange is not permitted between the theatre and lay-up prep; therefore an airflow protection of 0.28 + 0.06 closed-door airflow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

**New standard layout N° 2 - Suitable for a typical UCV theatre suite (Room sizes as specified in HBN 26)**

Room	Size m <sup>3</sup> <i>Derived from HBN26</i>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Prep	36	25	25	0.10
Scrub	-	-	25	-

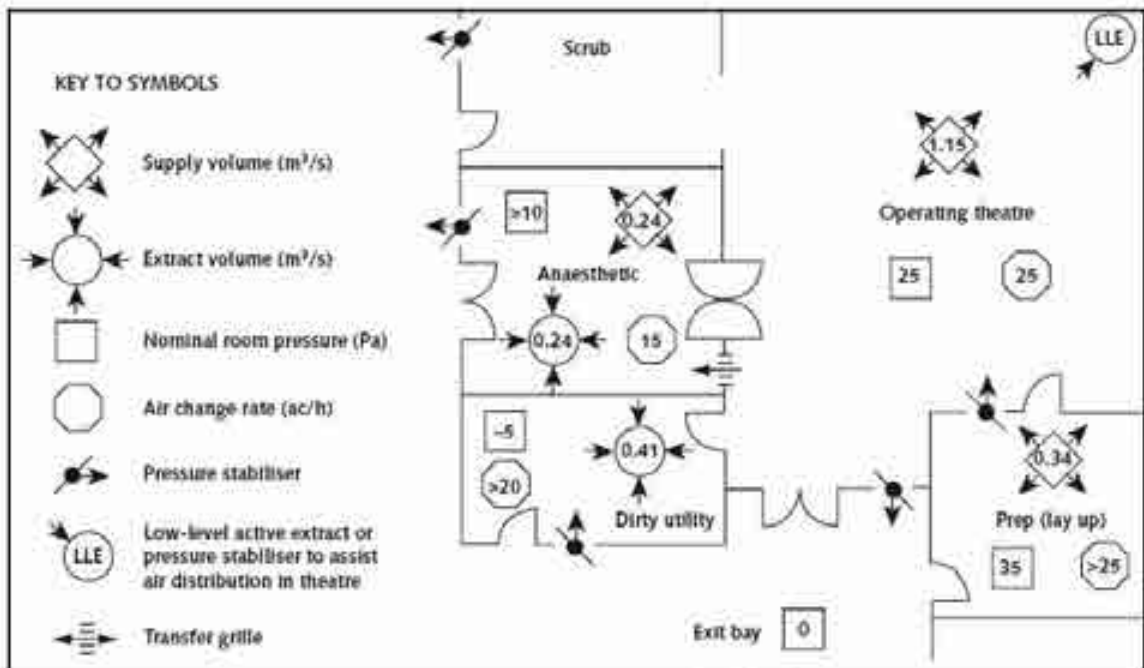

\*Separate scrub and not considered as part of theatre volume

\*\*Primary Fresh air Volume Only

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

**New standard layout N° 3 - Suitable for a typical Conventional theatre suite (Layout and room sizes are as illustrated in HBN 26)**

Room	Size m <sup>2</sup> <small>Derived from HBN26</small>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	165	25	25	1.15
Anaesthetic	57	15	14	0.24
Lay-Up Prep	36	>25	35	0.34**
Scrub	*	-	25	-
Dirty Utility	36	-	-5	0.41

\*Separate scrub not considered part of theatre volume.

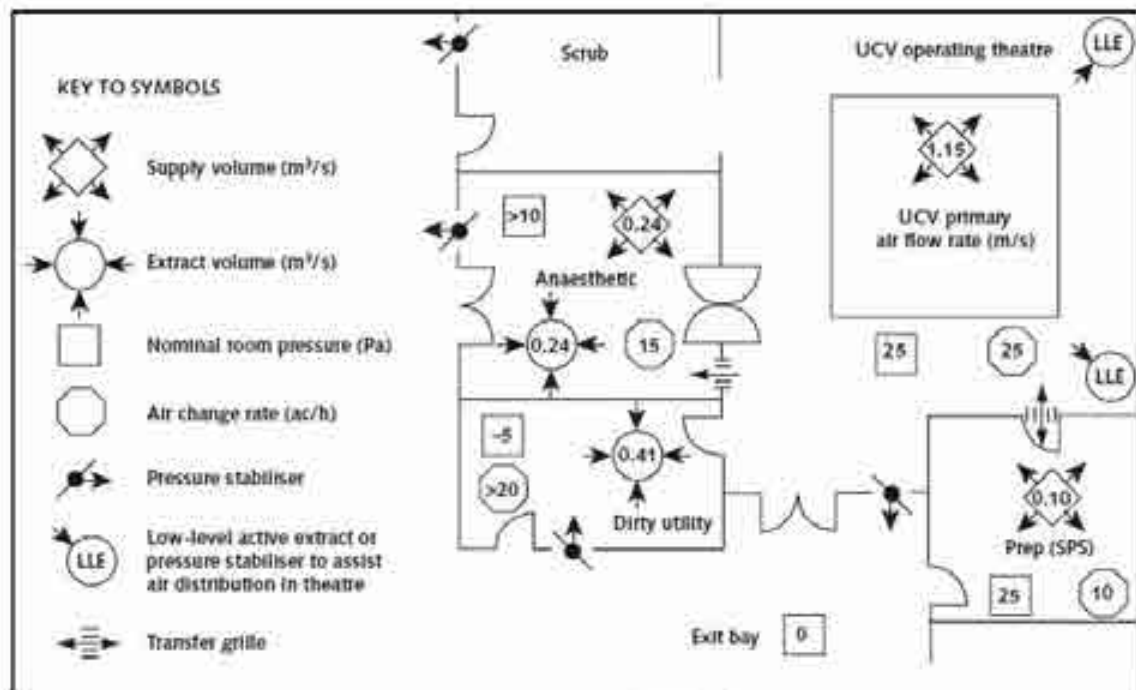

\*\*Interchange is not permitted between the theatre and lay up prep therefore as table 4 an airflow protection of 0.28 + 0.06 closed door air flow is required as a minimum.

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

**New standard layout N<sup>o</sup> 4 - Suitable for a typical UCV theatre suite (Layout and room sizes are as illustrated in HBN 26)**

Room	Size m <sup>2</sup> <small>Derived from HBN26</small>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	165	25	25	1.15**
Anaesthetic	57	15	>10	0.24
Sterile Pack Prep	36	10	25	0.10
Scrub	-	-	25	-
Dirty Utility	36	-	-5	0.41

\* Separate scrub not considered part of theatre volume

\*\*Primary Fresh air Volume Only

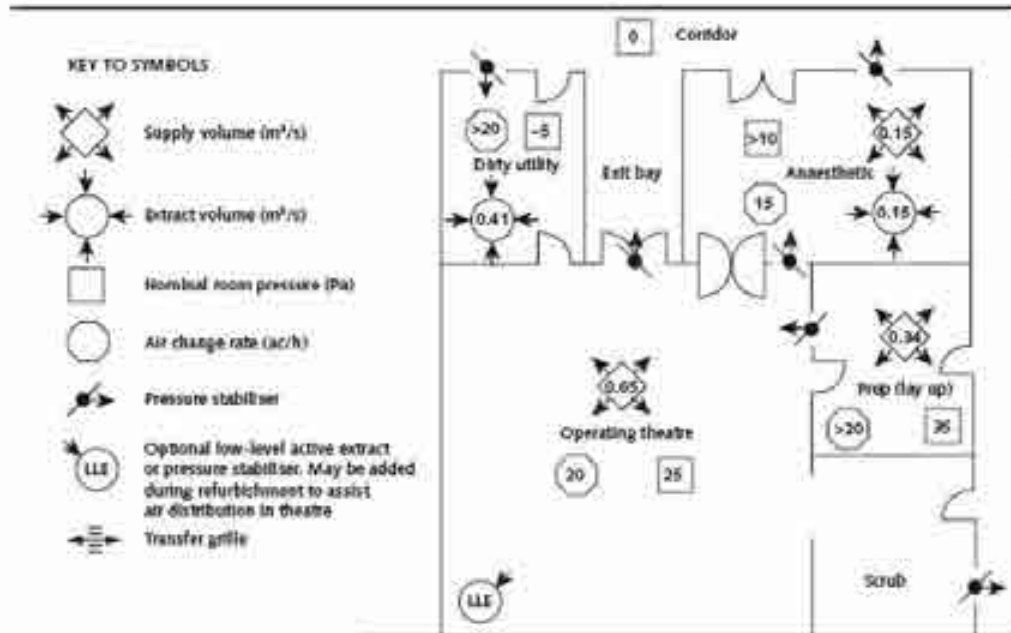

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the exits from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre may be either passive and fitted with pressure stabilizers or active and connected to the extract system. They should be located at low level and positioned to promote the ventilation of all areas of the space.

## New standard layout N° 5 - SHTM 2025 Existing standard plan '1b' typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

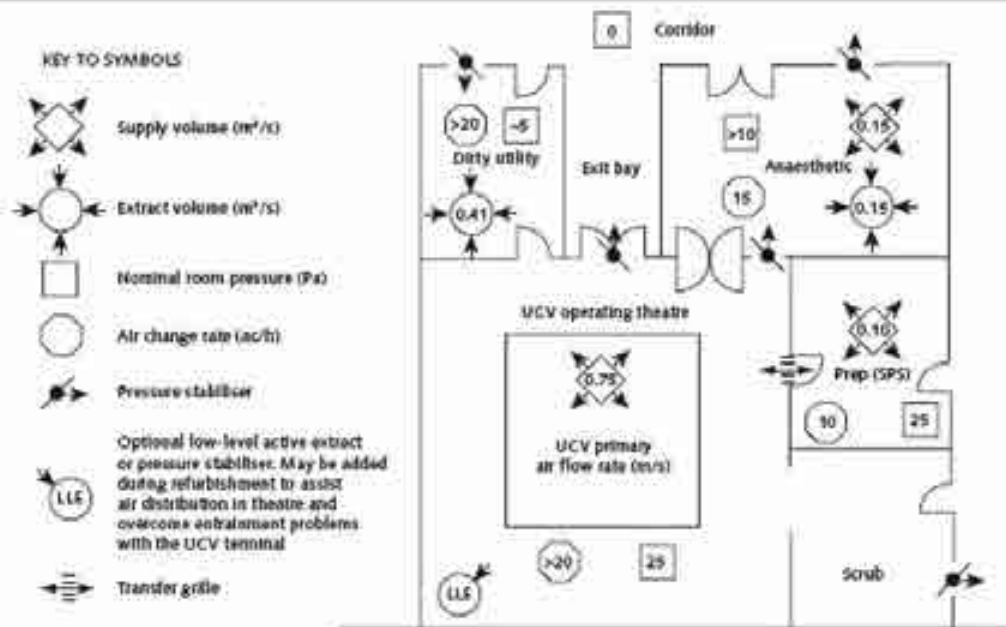

Room	Size m <sup>2</sup>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	Existing Theatre Suite To Be Measured On Site	20	25	0.65
Anaesthetic		15	14	0.15
Lay-Up Prep		-	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

## Standard layout N° 6 - SHTM 2025 Existing standard Plan '1a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

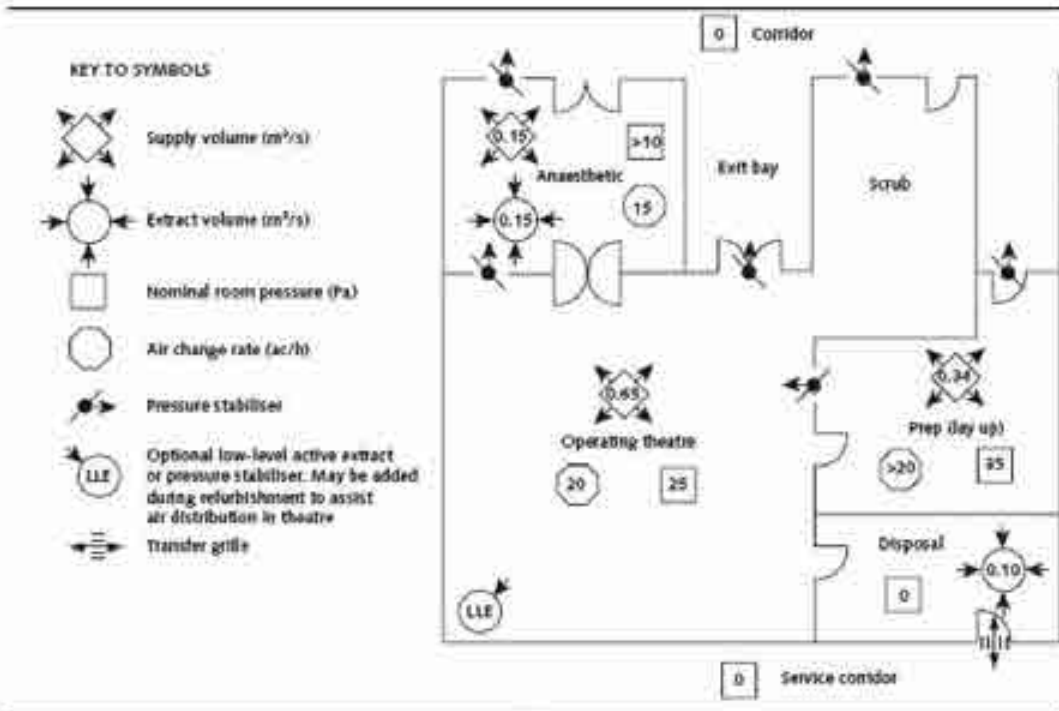

Room	Size m <sup>3</sup>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	Existing Theatre Suite To Be Measured On Site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Pack Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	-5	0.41

\*Primary fresh airflow volume

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor.

## Standard layout N° 7 - SHTM 2025 Existing standard Plan '5b' Typical layout for a conventional theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

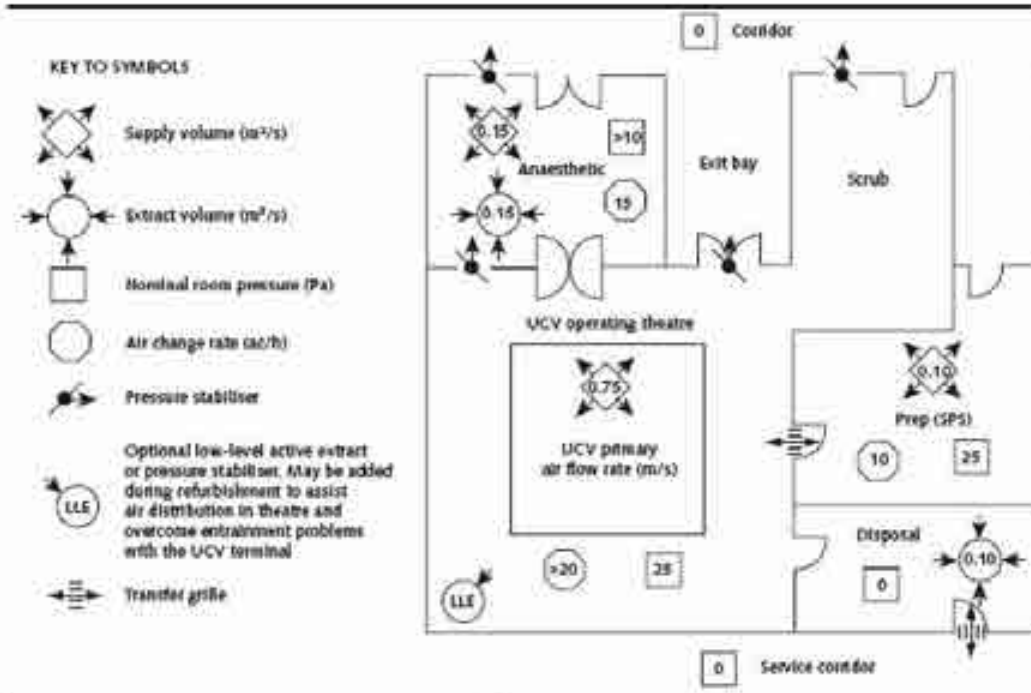

Room	Size m <sup>2</sup>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	Existing Theatre Suite to be Measured on site	20	25	0.65
Anaesthetic		15	>10	0.15
Lay-Up Prep		>20	35	0.34
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

## Standard layout N° 8 - SHTM 2025 Existing standard Plan '5a' Typical layout for a UCV theatre suite

This layout and data is for historical purposes only. The information is to be used for the evaluating of existing systems or rebalancing following ventilation system cleaning.

Room	Size m <sup>2</sup>	Air Change Rate per hour	Nominal Pressure Pa	Flowrate m <sup>3</sup> /s
Theatre	Existing Theatre Suite To Be Measured On Site	20	25	0.75*
Anaesthetic		15	>10	0.15
Sterile Prep		10	25	0.1
Scrub		-	25	Included within theatre
Disposal		-	0	0.1

\*Primary fresh air-flow volume only

The disposal layout detailed will remain the same should a hatch be utilised instead of a door onto the outer corridor. Alternatively the disposal room could be omitted and replaced with a disposal hatch between the theatre and corridor.

## Appendix 4 - Design of air-movement control schemes for operating theatres.

### General

- A4.1 Standard operating suite design solutions are given in Appendix 3. If these standard solutions cannot be used, the following procedure should be adopted, which will result in an acceptable design. Note that the method employed can equally be used to provide a design solution to a ventilated suite of rooms for any application.
- A4.2 The method is concerned with the calculation of airflow rates to ensure that correct air movement occurs between rooms when any one door is open. Under most circumstances, the air quantities required for air-movement control will approximate to those for either temperature control or bacterial contaminant dilution. This flow rate is sufficient to control the effects of any slight reverse flows occurring when a door is opened.
- A4.3 The progression through the design procedure is shown in the airflow design procedure chart (Figure A4/3) and is supported by worksheets WS1 to WS7 described in paragraph A4.4. It is recommended that a plan of the suite and an airflow network be made (Figure A4/2) to collate all information. Flow rates, air-transfer devices etc should be entered as required. The remainder of this Appendix may be treated as reference data to assist in the various steps. The following symbols are used:

$S_S$  – supply airflow rate for summer temperature control;

$S_W$  – supply airflow rate for winter temperature control;

$S_D$  – supply airflow rate for dilution of bacterial contaminants;

$S_L$  – supply airflow rate for heat loss;

$S_G$  – supply airflow rate for heat gain;

$E_D$  – extract airflow rate for dilution of bacterial contaminants;

$S_F$  – final supply airflow rates;

$E_F$  – final extract flow rates;

$S_{AMC}$  – air-supply flow rate for air-movement control;

$E_{AMC}$  – air-extract flow for air-movement control;

$L_{OUT}$  – leakage airflow rate outward;

$L_{IN}$  – leakage airflow rate inward;

$\Sigma_{OUT}$  – total airflow rate outward;

$\Sigma_{IN}$  – total airflow rate inward.

A4.4 To simplify the procedure, standard worksheets (WS1 to WS7) have been devised. For each operating suite, a set is required comprising one each of WS1, WS3, WS5, WS6a, WS6b and WS7, one WS4 for each corridor and one WS2 to cover each peripheral room. WS2 has five versions:

- WS2a single flow;
- WS2b parallel/series multi-flow;
- WS2c parallel multi-flow or series multi-flow (unbalanced);
- WS2d series multi-flow (balanced); and
- WS2e bay (semi-open).

### Peripheral room type

A4.5 The rooms in the operating suite other than the operating room and corridor are referred to as peripheral rooms. Peripheral rooms have been classified according to the flows in and out. These room classifications are defined below in paragraphs A4.6 – A4.11.

#### Single flow

A4.6 This is a room with only one door and a net surplus of supply or extract air.

#### Parallel multi-flow

A4.7 This is a room with two or more doors through each of which the air-flows either outwards (high-pressure) or inwards (low-pressure) (for example the Prep (lay-up) in standard layout 5 in Appendix 3).

#### Parallel/series multi-flow

A4.8 This is a room having a net surplus of supply or extract and with two or more doors. One or more doors will be to an area of equal cleanliness and need not be protected; hence, the flow may vary between inwards and outwards, the remaining door being to an area of greater or lesser cleanliness (for example the Prep (SPS) in standard layout 6 in Appendix 3).

#### Series multi-flow (unbalanced)

A4.9 This is a room having a net surplus of supply or extract and with two or more doors. Air flows inwards through one or more doors and outwards through one or more doors.

### Series multi-flow (balanced)

- A4.10 This is a room as in paragraph A4.9 above, but having either no mechanical ventilation or no net surplus of supply or extract. (for example an anaesthetic room).

### Bay

- A4.11 A room that has a permanent opening to the operating room may be considered as a bay off the latter (for example a scrub). Two categories exist:
- open bay – the opening is larger than a normal single door opening. The bay may be considered as part of the main room;
  - semi-open bay – the opening is no larger than a normal single door opening. In this case it is possible to protect the bay from the main room by provision of air supply or extract in the bay, or by passing air to or from another area.

### Air-movement control in peripheral rooms

- A4.12 For the design of air-movement control, two types of air-transfer device are considered. These are transfer grilles and pressure stabilisers. Each has a particular field of application within the design, as described in paragraphs A4.34 – A4.43. Air movement is controlled in each of the different room types described in paragraphs A4.13 – A4.31.

**Note:** This key applies to each diagram in 4.13 - 4.27.

### Single flow rooms

- A4.13 An appropriately sized transfer grille should be located in or adjacent to the door of each single flow room to relieve the pressure differences across the door when closed.

### Parallel multi-flow rooms

- A4.14 The pressure difference across the closed doors must be relieved, but transfer grilles are not appropriate where two doors lead to areas of different pressures, because reverse flow could occur when the other door is open. For this reason, pressure stabilisers are used.

- A4.15 These rooms will be either high-pressure or low-pressure with respect to the adjacent areas (see preparation lay-up room and disposal room, respectively, in standard layout 5 of Appendix 3). The pressure-relief damper is always situated between the room and area, which results in the smaller differential pressure to ensure best use of air.

- A4.16 Just as reverse flow can occur if transfer grilles are used, it can similarly occur via door gaps when the other door is opened. It is not possible to avoid this, except by using air locks, but due to the low flow rates and short durations involved, this is not considered to be of importance.

### Parallel-series multi-flow rooms

- A4.17 These rooms are similar to those in paragraph A4.14 above, but because the room is of equal cleanliness to one of the adjacent rooms the nominal pressures will be equal and air may flow through the adjoining doorway in either direction. (for example the Prep (SPS) in standard layout 6 of Appendix 3).

- A4.18 Where the nominal room pressure equals that of the higher-pressure adjacent room, the best use of air is by supplying air required for bacterial dilution only and allowing this to exhaust via a transfer grille to the area of equal cleanliness. The doorway to the lower pressure area is protected by the combination of the supply air and the air that will flow inwards through the transfer grille from the area of equal cleanliness.

- A4.19 Conversely, where the nominal pressure equals that of the lower-pressure adjacent room, extract ventilation and a transfer grille to the lower pressure adjacent room should be provided. (for example, the disposal room in standard layout 8 of Appendix 3).

**Series multi-flow (unbalanced)**

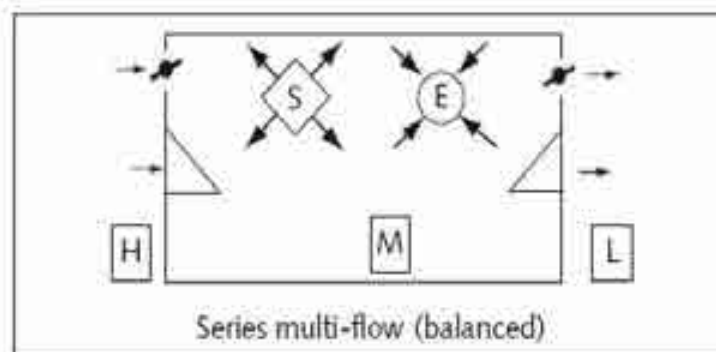

- A4.20 These rooms are somewhat similar to those in paragraph A4.15 above, but because the pressure lies between that of the rooms on either side, the back-flow problem does not exist.

- A4.21 Where the room has a net surplus of mechanical supply air, a transfer grille should be located in or adjacent to the door through which air flows outwards, and the mechanical supply flow rate to the room should be chosen to give protection when this door is open.
- A4.22 Where the room has a net surplus of mechanical extract air, a transfer grille should be located adjacent to the door through which the air flows inwards, and the mechanical extract flow rate to the room should be chosen to give protection when this door is open.
- A4.23 The grille must be sized for the protection requirement of the opposing door when open. When the room on the high-pressure side depressurises, there is a possibility of back-flow through gaps around the door, but this problem may be ignored.

**Series multi-flow (balanced)**

- A4.24 In these rooms, a transfer device adjacent to each doorway is required in order to provide a flow path for the air required to protect the opposing door when opened.

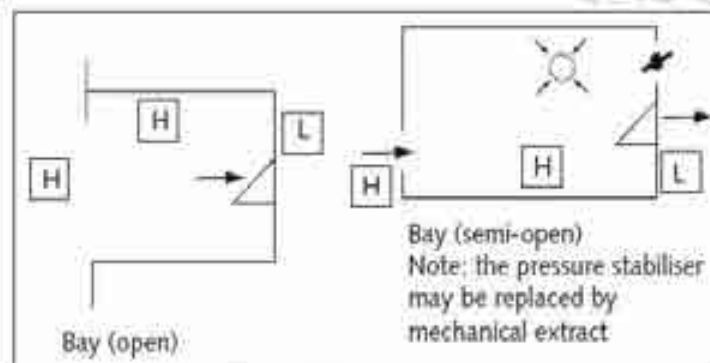

- A4.25 These transfer devices will normally be pressure stabilisers, although transfer grilles may be used where a large amount of excess air is to be exhausted from the operating room when all doors are closed. (for example, anaesthetic rooms).
- A4.26 The calculation procedure is to assume that pressure stabilisers are being used; then (if there is sufficient excess air) change to transfer grilles as described in paragraph A4.50.

## Bay

### Open bay

- A4.27 A bay of the open type (for example scrub-up) is considered to be part of the operating room. Provided air movement is satisfactory, no specific extract is required.

### Semi-open bay

- A4.28 In a bay of the semi-open type, protection of one area from the other is possible. (for example scrub-up).
- A4.29 As stated previously, the need for protection between operating room and scrub-room is not very great. Better use of air can therefore be achieved in this case by installing a pressure stabiliser between the scrub-room and clean corridor. This will allow a flow of air through the scrub-room at all times, except when a door is opened elsewhere in the suite. The pressure stabiliser will then close and the air will be diverted to the other door. When it is considered necessary to protect the scrub-room at all times, either a transfer grille to the corridor or mechanical extract in the scrub-room should be provided.

### Operating room

- A4.30 Once the peripheral rooms have been considered, the operating room requirements may then be decided and the supply flow rate required for air-movement control calculated. This flow rate should be such that, with any one door open, the correct air movement directions are maintained. There will be one door in the suite that will require the largest supply flow rate to the

operating room for protection when open. This is called the “key door” and is discussed separately in paragraph A4.33. Use of this concept avoids repetitive calculations for each door in turn. Having established the required supply flow rate, a relief route must be provided to the clean corridor for any excess air when the doors are closed. This would be via transfer grilles or pressure stabilisers through a series-flow room or via pressure stabilisers to the clean corridor directly.

### Corridors

- A4.31 All surplus air from the suite, except that lost through structure leakage and any passing to the outer corridor, will arrive in the patient/staff corridor. Should this air be insufficient to achieve the required air-change rate (see Appendices 1&2), some additional air supply should be provided. (The air balance should take account of structural leakage.)

### Door opening

- A4.32 Whereas the resulting pressures are dependent on ductwork layout, room relationships and characteristics of the fan, the generalisations shown in Appendix 2 can be used to estimate the change in room pressure when a door is opened.
- A4.33 The “key door” will be the open double door which leaves the operating room at the highest pressure, and/or requires the largest air flow. This should be determined using the procedure in worksheet WS3.

### Transfer grilles

- A4.34 These may be used to limit the pressure differences across the closed door of a single-flow room or, in some instances, for protection of a series-flow or parallel-series-flow room. They allow airflow in both directions and may not be suitable for all applications.
- A4.35 The free area of a grille is calculated from the following equation:

$$A = \frac{Q}{0.84\sqrt{\Delta P}}$$

where:

*A* is free area (m<sup>2</sup>)

*Q* is flow rate (m<sup>3</sup>/s)

*P* is pressure difference (Pa).

- A4.36 The flow through a grille at a different pressure may be found from the following equation:

$$Q_2 = Q_1 \sqrt{\frac{\Delta P_1}{\Delta P_2}}$$

where:

$Q_1$  and  $P_1$  are original flow and differential pressure

$Q_2$  and  $P_2$  are new flow and differential pressure.

- A4.37 The transfer grille may be replaced by carefully proportioned door undercuts of the equivalent free area.
- A4.38 The function of the transfer grille is to provide a means of airflow control by which the volume and pressure loss can be established. If a grille is used, it should have an easily removable core to facilitate cleaning.

### Pressure-relief dampers

- A4.39 The functions of a pressure-relief damper are now carried out by pressure stabilisers. Accordingly, all further mention of them has been removed from this document.

### Pressure stabilisers

- A4.40 Pressure stabilisers can be adjusted to hold the pressure constant over a wide range of flow rates. They are used where requirements exist for accurate room-pressure control or rapid shut-off on pressure fall.
- A4.41 The installation of a grille or baffle in association with a stabiliser will alter the operating characteristics. It is recommended that a location be chosen to avoid the need for visual screening, for example, at high level. The location should be chosen to minimise the likelihood of damage.
- A4.42 The stabilisers used should be virtually silent in operation, adjustable on site, maintenance-free and of a type that cannot be wrongly inserted. They should not be used in external walls or where the pressure difference is less than 5 Pa. The required size of a pressure stabiliser is dependent on the design pressure difference across it and flow rate through it. The manufacturer should provide data relating pressure difference to mean velocity (or flow rate per unit area). From this, the required area can be calculated and then rounded-up to the nearest size manufactured or nearest combination of smaller sizes.
- A4.43 It is sometimes possible to arrange for a pressure stabiliser to perform two tasks. In an anaesthetic room, for example, the two pressure stabilisers may be

made to pass the open door protection air, and also control the operating and anaesthetic room pressures with the door closed. To achieve this, the stabilisers are sized for the flow rate required with one of the doors open, but the pressure setting is adjusted to be the value required with the doors closed. This is shown in Figure A4/1.

Figure A4/1

### Door leakage flows

- A4.44 For an air-movement control scheme to work satisfactorily, it is essential that the estimates of door-gap leakage made at the design stage are closely related to those which are achieved in practice. The calculation of gap-flows is complicated by the fact that such flows generally fall into the transition region between laminar and turbulent flow and hence do not follow the normal flow equations. The gaps assumed are 4 mm along the bottom, 3 mm at the top and sides, and 2 mm between double leaves. Doors should not have wider gaps than these. Tighter gaps would result in lower flow-rate requirements and hence lower fan power, but care should be taken to ensure that all doors in the suite have similar gap dimensions. It may be possible to ignore the door leakage and so reduce the airflow requirement (see the notes in Appendix 3).

### Room temperature estimation

- A4.45 The air-flow rate required to prevent back-flow through an open door is dependent on the temperature difference across the door. The design figures shown in Appendix 3 are based on the temperature differences that will normally occur in practice, assuming heat gains and losses in accordance with Appendix 2.

A4.46 In accordance with the airflow design process, the temperature differences across the doors of all rooms classed as “sterile” is calculated. Worksheet WS6 is recommended for the calculations, using the following criteria:

- assume that the operating room is being controlled at 20°C and calculate the incoming air-supply temperature as shown on worksheet WS6;
- the calculation should be repeated for both summer and winter conditions, with an operation in progress;
- assume all doors are closed;
- use the room supply flow rates from WS1;
- use the inward air flows through air-transfer devices and closed door leakages from WS2a to WS2e;
- the formula used in worksheet WS6 is as follows:

$$T = \frac{(t_1Q_1 + t_2Q_2 + \dots + t_nQ_n) + 0.828H}{(Q_1 + Q_2 + \dots + Q_n)}$$

where:

$Q$  = flow rate from source (m<sup>3</sup>/s)

$t$  = the temperature of source (°C)

$H$  = the room heat gain (kW).

A4.47 If the evaluated temperature differences between rooms do not exceed 2°C, the solution is satisfactory, otherwise proceed as follows:

- check the assumption on which the heat gains are based;
- take steps to reduce the heat gains;
- if the door is to a corridor, the flow through the open door will be larger than the value given in Appendix 2. Calculate on WS3, assuming it is the “key door” with door-flow unknown, and the supply as known;
- if the door leads to a room with mechanical supply, install a trimmer heater in the supply to the room controlled by either a differential thermostat or a thermostat slaved to the operating room thermostat to ensure that  $T$  is minimized.
- If the door leads to a room with no mechanical supply, increase the door protection flow as follows:

$$Q_{\text{new}} = Q_{\text{old}} \left[ \frac{\Delta T + 1}{2} \right]$$

A4.48 These options should be considered in the above order, and the first three should be investigated thoroughly before proceeding to the latter two. The mechanical supply may need to be increased in order to achieve the desired air-change rates.

## Relief of excess air from operating room when all doors are closed

- A4.49 As the mechanical supply to the operating room is sized to provide an appropriate flow outward through any door that is opened, it follows that when all doors are closed, there will be more air supplied to the operating room than can exit from it via leaks etc. This “excess” air can be relieved by either of the two methods described in paragraphs A4.50 - 4.54.

### By transfer devices via the anaesthetic room

- A4.50 For door protection, the transfer devices in the anaesthetic room are typically designed to pass 0.47 m<sup>3</sup>/s at a differential pressure of 14 Pa. When the doors are closed, the differential pressure will change to 11 Pa between theatre and anaesthetic room, and 14 Pa between anaesthetic room and corridor; the volume of air passed by the transfer devices will be modified as shown in the following formula:

$$\begin{aligned} Q &= Q_1 \left( \frac{\Delta P_1}{\Delta P_2} \right)^{1/2} \\ &= 0.47 \left( \frac{11}{14} \right)^{1/2} \\ &= 0.42 \text{ m}^3/\text{s} \end{aligned}$$

where:

Q = “excess” air to be vented with doors closed;

Q<sub>1</sub> = air-flow required for door protection through transfer device;

ΔP<sub>1</sub> = nominal differential pressure with door to operating room closed and door to corridor closed;

ΔP<sub>2</sub> = nominal differential pressure between either the anaesthetic room and corridor when the operating room door is open, or the anaesthetic room and operating room when the corridor is open. This differential pressure is used when selecting size of both devices.

- A4.51 If the “excess” air is less than 0.42 m<sup>3</sup>/s, a pressure stabiliser is required to ensure that the correct protection airflow is available to pass through the door.
- A4.52 If the “excess” air is greater than 0.42 m<sup>3</sup>/s, a transfer grille is acceptable because at all times the airflow will exceed the flow required for door protection.

### By pressure stabilisers to the corridor

- A4.53 If it is undesirable to pass operating room air through the anaesthetic room, it may be passed directly to a corridor via a separate pressure stabiliser.

A4.54 If there is sufficient "excess" air, the transfer grille solution at paragraph A4.52 should be adopted, as it provides the simplest solution and, once set up, will require no further maintenance. With less excess air, it is recommended that the air be passed through the anaesthetic room via the pressure stabilisers as at paragraph A4.51, thus keeping the number of pressure stabilisers to a minimum. Both these solutions increase the air-change rate in the anaesthetic room, but care should be taken to avoid passing excessive amounts through that would cause discomfort to the occupants.

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
1	<b>Lighting in Fire Fighting Stairwells</b>	<p>The lighting within the 7 fire fighting shafts / stairwells and associated lobby has been installed with single circuit from the local lighting distribution boards that are not supplied by the fire rated cables.</p> <p>The Board believes all fire fighting stairwells should be supported by a primary and secondary fire rated power supplies from dedicated distribution boards and automatic changeover for dual fire rated supplies.</p>	<p>Safety of all occupants in the building - The implication of this is the Scottish Fire and Rescue Service may not be able to access the firefighting stairwell in a fire due to inadequate lighting levels.</p>	<p><b>1. Safety</b> The Fire Fighting Shaft / Stair will be used by the Fire Brigade to access all levels of the building to fight a fire. The fire brigade requires sufficient lighting in the event of power failure.</p> <p><b>2. Good industry practice</b> The good industry practice is to have electrical installation designed in accordance with IEE Wiring Regulation therefore compliant with BS 8519. As recent comparative examples, the Board understand both Alder Hay and Dumfries and Galloway Royal Infirmary have electrical installation for firefighting stairwells designed and installed in accordance with BS 8519.</p> <p><b>3. Board's Construction Requirements</b> The 8.1 n) of BCRs (Minimum Engineering Standards) reference the BS 7671:2008 (IEE Wiring Regulations). The IEE Wiring Regulations (Section 110.1.3) outlines the requirements for electrical installation for (x) Life Safety and firefighting applications as BS 8519 (Selection and installation of fire resistant power and control cable systems for life safety and firefighting applications – Code of practice).</p> <p>Section 6 (Power Supplies) of BS 8519 indicates the requirement for secondary power supplies and cross refers to Figure 1 and 2. Both supplies (primary and secondary) should be fire rated.</p> <p><b>4. Project Co's Proposals</b> Furthermore, as per Appendix A (Lighting Schedule) of 4.23.3 of Project Co Proposal, dual circuits should have been provided for lighting in stairwells.</p> <p>In addition, section 7.1 (Low Voltage Distribution) of 4.23.3 of Project Co Proposals confirms: "Power supply cabling to fire fighting applications shall be selected and routed in accordance with the requirements of BS 8519 and LPC Technical Bulletin 210."</p> <p><b>5. Non Domestic Technical Handbook</b> Project Co (TUV SUD) have advised that as BS 9999 2010 is not referred to in the WSP Fire Strategy nor within the Non- Domestic Technical Handbook, that it is not applicable to the Project.</p> <p>The Board notes the following on the Non Domestic Technical Handbook 4.5.1 Electrical Installations of Non Domestic Technical Handbook states: "Electricity, when properly used, is a safe and convenient source of energy for heat, light and power within buildings. However misuse may lead to significant harm to individuals and buildings alike. Risk of fire from an electrical installation should be minimised. In normal operation, taking into account the surroundings, it should not create the risk of fire, burns, shock or other injury to people. An electrical installation should be designed, constructed, installed and tested such that it is in accordance with the recommendations of BS 7671: 2008."</p> <p>Furthermore, the Fire Strategy is based on SHTM 81, which in turn refers to BS 9999 therefore is applicable. The 38.2.3 of BS 9999 advises that the normal lighting within the Fire Fighting Shaft should be supported by a secondary power supply. The secondary power supply should be from an alternative source and the primary &amp; secondary cabling should be fire rated, diversely routed, terminating within the Fire Rated Compartment. The BS 9999 confirms the requirements set out by BS 8519.</p> <p>The IEE Wiring Regulations (BS 7671) are compulsory regulations for design, installation, commissioning and certification of electrical installation in the UK.</p> <p><b>6. Battery Back Up</b> Project Co suggest a self-contained, battery backed up emergency lighting is being provided, however this does not comply with the guidance.</p>

<p>2</p>	<p><b>Non Fire Rated IPS / UPS cabling</b></p>	<p>For compliance with BS 7671 and Guidance Note 7, and also BS 8519 circuits associated with essential life-support services should be either fire-rated or fire-protected. The implication of this is, in the event of a fire, power may be lost to essential life safety medical equipment in critical areas.</p> <p>Current Project Co's design consist of non fire rated cables to IPS bards serving critical areas.</p>	<p>The implication of this is, in the event of a fire, power may be lost to essential life safety medical equipment in critical areas.</p>	<p><b>1. Safety</b>                  In Group 2 Medical Locations, the continuity of electrical supplies are essential to maintain the life of the patients, the power supplies for medical IT equipment should be protected from fire. The LV distribution circuitry up to the sub-distribution board used to connect the IPS and UPS systems, should be deemed as life safety system.                  Guidance Note 7, Group 2 Medical Location:  <i>"Medical location where applied parts are intended to be used, and where discontinuity (failure) of the supply can cause danger to life, in applications such as:</i>                  (a) <i>intracardiac procedures; and</i>                  (b) <i>vital treatment and surgical operations."</i></p> <p><b>2. Good industry practice</b>                  The good industry practice is to have battery plant adjoining Category 5 rooms, however in RHSC DCN the battery plant is centralised with the circuitry to sub main DBs with long cable runs passing through several fire zones. On that basis the cables providing power to life safety equipment should be fire resistant.</p> <p><b>3. Board's Construction requirements</b>                  The 8.1 n) of BCRs (Minimum Engineering Standards) reference the BS 7671:2008 (IEE Wiring Regulations).                   As per IEE Wiring Regulations (BS 7671) section 110, the method of fire protection should be considered for services essential to maintain the operation of the life safety systems as per BS 8519 (section 6). As per Figure 1 and 2 of the BS 8519 the life safety systems should be provided with dual supplies which are fire resistant.   <i>"The electrical distribution system supplying the life safety and fire-fighting equipment should be designed in such a way as to ensure that power is available at all times. In order to achieve this, dual supplies should be provided, to each of the critical systems, via an automatic changeover device, installed within the protective enclosure of the critical equipment.</i>                  NOTE 1 <i>The primary supply is generally derived from the mains or utility supply, whilst the secondary supply is derived from either a standby generator or an independent secondary mains supply."</i></p> <p>9.6 Supplies of Guidance Note 7 states:  <i>"In medical locations, the distribution system shall be designed and installed to facilitate the automatic changeover from the main distribution network to the electrical safety source feeding essential loads, as required by Regulation 560.5."</i></p> <p>9.18.6 Circuits of safety services of Guidance Note 7 states:  <i>"The circuit that connects the power supply source for safety services to the main distribution board is considered a safety circuit."</i></p> <p><b>4. Project Co's Proposals</b>                  PCP 4.23 (Specifications - Building Services) section 420L confirms the use of 120min Fire Resistant cables between the central battery system and DBs:                  420L FIRE RESISTANT, INSULATED AND SHEATHED CABLES. Sub mains from Central Battery System to local distribution boards.  <ul style="list-style-type: none"> <li>• BS 5266-1.</li> <li>• BS 8519:2010, 120 minute fire survival.</li> <li>• Third party certification: British Approvals Service for Cables (BASEC) certified and LPCB.</li> <li>• Manufacturer: As Prysman Cables FP600S.</li> <li>- Product reference: Submit proposals.</li> </ul></p> <p><b>5. Project Co's argument</b>                  Medical equipment will be equipped with self contained batteries hence no additional resilience is required.</p>

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
3	<p><b>No earth bonding in certain required areas.</b></p> <p><b>(Equipotential Bonding in Rooms)</b></p>	<p>No equipotential bonding has been installed 144 Group 1&amp;2 rooms. Equipotential bonding is required to prevent electric shock to patients, staff and visitors.</p> <p>A sample room has been offered by Project Co to the Board for witnessing indicating installation of equipotential bonding boxes. The Board understands this will now be installed in all 144 Group 1&amp;2 rooms.</p>	Patient and staff safety.	<p>1. Safety The equipotential bonding is required to prevent electric shock to patients, staff and visitors.</p> <p>2. Board's Construction requirements The 8.1 n) of BCRs (Minimum Engineering Standards) reference the BS 7671:2008 (IEE Wiring Regulations). The BS 7671 and Guidance Note 7 indicates that Equipotential Bonding Bars are required in both Group 1 &amp; Group 2 rooms to equalize the potential differences between the various parts of the installation within the room.</p> <p>3. Background to Project Co position Project Co degraded the categorisation and grouping of certain rooms, without consultation with the Board, in order to achieve electrical certification from Group Management Systems.</p>

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information																																																																																
4	<p><b>Bedroom ventilation pressure regime and air change rate rooms for neutropenic patients</b></p>	<p>Bedrooms for neutropenic patients have been designed as other single bedrooms, i.e. balanced pressure with 4ac/h supply air and extract via ensuite at the rate of min 10ac/h.</p> <p>However as per SHTM 03-01 (2014), rooms for neutropenic patients should have +10 (Pascals) pressure and supply at 10ac/h.</p>	<p>Operational and infection control risk.</p>	<p><b>1. Safety</b> Neutropenic patients are highly susceptible to infection hence the design should prevent any such patient to be exposed to potential infection from outside of the room. i.e. the air from the room should be pushed to outside preventing any infected air ingress the room.</p> <p><b>2. Board's Construction Requirements</b> The 2.3 (NHS Requirements) of the BCRs references all SHTMs. The Appendix 1:Recommended air-change rates of SHTM 03-01 Part 1 states: <a href="#">Appendix 1: Recommended air-change rates</a></p> <table border="1" data-bbox="1359 556 1952 934"> <thead> <tr> <th>Application</th> <th>Ventilation</th> <th>Pressure</th> <th>Pressure (Pascals)</th> <th>Supply Air</th> <th>Change Rate (ACH)</th> <th>Temp. Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
5	<b>25% spare capacity</b>	<p>The 25% spare capacity should be provided by Project Co in terms of main and sub main distribution containment, UPS boards, AHU, physical space in voids and ceilings, risers.</p> <p>Its apparent from site visits, the spare capacity has not been provided.</p>	Operational and clinical risk for future expansion.	<p>1. Board's Construction Requirements Compliance with BCRs section 9.6.1, 8.8.1, 8.8.2, 8.13, 8.14.</p> <p>2. Project Co's Proposals 4.9 (Mechanical &amp; Electrical Engineering) of Section 4 (project Co's Proposals) of Schedule Part 6 (Construction Matters) confirms the 25% capacity in various areas of design as per the requirements of BCRs.</p> <p>3. Board's compliance argument It is evident from the installation on site, i.e. cable containment, ceiling voids, UPS boards, that the spare capacity has not been provided. Project Co submitted two derogations at FC:</p> <ol style="list-style-type: none"> <li>1. CAT6a cables</li> <li>2. Spare capacity in general. This derogation was meant to be reviewed in conjunction with the Board during RDD process however no evidence from PCo undertaking this exercise until a schedule was issued early in Feb 18.</li> </ol>
6	<b>HV distribution</b>	<p>In relation to system resilience, the Board believes Project Co's design for HV Distribution is non-compliant with the Board's Construction Requirements (BCR's), Project Co Proposal's (PCP's) and SHTM Guidance for the following elements;</p> <ol style="list-style-type: none"> <li>1. Resilience of the HV main intake switch room,</li> <li>2. HV cable distribution,</li> <li>3. HV / LV substations.</li> </ol> <p>The Board believes the design currently creates single points of failure at the HV side of the electrical distribution network.</p> <p>The Board understands Project Co are working on a revised design.</p>	<p>Patient safety risk</p> <p>From a clinical perspective the concern for the Board is following the approximate 1 hour UPS back up, the single points of failure present an unacceptable level of risk in relation to loss of power to the Facility, with the potential compromise of life support for 24 children in ITU and other patients, and other patients within Group 2 areas in RHCYP and DCN.</p>	Refer to Independent Expert Reports.
7	<b>4 bed ventilation</b>	<p>In relation to ventilation pressure regimes, the Board believes Project Co's design for ventilation is non-compliant with the Board's Construction Requirements (BCRs), Project Co Proposal's (PCPs), SHTM Guidance and RDD FC comments.</p> <p>In addition, the Board believe the intake air change rate and the extract air change rate are non-compliant.</p> <p>From a clinical perspective, the principal concern to the Board in continuing with Project Co's proposed pressure regime design means there is an unacceptable risk of the spread of bacterial airborne infections into corridors and surrounding patient rooms (positive to the corridor)</p> <p>The Board requires the pressure regime to be balanced or negative to the corridor.</p>	Operational and infection control risk	Refer to Independent Expert Reports.

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
8	<b>Bedhead trunking earth bonding points</b>	All bedhead trunking installed in Group 2 Medical Locations is provided with only 2 supplementary equipotential bonding points. This is not in compliance with GN7, which requires minimum 4 for medical IT sockets (IPS sockets).	Health & safety to patients and staff.	<p><b>1. Safety</b> The equipotential bonding is required to prevent electric shock to patients, staff and visitors. The supplementary bonding conductors in Group 2 Medical Locations shall be connected to the equipotential bonding busbar for the purpose of equalizing potential differences. A minimum of 4 but not less than 25% of the number of medical IT socket outlets provided per patient location.</p> <p><b>2. Board's Construction Requirements</b> The 8.1 n) of BCRs (Minimum Engineering Standards) reference the BS 7671:2008 (IEE Wiring Regulations). Guidance Note 7 of BS 7671 states:</p> <p><b>9.12 Supplementary equipotential bonding (additional protection)</b> 710.415.2.1 In each Group 1 and Group 2 medical location, supplementary equipotential bonding shall be installed and the supplementary bonding conductors shall be connected to the equipotential bonding busbar for the purpose of equalizing potential differences between the following parts, which are located, or that may be moved into, the 'patient environment':</p> <ul style="list-style-type: none"> <li>(a) protective conductors;</li> <li>(b) extraneous-conductive-parts;</li> <li>(c) screening against electrical interference fields, if installed;</li> <li>(d) connection to conductive floor grids, if installed; and</li> <li>(e) metal screen of isolating transformers, via the shortest route to the earthing conductor.</li> </ul> <p>Supplementary equipotential bonding connection points for the connection of medical electrical equipment shall be provided in each medical location, as follows:</p> <ul style="list-style-type: none"> <li>(f) Group 1: one per patient location; and</li> <li>(g) Group 2: a minimum of four, but not less than 25 per cent of the number of medical IT socket-outlets provided per patient location.</li> </ul> <p>Currently, within Group 2 Medical Locations, bedhead trunking is provided with only 2 supplementary bonding points rather than 4.</p>

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
9	<b>Lack of non IPS sockets in theatres, Critical Care and Resuscitation Rooms</b>	All sockets outlets within these departments except for Cleaners outlets and a limited number of "raw power" sockets in some areas, are Medical Equipment blue sockets. No provision has been made for equipment that should be plugged into an RCB protected outlet whilst in the patient zone.  Also, no x ray sockets (dedicated socket).	Operational risk and safety - The implications being if non Medical IT equipment, e.g. mobile imaging and diagnostic equipment, pc etc are plugged into the IPS socket, this may cause the IPS system to trip and potentially lead in loss of power to life support equipment.	<p><b>1. Safety</b> The IPS sockets are used to identify early faults in life safety equipment connected directly to patients and will not disconnect power supplies in the event of fault in such equipment. The non medical equipment should not be connected to IPS sockets which would increase the likelihood of tripping circuits and therefore losing power supplies for life safety equipment.</p> <p><b>2. Good industry practice</b> Within Cat 5 areas, the good industry practice is to have IPS sockets installed on pendants only within patient environment and limited number of IPS sockets on walls for additional Medical Equipment. Non IT circuits should be provided to allow connections of other non medical equipment items of equipment, such as computers and monitors.</p> <p><b>3. Board's Construction Requirements</b> As per the 3.6.2 (Equipment Requirements) of BCRs, Project Co shall design the infrastructure suitable for all items of equipment identified in Appendix 1 (Equipment Schedule) of Schedule Part 11 (Equipment). The items of equipment identified in Appendix 1 are, but not limited to, mobile X-ray, computers and image intensifiers.  As per 9.8.3 (TN systems) of Guidance Note 7 (Special Locations) of BS 7671 (IEE Wiring Regulations), the designer shall:  <i>"In final circuits of Group 2 medical locations (except for the medical IT system), RCDs having the characteristics specified in Regulation 415.1.1 shall be used in circuits for:</i> <i>(a) the supply of movements of fixed operating tables;</i> <i>(b) X-ray units; and</i> <i>(c) large equipment with a rated power greater than 5 kVA.</i> <i>Notes:</i> <i>(i) The list of circuits (a) to (c) above is not exhaustive. This implies that the designer is not restricted to providing only medical IT final circuits in a Group 2 medical location, but should also consider the wider implications of Group 2 medical location design."</i>  The RCDs referred above are non IPS circuits and should be provided for items such as X-ray units and computers brought to patient environment.</p> <p><b>4. Project Co's Proposals</b> The FC drawing WW-SZ-SL-DT-500-010 indicates 13A twin switched socket outlet in operating theatres with only 1 no of 13A unswitched socket outlet located on the walls. The 7.2 of 4.23 (Building Services – Specifications) states that IPS sockets shall be double pole or unswitched, as follows: <b>Socket outlets fed by IPS units</b> shall be double pole or un-switched, clean earth sockets, with metal front plates, colour-coded blue, engraved in white lettering 'Medical equipment only'. If white sockets are preferred, they shall be mounted on a blue background, approximately 2 cm larger than the socket. The socket to be engraved 'Medical equipment only' in blue. Engraving shall be filled to allow clinical cleaning.</p>
10	<b>Drainage above IPS room / above IPS panels</b>	PCo have installed drainage above exclusion zones, electrical equipment and other high risk locations except above MRI rooms where this has been completely removed.	Leak may cause disruption and power outage. Risk to clinical equipment (MRI/CT) and clinical areas (theatres) the pipework is running above.	<p><b>1. Board's Construction Requirements</b> 8.14 of BCRs state that <i>"In order to minimise potential disruption to the Board due to maintenance of building services, Project Co shall where practicable route services through common spaces such as corridors and avoid through routing within department areas.</i></p> <p><b>2. Project Co's Proposal</b> Project Co submitted a derogation at Financial Close identifying the type of and location of M&amp;E services running outwith the corridor areas. Based on Project Co's derogation the Board assumed that no other services will be run through departments.</p>

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
11	<p><b>Protection on electrical cables</b></p> <p><b>(Cable discrimination and cable calculations)</b></p>	<p>Project Co has not submitted cable calculations through RDD for Board's review. This is required as per 4.23.2 (Mechanical &amp; Electrical Specification) Project Co Proposal. The Concern is that the selection, grouping, rating and fault levels of cables is inappropriate and non-compliant with BS 7671.</p> <p>As evidenced on site, there are several instances of cables being double and triple banked, as well as being grouped tightly together.</p>	<p>Patient Safety - The Concern is that the selection, grouping, rating and fault levels of cables is inappropriate. There could be a fire risk if cables overheat.</p>	<p>Project Co has not submitted cable calculations through RDD for Board's review. This is required as per 4.23.3 (Mechanical &amp; Electrical Specification) Project Co Proposal.</p> <p>The concern is that the selection, grouping, rating and fault levels of cables is inappropriate and non-compliant with BS 7671.</p> <p>4.23.3 (Mechanical &amp; Electrical Specification) Project Co Proposal:</p> <p><b>V24 High voltage cabling</b></p> <p>To be read with Preliminaries/ General conditions</p> <p><b>PRODUCTS</b></p> <p>310A HIGH VOLTAGE CABLES GENERALLY</p> <ul style="list-style-type: none"> <li>• Materials: <ul style="list-style-type: none"> <li>– Underground cable networks for housing developments: in accordance with ENA ER C61-2</li> <li>– 11 kV, underground industrial and commercial connections: in accordance with ENA ER C61-5</li> </ul> </li> <li>• Provide electrical power cable terminations: To BS 7107</li> <li>• Proposed high voltage cabling: Submit drawings, technical information, calculations and manufacturer's literature.</li> <li>• Spare capacity (percentage of current carrying capacity): 25%</li> </ul> <p><b>SYSTEM PERFORMANCE</b></p> <p>220A GRADING STUDY</p> <p>The calculations forming the basis of the design of the LV distribution system are theoretical based upon cable lengths measured from drawings, theoretical fault levels, voltages and impedances and Outgoing Circuit protective device data which may or may not correlate with those finally selected. Project Co. shall undertake a grading study based upon the actual installed measured characteristics of the LV distribution system and actual equipment selected.</p> <p>The study shall be undertaken under all 'worst case' conditions i.e. mains healthy, an minimal generator supply, faults etc. generators in parallel, and taking into account the effect of the C&amp;P work on fault levels.</p> <ul style="list-style-type: none"> <li>• Scope: Complete low voltage distribution system.</li> <li>• Qualifications of study author: Member of the Institute of Electrical Engineers (IEE)</li> <li>• Fault calculations: include fault impedance, and short circuit fault current analysis.</li> </ul> <p><b>V32 Low voltage cabling</b></p> <p><b>PRODUCTS</b></p> <p>310 CABLES GENERALLY</p> <ul style="list-style-type: none"> <li>• Standard: To BS 7671.</li> <li>• Proposed selection of low voltage cables: Submit drawings, technical information, calculations and manufacturer's literature. Submit British Approvals Service for Cables (BASEC) and where appropriate Loss Prevention Certification Board (LPCB) certification for ALL cables.</li> <li>• Conductor sizes (minimum): <ul style="list-style-type: none"> <li>– Sub main cables: 10 mm<sup>2</sup></li> <li>– Lighting final circuits (including CPC): 2.5 mm<sup>2</sup></li> <li>– Power final circuits (including CPC): 4 mm<sup>2</sup></li> </ul> </li> <li>• Spare capacity (percentage of current carrying capacity): 25%</li> <li>• Cable sizes as per cable schedules and distribution board schedules</li> </ul>

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information																																								
12	Lack of tamper proof flush fitted sockets in anti ligature areas, including CAMHS	Sockets not installed as per small power layout drawings. i.e. flush fitted tamper proof sockets.	Patient Safety	<p><b>1. Safety</b>                      Tamper proof sockets / outlets are required in all anti ligature areas to prevent vulnerable patients from injuries to themselves, staff and visitors.</p> <p><b>2. Board Construction Requirements</b>                      2.3 (NHS Requirements) of BCRs refer to HBN. The paragraph 8.53 of HBN 03-01 states:  <i>"Each room should have tamper-proof mechanical and electrical services fittings and fixings. The lighting, water and electrical override controls should be located external to the bedroom."</i></p> <p>11.11 of HBN 03-01  <i>"Engineering service outlets, fixtures and fittings, including heat emitters, ventilation grilles, luminaires, drainage systems etc, are required to be of robust high-quality construction, and in all service user areas should be designed to be tamper-proof and to minimise the potential for use as ligature points. Where it is not possible to provide anti-ligature fixtures, the engineering service fixture should not be able to bear weight. All such instances should be agreed with the service user group service provider."</i></p> <p>11.13 of HBN 03-01  <i>"Appropriate tamper-proof fixtures and fittings devices should be installed to enable staff external to the room to control and isolate individually electrical power, lighting, heating and water services to each service user bedroom/en-suite area and isolation room. These devices should be located either within the adjacent lobby or corridor or at a central point elsewhere within the unit as required."</i></p> <p>SHTM 06-01  <i>"16.49 All sockets should be suitable for the local environment. While this may appear obvious, it ensures that suitable precautions (IP ratings) are made for sockets in kitchens, laboratories, plantrooms and general circulation spaces. Metal-finished sockets should be installed within a clinical risk Category 3 area and above in order to limit the effect of electromagnetic interference and the increased mechanical protection. All switch plates and socket (electrical outlets) need to be flush and stainless steel in in-patients areas."</i></p>																																								
13	Single Bedroom Ventilation air changes	Air change rates proposed by Project Co for single bedrooms are not in compliance with SHTM 03-01 and Board's comments. 4ac/h supply provided to the bedrooms instead of the required 6ac/h. The ensuite extract rate proposed in excess of 10ac/h where requirements of SHTM 03-01 is 3ac/h.	Operational and infection control risk	<p>SHTM 03-01 (2014) Part A Appendix 1: Recommended air-change rates:  <a href="#">Appendix 1: Recommended air-change rates</a></p> <table border="1" data-bbox="1359 1207 1923 1438"> <thead> <tr> <th>Application</th> <th>Room Use</th> <th>Pressure</th> <th>Primary Purpose</th> <th>Supply Rate</th> <th>Supply (l/s)</th> <th>Exhaust (l/s)</th> <th>General Ventilation (l/s)</th> </tr> </thead> <tbody> <tr> <td>General ward</td> <td>S/T/E</td> <td>0</td> <td>+</td> <td>0.4</td> <td>30</td> <td>18-20</td> <td></td> </tr> <tr> <td>Consultation ward</td> <td>E</td> <td>0</td> <td>+</td> <td>0.4</td> <td>40</td> <td></td> <td></td> </tr> <tr> <td>Single room</td> <td>S/T/E/N</td> <td>0</td> <td>0 or +</td> <td>0.4</td> <td>30</td> <td>18-20</td> <td></td> </tr> <tr> <td>Single room WC</td> <td>E</td> <td>0</td> <td>+</td> <td>0.4</td> <td>40</td> <td></td> <td></td> </tr> </tbody> </table> <p>Board rejection of Project Co Change / Derogation as per MM-GC-002006:</p> <p>"Following the review of PCo's derogations (WW014 &amp; 015) the Board cannot accept this proposal.</p> <p>As per the BCRs, PCo are required to provide room heat recovery with balanced ventilation at specified air change rates. Based on PCo derogations, in order to achieve balanced pressure regime (in 4 bedded room 1-L1-100), the en-suite extract would have to be in order of 36ac/h. This is in excess of SHTM recommendation of 3ac/h. Also it means that heat recovery from this air cannot be achieved.</p> <p>Can Project Co please confirm how compliance with SHTM in relation to air change rates, balanced ventilation and room heat recovery will be met."</p>	Application	Room Use	Pressure	Primary Purpose	Supply Rate	Supply (l/s)	Exhaust (l/s)	General Ventilation (l/s)	General ward	S/T/E	0	+	0.4	30	18-20		Consultation ward	E	0	+	0.4	40			Single room	S/T/E/N	0	0 or +	0.4	30	18-20		Single room WC	E	0	+	0.4	40

Item No.	Issues for Discussion	Detail of Issue	Risk	Technical Information
14	Smoke clearance in fire fighting stairwells	As per the Non Domestic Technical Handbook and project specific Fire Strategy, all fire fighting stairwells shall be provided with appropriate ventilation for heat and smoke control. Currently only a percentage of stairwells appear to have openings for high level ventilator. No details of electrical connections including fire rated cables for fire fighting plant as per BS 8519.	Patient Safety - The implication of this is the Scottish Fire and Rescue Service may not be able to access the firefighting stairwell in a fire due to inadequate lighting levels.	The Fire Fighting Shaft / Stair will be used by the Fire Brigade to access all levels of the building to fight a fire. The fire brigade requires sufficient conditions in a stairwells to be able to access the building.  2.14.6 Heat and smoke control of Non-Domestic Technical Handbook 2011 indicates that a ventilator shall be provided for each fire fighting stair. The ventilator shall be automatically controlled, from SFRS access point, if not easily accessible.  Also, as per BS 8519, fire rated cables should be provided for the fire fighting plant.
15	Access hatches in Theatre Suites	Proliferation of Access hatches have been installed within theatre suites which is non-compliant with BCR clause 8.14 Service Routes and "Good Industry Practice".	Downtime of clinical areas – clinical clean required after hatch opened.	BCR 8.14 Access to services shall not be given in clinical areas. In order to minimise potential disruption to the Board due to maintenance of building services, Project Co shall where practicable route services through common spaces such as corridors and avoid through routing within department areas.  HBN 00-10 3.24 In operating theatres/areas, aseptic suites and laboratories, access through the ceiling should be avoided. A local risk assessment should be undertaken as this list is not exclusive.  HBN 26 CEILINGS 6.33 Modular ceilings are not acceptable in the operating theatre but may be required in associated areas for maintenance purposes. The ceiling in the operating theatre should also be able to withstand an occasional wash and have a completely sealed finish to maintain microbiological standards. If access hatches are required they should be of the sealable type.

Matthew

Please find attached a self explanatory letter in response to your Notice which we received on Monday 11th June, 2018.

We will also respond via Aconex and hard copy to your legal agents as both parties have on previous matters of this nature.

Regards

Brian

REF: 180622.MT.BC. Notification of Delay\_ Flooding information

Brian Currie  
Board's Representative  
Lothian Health Board  
Waverly Gate  
2-4 Waterloo Place  
Edinburgh  
EH1 3EG

**By Email and Post**

Dear Brian,

**Re-Provision of RHSC & DCN at Little France, Edinburgh.**

**FLOODING – FIRST, GROUND & BASEMENT LEVELS  
NOTICE OF RELIEF EVENT  
NOTICE OF DELAY EVENT**

We refer to our letter of 11 June 2018 notifying the Board of a Relief Event and Delay Event, and your letter dated 13 June 2018. We now provide further particulars in accordance with Clause 29.4.

**Statement of Delay Event and Circumstances**

As was set out in our earlier letter, the Delay Event is based on Clause 29.3.6, being a Relief Event. The circumstances giving rise to the event are a flooding incident at the new build facilities. On the evening of 6 June 2018, on Level 1, a failure of the domestic hot water supply pipework caused flooding to Levels 1, Ground and Basement Floors. The un-controlled release of water from the affected pipework was isolated and stopped on the morning of 7 June 2018. The flooding and cause thereof is a Relief Event under the Project Agreement, Clause 30.1.1, which includes "...flood, bursting or overflowing of water tanks, apparatus or pipes...". The extent of reinstatement that is required is addressed below.

**Records**

We intend to maintain the following records to substantiate any claim for additional time. Upon receipt of estimates for time and cost from each of the trade sub-contractors and the release of work instructions from Multiplex, Multiplex will maintain the following on behalf of Project Co:

- Extent of works affected
- Reports required from the trade sub-contractors (where relevant)
- Dated handover/completion records for relevant trades in affected areas

## Consequences

The full extent of the damage caused by the flooding is still in the process of being investigated and ascertained. Whilst investigations continue, it is already clear, that relatively substantial reinstatement works will be required to areas within the first, ground and basement floors. Subject to the conclusion of the investigations the reinstatement works may include;

- The removal and replacement of finished flooring;
- The removal and the replacement of some FF&E;
- The removal and replacement of isolated areas of plasterboard and insulation to internal walls and subsequent reinstatement of Mechanical and Electrical fittings, wall painting and making good;
- The removal and replacement of damaged ceilings and the subsequent reinstatement of final fix services (fire and smoke detection systems, ventilation grills, lighting and the like) and decorations; and
- A revised Inspection regime to re-inspect finished areas.

The foregoing activities may impact upon the completion of the Works. Currently, Multiplex has programmed to complete its Works by 31 October 2018. It is too early in the investigation phase to determine whether the foregoing activities or like activities will inevitably affect that planned completion but we would propose to provide updates to the Board under Clause 29.5 as and when further information becomes available from those trades investigating the extent of damage and reinstatement required.

Please be advised Project Co has notified matters to the project insurers, and a loss adjuster appointed by the insurers has visited the site to inspect the physical damage. The overall financial impact can only really be assessed once the nature and extent of the reinstatement works necessary are ascertained, together with the time those works will take and insurers position on cover.

## Mitigation Measures

Based on recent Board Changes and the works that Multiplex have agreed to progress without prejudice, the current completion date is, as above, being reported as 31 October 2018. Once the full extent of damage and necessary reinstatement has been established, the following mitigation options can be developed and measured against a planned 31 October 2018 completion date:

- Surveys to establish the scope of reinstatement works;
- Limited early instructions for stripping out damaged material and removal of fixtures and fittings;
- Limited early instructions for pre-ordering of bulk material before Instructions;
- Sequencing of the works to allow earliest access for the Lothian Health Board works to progress;
- Liaison with affected trades to secure necessary resource; and
- Maximising manpower as workfaces become available.

We trust that the foregoing provides the Board with an update on matters as of today's date. Further updates will be provided as and when the underlying information becomes available to us.

Yours faithfully

A large black rectangular redaction box covering the signature area.

Wallace Weir  
Project Co Representative  
For and behalf of IHS Lothian Limited

18<sup>th</sup> October 2018

Dear Sirs

**Project Agreement dated 12th and 13th February 2015 between Lothian Health Board and IHS Lothian Limited ("Project Agreement")  
Notices of Delay, Delay Events and Compensation Events**

We refer to the Project Agreement. Unless otherwise stated, capitalised terms used in this letter shall have the meaning given to them in the Project Agreement.

In order to fulfil our obligations under the Construction Contract and Clause 29 of the Project Agreement, we hereby notify you of the delays in completion of the Works, the Delay Events and the Compensation Events all as detailed in the attached correspondence from the Contractor to Project Co dated 9 October 2018 in respect of:

- (1) 4 bed ventilation;
  - (2) Board Change 119 in respect of patient absconding;
  - (3) Board Change 133 in respect of additional security doors;
  - (4) Board Change 137 in respect of the doors in CAMHS; and
  - (5) MRI quench pipes;
- (together the "Letters").

The Letters shall be deemed to be letters from Project Co to the Board. Without prejudice to the generality of the foregoing, all references in the Letters to:

- (1) "Multiplex" shall (where the context permits) be deemed to be references to "Project Co";
- (2) "IHSL" or "Project Co" shall (where the context permits) be deemed to be references to "the Board";
- (3) Clause 29.1, Clause 29.4 or Schedule Part 16 shall be deemed to be references to Clause 29.1, Clause 29.4 or Schedule Part 16 (as the case may be) of the Project Agreement;
- (4) "NHSL Change" shall be deemed to be references to "Board Change";
- (5) "Construction Contract" shall (where the context permits) be deemed to be references to the Project Agreement.

Yours faithfully

Wallace Weir  
Project Co Representative

cc The Chief Executive, Lothian Health Board

For the Attention of Mr. Wallace Weir

Dear Sirs

**RE-PROVISION OF RHSC AND DCN AT LITTLE FRANCE  
 4-BED VENTILATION  
 DELAY EVENT/COMPENSATION EVENT**

We refer to the above matter. As you are aware discussions continue between the Board, Project Co and Multiplex in connection with, inter alia, (a) the without prejudice works undertaken by Multiplex including the 4 bed ventilation changes (b) the further payments due to Project Co and Multiplex in connection with work including the changes to the 4 bed ventilation and (c) a revised Completion Date to apply under both the Project Agreement and Construction Contract in relation to the works.

Naturally Multiplex is keen to arrive at a settled position in connection with the foregoing issues as soon as possible.

In the meantime, and in order to protect Multiplex's position we hereby give formal notice of a Delay Event in respect of the changes instructed to the 4-bed ventilation design. We do not set out in this letter the various reasons underlying our position that the instruction to negatively/balance pressure in these areas is a change. Detailed communications have already passed between the parties in that regard and we understand that Project Co does not disagree with Multiplex.

The purpose of this letter is to notify Project Co and the Board of the impact of the change to the 4 bed ventilation on the Completion Date. Ordinarily that impact would be dealt with

Multiplex Construction Europe Limited is registered in England and Wales  
 Registered Office: One Broadgate, 1st Floor, London EC2M 2QS, United Kingdom  
 Company No. 03808946 VAT No. 749 323 906

— A Brookfield Company —

through the raising of Board Change paperwork under Schedule Part 16, by the Board and in turn Project Co. However, to date the Board and Project Co have neglected to do that.

Upon that basis, we would advise that our estimate of the impact of the change on the Completion Date is 201 days. That is the period from 26 March 2018, when the variations were put in train, through to our forecast completion of these works on 11 October 2018.

Whilst our position remains that this matter ought to have been addressed through Schedule Part 16, we are happy to provide further particulars equivalent to those arising under Clause 29.4 upon request by Project Co.

We recognise that in the event the current discussions which we advert to at the start of this letter reach a settled position then they may come to supersede and regulate Multiplex's entitlement to additional time in connection with this Delay Event. However, given the current situation Multiplex must insist on its contractual right to receive an extension of time and revised Completion Date for this Delay Event.

In that regard, 201 days from the revised date for completion of 9 July 2017 is 26 January 2018 and, subject to any further particulars requested, we ask that you now formally revise and extend the Completion Date under the Construction Contract to at least 26 January 2018. We reserve the right to revisit this estimate of delay to completion to the extent it later turns out to be less than we are entitled to.

Separately, the circumstances giving rise to the Delay Event also constitute a Compensation Event. They have generated significant additional cost for Multiplex in providing the works. We would welcome an urgent discussion in an effort to agree the relevant costs in the event the current discussions which aim to regulate Multiplex and Project Co's entitlement to time and money for such matters do not achieve that aim.

Yours faithfully

**RE-PROVISION OF RHSC AND DCN AT LITTLE FRANCE  
NHSL Change 119 Patient Absconding  
DELAY EVENT/COMPENSATION EVENT**

We write under reference to earlier correspondence in connection with the revised Board Change 119 in respect of patient absconding. As you are aware, the Board have now instructed and approved Multiplex costs for MVC 119 on 29 August 2018. In view of this instruction and change these works will delay completion.

Whilst strictly an allowance for the necessary additional time should be dealt with under the Schedule Part 16 process, we write to notify that the Board Change will delay completion of the works.

In that regard, this letter should be treated as our notification of a Delay Event under Clause 29.4, and to avoid any doubt, notice of an event which is likely to delay completion of the works under Clause 29.1. We shall provide further written particulars equivalent to those required under Clause 29.4 in due course.

Yours faithfully

Dear Sirs

**RE-PROVISION OF RHSC AND DCN AT LITTLE FRANCE  
 NHSL Change 133 Additional Security Doors  
 DELAY EVENT/COMPENSATION EVENT**

We write under reference to earlier correspondence in connection with additional doors. As you are aware, the Board have now instructed and approved Multiplex costs for MVC 133 (additional doors).

As noted in 'Contractors Estimate Section 1. Implementation Timetable', this change could not have been guaranteed to complete by 31 October 2018 due to the lead in period required for materials. As noted in 'Section 2. Requirement for Relief from Compliance with Obligations' Multiplex proceeded on the basis that Multiplex reserved the right to claim for an extension of time if appropriate relief/time was not granted as part of the on-going discussions about the completion date for the remainder of the works.

Approval was granted by IHSL on 18 September 2018. As noted above, due to the lead in requirement for materials, it will not now be possible to complete the works by 31 October 2018.

Whilst strictly the matter should be dealt with under the Schedule Part 16 process, the decision by the Board and IHSL to seek a more general agreement on time for completion should not prejudice Multiplex for any Delay Events.

Multiplex Construction Europe Limited is registered in England and Wales  
 Registered Office: One Broadgate, 1st Floor, London EC2M 2QS, United Kingdom  
 Company No. 03808946 VAT No. 749 323 906

Dear Sirs

**RE-PROVISION OF RHSC AND DCN AT LITTLE FRANCE  
QUENCH PIPE  
DELAY EVENT/COMPENSATION EVENT**

We write to notify you under Clause 29.1 and Clause 29.4 of a Delay Event in connection with the design, procurement and installation of the MRI Quench pipes by the Board's specialist contractors.

As you know the relevant works were omitted from Multiplex's scope via Board Change 105. The installation of relevant work continues and is unlikely to be completed by the dates currently being reported in that regard. That will affect Multiplex and cause a delay to completion of Multiplex's works.

We shall provide further written particulars in accordance with Clause 29.4 in due course.

Yours faithfully

Mr. Darren Pike  
Project Director  
Multiplex Construction Europe Ltd

Works: Re-provision of RHSC and DCN at Little France  
Situated at: Little France Crescent, Edinburgh EH16 4TJ

Under the terms of the above-mentioned Project Agreement, we certify that the Works failed to achieve Actual Completion on the 31<sup>st</sup> October 2018 as notified to the IT by Project Co. The attached schedule lists the outstanding and non-compliant items noted by the Independent Tester.

To be signed by or for the issuer named above.

Signed

Enc. Schedule of Outstanding Matters

REF	SCHEDULE OF OUTSTANDING MATTERS
1	Movement Joints through Critical Areas non-compliant with requirements
2	Internal Drainage System
3	Ventilation to Isolation rooms
4	Lighting of Firefighting Stairs
5	Helipad not compliant with HBN 15-03 or CAP 1264
6	Heater batteries in Isolation room lobbies
7	Fire Protection System Compliance with SHTM 82
8	Interleave power supplies to Critical areas
9	Opening windows as part of lobby smoke ventilation >100mm
10	Theatre Scrub taps fitted at wrong height.
11	Threshold to Spiritual Care - not barrier free
12	Goods Yard Access to loading bay - constriction by compactor
13	Key Suiting ready for Handover – not ratified
14	Acoustic Testing - Certification not available
15	Medical Gas Systems incomplete - Dependency on Turnkey Works
16	Completion Documentation required by the IT incomplete
17	Handover Clean - not appropriate standard in some areas
18	Removal of site Establishment - not completed
19	Reinstatement of damage to Car park E- not completed
20	Operating Theatre requirements - not achieved in all areas
21	Building Warrant Completion Certificate - Outstanding
22	Fire Alarm altered but supporting Change - not completed
23	Water systems treatments in accordance with CIBSE Commissioning Code W and SHTM 04-01 - not completed
24	Pneumatic Tube transfer - Pipe runs through bed rooms - agreement to change not provided
25	Ductwork physical cleaning certification in accordance with SHTM 03-01 and the HVCA (2005) TR/19 – Guide to good practice.
26	Proving of isolation rooms differential pressure - not completed
27	External Signage - outstanding issues
28	Proposed change to LTHW Pipework - not ratified
29	Helipad Height Reduction - not ratified
30	Changes to Zone A Level 4 Plantrooms - not ratified
31	Changes to Link Building - not ratified
32	Changes to Gas Meter Housing - not ratified
33	Changes to Entrance Matting - not ratified
34	BREEAM Certification - not provide
35	Temperature Control / Monitoring - not provided
36	Positioning of Node Rooms in basement - not ratified
37	Changes to Curtain Tracks - not ratified
38	Changes to MRI (access) - not ratified
39	Changes to Ceiling Heights - not ratified
40	Changes to Service Yard (Crib Wall) - not ratified
41	Radiology WC Room omission not ratified
42	Changes to Over panels to Doors - not ratified
43	Changes to Standing Seam Roof - not ratified
44	Changes to Warning lights - not ratified
45	Skirting Change - not ratified

46	Changes to Bed Lift Core 3 - not ratified
47	Provision of gas store to level four - not ratified
48	Provision of shower trays and pumping - not ratified
49	Fire strategy - Sprinkler Omission - not ratified
50	Tactile sensors to anti-lig sanitary spaces - not ratified
51	OUT904 Connections - not ratified
52	Timing of the Audiology Acoustic tests - not ratified
53	Change to SHPN 40 Intercom / Isolation Suite Functionality - not ratified
54	Changes to As Built Energy Model/ Seasonal Commissioning - not ratified
55	Neutropenic ventilation change - not ratified
56	Single Bed Ventilation alteration - not ratified
57	FCU traps change - not ratified
58	Change to High Level Drainage - not ratified
59	Change to Node Room cooling - not ratified
60	IPS Room Ceilings change - not ratified
61	4-COR-007 Ceiling Height - not ratified
62	0-A1-062 Ceiling Height - not ratified
63	Group 2 Socket change not ratified
64	Omission of RIE Adult Ambulant Canopy - not ratified
65	Number Plate Recognition - Revision not ratified
66	Fire Evacuation Strategy not ratified
67	IOMRI Change Instruction - not ratified
68	Ventilation Ductwork in MRI Equipment Rooms - not ratified
69	ED Store Ventilation - CONSTRUCTION - not ratified
70	Cycle Racks change - not ratified
71	Angiography Procedures Machine Room - not ratified
72	Testing and commissioning documentation to be completed following outstanding works and current issues resolved
73	Issues with water proofing and gas proofing specification - not resolved
74	RDD items not reaching status A or B to be completed

The Scottish  
Government

Dear Colleague

## A POLICY ON DESIGN QUALITY FOR NHSSCOTLAND: 2010 REVISION

### Summary

1. This letter provides colleagues of a revised statement of the Scottish Government's Policy on Design Quality for NHSScotland ([Annex A](#)). This policy articulates the Scottish Government Health Directorates ambition for NHSScotland's asset base and to embed the need for well-designed, sustainable healthcare environments as an integral part of high quality service delivery.
2. The Policy also sets out the principles which a NHSScotland Body's strategic Design Action Plan and the supporting project-specific Design Statement should address ([Annex B](#)). Two further annexes provide reference to relevant Scottish Government Health Directorates asset-related policies and supporting guidance ([Annex C](#)) and, useful references and web links ([Annex D](#)).
3. This CEL and the attached policy statement supersedes NHS HDL(2006)58. This CEL also provides information on Design Assessment within the SGHD CIG Business Case process.

### Action

4. **Addressees should ensure that a copy of this CEL with Annexes is cascaded to all appropriate staff within their area of responsibility.**
5. **The revised Policy on Design Quality for NHSScotland and associated Mandatory Requirements take immediate effect.**

### Background

6. HDL(2006)58, issued in 2006, announced the first publication of a Policy on Design Quality for NHSScotland which provided a policy framework to implement the aims of the then Scottish Executive Health Department, supported by a 3-year Framework Agreement with Architecture and Design Scotland. This Framework Agreement has now ended and therefore a revised policy statement is required to ensure that

**CEL 19 (2010)**

**2 June 2010**

### Addresses

### Enquiries to:

Ian Grieve  
St Andrew's House  
Regent Road  
Edinburgh EH1 3DG

Tel: [REDACTED]  
Point of contact  
details@scotland.gsi.gov.uk

[REDACTED]  
<http://www.scotland.gov.uk>

<http://www.pcpd.scot.nhs.uk>

the outcomes of development projects meet the Scottish Government's objectives and expectations for public investment. Support for the implementation of the design agenda will be provided by means of a coordinated, tripartite working arrangement between Scottish Government Health Directorates (SGHD), Health Facilities Scotland (HFS) and Architecture and Design Scotland (A+DS) to facilitate the procurement of well-designed, sustainable, healing environments which support the policies and objectives of NHS Boards and the Scottish Government Health Directorates.

7. The attached policy statement reflects consultation with stakeholders in the Scottish Government, Architecture and Design Scotland and Health Facilities Scotland. It provides a concise definition of policy along with details of Mandatory Requirements which must be complied with by NHSScotland Bodies. For those Special Health Boards (and Operating Divisions within) which are not actively engaged in the procurement of new healthcare premises and refurbishment of existing health care premises for the purpose of service provision, the general principles of the attached policy should be applied, such as when considering premises for lease or occupation.
8. The principle upon which this policy is founded builds upon the core principle of the 2006 policy statement - to ensure that all NHSScotland bodies fully integrate design quality and sustainable development principles throughout all stages of the healthcare building procurement process as an integral part of the commitment to deliver a high quality, safe, sustainable environment for patient care.

## Implementation

9. SGHD, A+DS and HFS have developed a range of initiatives to assist NHSScotland in addressing design quality issues in the procurement of healthcare building projects, the summary objectives of which are to:
  - raise the level of design quality achieved through infrastructure investment;
  - increase the capacity of health boards and central agencies in respect of the above; and
  - assist in sharing good practices.
10. In order to meet the above objectives, A+DS will deliver 3 main activities on behalf of SGHD.

### *Activity 1*

Engaging with partner organisations and central procurement agencies in order to assist them in their work and in raising design awareness of 'external' parties involved in delivery.

### *Activity 2*

Providing, in partnership with HFS, a co-ordinated assessment of the potential quality of proposed projects to support those responsible for decision making within the business case process.

This will involve contributing particular expertise on the aspects of design relating to Government policy on design and place making to a process administered and led by HFS who will, in addition to the administrative elements, provide particular expertise

on the aspects of design relating to functionality, particularly technical and sustainability standards developed by HFS and the Department of Health in England.

### *Activity 3*

Assisting in building a body of knowledge and evidence of good practice in both process and product across NHSScotland.

A strand of this activity is the development and management of a website, '**Healthier Places**', which has been designed to house information on good healthcare design to assist NHS Boards in the development of the project brief and to raise awareness of the good practice being developed and delivered across NHSScotland and elsewhere. In addition to providing guidance on the development of 'Design Statements' and, articles on healthcare design topics, the website holds a project resource - '**Pulse**' - a database of projects and examples of good practice.

<http://www.healthierplaces.org/>

## **Design Assessment and the Business Case process**

11. An assessment of design quality is now part of the SGHD Business Case process. All projects submitted to the SGHD Capital Investment Group for approval are now subject to an assessment of design quality and functionality, including technical and sustainability standards. This Design Assessment will take place at the Initial Agreement, Outline Business Case and Full Business Case stages of approval.
12. The Scottish Government Health Directorates' purpose in developing and implementing this process is to ensure that the outcomes of development projects meet the Government's objectives and expectations for public investment. The aim of mapping design into the Business Case process is to support the implementation of this Policy by improving the level of design quality achieved across NHSScotland and, ultimately, the outcomes achieved by doing so.
13. To assist NHS Boards in utilising good design to achieve the best outcomes from their development projects, Boards are required to develop and produce a Design Statement prior to the submission of their Initial Agreement. The Design Statement is the first control document produced for a project and should be consistent with the Board's overall vision contained within the strategic Design Action Plan.
14. Additional guidance on Design Assessment and the Business Case process has been added to the [Scottish Capital Investment Manual](#). The guidance also includes advice on the preparation of the Design Statement.

Yours sincerely,

**Mike Baxter**

Deputy Director, Capital Planning and Asset Management

# A Policy on Design Quality for NHSScotland

2010

## A POLICY ON DESIGN QUALITY FOR NHSSCOTLAND

---

### Purpose

The purpose of this document is to provide NHSScotland Bodies<sup>1</sup> with a clear statement of policy on design quality. It also provides guidance on how NHSScotland Bodies can ensure that design quality is embedded within the healthcare building procurement process.

### Context

In recent years the value of good design has been increasingly recognised and a wealth of evidence based findings has demonstrated that good design adds value, not only from an economic perspective but also in terms of a range of social and environmental benefits. This capacity to add value is particularly important for healthcare environments, where the physical and psychological well-being of patients, staff and visitors is of paramount consideration.

In October 2000, the Prime Minister established a UK-wide 'Better Public Buildings' initiative to achieve a step change in the design quality of publicly procured buildings. Over the last decade, Scottish Ministers have in parallel, through their policies, sought to achieve a culture of quality in the procurement of publicly-funded buildings that embraces good design as a means of achieving value for money and sustainable development.

The Scottish Government has five strategic objectives; it is committed to creating a Scotland that is:

- wealthier and fairer;
- stronger and safer;
- healthier;
- greener; and
- smarter.

It is clear that the design quality of our built environment must, by necessity, play a vital part in our ability to meet all of these strategic objectives. Government, thus, continues to promote and to encourage investment in well-designed buildings and places in both the public and private sectors.

This document responds to Government's quality objectives within guidance and initiatives particular to NHSScotland.

Design quality is especially important in the context of healthcare building, where well-designed health buildings can help patients recover their spirits and their health and have a positive effect on staff performance and retention, as well as improving the efficiency of operational relationships and providing better value for money in the context of whole-life costs. The Scottish Government therefore recognises the importance of good building design as the physical means of delivery for a range of wider policy objectives.

The Scottish Government's Architecture and Place Division which was established to implement policy commitments, can offer advice on design and acts as the sponsor body for [Architecture and Design Scotland](#), an Executive Non Departmental Public Body established as the national champion for good architecture, design and planning in the built environment.

Health buildings can often be the places in which we may feel at our most vulnerable, whether as a patient, relative or friend. The quality of the building environment that we experience can provide us with calming reassurance or, conversely, it can accentuate our feeling of stress and unease.

Many factors can contribute to engendering a sense of ease, for instance: the first impression of the facility from the public realm, the entrance experience, the degree of natural light, brightness and airiness, colour and texture, an easily understood layout with clearly defined focal points, uncluttered signage and a clear distinction between the realms of public and private space, maintaining patient dignity.

In most health buildings, external public spaces are vitally important in that they can also provide the opportunity for positive respite for patients, visitors and staff in periods of stress. Sensitive landscaping and well-defined public space in a healthcare environment can provide far more than simply an attractive setting. Through careful design social or intimate, tranquil spaces can be created, providing an environment where people might want to sit or meet, even spaces for physical therapy and play and which further contribute to the healing process.

Scottish Ministers believe that a concern for the quality of Scotland's architecture must go far beyond the design of individual buildings. Distinctive, high quality places as well as high quality buildings are vitally important to the social, environmental and economic success of our cities, towns and rural communities.

The Scottish Government's National Outcomes set out what Scottish Ministers aim to achieve in the next ten years, and a key objective for the built environment is that "we live in well-designed, sustainable places where we are able to access the amenities and services we need".

A sustainable community is one which not only makes a positive contribution to mitigating the effects of climate change; a sustainable community is a place which is successful in the way that it continues to flourish socially and economically over time. The quality of healthcare facilities along with other public buildings and places can be a significant factor in making communities successful, because they can offer a great deal to the creation of a wider, attractive environment which people would wish to inhabit.

The overarching Purpose of the Scottish Government is to increase sustainable economic growth, and good place-making supports this Purpose in the following ways:

Good place-making can influence the economy of an area by making it an appealing place to live, to work, and to visit - It can provide environments and infrastructure which function well; link well with surrounding settlements; which attract business; and in which business can flourish;

- Good place-making can provide communities with an important cultural context, a sense of pride and belonging and, a sense of local and national identity;
- Through good design, safe, welcoming places can be created to which people would wish to return frequently, and which would have a greater chance of longevity;

- Good place-making can promote active, healthy, inclusive lifestyles by providing attractive and accessible green spaces, and through layouts which discourage car usage and which provide the right facilities within reasonable walking and cycling distance;
- Good place-making can embed community facilities into our communities in ways which are accessible and which provide a richness of opportunity for social interaction; and
- Good place-making can have a profound effect on the sustainability of our lifestyles, in respect of the impact that we have on the land and other scarce resources; how much energy we use; and, again, through reductions in car usage.

The Planning etc. (Scotland) Act 2006 requires Local Authorities to develop dynamic plans which describe a vision for the local community; establishing 'what goes where and why' in order to develop a community structure that supports strategic objectives. Health Boards are encouraged to be active participants in the development of these local development plans in order to:

- embed the principles of healthy urban development into the plan – those aspects needed to support local health promotion and help people make healthier lifestyle choices;
- embed the principle needs for the physical infrastructure needed to deliver on 'shifting the balance of care' such as the potential location of new healthcare facilities;
- establish major infrastructure strategies needed to support the delivery of the Single Outcome Agreement; and
- link the board's strategic asset management plan into the local development plan to consider both the beneficial use of public land assets and the transport implications of major changes in estate strategy.

The creation of a new or refurbished facility can bring with it the opportunity to show a positive civic presence, and the development of a high quality public building can do much to help the creation or regeneration of communities. It is thus also a matter of considerable importance that health buildings respond to the urban or rural contexts in which they sit. This includes considerations such as how they fit within historic contexts, how the approach and entrance act to welcome concerned families and friends, and how they contribute to the quality of their neighbourhoods, both in terms of the buildings themselves and the places they create around them. In considering the provision of healthcare facilities, it is important to also give careful thought to the opportunities for good 'place-making'.

Healthcare buildings play a significant part in the environment and, increasingly, patients are becoming "empowered" to demand better environments in which they receive healthcare. It is appropriate that we embrace such matters and introduce appropriate policies and initiatives in Scotland.

At the heart of this policy is the recognition that strong client commitment is required to deliver facilities that provide the high quality and sustainable caring environments we desire. We now expect NHSScotland bodies to develop their individual visions for the kind of places in which patients, staff and visitors would wish care to be provided:

- for patients - a welcoming, healing and reassuring place that supports life;
- for staff – a place that supports staff in their work and that will not constrain future work;

- for visitors – a place to meet and discuss, a place that I can leave loved ones.

These environments must be able to support the high quality healthcare services which are to be delivered within.

This aligns with the aims of the **Scottish Healthcare Quality Strategy**. The Strategy reflects the shared ambitions of everyone in Scotland whether a patient, a carer, or whether working for NHSScotland in a community, primary or acute care setting, to create high quality person-centred, clinically effective and safe healthcare services and to be recognised as being world-leading in our approach.

The aim is for everyone in Scotland to work together to ensure better health and higher quality healthcare services which are flexible and reactive to each individual circumstance. These principles are consistent with the aims of this policy, to embed the need for well designed, sustainable and safe healthcare environments as an integral part of service delivery.

**The term ‘good design’ is not merely a question of style or taste but describes what arises from the intelligent and creative synthesis of many interrelated factors such as: strategic planning of healthcare provision; social and physical regeneration; the local urban (or rural) context and forms; links to infrastructure and transport; sustainability agendas; the building’s sense of welcome; intelligibility of layout; security; unobtrusive supervision; ease of use and maintenance; efficiency; and, promotion of human dignity. It covers the way in which buildings sit within and, contribute to, their community as well as how they work and look. Successful healthcare design resolves a wide range of functional requirements efficiently whilst, at the same time, exploring the opportunities to provide an uplifting environment for patients, visitors and staff.**

Design, therefore, is just as much about process of change management as it is about what the final product looks like. Design is present in all projects - first you imagine what you are looking to achieve and test that this is possible. You then move on to sketching a limited number of possible worlds that, to varying degrees, will house and support your needs. By analysing these and making choices you narrow the options down to the world that you will build. You get the best result by using skill and a spark of creativity to make every element work hard to deliver more than one part of your vision. Therefore good design need not cost more and the difference between achieving good or poor quality outcomes is more often the result of having the right knowledge or advice, understanding, care and commitment.

**Good Design is the intelligent application of a scarce resource**

Good design can therefore be seen as largely objective. A design proposal can be evaluated through the use of appropriate tools such as Design Quality Indicators (DQIs) to assess whether the proposed building will function efficiently and effectively; whether there is clear evidence of thoughtful, imaginative and even inspirational proposals that will not only work, but will help the people within them to work and feel better; whether the proposed building will integrate with its surroundings in an appropriate manner and create a sense of place and; whether the materials, construction methods and the proposed layout will enhance long-term value for money. Indeed, Scotland’s Infrastructure Investment Plan 2008 establishes that good design is key to achieving best value from all public sector investment.

***“In developing Scotland’s infrastructure, the Scottish Government recognises that good building design should be responsive to its social, environmental and physical context. It should add value and reduce whole life costs. Good building design should be flexible, durable, easy to maintain, sustainable, attractive and***

***healthy for users and the public; and it should provide functional efficient adaptable spaces ... Equally important to the design of individual buildings is the design of sustainable places. Well-designed buildings and places can revitalise neighbourhoods and cities; reduce crime, illness and truancy; and help public services perform better”.***

Design evaluation, in particular Post Project Evaluation and Post Occupancy Evaluation, can contribute to the emerging field of “evidence-based design” which is proving a valuable tool in the design process towards both reducing costs and improving outcomes. Research has shown that evidence-based design methods, introduced early in the process of facility programming and design can improve the experience of patients who will be treated within the healthcare facility and assist in health recovery which results in improving medical outcomes, shorter bed stays, greater throughput and a reduction in patient and staff stress.

## The Way Forward

The Scottish Government has set out an ambitious agenda to modernise NHSScotland and its infrastructure. This agenda challenges NHSScotland Bodies to modernise the way in which healthcare is delivered to patients and challenges them to ensure that the infrastructure developed, deployed and maintained is capable of supporting high quality, modern patient care.

The NHS in Scotland has a vision for:

***‘an estate designed with “a level of care and thought that conveys respect”; buildings that grow from the local history and landscape, that are developed in partnership with the local community. A work of joint learning and joint responsibility that is particular to that community and that place; “not off-the-shelf show boxes”.’<sup>A</sup>***

The **Better Health, Better Care Action Plan**, published in 2007, affirms the Scottish Government’s commitment to improving the physical and mental wellbeing of the people of Scotland through supporting the provision of well designed, sustainable places. The Action Plan also articulates the Scottish Government’s vision of a mutual National Health Service, a shift to a new ethos for health in Scotland that sees the Scottish people and the staff of the NHS as partners, or co-owners, in the NHS.

These policy changes place health and wellbeing and the over-arching issue of sustainability at the centre of the lives of the people of Scotland as the NHS strives to become more accountable and patient-focused. If the commitment to create a healthier, wealthier, fairer, safer and stronger Scotland is to be realised, NHS Boards must ensure that in the context of designing new facilities, they deliver not only high quality solutions but also realise benefits for community development and the wider environment.

(Ref <sup>A</sup>: From an interview with Dr Harry Burns, Chief Medical Officer - *A Vision of Health: NHSScotland’s agenda for realising value in the developing healthcare estate*, Architecture and Design Scotland 2009)

## Frameworks Scotland

Evidence exists that the traditional approach to construction procurement fails to satisfy clients and does not generate the efficiency improvements delivered in most other industries. With regard to NHSScotland, this means available capital and revenue resources must be used more effectively, to deliver better outcomes and make the best use of ‘client-side’ skills and capacity.

Health Facilities Scotland has, on behalf of the Scottish Government and NHSScotland, led the development of a collaborative construction procurement initiative. **Frameworks Scotland – Excellence in Healthcare Construction** is a strategic and flexible partnering approach to the procurement of publicly funded construction work and complements other procurement initiatives for the delivery of health facilities in Scotland.

This partnering approach reduces the adversarial attitudes which can make it more difficult to deliver successful project outcomes. Partnering arrangements reduce waste in both the process and product streams, promote quality and also facilitate the sharing of best practice and lessons learned from one project to another.

It should be recognised by anyone involved in planning, designing and delivering NHSScotland's healthcare estate that there is currently an unprecedented opportunity and a need both to ensure and to demand well-designed, sustainable healthcare buildings. Framework Scotland therefore is and, should be, one of the primary vehicles for delivering sustainability in the construction, management and maintenance of the healthcare estate. Delivering design quality and sustainability through the Framework will require a consistent approach with the Scottish Capital Investment Manual guidance, alongside the application of and, proper attention to, AEDET and BREEAM Healthcare requirements at the appropriate stages of a project.

Further information on the Frameworks Scotland initiative can be found on the [Health Facilities Scotland](#) website.

## **The 'hub' Programme**

The **'hub' Initiative** is a major programme of the Scottish Futures Trust.

'hub' is a procurement vehicle supporting a long term programme of investment in community infrastructure for local authorities, NHS Boards and other public sector bodies across Scotland. It will provide a mechanism for delivering assets more effectively through a single partner, with continuous improvement leading to better value for money. The opportunity for a private sector delivery partner is to be part of a systemic approach to infrastructure planning and delivery in a territory over an extended time period.

'hub' will deliver projects from a core identified scope and, in future, from wider service development business cases, in particular those projects that promote joint working amongst community planning partners. Projects will focus on new build but could also include the refurbishment and asset management services of existing infrastructure.

The overarching objective of 'hub' is to improve the efficiency of community infrastructure delivery – with a particular emphasis on supporting the provision of more joint services across local authorities, health boards and other community partners. In Scotland there are good examples of joint premises development, but these tend to be one-offs and do not offer a model for the long term strategic planning of joint premises development and joint services delivery. 'hub' should provide a systematic approach to service delivery, from a model predicated on continuous improvement in both cost and quality. This can be achieved by the public sector by working in close partnership with a private sector partner, where both the public and private sector stakeholders have a financial interest in a successful outcome.

The first two Pathfinder Territories are the South East and North. More details can be found at <http://www.hubscotland.org.uk/>

It is critical that design issues are addressed regardless of the procurement method used to deliver healthcare buildings and, that the outcomes specified for these buildings in terms of the care environment are reflected in their design. However, the implementation of design quality and the procurement route used have a particular relationship and therefore the procurement method used can have a significant bearing on the development of design quality during the process. Although it can be argued that good design is independent of cost, its relationship with design management and procurement in practice needs careful examination. The National Audit Office report "[Improving Public Services Through Better Construction](#)" (March 2005) supports this view and advocates that all key stakeholders should be involved and all proposals subjected to independent challenge before key design decisions are made and that design and decision-making be based on "whole-life value".

The concept of 'evidence-based design' has already been mentioned in the context of Post Project Evaluations. There has been a historical assumption that each healthcare building has to be unique in order to fulfil the vision and aspirations of the brief which can, unfortunately, result in the repetition of mistakes, albeit perhaps unintentionally. The starting point for any new healthcare building should, logically, be the successes of one or a number of existing buildings based on a careful analysis of what constitutes the 'good' and what constitutes the 'bad'.

Also of importance is the emerging field of 'supportive healthcare design'<sup>B</sup>. Traditionally, there has been an assumption that the main requirement placed upon a healthcare facility should be the mitigation of infection or the risk of exposure to disease. Additionally, through decades of advances in medical science and technology, many healthcare designers and technicians have been conditioned to create buildings that are successful delivery platforms for new technology. By concentrating on the need for functional efficiency and the pathogenic concept of disease and health, healthcare facilities have been procured which contain environments which can be considered stark, institutional, stressful to their occupants and thus detrimental to the quality of care they are intended to provide. In spite of evidence of the major stress caused by illness and the subsequent traumatic experience of hospitalisation, there has, historically, been comparatively little emphasis on the creation of surroundings which can calm patients, reinforce their ability to cope in such environments and generally address their social and psychological needs.

The process of 'supportive design' begins by eliminating the environmental characteristics which are known to contribute to stress or can have negative impacts on outcomes and, importantly, continues by emphasising the inclusion of characteristics in the healthcare environment which research has indicated have the ability to calm patients, reduce stress and strengthen their ability to cope and promote healthy, healing processes.

(Ref<sup>B</sup>: Ulrich R S, 2000 - 'Effects of Healthcare Environmental Design on Medical Outcomes'  
Ulrich R S, 2000 - 'Evidence based environmental design for improving medical outcomes. Proceedings of the conference: *Healing By Design: Building for Healthcare in the 21<sup>st</sup> Century*', McGill University Health Centre, Montreal)

**Due to the length of time that healthcare buildings may be in use, there is potential to constrain changes in delivery practices. It is therefore vitally important that design processes are an integral part of a robust procurement mechanism in order to ensure that buildings are not only functional when constructed but are flexible and adaptable over their entire lifetime.**

---

SGHD will continue to play its part in supporting and implementing wider Scottish Government procurement strategies and policies by setting these within a healthcare-specific context.

---

## Policy Aims

- The purpose of this policy is to articulate the Scottish Government Health Directorates ambition for NHSScotland’s asset base and to embed the need for well-designed, sustainable healthcare environments as an integral part of high quality service delivery. It also provides guiding principles which a NHSScotland Body’s strategic Design Action Plan and the supporting project-specific Design Statement should address ([Annex B](#)) and two further annexes providing reference to relevant Scottish Government Health Directorates asset-related policies and supporting guidance ([Annex C](#)) and, useful references and web links ([Annex D](#)).
- The Scottish Government is committed through its stated Purpose to encouraging sustainability by the development of infrastructure and place: “providing sustainable, integrated and cost-effective public transport alternatives to the car as well as a planning and development regime which is joined up and geared towards achieving sustainable places and sustainable economic growth”. The Government recognises that the Scottish planning and building standards mechanisms have a role in the delivery of a high quality, sustainable physical infrastructure. However, the Government also recognises that everyone connected with the delivery of this infrastructure has a role to play in driving up standards for the planning, design and maintenance of the built and natural environment. The Scottish Government Health Directorates believe that improving the quality of our caring environments is crucial to delivering this commitment and to achieving the Government’s National Outcome of ensuring that ‘we live in well-designed sustainable places where we are able to access the amenities and services we need’. Improved caring environments also act in support of the ‘Healthier’ Strategic Objective to help people to sustain and improve their health, especially in disadvantaged communities, ensuring better, local and faster access to health care.
- **Therefore this policy statement requires that all NHSScotland Bodies, as an integral part of the commitment to deliver the highest quality of environment for patient care, ensure that design quality is fully integrated into the healthcare building procurement process and is apportioned appropriate emphasis throughout all stages of this process.**

## Scope

This policy must be considered alongside other Scottish Government Health Directorates policies and supporting guidance bearing upon NHSScotland assets including those for capital procurement, asset management, sustainable development, environmental management, fire safety, and, property transactions. Such central policy statements and supporting guidance are intended to inform the formulation and updating of an NHSScotland Body’s operational policies and of supporting guidance. Such operational policies and asset strategies are important corporate expressions of a NHSScotland Body’s intentions and as such should be a manifestation of integrated service planning and the appropriate involvement of all relevant interests.

This policy must also be considered alongside other relevant Health Directorates, Scottish Government and UK Government policies and commitments.

## Policy Statements

**Statement 1** All NHSScotland Bodies<sup>1</sup>, as clients, must commit to the integration of design quality in the procurement of healthcare building throughout all stages of the process, regardless of procurement route used.

**Statement 2** All NHSScotland Bodies must have a strategy for design quality – a Design Action Plan - consistent with and supportive of the Health Directorates and wider Scottish Government asset-related policy and supporting guidance (listed at Annex C) and, with the policy guidance contained within Annex B of this document.

**Statement 3** The SGHD must provide guidance on compliance with those aspects of statutory and mandatory requirements which are particular to the procurement, design and delivery of healthcare buildings and guidance on best practice. This will be effected through the support to be provided by Health Facilities Scotland and Architecture and Design Scotland under the tripartite working partnership with SGHD.

## Mandatory Requirements

1. Each NHSScotland Board must have a clear, articulated vision for its estate and strategy for using good design to deliver that vision – a Design Action Plan – consistent with Health Directorates and wider Scottish Government policy. The Design Action Plan must be appended to a Board's Property and Asset Management Strategy (PAMS) and reviewed annually as part of the PAMS review process.
2. Each NHSScotland Board must appoint a member of the NHS Board to act as Design Champion at a strategic level to assist in articulating and promoting the Board's design vision and, where not impractical, also a Senior Officer to act as supporting Design Champion at a technical level with knowledge and experience in capital investment procedures and expertise in technical matters.
3. All NHSScotland Bodies engaged in the procurement of both new build and refurbishment of healthcare buildings must do so in compliance with EU, UK and Scottish Government procurement policy and guidance.
4. All NHSScotland Bodies engaged in the procurement of both new-build and refurbishment of healthcare buildings must, prior to the submission to SGHD of the Initial Agreement, develop a Design Statement for each project as a means of establishing the design standards for which the project and how these will be assessed by the Board within the Business Case approvals process. The Design Statement must be consistent with the strategic Design Action Plan.
5. All NHSScotland Bodies, as clients, must ensure the development of a clear project brief which should not only describe the physical requirements of the building but should also articulate the Board's vision and aspiration consistent with the strategic Design Action Plan. The 'Design Statement' may be used or developed for to this purpose, and should be included in briefing and in the HLIP issued to prospective PSCPs
6. All NHSScotland Bodies engaged in the procurement of both new-build and refurbishment of healthcare buildings must carry out independent environmental accreditation for projects. The Scottish Capital Investment Manual requires that all new builds above £2m obtain a BREEAM Healthcare (or equivalent) 'Excellent' rating and all

refurbishments above £2m obtain a 'Very Good' rating. If the capital costs are less than £2m, projects should undertake a BREEAM pre-assessment to establish whether BREEAM Healthcare is a viable option.

7. All NHSScotland Bodies engaged in the procurement of both new-build and refurbishment of healthcare buildings must use and properly utilise the English Department of Health's Activity DataBase (ADB) as an appropriate tool for briefing, design and commissioning.

[If deemed inappropriate for a particular project and an alternative tool or approach is used, the responsibility is placed upon the NHSScotland Body to demonstrate that the alternative is of equal quality and value in its application.]

8. All NHSScotland Bodies must use Design Quality Indicator (DQI) tools as appropriate to manage their design requirements through the life of a project. The English Department of Health's Achieving Excellence in Design Evaluation Toolkit (AEDET Evolution) and associated supplementary tools such as ASPECT are recognised as the exemplars towards achieving the appropriate level of project design management.

## Monitoring

9. SGHD will monitor the integration of design quality into healthcare building procurement through the Business Case approvals process which will be facilitated through a coordinated assessment of the potential quality of proposed projects to support those responsible for decision making within the Business Case process.

This assessment will involve the contribution of particular expertise on the aspects of design relating to government policy on design and place-making from Architecture and Design Scotland and, of particular expertise on the aspects of design relating to functionality, particularly technical and sustainability standards, from Health Facilities Scotland.

10. All NHSScotland Bodies engaged in the procurement of both new-build and refurbishment of healthcare buildings must conduct thorough and, independent, Post Project Evaluations (PPEs) and Post-Occupancy Evaluations (POEs) and make available to SGHD any resulting evaluation data which will be used in the formulation of generic reports to inform future policy and disseminate nationally the lessons learned.

The planning of Post Project Evaluations and Post Occupancy Evaluations is a mandatory requirement of the Scottish Capital Investment Manual for all projects in excess of £1.5 million and should be considered best practice for all projects.

**For projects between £1.5m and £5m, the NHSScotland body's internal governance arrangements should ensure the production and reporting of PPEs and POEs. An annual summary report in respect of such projects should be submitted to the Scottish Government Capital Planning and Asset Management Division.**

**For projects in excess of £5m, PPE and POE Reports must be submitted to the Scottish Government Capital Planning and Asset Management Division. Timescales for the production and delivery of such reports will be monitored by SGHD in common with other key milestones in the project lifecycle.**

**Full Business Cases for capital projects will not be approved unless Post Project Evaluation and Post Occupancy Evaluation has been properly planned in advance and suitably incorporated into the Full Business Case.**

## Support

11. Support for the implementation of the design agenda will be provided by means of a coordinated, tripartite working arrangement between SGHD, [Health Facilities Scotland](#) and [Architecture and Design Scotland](#) to facilitate the procurement of well-designed, sustainable, healing environments which support the policies and objectives of NHS Boards and the Scottish Government Health Directorates.

<sup>1</sup> NHSScotland Bodies in the context of this document means all Health Boards, Special Health Boards and the Common Services Agency performing functions on behalf of Scottish Ministers

## Policy Guidance

A NHSScotland Body's **Design Action Plan** and supporting project-specific **Design Statement** should be consistent with and supportive of the guidance contained within this Annex and the policy and guidance documents listed at [Annex C](#).

[The following guidance aligns in part with the Scottish Government "*Construction Procurement Manual: Section 6 – Design quality in building procurement*" but with appropriate additions and amendments in order to apply to the healthcare context.]

## Design Quality

### Establishing and evaluating design quality

#### General

Boards are required to establish design quality criteria (non-negotiable project aims and benchmarks) for all development projects in the form of a project 'design statement'. As we use buildings, for the most part, to house and support human activity, these criteria are to be built around the needs of the people who the facility will directly impact upon and further expanded to include the elements needed to deliver on the broader responsibilities of using public money – that of addressing local and national needs. The Design Statement then includes the board's proposals for self assessment of the project as it progresses, describing the key stages at which the decisions will be checked against the established design quality criteria, how this will be done and what skills and information will be needed.

Assessing design quality is not a wholly subjective activity. Many other design issues can be assessed objectively - whether a building will function efficiently and effectively; whether there is clear evidence of thoughtful, imaginative and even inspirational proposals that will not only work, but support people to feel and work better; whether it responds positively to its surroundings; whether it provides well-defined and meaningful public spaces for patients and the community; and whether the materials, construction methods and the proposed layout will enhance long-term value for money. The Scottish Government [Construction Procurement Manual: Section 6 – Design quality in building procurement](#) lists a number of key issues to be considered in evaluating a design.

General guidance on achieving value for money (VFM) in works procurement, based on seeking to achieve an optimum combination of whole life cost and quality, is set out in [Section 2 of the Scottish Executive Construction Procurement Manual](#). Evaluating and achieving consensus on quality can be facilitated through the use of formal techniques and there are a number of tools which can help. The Construction Industry Council (CIC), for example, has developed its Design Quality Indicator (DQI) to evaluate the design quality of buildings throughout the development and life cycle of a project.

#### Healthier Places Website

This website has been designed to house information on good healthcare design to assist boards in brief development and to raise awareness of the good practice being developed and delivered across NHSScotland and elsewhere. In addition to providing guidance on the development of 'design statements' and, articles on healthcare design topics, the website holds a project resource - '[Pulse](#)' - a database of projects and examples of good practice that can be used in two main ways:

- **Search by project type** : to find out about recent and current developments in NHSScotland, and elsewhere, that are of a similar type to the one being considered by the client team. This will provide basic details on the project, the key team members involved and images where available. Key design documents, such as the 'Design Statement' and Post Occupancy Evaluations will be included once they are in the public realm to allow greater learning from what has gone before. It is envisaged client teams will use this search primarily at the outset of a project to
  - Establish similar works by colleagues in other boards
  - Facilitate contact to allow shared learning

- Establish possible visit lists for the client team and key stakeholders to raise awareness and understanding.
- **Search by area** : to find photographs of different areas of the healthcare estate (such as entrance areas and consulting rooms) to raise awareness of what has been achieved elsewhere. It is envisaged client teams will use this search primarily to assist benchmarking within the 'design statement' being developed for projects.

The '**Pulse**' resource will be maintained by A+DS using project information submitted to the NHSScotland Design Assessment Process (once the Business Case is in the public realm), case studies of completed developments, and supplemented by images submitted by users of the site. NHS Boards are encouraged to upload photographs taken during visits to inspirational developments (especially those outwith Scotland) to assist knowledge transfer between project teams.

#### Achieving Excellence Design Evaluation Toolkit (AEDET Evolution)

However, healthcare building design frequently involves complex concepts which are more difficult to measure and evaluate. In order to address these specifics in a DQI context the Department of Health (England) Estates and Facilities Directorate has developed the **Achieving Excellence Design Evaluation Toolkit (AEDET Evolution)**, the latest version of which is AEDET Evolution and is a tool specifically directed towards achieving excellence in design rather than ensuring compliance with legislation, regulation and guidance. High scores in AEDET do not therefore necessarily guarantee compliance with statute.

The AEDET Evolution toolkit assists NHS Bodies in managing their design requirements from initial proposals through to post-project evaluation. It is a benchmarking tool and forms part of the guidance for PPP, joint ventures including "hub" and, conventionally funded schemes. AEDET Evolution contains evaluation criteria which ensure that design takes place within a common, industry wide framework. The toolkit enables the user to evaluate a healthcare building design in a non-technical way that covers the three key areas of **impact, build quality and functionality**. AEDET Evolution tool is complemented by A Staff and Patient Environment Calibration Tool (ASPECT).

Unpublished research into the use of AEDET Evolution and ASPECT suggests these tools are reliable, presenting high correlations between different judges using them to evaluate healthcare design. More recent independent, unpublished research into the experience of collaboration between designers and clinicians using AEDET Evolution indicates that the tool facilitates improved design quality. It achieves this by further facilitating a recursive discovery and a mutual utilisation of the considerable skills and factual knowledge of the designers and clinicians thus serving to improve their skilled performance.

AEDET Evolution uses ten key criteria that have evolved from sources including the Commission for Architecture and the Built Environment (CABE) and the Construction Industry Council (CIC) to establish an industry-wide framework for assessing design. The ten key criteria are:

##### **Uses**

Service philosophy, functional requirements and relationships, workflow, logistics, layout, human dignity, flexibility, adaptability and security.

##### **Access**

Vehicles, parking, pedestrians, disabled people, wayfinding, fire and security.

**Spaces**

Space standards, guidance and efficient floor layouts.

**Character and innovation**

Excellence, vision, stimulation, innovation, quality and value.

**Citizen satisfaction**

External materials, colour, texture, composition, scale, proportion, harmony and, aesthetic qualities.

**Internal environment**

Patient environment, light, views, social spaces, internal layout and wayfinding.

**Urban and social integration**

Sense of place, siting, neighbourliness, town planning, community integration and landscaping.

**Performance**

Daylight, heating, ventilation, air conditioning, acoustics, passive thermal comfort.

**Engineering**

Emergency systems, fire safety, engineering standardisation and prefabrication.

**Construction**

Maintenance, robustness, integration, standardisation, prefabrication, health and safety.

### Using AEDET Evolution

AEDET Evolution is a tool for evaluating the quality of design in healthcare buildings. It delivers a profile that indicates the strengths and weaknesses of a design or an existing building. It is not meant to produce a simplistic single overall score. Because of the nature of design, which inevitably involves trade-offs, it may not be possible to produce a building which would have the maximum score for all the sections. Indeed it may quite often be the case that a high score for one statement reflects a design which inevitably may be scored low on another statement. A single overall score would thus be misleading and uninformative.

AEDET Evolution can either be used by individuals or in workshops by groups. In the latter case it is probably desirable that an independent experienced user of AEDET Evolution should facilitate the group to avoid excessively lengthy debate. AEDET Evolution can be a helpful tool in enabling a group to come to a common understanding with the help of a facilitator who can moderate group discussions.

AEDET Evolution can be used at different 'scales' in evaluating the design of a healthcare building, e.g. at a building scale, a department scale or a complete site scale. The level of detailed information available may dictate the scale of the evaluation.

AEDET Evolution is designed to be used by those involved in the commissioning, production and use of healthcare buildings. In particular public and private sector commissioning clients, developers, design teams, project managers, estates/facilities managers and design champions may find AEDET Evolution a helpful and useful tool. User clients such as patient representatives and members of the general public should also be able to use AEDET albeit within a workshop environment alongside other more experienced professionals.

### When to use AEDET Evolution

AEDET Evolution can be used to evaluate existing buildings in order to compare them or understand their strengths and weaknesses.

AEDET Evolution can be used on the plans for new buildings in order to evaluate and compare designs.

AEDET Evolution can be used on “imaginary” buildings in order to set standards for preparation of a brief.

AEDET can be used at various stages during the design of healthcare buildings – as the level of detail of the information available increases it should be possible to respond to more of the statements in the tool.

### A Staff and Patient Environment Calibration Tool (ASPECT)

To complement AEDET Evolution, the Department of Health (England) Estates and Facilities Directorate has developed the [ASPECT toolkit](#). ASPECT stands for A Staff and Patient Environment Calibration Tool and is based on a database of over 600 pieces of research. That research deals with the way the healthcare environment can impact on the levels of satisfaction shown by staff and patients and on the health outcomes of patients and the performance of staff.

This research and the ASPECT toolkit itself are set out under 8 headings. ASPECT can be used as a stand alone tool, or it can be used to support AEDET Evolution to provide a more comprehensive evaluation of the design of healthcare environments.

When used to support AEDET Evolution it enables the user to score the Staff and Patient Environment Heading of AEDET Evolution in a more detailed, accurate way.

The toolkit has 3 layers which allow users to create a design evaluation profile:

- the SCORING layer on which you score;
- the GUIDANCE layer that gives more detailed help;
- the EVIDENCE layer that points to available research evidence.

### Inspiring Design Excellence and Achievements

[Inspiring Design Excellence and Achievements](#) (IDEAs) is another useful design tool published by Department of Health (England) Estates and Facilities Directorate to assist in the generation of design briefs, proposals and schemes

IDEAs was conceived and developed by the University of Sheffield as a way of utilising the latest research evidence. IDEAs starts the design of healthcare places with people – patients, staff and visitors – and responds to the emotional and functional requirements of healthcare delivery.

IDEAs deals with activities rather than individual spaces or rooms. Examples of activities that occur in healthcare places include:

- arrival
- bathing

- bed / rest
- circulating
- consulting
- shopping
- sanctuary
- socialising
- waiting

IDEAs can be used either as a standalone tool within a workshop context or as a web-enabled integrated tool by individuals.

### **Role of Health Facilities Scotland**

Health Facilities Scotland (HFS) is a division of National Services Scotland and provides operational guidance to NHSScotland Bodies on non-clinical topics such as:

- estates engineering;
- building and architecture;
- procurement;
- fire safety;
- environment;
- energy;
- property management;
- clinical waste management;
- decontamination
- legionella and other estates related pathogenics;
- hazards and safety action notices.

This assists NHSScotland in meeting the Government's policy and strategic aims and the establishment of professional/technical standards and best practices, including the promotion of new initiatives in the field of healthcare practice and management. Clearly HFS can have a pivotal role to play in generally supporting the implementation of this Policy, through the provision of supporting guidance and through their Continuous Professional Development (CPD) programme which provides essential training to NHSScotland personnel on operational issues as impacted by national policies and objectives.

**With particular regard to the objectives of this Policy, HFS will lead the agenda through the central operation of Frameworks Scotland and through the administration of the Design Assessment process now mapped into the Business Case process. HFS will provide technical expertise including those aspects of design which relate to functionality and, particularly, technical and sustainability standards. This will underpin the strands of work identified to support the design agenda in NHSScotland through the coordinated tripartite working relationship between HFS, SGHD and A+DS and with NHSScotland stakeholders.**

### **Role of Architecture and Design Scotland (A+DS)**

Architecture and Design Scotland has been established by Scottish Ministers as the National Champion for Good Architecture, Design and Planning in the built environment. Its aim is to operate within the Scottish Government's policy framework on architecture and design, as well as in partnership with a range of bodies in the private and public sector to help turn the aspirations of policy into reality.

The aim is to raise the quality of new development, so that high standards of layout and design are the rule, not the exception. Overall, the development of well designed and

attractive cities, towns and villages will support the Scottish Government's National Outcomes for the built environment.

These Outcomes are designed to ensure that Scotland has the infrastructure, the physical services, the economic ability, the healthy environment, the cultural references and the social networks that allow our current and future generations to achieve their potential in a balanced manner.

SGHD and A+DS have developed a range of initiatives to assist NHSScotland in addressing design quality issues in the procurement of healthcare building projects, the summary objectives of which are to:

- raise the level of design quality achieved through infrastructure investment;
- increase the capacity of health boards and central agencies in respect of the above; and
- assist in sharing good practices.

In order to meet the above objectives, Architecture and Design Scotland will deliver 3 main activities on behalf of the Scottish Government Health Directorates.

#### **Activity 1**

Engaging with partner organisations and central procurement agencies in order to assist them in their work and in raising design awareness of 'external' parties involved in delivery. This will be done through actions such as:

- assisting in the development of policy and guidance relating to the procurement of, and design quality in, the built estate;
- participation in steering groups such as those developed for Frameworks Scotland and in the development of strategies and processes (such as team selection and KPIs) for central procurement agencies. Also assisting, as requested by such central teams, in providing advice to client teams on matters effecting design quality, particularly pertaining to preparation for the assessment described in 2 below; and
- assisting Health Facilities Scotland (HFS) and others in the development of training and awareness sessions.

#### **Activity 2**

Providing, in partnership with HFS, a co-ordinated assessment of the potential quality of proposed projects to support those responsible for decision making within the Business Case process.

This will involve contributing particular expertise on the aspects of design relating to government policy on design and place making to a process administered and led by Health Facilities Scotland who will, in addition to the administrative elements, provide particular expertise on the aspects of design relating to functionality, particularly technical and sustainability standards developed by HFS and the Department of Health in England.

#### **Activity 3**

Assisting in building a body of knowledge and evidence of good practice in both process and product across NHSScotland, through:

- the development and management of the web-based project resource, '[Pulse](#)';

- the development of case studies of projects on the ground;
- providing dedicated support to 'demonstration projects' where ambitious parties are taking on particular aspects of work, particularly around cross-sectoral working; and
- identifying and commissioning targeted pieces of work by relevant specialists to inform, test, and develop concepts and tools to support Health Boards and their stakeholders in their delivery of good design.

### **Role of the Scottish Futures Trust**

The Scottish Futures Trust is an independent company, established by the Scottish Government with a responsibility to deliver value for money across all public sector investment. SFT operates at arms length from the Government but works closely with the public sector to seek and deliver improved value for tax payers.

Currently the Scottish Government and other public sector bodies in Scotland invest some £5billion annually on infrastructure. By any measure this is a substantial amount of money and spend on investment is recognised to be a strong contributor to economic growth. In today's tight financial environment, improving the value for money of this spend, and finding innovative ways to finance infrastructure investment to enhance economic growth are imperative and are SFT's primary functions.

Recommendations from Audit Scotland, the National Audit Office and others have included the requirement for many of the services that SFT is now providing. The company brings focused commercial and financial skills in infrastructure financing, procurement and delivery into the public sector. SFT retains and grows this knowledge within infrastructure-investing organisations across the public sector.

SFT is leading the £1.25 Schools Investment Programme and has developed a National Housing Trust to deliver an initial £130million of housing. SFT is also involved in a wide range of major transport and accommodation infrastructure projects and by the end of 2010/11 SFT's portfolio of projects are expected to be valued at more than £7billion.

In relation to this policy SFT is responsible for managing the 'hub' programme. Their remit includes:

- Enabling the establishment and development of hub groups
- Help motivate change
- Help promote the strategy and disseminate best practice
- Steer the implementation of the procurements
- Develop processes, procedures, supporting documentation and guidance
- Support the drive for continuous improvement
- Manage the administration of the enabling fund
- Develop and implement methodology for benefits evaluation

SFT may also get involved in an advisory or validation role on other projects, and therefore has an interest across all healthcare work.

## NHSScotland Design Champions

The Scottish Government Health Directorates requires that NHS Board Chairs are responsible for nominating a member of the NHS Board and a Senior Officer to take on the roles of Design Champions for the Board. The Senior Officer should have knowledge and experience in capital investment procedures and expertise in technical matters. Both must be in a position to influence the overarching policies, procedures and ethos of the organisation, albeit in their own manner.

A Design Champion should be:

- well respected and an excellent communicator who is able to promote the need for good design to a wide variety of audiences, both within the Health Board and externally. Both appointees should be able to persuade colleagues and the wider community of the benefits of well designed healthcare buildings;
- a consensus builder, able to bring together the various stakeholders both within the local authority and the wider community; and
- able to see the 'bigger picture' and help develop a 'vision'.

The Design Champions, ideally, are in a position to influence the work undertaken by the Health Board but it is important that the roles are not created for status but, for action.

- The role of the Design Champion is not project specific but is to advocate design quality and to ensure that mechanisms are in place within the NHS Board to deliver the design agenda. NHS Design Champions will be supported, where possible, by Architecture and Design Scotland through ad hoc requests for assistance.

Design Champions will be expected to work with all the necessary disciplines. The role of the Design Champion is expected to include a responsibility to ensure that:

- the building promotes civic pride;
- patients and staff are consulted and their views addressed;
- the building fits into the local surroundings and settings;
- the building is fit for purpose;
- the building takes on board modern technology;
- the design considers sustainability issues;
- quality is questioned throughout the process; and
- there is support for resisting change which reduces quality and VFM.

The Design Champion should ensure that:

- aspirations for design quality underpin all projects undertaken across the NHS Board;
- a Board Design Action Plan is produced and delivered;

- a Design Statement is produced for all development projects establishing the design quality criteria for that project, the key points which these criteria must be given value and profile and, the process by which the board shall assess the developing project against those criteria. **The Design Champions must ensure that appropriate skills are utilised in the self assessment. Depending on their own background and role, this may be either by their own personal actions and involvement or through the appointment of others with appropriate skills;**
- an assessment is made of the current environment for patients, staff and visitors;
- the Achieving Design Excellence Evaluation Toolkit (AEDET) is used throughout a project where appropriate;
- the evaluation of tenders is based on VFM and not lowest cost;
- budgets and timetables are realistic;
- the Board has the correct skill mix to deliver the design agenda; and
- the scheme includes the full involvement of the local community and the support of clinical and other staff.

The Design Champion will raise the profile of design excellence by:

- encouraging the selection of designers with a proven track record of good design or design awards;
- promoting awareness of national and international best practice in healthcare design;
- encouraging schemes, either refurbishments or new build, to be put forward for local and national competitions and awards;
- maintaining a forum for regular review and feedback to the Board; and
- recognising the support, guidance and initiatives available.

It is important that NHS Boards acknowledge the fact that the role of Design Champion is one that requires a considerable amount of time. Design Champions are required to understand what constitutes good design across a range of different and, sometimes very technical, disciplines and the amount of time required to do so can easily be underestimated.

### **Maintaining design quality on site**

There is a risk that, once a project moves on to site, the client may underestimate the effort which will continue to be required to maintain design quality. Any shortcuts taken at this stage can put the overall design quality of the project at risk. The client's design advisers must be retained throughout the construction process in order to monitor the quality of design and finishes.

These advisers should also ensure that design aims are not sacrificed in the management of change during the running of the project. If design standards and quality thresholds are clearly defined, then the review process throughout the delivery stage should provide sufficient safeguards against quality dilution. A structured process of quality checks during construction is important to ensure that what has been agreed is actually being provided. All partners should be involved in these checks as the risks of unsupervised changes on site

can affect a wide range of matters, such as the provision of resource areas necessary for facilities management and the quality of finishes, which in turn may affect both cleaning and maintenance.

## Public Space

It is important that public space is not considered as an afterthought. New public buildings need to be responsive to their contexts, both in terms of their scale and form, and in the materials they use. It is not enough to simply respond to the appearance of surrounding buildings; it is important to also think in terms of the integrity of surrounding public spaces. In the creation of new public buildings, it is important that the design team is perceptive of the buildings' relationships to the maintenance or improvement of existing public spaces or the potential for new public spaces.

The creation of public buildings can also give something positive to the public realm rather than simply create residual areas around them, and clients may wish to consider whether the location of a building is sufficiently sensitive to merit the inclusion of an urban design specialist on the team. An approach is required which gives due consideration to the way in which the spaces created by buildings will be used, and to the needs of users in terms of accessibility, safety, lighting, shading, shelter, orientation, views, surfaces, seating, planting, and maintenance.

## Transport and car-parking

NHSScotland Bodies are required by Scottish Government policy to co-operate with local authorities, regional transport partnerships and other stakeholders in the planning and implementation of local and regional transport strategies towards ensuring that through integrated transport policies NHSScotland facilities, in particular new developments, are accessible to all by public transport, walking and cycling. NHSScotland Bodies operational policies should take into account the strategy for internal NHSScotland systems and car parking. The organisation's Travel Plan is the integral document to addressing these goals.

**Detailed guidance can be obtained from [Health Facilities Scotland](#).**

It is important to realise the need to adopt a robust design strategy for on-site car parking and people movement which is consistent with the NHS Body's Travel Plan. The design strategy should address:

- space utilisation;
- traffic and pedestrian flow;
- access for short-stay visitors, mobility-impaired persons and late night/shift workers;
- wayfinding and markings;
- landscaping;
- security, technology and lighting.

The availability of parking for both cars and cycles can influence transport choices for those using a facility. All new and re-development proposals should be designed for safety and the

convenience of all users. Good design and layout of a development can significantly improve the ease of access by non-car modes, for example:

- entrances to be as close as possible to pedestrian routes and bus stops; and
- links to cycle networks, with secure parking near the main entrance.

Proposals should be specifically tailored to local circumstances, aspirations and priorities, for example speed management strategies, attractive green space and landscaping, in order to bring a wide range of social and community benefits and improve quality of life. Design of public transport facilities should be user friendly and attractive as well as functional to encourage and retain modal shift.

### Use of the arts in healthcare

There may be scope for the involvement of artists or craftsmen in a project. When successfully implemented, artworks can help to create more distinctive and attractive buildings and urban spaces and enhance the public's experience of an architectural space. In a healthcare perspective, artwork can have an even more positive effect. NHSScotland can benefit in many ways from the adoption of the arts in healthcare programmes including better patient environments and an improvement in staff morale. It is recognised that art in healthcare can benefit the NHS through the promotion of user and staff involvement in the design of the healthcare environment and can subsequently have an impact on health outcomes. There is growing evidence that patient recovery rates and stress levels are improved by the adoption of appropriately selected art in healthcare programmes. The integration of art can also assist in improving the communication of health information and the redesign of services. The involvement of staff, patients, artists and local communities at the earliest stages of the design process for new buildings and refurbishments can result in innovative, creative solutions.

It is important to also realise that a person's perception of environmental stimuli is influenced by their feelings or emotional state. Although scientific research has produced evidence that emotionally appropriate art can improve certain patient outcomes, there is also evidence that inappropriate styles and subject matter can have an opposite effect. This is especially pertinent to psychiatric patients, who, by nature of their illness can be vulnerable to disturbing interpretations of visual arts, thus exacerbating their condition.

The use of art in a healthcare setting need not be restricted to the visual arts. Other arts activities which involve music, performing arts, storytelling and patient workshops can have therapeutic benefits and can have great value in certain healthcare environments. Art-related therapy, e.g. dance, music, drama or art creation, is recognised as an integral psychological and creative tool for the improvement of physical and mental well-being.

Some NHS Boards retain the services of "artists in residence". However, Boards may also wish to seek specialist advice from public art agencies with regard to including artwork within a project.

Boards may wish to consider allocating a specific budget for the inclusion of artwork as an integral element of a project. However, care should be taken to ensure that any resulting expenditure is proportionate to the benefits and is appropriate to the building's status and function, in order to avoid subsequent criticism of the project for inappropriate use of public funds.

Traditional building procurement allows for a detailed design to be developed prior to building contracts being issued. However, under Public Private Partnerships (PPP) projects contractual commitments are made with the private sector partner before the detailed design is complete and thus once contractual agreements are in place any additions or changes to them will incur significant additional costs. The requirements of the design are defined in advance by identifying the outputs required which in turn set the framework for the design, within which more detailed specifications for the services to be provided can be accommodated. **To ensure that the arts are incorporated into both the building and maintenance contracts they must be part of the output specifications.**

---

## Design quality in building procurement

### Key issues

- Good design is not an alternative to value for money (VFM), but is integral to its achievement. A good building project must also contribute to the environment in which it is located, deliver a wider range of social and economic benefits and be adaptable to accommodate the needs of future users. An enhanced built environment which incorporates principles of good design can improve the quality of life of those who use and work in public buildings. Throughout the life of a building, design excellence can improve the standard of public service delivery, make it more efficient and contribute to staff recruitment and retention. Good design can ensure that capital costs are competitive and that savings can be achieved on running costs through reduced maintenance, energy and operating costs without compromising the attractiveness and quality of the building. **Therefore investing in good design can make the most beneficial and effective use of resources, can add value and represents a sound investment in the future. High quality building design is therefore a key mechanism in providing VFM in the provision of healthcare services.**
- As the aim of any procurement exercise should be to achieve Value for Money, it is recommended that the "most economically advantageous" evaluation be employed. Value for Money is defined as the optimum combination of whole life costs and quality (or fitness for purpose) to meet the customer's requirements and can be taken to be largely analogous with "most economically advantageous".
- Using an evaluation based on the "most economically advantageous" offer gives the procuring organisation the opportunity to take factors other than price into account when awarding contracts.
- **Good design is not merely a question of visual style or personal perception but arises from the careful synthesis of many interrelated factors including architectural vision, functionality and efficiency, structural integrity and build quality, accessibility, security, sustainability, lifetime costing, flexibility in use and a sense of space in the community.**
- Clients must be clear about the level of funds available for a project from the outset and ensure that their aspirations for quality are underpinned by realistic and affordable assumptions.
- Clients must carefully assess and define their priorities before appointing design consultants.
- The process must allow for effective consultation with all stakeholders to establish a clear, well-defined brief.
- Sufficient time and resources should be allocated towards establishing the client's design quality aspirations.
- Post Project and Post Occupancy Evaluations of building programmes are mandatory for major projects and any lessons learned must be shared with the Scottish Government and other NHSScotland bodies.
- Quality Based Selection (QBS) is a structured procedure for selecting a design team and professional advisers. Design competitions are a means to primarily select specific design ideas or outline design ideas for a project, rather than the design team personnel.

- All public sector appointments, irrespective of the client's preferred nature of competition or reference to any other guidance on design competitions, must be consistent with EU procurement rules in terms of process and outcome. Generally, public sector clients must ensure that design team appointments follow the procedures described in [Section 3](#) of the works procurement guidance part of the Scottish Government Construction Procurement Manual. **However, in the NHSScotland context, detailed guidance on the appointment of consultants, conditions of contract and contract guidance in should be sought from [Health Facilities Scotland](#).**
- The role of an informed client is vital in ensuring the successful delivery of the project within the agreed timescale and budget and to the required standards and requirements of all users.

### Achieving good design

From the outset, clients must be clear about the level of funds available for a project and ensure that their aspirations for quality are underpinned by realistic and affordable assumptions through establishing the right budget. These quality matters and functional requirements must then be set out in a clear and thorough project brief. In order to monitor and control the procurement, design and construction processes, procedures and responsibilities should be clearly defined (and assigned). Ideally, designers should engage in challenging and constructive dialogue with the client, building users and those involved in supplying and manufacturing materials, goods and services. All concerned should work to a realistic and robust timetable, which gives the design team enough time to develop and achieve a good solution.

An informed, demanding and committed client is vital in ensuring that aspirations for quality are maintained throughout the procurement, design and construction processes.

By nature of their complexity, healthcare buildings can be expensive to manage and maintain due the imposition of build cost constraints during the procurement process in order to adhere to a short-term financial hurdle. The influence of design is fundamental to the successful outcome of a project not only in terms of how the building will deliver its intended functions but also its long-term operational efficiency. An appropriate level of investment in the design stage early in the process incurs a comparatively small capital outlay but ultimately influences the revenue streams associated with the operation of the facility and also influences the successful provision of the services to be delivered. **It is therefore imperative that the process recognises the need to address the whole-life cycle of the building and the integral part that good design can play in mitigating potential future financial and operational penalties imposed by the adoption of short-term vision. Whole-life costing must be the standard for investment decisions. Those involved in the making of such decisions will be ultimately judged on the lifetime VFM of their decisions rather than whether they managed to get a project past the initial financial hurdle.**

Healthcare facilities and the associated equipment used therein must be designed to support all the people who are likely to use them in order to operate effectively. It is therefore vital that all potential users of a proposed facility – staff, public and patients – are involved early in the design process and throughout its progress. Additionally, stakeholders such as regulators, professional bodies, community bodies, etc, should also be engaged throughout the process as this has the potential to provide a valuable source regarding the projected use of the facility, the processes which will be undertaken therein and how the facility's users will work or interact with it. Early user involvement in the design process can help ensure that a planned facility will support the people who are to use it.

The standardisation of systems and processes to be carried out within a proposed facility, layouts, room orientation, human interfaces, wayfinding and even storage can provide many benefits for patients, staff and visitors. Standardisation can help reduce mental workload and thus reduce errors, can make errors and departures from normal working easier to detect and can allow the transfer of skills and staff between departments with reduced training needs. Thus standardisation in conjunction with a wider engagement with users and stakeholders can also enhance safety.

**The Scottish Government Health Directorates requires that NHS Boards appoint Design Champions at Board and Senior Officer level to consolidate a commitment to the championing of good design.**

### Evaluating good design

Design evaluation can be structured around a number of key design issues. To support the continual improvement of the construction and procurement process, Post Project Evaluations (PPEs) and Post Occupancy Evaluations (POEs) of building programmes are mandatory for major projects with a cost in excess of the delegated limits and are an integral requirement of the [Scottish Capital Investment Manual](#). However, it is recognised that all projects would benefit from such evaluation and any lessons learned should be shared with the Scottish Government and other NHSScotland bodies in order to inform best practice and future policies. Independent PPEs should be carried out before the break up of the design team to review the success of the project against its original objectives, its performance in terms of time, cost and quality outcomes and whether it has delivered value for money.

Guidance on Post Project Evaluations and Post Occupancy Evaluations can be found within the [Scottish Capital Investment Manual](#).

Post-Occupancy Evaluations have a significant role. The key advantage of POEs is the opportunity to achieve improvements in the ways future buildings will support operational objectives. Participants often identify areas where design improvements could be made and ways in which buildings and equipment could be used more cost effectively. These may only be minor, but they could produce significant benefits to future designs. The process of evaluation can provide important feedback on whether resources are being targeted at the most important areas. This can also enable poorly functioning or seldom used features to be eliminated from future designs and the repetition of mistakes to be avoided.

The nature of PPE and POE reports must be set out and agreed at the start, and project sponsors must ensure that provision is made for the independent preparation of both when setting budgets and timetables.

PPEs and POEs can be valuable in the formulation of “evidence based design” methodology. As has been stated in the preambles to this policy document, the field of “evidence-based design” is proving a valuable tool in the design process towards both reducing costs and improving outcomes. Research has shown that evidence-based supportive design methods, introduced early in the process of facility programming and design can have significant impact on the design of physical environments which can affect patient medical outcomes and care quality. An important impetus for the growing international awareness of healthcare facility design has been mounting scientific evidence that certain environmental design strategies can promote improved outcomes whereas other approaches can worsen patient health.

## The Business Case

The Business Case process must include statements of expectation for design quality. Discussions with professional advisers at the earliest stage will assist in determining and defining design priorities and setting project objectives. Consideration of the design issues must continue throughout the entire process.

Detailed mandated guidance on the preparation of the business case is contained within the [Scottish Capital Investment Manual](#).

## Design Assessment

An assessment of design quality is now part of the SGHD Business Case process. All projects submitted to the SGHD Capital Investment Group for approval are now subject to an assessment of design quality and functionality, including technical and sustainability standards. This **Design Assessment** will take place at the **Initial Agreement**, **Outline Business Case** and **Full Business Case** stages of approval.

There are two complimentary areas of consideration in the design of healthcare buildings. These can broadly be described as healthcare specific design aspects – the areas generally covered by guidance issued by Health Facilities Scotland - and general good practice in design considering the human experience of being in and around buildings. These are brought together in this process and in the collaboration between Health Facilities Scotland and Architecture and Design Scotland in the NHSScotland Design Assessment Group which reports to the SGHD Capital Investment Group. This process forms part of the coordinated tripartite working relationship with SGHD and A+DS.

The Scottish Government Health Directorates' purpose in developing and implementing this process is to ensure that the outcomes of development projects meet the Government's objectives and expectations for public investment. The aim of mapping design into the Business Case process is to improve the level of design quality achieved across NHSScotland and, ultimately, the outcomes achieved by doing so.

[CEL 19 \(2010\)](#) which announces this Policy also announces commencement of this requirement and its incorporation into the Scottish Capital Investment Manual. The SCIM also addresses the Scottish Government's sustainability objectives in the context of the [Business Case Guide](#).

## The Design Statement

To assist NHS Boards in utilising good design to achieve the best outcomes from their development projects, Boards are required to develop and produce a Design Statement prior to the submission of their Initial Agreement. The Design Statement is the first control document produced for a project and should be consistent with the Board's overall vision contained within the strategic Design Action Plan.

The design statement is a means of setting out a Board's objectives in a series of agreed statements of intent and subsequently then describing a benchmark for how the physical result of the project will help deliver those investment objectives but not by giving a pre-determined design outcome, rather a view of what "success" might look like.

NHS Boards should also use the completed Design Statement as:

- a **briefing tool** to describe the design intention, or design vision, supplemented by more detailed briefing materials such as schedules of accommodation, key adjacencies and room data sheets as and when prepared;
- a **communication tool** to communicate the direction of the project to stakeholders and allow some early view of the benefits to assist both in building momentum/obtaining buy-in and in allaying the concerns that often accompany the commissioning of a new facility;
- an **advertising tool** to build confidence in the market in the direction and, by showing preparedness, viability of the project; and to motivate the market to bring its best and most appropriate skills to the table (in terms of the vision described).

Further guidance on the development and use of Design Statements can be found within the [Scottish Capital Investment Manual](#) and on the [Healthier Places website](#).

### Fire safety

Fire safety legislation and standards generally state that all people should be evacuated from a building in the event of fire. In terms of healthcare premises, this is not the case due to certain circumstances. Fire in a hospital or other healthcare building can be especially serious because of the difficulties and dangers associated with the emergency evacuation of patients, many of whom will be highly dependent. Therefore in such buildings the concept of progressive horizontal evacuation is the norm and is cited as so within the [Technical Handbooks to the Building \(Scotland\) Regulations 2004](#). However, because of other special requirements particular to fire safety in healthcare buildings, guidance and recommendations contained in NHSScotland Fire Safety Management guidance, including NHSScotland Firecode, which is additional to the mandatory requirements set out in the Technical Handbooks to the Building (Scotland) Regulations 2004, must be adhered to. This additional guidance is ratified by the [Scottish Government Health Directorates' Fire Safety Policy](#). The requirements of NHSScotland Firecode must be considered throughout the design process in addition to the requirements of the Building (Scotland) Regulations 2004. NHSScotland Firecode is published by [Health Facilities Scotland](#).

Clients must ensure that there is close collaboration between all those who have an interest in the fire safety provisions of the proposed premises at the earliest stage in the design and, be satisfied that all such premises comply with all statutes bearing upon fire safety.

### Designing for equality

NHSScotland, as a provider of services, is subject to equality legislation which requires the provision of services which are accessible to everyone. In a healthcare environment, it is important to recognise the complexity and the number of difficulties with which patients, staff and visitors may have to cope on a day-to-day basis. Sensory impairments, perceptual problems, reduced mobility, chronic pain, communication barriers, are but a few. Informed planning and design plays an important role in enabling people of all abilities access to services and facilities. It is therefore essential that the concept of "access and egress for all" is incorporated early in the design process and throughout its progress and that best practice guidelines are followed. By considering equality issues early in the design process, costs associated with addressing equality issues can be minimised which would inevitably prove more onerous if addressed retrospectively.

Egress for all in the case of an emergency must also be considered during the design process. Everyone rightly expects that if they are in a public building when an emergency occurs they should be subject to evacuation procedures which come into force to ensure their safety. However, in healthcare buildings there may be many persons who, by nature of their presence there or otherwise, may be particularly vulnerable. In particular, in larger healthcare buildings such as hospitals it will not be possible to ascertain the number of people who may have an impairment, let alone the type of impairment, or the number of people who may have cognitive or communication or language difficulties. Addressing the needs of all in the context of emergency egress early and throughout the design process will have significant benefit towards the procurement of a facility which ensures the safety of patients, staff and the general public.

To assist NHSScotland bodies in complying with the current equality and diversity legislative framework, the Scottish Government has produced an [Equality and Diversity Impact Assessment Toolkit](#) which was issued under cover of [NHS HDL \(2005\)9](#).

### Designing for dementia

There are over 65,000 people living in Scotland who have dementia and they, in common with other people with cognitive impairment, are users of healthcare facilities on a day to day basis across the country. Most people with dementia (60-80%) live in the community, and many of them have multiple health centre and hospital appointments and admissions in any year. As with designing for equality, designing for people with dementia embraces the concept of 'inclusive' design which tries to ensure that the built environment does not present insurmountable barriers to those who use it. Users will include people with physical, sensory and cognitive impairments, which may be progressive, intermittent or permanent and may also include people who may have temporary disabilities

**Considering equality issues and the needs of those with dementia throughout the design process will benefit everyone, including people who use wheelchairs and walking aids, have other types of impairment, older people and families.**

The University of Stirling Dementia Services Development Centre published guidance on designing for dementia in 2007. '**Best Practice in Healthcare Design for People with Dementia**' is a resource pack on dementia-friendly design which reflects a growing awareness of the need to create caring environments that meet the needs of people with dementia. Many of the features identified are the result of researched case studies and/or international best practice. The Dementia Services Development Centre at the University of Stirling has a specialist online library and information service and holds a large collection of documents relating to care of people with dementia: [www.dementia.stir.ac.uk](http://www.dementia.stir.ac.uk) .

A component of the dementia resource pack is a **Dementia Design Checklist** prepared by Health Facilities Scotland and intended for use across all healthcare properties. It covers areas of healthcare premises, including primary care premises and those operated by independent contractors, where people with dementia are likely to attend as patients or visitors. Although the Checklist has been developed primarily for use in existing buildings it can provide a useful reference throughout the project design development process. The Dementia Design Checklist is available from the Health Facilities Scotland website: [www.hfs.scot.nhs.uk](http://www.hfs.scot.nhs.uk) .

### Role of the Client

The key role of the client is to develop a clear, well-defined brief. At the beginning of the project, the client will need to establish the nature and scale of what is required. Clients should establish the views and aspirations of all stakeholders, and their aims will become the

reference point throughout the design and construction stages and can be used to test the overall success of the project over the long term. As with any building project, the initial stages are vital and a period when the most value can be added. Providing sufficient time and resources for strategic thinking will produce dividends in the long run. An informed and motivated client is critical to the success of a project.

As part of their responsibilities, the client must:

- fully develop a client strategy which has identified the need for the building whilst setting and securing a budget for the project. Understand that the budget cannot be finally established until the brief is settled;
- set a realistic and achievable timetable allowing sufficient time for consultation, brief development and for design;
- involve their Design Champion throughout the briefing and project delivery and listen to their comments;
- allocate sufficient time and resources to establish the client's design quality aspirations and set out clear benchmarks which the client must reinforce through all stages of the process;
- consider the skills and experience required of individual client team members, assess in-house skills and, where necessary, engage external consultants;
- where appropriate, appoint a Client Design Adviser to aid in the preparation of the brief and the assessment of the schemes that come forward through any competitive design process;
- consult with stakeholders to establish a clear, well-defined brief;
- be informed and demanding about operational requirements and quality objectives to get the best possible outcome from the procurement process;
- articulate the Board's requirements not only through the use of DQIs but in a clearly expressed brief that establishes and communicates their vision for the development;
- show commitment to achieving a well-designed and constructed project by giving design quality a high percentage in the assessment of bids and publishing that ratio. Make sure that bidders understand that poor or mediocre developments are not acceptable;
- establish clear and effective routes for communication between the Client Team and the bidding Design Teams during the bidding process so that the Board's needs and aspirations can be more fully discussed and incorporated into the designs that are brought forward;
- choose a Delivery/Design Team which is committed to achieving the best quality possible within the agreed budget and timetable; allow sufficient fee budgets for the work that the designers must do;
- not allow design time to be squeezed in order to recover time lost in the programme for other reasons – good design takes time; and

- carry out Post project Evaluations (PPEs) and Post Occupancy Evaluations (POEs) and ensure that the reports from these are available to SGHD for formulation of generic reports which can properly feed back into future procurement processes.

## Project Brief

A vital factor in achieving high quality design is that clients have a firm and well-developed view of what they want, before appointing design consultants, and that this is clearly stated in project briefs. A well-developed brief, with common consensus on operational and quality priorities, is essential for the provision of better design. A rigorous approach to this stage of work will significantly improve the client's capacity to deliver a quality project.

On the other hand, proceeding with sketchy and under-investigated assumptions can be detrimental to the outcome of the project. Statements that set out the client's aspirations on design in terms of matters such as character and durability should be incorporated into briefs.

**Detailed guidance can be obtained from [Health Facilities Scotland](#).**

## Healthcare Associated Infection (HAI)

Of particular importance in the context of healthcare buildings is the need for the Project Brief to incorporate policy, guidance and best practice in relation to reducing Healthcare Associated Infections (HAI). It is vitally important to have a clear understanding of how the briefing, planning, design, procurement, construction, commissioning and ongoing maintenance of our healthcare property can contribute to the prevention and control of HAI. Guidance to ensure that prevention and control of infection issues are identified, analysed and planned for at the earliest stage of the provision of new or refurbished healthcare facilities is contained within Scottish Health Facilities Note 30 (SHFN 30): 'Infection Control in the Built Environment: Design and Planning', published by [Health Facilities Scotland](#). Additionally, Health Facilities Scotland has developed a system which aims to assess and manage the risk of infection in the built healthcare environment called HAI-SCRIBE, an acronym for Healthcare Associated Infection System for Controlling Risk in the Built Environment. HAI-SCRIBE has been designed as an effective tool for the identification and assessment of potential hazards in the built environment and the management of these risks. The tool should be applied from the design and planning stages of a project through to the occupation and operation of the facility.

## Sustainability

The project brief should also contain statements on the client's desired approach to sustainability. Integral to the design and procurement process, a commitment to sustainable design can bring real benefits in terms of reduced running costs and quality of environment for users. Further general guidance on achieving sustainability in construction procurement is set out in [Section 7 of the Scottish Executive Construction Procurement Manual](#).

Construction of new NHSScotland premises also provides an ideal opportunity to significantly reduce an organisation's environmental footprint. Designing the building and the processes that will be carried out within it with the aim of minimising the whole life costs and environmental impact of the facility can cut costs, improve client satisfaction, improve the healthcare body's public image and help deliver the nation's environmental objectives.

A NHSScotland Body, when setting specifications and letting contracts, should emphasise and promote environmentally preferable features in both the construction and the operation/running of buildings and, in the organisation of the services delivered within them,

to ensure sustainability over the projected property lifespan. The decision making criterion for selection of components and equipment should take into consideration the whole life costs and the environmental impact by setting out all the operational and physical components and risk aspects that contribute to these. Environmentally preferable solutions should be preferred unless there is clear evidence that their adoption would have outweighing disadvantages elsewhere.

To assist NHSScotland Bodies in delivering sustainable solutions and embedding energy efficiency into healthcare building projects, Health Facilities Scotland has developed a **Sustainable Development Strategy for NHSScotland** which provides a framework for sustainability issues in NHSScotland, including new builds and refurbishments. The use of this guidance in the preparation of Business Cases is a requirement of the Scottish Capital Investment Manual. Further useful guidance is also available within the Scottish Ecological Design Association Design Guides on design and detailing for more sustainable construction: **Design and Detailing for Deconstruction; Design and Detailing for Airtightness** and; **Design and Detailing for Toxic Chemical Reduction in Buildings**.  
<http://www.seda.uk.net/guides/>

The Project Brief should also cite the use of the exemplar Environmental Management System, GREENCODE, through which NHSScotland Bodies can continually aim to improve the environmental performance of their property and, the exemplar energy efficiency guidance, EnCO<sub>2</sub>de, which aims to ensure that everyone involved in procuring, managing and using healthcare buildings and equipment thinks about the implications of energy use.

### Activity DataBase (ADB)

Activity DataBase (ADB) is the briefing, design & commissioning tool for both new-build and refurbishment of healthcare buildings. It is a briefing and design package with an integrated textual and graphical database, an interface with AutoCAD and an extensive graphical library - the complete tool for briefing and design of the healthcare environment.

ADB is produced by the Department of Health in England and is mandated for use in Scotland by the Scottish Government Health Directorates as the preferred briefing and design system for NHSScotland (see Mandatory Requirement 7 of this Policy). It has been developed to assist in the construction, briefing development, design and alteration of healthcare facilities.

Spaces designed using ADB data automatically comply with English planning guidance (such as Health Building Notes (HBNs) and Health Technical memoranda (HTMs) as ADB forms an integral part of the English guidance publication process. Whilst Scottish users can create their own project-specific briefs and designs using ADB's extensive library of integrated graphics and text which includes room data sheets, room layouts and departmental room schedules, extreme care should be taken to ensure that such data generated by the package are consistent and compliant with Scottish-specific guidance\* such as Scottish Health Planning Notes, Scottish Health Facilities Notes (SHFNs) and Scottish Health Technical Memoranda (SHTMs) as published by Health Facilities Scotland.

\* In the near future, all technical guidance will be available from the 'Space for health web resource. The Space for Health website will provide a single portal to the knowledge and expertise of the four UK health organisations. It will draw together the technical guidance published by HFS, the DoH and their equivalents in Northern Ireland and Wales. Further information is available from Health Facilities Scotland.

## The Design Team

### Design Team selection

There are several methods of selecting the appropriate design team for a project, including Quality Based Designer Selection (QBS) which is a structured procedure for selecting a design team and, design competitions, which primarily select specific design ideas or outline designs for a project, rather than the design team personnel.

Where **Frameworks Scotland** is the chosen project procurement method, the design team will form part of the Principal Supply Chain Partner's (PSCP) delivery team and the members of the design team will have been assessed during the process of selecting the PSCP from the Framework. Although the design team will be managed by the PSCP they will work closely with the NHS Client in a collaborative fashion in delivering the design. (Further detail of the PSCP Appointment Process is available in the **Frameworks Scotland** section of the [Health Facilities Scotland website](#)).

The Scottish Government [Construction Works Procurement Guidance: Section 3 – Procurement Strategies and the Appointment of Consultants and Contractors](#) provides general information on some of the different procurement strategies available and the consultancy roles and professional advice that may be required at the various projects stages. Further general advice can be found on the [Office of Government Commerce website](#).

**In the NHSScotland context, detailed guidance should be sought from [Health Facilities Scotland](#), and, for 'hub' projects, [Scottish Futures Trust](#).**

Regardless of the procurement strategy adopted, the appointment of a design team, consultants, professional advisers, etc, should be based upon the principles adhered to in Quality Based Selection methodology, outlined below. The [Royal Institute of British Architects \(RIBA\)](#), together with the [Construction Industry Council](#), has published a booklet of Guidance for Clients to Quality Based Selection.

### Quality Based Designer Selection (QBS)

QBS looks for an appropriate balance of design skills, experience, innovation, and an ability to perform on schedule to the required standards and within budget. A client, or client committee, selects a team based upon a weighted scoring of a list of relevant factors, including technical capacity, resources, previous experience of similar projects, deliverability of the design and partnering arrangements, aimed at determining which design team is most able to handle the project successfully and deliver a high quality result.

Throughout a building project, designs will be developed through constant dialogue with the design team, so it's essential that a key selection consideration is inter-personal skills; the client must feel that it has the ability to work with the designers.

It is essential to know that a design team's claimed expertise is actually currently available. The question of whether a design team has completed major quality projects within the past five years may give a more fair comparison between long established and new design teams. It is important to ensure that the principal designer responsible for successful past projects is present for the interview, and such individuals should be named in the contract if that design team is successful.

## Design competitions

A competition to select an outline design, rather than the design team members, requires the client to have a well-developed brief for the project. Design competitions may be appropriate where there is either a unique problem that will benefit from a wide range of design approaches being explored (along with likely considerable public interest - which may be the case on a major new public building) or where the competition promoter wishes to encourage the development of new talent.

## Procedure for appointing the Design Team

All public sector appointments, irrespective of the client's preferred nature of competition or reference to any other guidance on design competitions, must be consistent with EU procurement rules in terms of process and outcome.

The appointment or competition must therefore:

- strike the correct balance between quality and price to achieve whole-life VFM;
- evaluate the quality and price aspects against clear, unambiguous and pre-determined criteria;
- assess the technical and financial capacity of the design team (including design partnership arrangements) to deliver the project to the required standards of quality as well as the project on time and within budget; and
- maintain a full and transparent record of all aspects of the competitive process from start to conclusion, including the evaluation of the pre-qualification questionnaires as well as the selection and award stages.

Generally, as Public Sector clients, NHS Bodies are required to ensure that design team appointments follow the procedures described in [Section 3](#) of the works procurement guidance part of the Scottish Government Construction Procurement Manual. **However, in the NHSScotland context, detailed guidance should be sought from [Health Facilities Scotland](#).**

## Design Team selection criteria

Selection criteria should include design ability, aspiration, financial status, insurance provisions and technical capacity; the last of these enables consideration to be given to resources, technical suitability and past performance. This stage also aids production of an objective and transparent short list of the most suitable organisations, from all those that expressed interest in providing design services.

## Selection criteria at the bidding stage

The award criteria enables a further qualitative assessment to be made of the specific proposals for the project - not just technical merit of the design proposals but also other aspects of successful delivery such as proposed team-working, management arrangements, and project team organisation.

Where design partnerships are proposed - perhaps to combine the innovative skills of a new or small design practice with the experience and resources of a longer-established designer - the award criteria enables the client to assess the ability of both parties to fulfil their responsibilities and to evaluate the compatibility of working cultures and practices. Visits to

the design offices of all candidates, including those forming partnerships, should follow a consistent approach and involve the same personnel.

NHSScotland Bodies, as clients, should consider the benefits to be accrued from requesting an Interim Bid Submission from bidders, particularly in a PPP or joint venture (such as 'hub') initiative context. This should be based upon clearly specified requirements within the Invitation To Negotiate (ITN) documentation and should be undertaken at an approximate mid-point stage through the period from release of OJEU to the return of ITN documentation with clear expectations on outputs from bidders that are measured but, not too cumbersome, perhaps structured by means of the use of the AEDET Evolution design evaluation tool.

Client organisations should consider the merits of visiting completed buildings by the shortlisted teams to investigate both their past work and allow the opportunity to meet previous clients and hear their experience of working with the team. Although this does take some time, the investment is small in comparison to the necessary investment of time and resources in the new project, and the potential learning in terms of the bidding teams ability and working relationships is invaluable.

### **Relation of selection criteria to budget considerations**

The qualitative criteria adopted at the selection and award stages should be appropriate for the individual project and weighted to suit the circumstances. It is important that these aspects aren't considered in isolation but should be assessed as part of the VFM evaluation which takes account of fee proposals. Section 3 of the Scottish Government Construction Procurement Manual describes other aspects of appointing consultants, including the various ways of paying for professional services. In circumstances where *ad valorem* (usually percentage) fee structures are appropriate, consideration must always be given to the application of an abatement or capping mechanism in order to contain fee costs at a fair and appropriate level.

Criteria used during selection and award stages must be applied consistently by all of those involved in that stage of the procurement procedure. In other words, once selection and award criteria are established, individual members of a sift or tender evaluation panel must not apply different criteria. Furthermore, once selection criteria are established, they should be made available to candidates. Award criteria must be set out in either the OJEU contract notice or the contract documents; however it is recommended that criteria be advertised in the OJUE notice to demonstrate the client's commitment to valuing quality in the selection and hence assist in attracting similarly ambitious teams.

# SCOTTISH CAPITAL INVESTMENT MANUAL

## Introduction

## 1 Introduction

The Scottish Capital Investment Manual (SCIM) provides guidance in a NHS context on the processes and techniques to be applied in the development of all infrastructure and investment programmes and projects within NHSScotland.

It provides guidance on the cyclical process of project development from inception at the service planning stage, to post project evaluation of service benefits realised once a new building is occupied. The guidance not only covers issues around investment appraisal, financial (capital and revenue) affordability and procurement, but also the project management and governance arrangements required to support the development of such programmes and projects.

The principles set out in SCIM are applicable to the development of all infrastructure and investment schemes regardless of their size or complexity; and shall be applied by all NHSScotland Bodies (including Integration Joint Boards, and similar, requiring NHS investment support). It will thus provide an audit trail and assurances that appropriate steps have been followed in the investment decision making process. These principles are also recommended as good practice for service planning purposes when investment may not be the intended outcome.

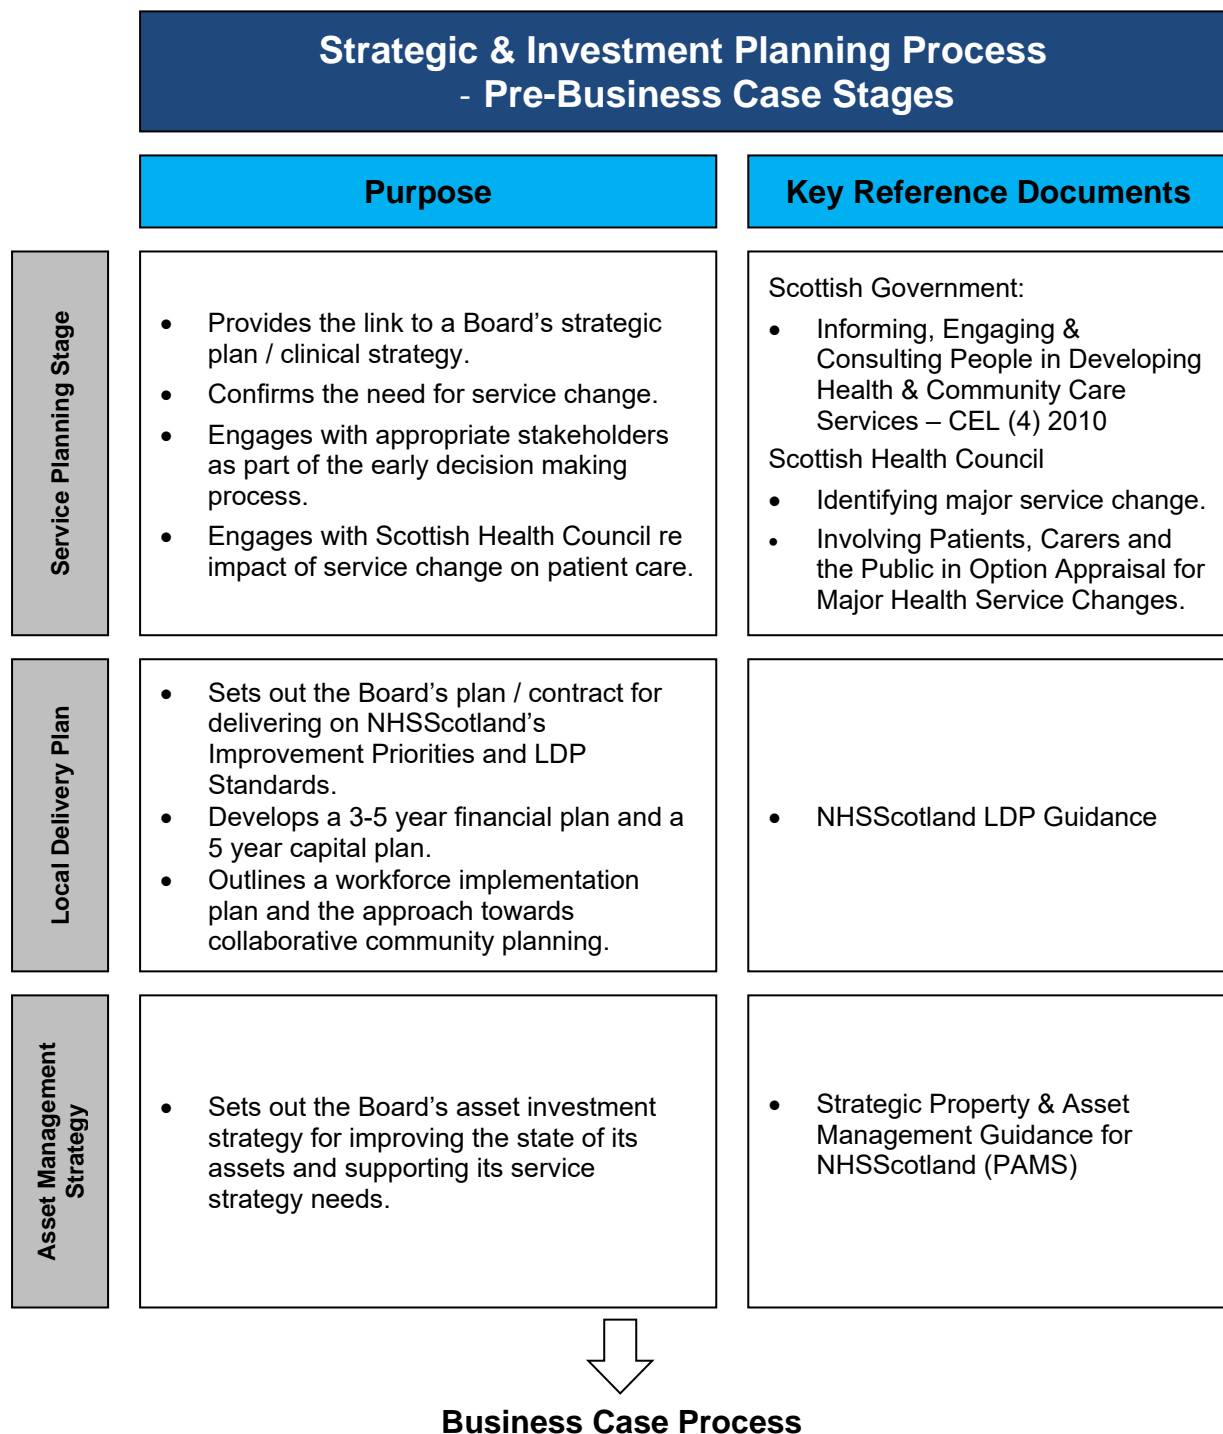

The SCIM has been revised to update the practices and processes associated with the development and approval of capital and revenue funded projects within NHSScotland. These changes mainly result from the development of improved approaches and techniques which support the development of investment schemes across NHSScotland.

In developing the revised SCIM recognition has been made of the guidance that currently exists on a Scottish, UK and international basis (particularly from Australia and New Zealand), with a view to drawing together best practice that can be applied within an NHSScotland context.

## 2 Links to the Strategic Planning Process

The business case process forms the link between formative service planning stages, and investment decision making towards implementation of a project. The strategic context and purpose of these pre-business case planning processes is described below:

### 3 Overview of the Business Case Process

A quality business case process brings together the necessary evidence in support of the need for investment and provides assurance, (to stakeholders, the public and Scottish Ministers), that the best value solution has been identified for delivering the project's objectives, benefits and declared outcomes. There are four main stages, the purpose of which is described in the following diagram:

Strategic & Investment Planning Process - Business Case Stages		
	Purpose	Key Reference Documents
Strategic Assessment	<ul style="list-style-type: none"> <li>• Describes the scope of a new proposal.</li> <li>• Informs Scottish Government of the project.</li> <li>• Gains consensus &amp; support from stakeholders.</li> <li>• Highlights service need &amp; benefits.</li> <li>• Demonstrates priority over competing projects.</li> </ul>	<ul style="list-style-type: none"> <li>• Strategic Assessment guide (ref. New SCIM website)</li> </ul>
Initial Agreement	<ul style="list-style-type: none"> <li>• Sets out current arrangements from which change will take place.</li> <li>• Provides the evidence base supporting the need for change &amp; benefits to be realised.</li> <li>• Sets out the initial benefits realisation plan</li> <li>• Reviews alternative strategic / service solutions against investment objectives</li> <li>• Identifies a preferred strategic / service solution(s).</li> </ul>	<ul style="list-style-type: none"> <li>• Initial Agreement guide (ref. New SCIM website)</li> </ul>
Outline Business Case	<ul style="list-style-type: none"> <li>• Confirms status of the Strategic Case</li> <li>• Economic appraisal of alternative options for implementing the preferred strategic / service solution(s)</li> <li>• Identifies a preferred &amp; affordable option.</li> <li>• Sets out the arrangements for delivering the preferred option and realising benefits</li> <li>• Confirms a readiness to proceed to procurement.</li> </ul>	<ul style="list-style-type: none"> <li>• Outline Business Case guide (ref. New SCIM website)</li> </ul>
Full Business Case	<ul style="list-style-type: none"> <li>• Confirms that management, commercial, funding and financial arrangements are in place to deliver the project</li> <li>• Sets out the contractual details of the project which the Board is being asked to sign-off</li> </ul>	<ul style="list-style-type: none"> <li>• Full Business Case guide (ref. New SCIM website)</li> </ul>

### 3.1 The Business Case Stages

Further details of the main focus of the four business case stages are described below:

The overarching purpose of the **Strategic Assessment** stage is to briefly outline the need for service change and describe early thoughts on the potential benefits to be gained from such an investment. It will become an integral component of a Board's Property & Asset Management Strategy (PAMS), used to identify its own priorities for investment. It will also present an outline of the proposal to Scottish Government who will consider it against other competing investment needs before giving its support for a project to proceed to Initial Agreement stage.

The **Initial Agreement** stage will provide the evidence behind the need for investment and demonstrate that the proposal is a good thing to do. It will identify the preferred strategic / service solution(s) for realising the project's investment objectives and expected benefits. It shall only be developed once a proposal's Strategic Assessment has been incorporated into the Board's PAMS and demonstrated to be an investment priority over other competing investment needs.

The **Outline Business Case** stage will identify the preferred option for implementing the strategic / service solution confirmed at Initial Agreement stage. It will demonstrate that the preferred option will deliver the necessary service change, optimise value for money, and be affordable. It will also set out the supporting commercial and management arrangements to be put in place to successfully implement that option.

The **Full Business Case** stage will set out the agreed commercial arrangements for the project whilst also confirming that it remains value for money, is affordable, and that the organisation is ready to proceed towards implementation of that option. It will be developed within the final procurement phase of the project and record the detailed assessment and/or negotiations with potential service providers / suppliers prior to the formal signing of contracts.

### 3.2 Scalability and Delegated Authority

The business case process is intended to be scalable and flexible to ensure that the analytical effort is fit for purpose and matches the scale and type of decision required. The level of detail required will be dependent upon the scale, risk and nature of the investment proposal. It should, however, meet the expectations and information needs of Scottish Government's Capital Investment Group who can be consulted for further advice on these expectations.

The following sets out the current delegated limits with regards to business case submission and subsequent approval process for all NHSScotland bodies. It is supported by CEL 32 (2010) Annex C:

NHS Board	Delegated Limit (£m)	Approval Process		
		Capital Value <£1m	Capital Value £1-5m	Capital Value >£5m
Borders	1.0	FBC approved locally	SA, IA & FBC to CIG	SA, IA, OBC & FBC to CIG
Dumfries & Galloway	1.0			
Orkney	1.0			
Shetland	1.0			
Western Isles	1.0			
Special Boards and NSS	1.0			
Ayrshire & Arran	1.5		SA, IA & FBC to CIG above D.L.	
Fife	1.5			
Forth Valley	1.5			
Highland	1.5			
Grampian	3.0			
Lanarkshire	3.0			
Tayside	3.0			
Greater Glasgow	5.0			
Lothian	5.0			

All hub & NPD projects will require a Strategic Assessment, Initial Agreement, Outline Business Case, & Full Business Case (all requiring Scottish Government approval).

Further details, including the approval process for IM&T projects, and delegated authority for approvals is available on the Scottish Government's SCIM website.

### **3.3 Responsibility for Producing the Business Case**

The 'ownership' and responsibility for the investment planning process rests with the NHSScotland body developing or leading the development of the programme/project in question.

Issues of governance are dealt with in the Management Case of each business case stage. Most projects are likely to need a Senior Responsible Officer, Project Director and Senior Project Manager; however, smaller or less complex projects may not need separate individuals for these roles. The suitability and capability of individuals for these roles is discussed in the Management Case of the Outline Business Case.

Under no circumstances should responsibility for the direction and lead production of the business case be 'outsourced' to external consultants. However, external consultants could be considered to support the project where the necessary skills and resources are not available in house.

Similarly, the production of the business case should not be regarded as an adjunct to the project manager's role, and a hurdle to jump for approval purposes. Instead, it must be viewed as a fundamental part of the overall investment planning process, which requires advice and guidance from business managers, clinicians, users and technicians involved in the scheme.

### 3.4 Stakeholder Engagement and Communication

The Scottish Health Council rightly advocates the importance of involving patients, carers and the public in the planning process leading to changes in local health services, and guidance is available on their website on how this should be managed at service planning stage. There is also a requirement across the Scottish public sector to optimise collaboration and co-production between public bodies and this should be demonstrated at all stages of investment planning.

Experience shows that a combination of workshops and meetings are a useful way of engaging stakeholders in a project's planning and decision making processes. Opportunities for such events should be determined locally, which may include some or all of the following:

1. Strategic Assessment (SA) stage: reviewing the needs and scope of the proposal in order to complete the SA template.
2. Initial Agreement (IA) stage: developing the service model; confirming the need for change; identifying the investment objectives, benefits to be realised and risks to be managed; reviewing alternative solutions; and confirming the preferred strategic solution.
3. Outline Business Case (OBC) stage: carrying out an option appraisal exercise to confirm the preferred option; developing proposals for service change arrangements, benefits realisation, risk management, etc.
4. Full Business Case (OBC) stage: reviewing submitted commercial offers / tenders to agree on the preferred contractor / commercial partner.
5. Design Assessment process: agreeing the design statement and assessing the developing design at OBC & FBC stages.
6. Service Benefits Evaluation: covering a review of benefits realised, user feedback on the new facility, and the impact of any service change.

Any such event should be planned ahead and carefully managed to ensure that outcomes are optimised and continued support for the project is maintained.

### 3.5 Project Assurance

In respect of Scottish Government funded projects and programmes, the two main models of independent project assurance are Gateway Reviews and Key Stage Reviews.

Gateway reviews are managed by Scottish Government's Programme and Project Management Centre of Expertise (PPM-CoE) and all Key Stage Reviews are managed by Scottish Futures Trust (SFT). Further details of the Gateway Review process are available on the Programme and Project Management Centre of Expertise website.

It is mandatory for PPM-CoE to be able to consider all programmes and projects for Gateway Review with a total budget of £5m+ inclusive of fees and VAT. All NPD (and similar) and hub projects will undergo a Key Stage Review.

The Scottish Government also reserves the right to instigate an early stage review on any major change initiatives

A diagram is available on the new SCIM website which describes how the business case process aligns with both the project assurance and the design development stages - the 'SCIM process and outcomes' diagram.

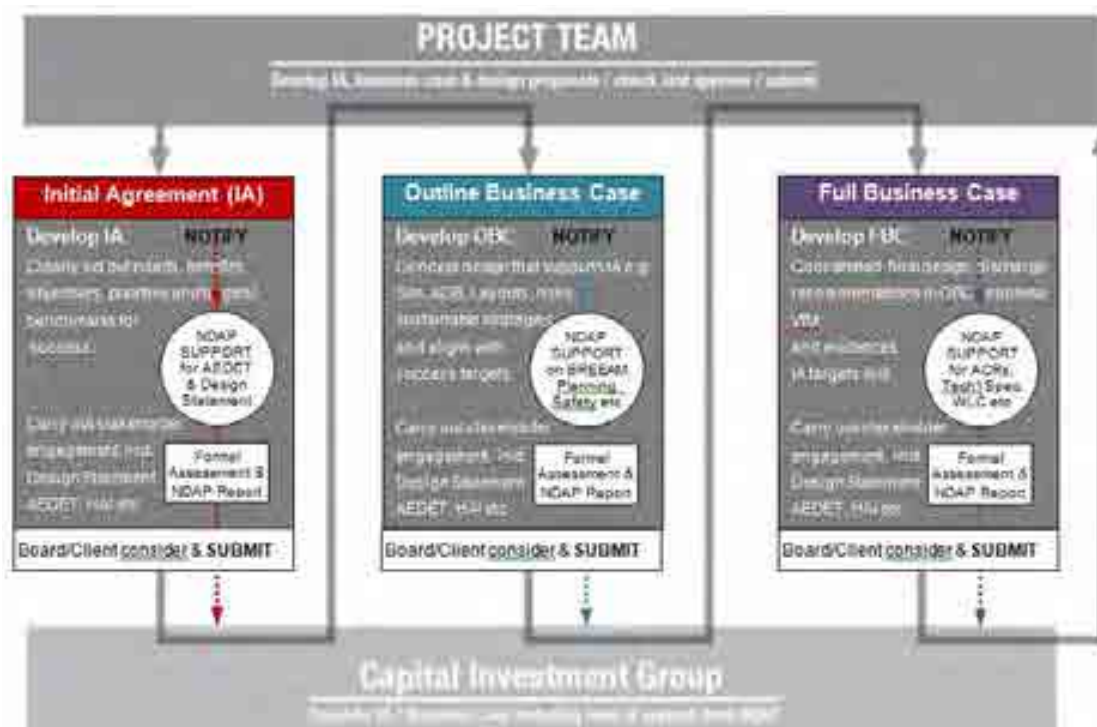

## 4 Links to Design Process

The assessment of design quality is an integral part of the business case approval process which aims to ensure that the outcomes of design development projects meet the Government's strategic objectives and expectations for public investment.

The requirement to refer projects to the NHSScotland Design Assessment Process applies to all projects that are to be considered by the Capital Investment Group (CIG). It is expected however that Boards will develop 'design statements' and utilise the self assessment methodologies on all development projects.

The Design Statement, which is to be produced by the Boards for each project prior to the submission of the Initial Agreement (IA), is central to the consideration of design matters within the business case approvals process as it is this document that establishes the design criteria against which the project will be assessed. The benchmarks set by the Board will also be assessed to ensure that they are in line with the expectations established in national policy.

The following flow diagram shows the key NDAP activities and information flow at each Business Case stage. Early engagement and dialogue with Project Teams in NDAP is key to reducing surprises / risks at the Formal Report stage.

# RIBA Plan of Work 2020 Overview

## Foreword

Since 2013, when the RIBA Plan of Work had its first major overhaul in its 57 year life, the RIBA has been gathering feedback from the construction industry.

As with anything that has undergone significant change, the RIBA Plan of Work 2013 needed to be used and evaluated, and we have been listening to users to inform how we modify the core guidance to even better meet the needs of project teams. We see this update as a clarification of the 2013 structure but with a closer, more contemporary, fit.

In June 2019 the UK Government committed to be net zero carbon by 2050, and the RIBA, along with a large proportion of the construction industry, believe that to meet this target we must design and construct new projects and undertake refurbishments that do not need to be retrofitted again before 2050. The RIBA have set a deadline of 2030 to do this, and for this to be successful the industry must be attempting it on all projects now.

The biggest addition to the new RIBA Plan of Work comes in the form of the new sustainably project strategy. This challenges design teams to design with a focus on sustainable outcomes from the outset of the project. These outcomes and associated targets should be defined and agreed with the client during Stage 1 briefing, reality-checked throughout the design and construction process, and finally verified in Stages 6 and 7 post occupancy evaluation. The definition of sustainable outcomes and associated metrics, together with current tools for measurement and verification, are included in the RIBA Sustainable Outcomes Guide.

In addition to the sustainability changes, this update has concentrated on improving the guidance in relation to the planning process, procurement and information requirements at each stage. Most importantly we have set out detailed stage descriptions and new guidance on core project strategies which can be found in chapter 6.

The RIBA Plan of Work is still the definitive design and process management tool for the UK construction industry and is gaining traction internationally too. This update brings into focus the trends and innovations that are changing the construction industry and provides space for these to thrive on our projects while ensuring a simple and robust framework remains in place.

My thanks go to those named at the end of this publication that have dedicated their time as volunteers over the past few years to produce this new and indispensable guide.

Professor Alan M Jones  
RIBA President 2019-21

## Introduction

The RIBA Plan of Work was initiated in 1963 to provide a framework for architects to use on projects with their clients, bringing greater clarity to the different stages of a project. It has evolved over the years to reflect changing trends in project approaches and has become an industry-wide tool.

The RIBA Plan of Work received its first major overhaul in 2013. It was updated to be suitable for use with any form of procurement, reflecting its primary role in mapping the design process between briefing and construction. The core design stages remained fundamentally intact, but were supplemented by a Stage 0, acknowledging the need for greater strategic consideration at the start of a project, and Stage 7, to reflect the use and life span of a building. A (Town) Planning task bar was created for dealing with the planning process, a Programme task bar acknowledged that some stages might need to overlap, depending on the procurement route, and a Procurement task bar set out tendering tasks during the design process would be necessitated by the choice of procurement route.

The past five years have seen further changes in the construction industry. Digital innovation continues to transform many aspects of project workflow, arguably moving towards a paradigm shift rather than a tweaking of more traditional ways of working. Modern methods of construction, including volumetric modular, are transforming the residential sector, pointing to new future business models. Changes in project drivers – ranging from delivering best value to an increased awareness of ethics – continue to add to the complexities of maintaining a coherent and consistent approach to the project process. Sustainability, including the rise of circular economy considerations, continues to grow in importance. A core challenge for the design team is how to meet changing client requirements while navigating this wide range of topics – from compliance with regulations, to clearing the increasingly important ethical bar, through to global best-in-class approaches.

Alongside the complexity of absorbing and responding to this diverse range of topics, project teams must deliver their projects as they have always done. They must first set the strategic scene, then apply the management overlay for the project, covering the development of the brief, the design of the building in response to the brief (including engineering and specialist inputs) and coordination of information before the process of manufacturing and construction commences. They must work as a team to deliver on time and to budget through to handover, when the baton is taken over by those dealing with maintenance or tasked with resolving users' day-to-day issues.

Adding to the complexity of this process, the rate of technological change is accelerating, requiring ongoing reviews and incremental improvements in the way that projects are undertaken. As we enter an era of continuous innovation, a core challenge for project teams is the need to constantly hone their ways of working, to maintain both their competitiveness and the quality of their design output.

The RIBA Plan of Work is not intended to be a contractual document. It defines what outcomes the project team should achieve at each stage, but it does not define who

should undertake the core tasks. Project specific contractual documents are required to bring clarity and consistency to the issues of what information is required, who will produce it and when it needs to be extracted from the design process for use in procurement or discussions with stakeholders.

Despite the ongoing transformation in how buildings are designed, built, maintained and used, the RIBA Plan of Work continues to be a resilient and relevant process map. It remains applicable to a wide range of project approaches and project scales. However, feedback from various clients and project teams has shown a need for greater clarity on how and when a number of aspects of the RIBA Plan of Work are applied to projects. Consistent use of the RIBA Plan of Work across different projects will help to provide everyone in the industry with confidence that their workflow will be robust as they move from one project to the next. Of course, any client is welcome to interpret the RIBA Plan of Work in their own way and to set their own overlay of tasks or documents. In a world of continuous change, bringing clarity to each stage allows everyone involved to develop their own innovations, without the perpetual need to discuss the strategic aspects of who should do what when.

PART

Background

## 1 CHAPTER ONE

# What is a plan of work?

In many countries there is no formal set process for designing a building. 'The way to do it' is unwritten and unrecorded, with informal processes handed down from one generation of professionals to the next. Regardless of where in the world a building is required, the core tasks are broadly the same:

- Agree appointments with the professional team
- Develop a brief with the client
- Create concept designs options
- Coordinate the design
- Prepare a planning application
- Apply for planning consent
- Develop a set of construction information
- Prepare a tender
- Obtain consents required prior to construction
- Award a Building Contract
- Construct the building
- Inspect the construction as it progresses
- Hand over the building.

When buildings are designed using repeatable, consistent and intuitive processes, this informal approach works – for example, when a clear process for briefing and design is aligned to a consistent means of obtaining statutory consents and where a single procurement route is consistently used. As the design process becomes more complex, influenced by many factors – such as new forms of procurement, modern methods of construction or new drivers, for example sustainability and maintainability – this approach becomes unsustainable. Without a process map, different members of the project team will have different versions of the 'right way to do it', making it inevitable that the project will be undertaken inefficiently.

There are several design process maps, or plans of work, used throughout the world to guide clients through briefing, design and construction, handover and beyond. In most countries, the process maps are set by the professional institutes or by sector bodies. Figure 1 illustrates some of these. Some have pre-design stages, some do not. Some go beyond completion of construction, others do not. All have construction as a single stage.

There are several key differences between these international plans of work:

- Some incorporate tendering stages, while others are procurement agnostic, focusing on the design rather than procurement process.
- The number of design stages varies from two to four. This underlines the challenges in the design process and the need to divide design into a number of coherent stages, each with a clearly defined purpose, prior to construction commencing.
- Few consider the importance, and benefit, of good briefing, including identifying the need for a building at the outset and how to use feedback from previous projects to inform the brief.

- Not all consider the life of the building beyond construction. However, some are beginning to address this, and how the design process and the building's handover processes impact on a building's performance.

Although each of these plans of work is different, they all have the same goals: to provide the project team with a road map for promoting consistency from one stage to the next, and to provide vital guidance to clients undertaking perhaps their first and only building project.

## 2 CHAPTER TWO

# The changing nature of the project team

The relationship between the client team and the design team has become more complex over recent years, as the industry wrestles with different ways to improve procurement. The interface between the design team and the construction team has also become more complex, as aspects of building design are increasingly being carried out by specialist subcontractors. The harnessing of modern methods of construction is complicating this crucial project relationship further. These increasing complexities add to the burden of work for the lead designer, requiring greater management of issues outside the boundaries of the design team.

The client team might comprise an individual or, on the largest of projects, several practices and individuals. The client team are not responsible for undertaking any design work, but must compile the **Project Brief** and review the design during and at the end of each stage. Many client teams employ external professional advisers, others have in-house teams to guide them through each project stage.

The design team has not fundamentally changed over the years, comprising the architect, structural and building services engineers and the cost consultant, although it is commonplace for other specialist consultants, such as acousticians or fire engineers, to contribute to the development of the design.

The construction team are responsible for manufacturing, assembling or constructing a building, including the logistics and contractual relationships connected with this.

Although the composition of the project team has remained broadly unaltered over the years, there are various ways in which the members can be connected contractually. This is shaped by the **Procurement Strategy**. Ultimately, there is no right or wrong approach to procurement. Each client must assess the pros and cons of different procurement strategies and decide which one will work best for them.

### The client team

The client is the commissioning entity for a project. Without a client there is no project. Clients come in many forms, ranging from consumers who want to convert their attics, to developers with billion-pound estates and who commission major buildings on a regular basis. When considering who might be in the client team, it is essential for the client to consider that – regardless of their experience, the project size or the business sector – the client team will have to undertake the following broad tasks:

- Set out the **Client Requirements** and consider whether a building project is the best means of achieving the **Client Requirements**
- Develop the **Project Brief**, including functional requirements, the **Project Budget** and **Project Outcomes**
- Agree on the most appropriate **Procurement Strategy**, and when the construction team will join the project team
- Appoint the design team, with appropriate knowledge, skills and experience

- Establish the **Project Programme**
- Review and comment on key aspects of the design as it progresses, including signing-off finishes and fittings to be used in the project
- Sign off the **Stage Report** at the end of each stage
- Make payments to the design team, construction team and any client team members as the project progresses, in line with the relevant contracts
- Manage stakeholder relationships and **Project Risks**

The client is central to the decision making process at every stage, but the extent to which they are involved is a matter of preference.

Some clients like to be central to the decision-making process, including the nitty-gritty decisions. Others are happy to delegate decision making and to follow the recommendations of their professional advisers or construction teams. The client will need to consider their role in decision-making when assembling the client team to ensure they have the expertise required.

An RIBA Client Adviser might assist the client in the early project stages, to give them impartial advice and to help them frame the **Project Brief** and select the design team.. Each client needs to determine what roles will be required to assist them through each project stage. In order to have the requisite skills to carry out the core tasks set out above, the client team might comprise the following roles:

- RIBA Client Adviser
- project manager
- client representative
- cost consultant
- contract administrator (employer's agent)
- information manager
- Plan for Use / Soft Landings champion
- additional client monitoring team

The client may also employ other specialist consultants into the client team to provide focused advice on a particular area. These may include:

- health and safety adviser
- sustainability adviser
- legal adviser
- financial adviser
- representatives from funders
- security adviser
- construction advisers
- operational adviser
- asset information adviser
- BREEAM adviser

This list is not exhaustive and will vary from client to client and from project to project, depending on the unique drivers and risks associated with each site and brief. The crucial difference between these advisers and those in the design team, is that these advisers have no design responsibilities though they may have design skills. While they may set

constraints or strategies, it is ultimately the role of the design team to produce a design that meets the requirements set by the client team, unless agreed otherwise.

### RIBA Client Advisers

RIBA Client Advisers are selected by the Royal Institute of British Architects from its membership for their all-round procurement expertise, design experience, business knowledge and track-record of delivering results in construction projects. A RIBA Client Adviser is usually an experienced architect and professional practitioner (but not the one designing the building) working in the client team, independent of the design team, monitoring and helping the client to follow a robust decision making process from the very start and throughout the project.

[www.architecture.com/working-with-an-architect/client-adviser](http://www.architecture.com/working-with-an-architect/client-adviser)

### The design team

The design team are responsible for the design of the building and for producing the information required to manufacture and construct it. The design team is led by the lead designer, who is responsible for coordinating the inputs and information from each team member. Anyone who designs, engineers or contributes advice or information that will be used as part of the design process needs to be in the design team. However, this does not include the preparation of the **Client Requirements** or **Project Brief** which are developed by the client team. On smaller projects some designers may start in the client team to help develop the **Project Brief** then become part of the design team.

The core members of the design team typically comprise:

- lead designer
- principal designer (usually a sub-function of the lead designer role)
- designers: architect, interior designer and landscape architect
- engineers: civil and structural and building services engineers
- cost consultant
- construction advisor
- specialist consultants

Many specialist consultants – with detailed knowledge and experience of a particular subject – may be involved in the design of a building. The need for their input will depend on the **Project Brief** and the experience and skills of the core design team members. Specialist consultants might include:

- fire engineer
- acoustic consultant
- security consultant
- façade engineer
- sustainability consultant
- specification consultant
- BIM consultant

Not every member of the design team is a designer, but all design team members actively contribute to the development of the design. For example:

- the cost consultant's advice shapes the development of the design
- the sustainability consultant might determine the energy source for the project
- the fire engineer's calculations might dictate how the design of an atrium space is developed
- the acoustic consultant might help to determine the specification for glazing adjacent to a railway
- the security consult might configure the arrangements in an entrance hall

### Principal Designer

In the UK, the principal designer is a statutory role under the Construction (Design and Management) Regulations 2015. The principal designer's role is to plan, manage, monitor and coordinate health and safety in the pre-construction phase of a project. The intent of the Health and Safety Executive (HSE) is for designers to take responsibility for the health and safety aspects of their design, including any implications for maintenance and operation, and to ensure that a Principal Designer takes responsibility for coordinating health and safety in the design process.

The RIBA Plan of Work includes the need to prepare a Health and Safety Strategy. This is the responsibility of the principal designer (usually the lead designer), although they may be supported by a health and safety adviser.

See HSE publication L153: *Managing Health and Safety in Construction* (HSE Books, 2015) for more information.

### The construction team

The construction team are contracted under the **Building Contract** to undertake the construction works.

In the past, construction teams would directly employ the labour required to build a project. Most building contracts are now let to teams who manage the construction process using limited or no direct labour. Building work is subcontracted in packages to subcontractors experienced in particular aspects of the project, for example for cladding, partitions, electrical or landscaping work. As the industry shifts towards the manufacturing and assembly of modular components, or sub-assemblies, new tasks are required of the construction team.

The role of the construction team includes the following tasks:

- Ensure that the building is constructed safely, with health and safety at the heart of the process.
- Secure the site and arrange shared items of plant, such as craneage or hoists.
- Liaise with the statutory authorities in relation to temporary requirements, such as for cranes, office accommodation and site welfare facilities, and seek approval for these as required.
- Prepare the **Construction Programme**.

- Divide the work into packages (considering any interfaces) and tender it to the most appropriate subcontractors and specialist subcontractors.
- Procure the work of subcontractors and specialist subcontractors.
- Manage and coordinate the construction work of the different subcontractors.
- Deliver the completed project in line with the time, cost and quality requirements of the **Building Contract**, as well as meeting all statutory requirements
- Assess and manage construction risks.

The construction team need a range of skills additional to those of the subcontractors, to assist with procurement, to manage construction and to facilitate logistics. Roles within the construction team might include:

- principal contractor
- commercial team
- procurement team
- package managers
- design manager
- information manager
- construction programmer
- construction managers
- logistics team.

## Stakeholders

**Project Stakeholders** are any party outside the project team who might influence the direction of the design or create a project constraint. Both the client team and design team may need to engage with different **Project Stakeholders**. Stakeholders might include:

- planning departments
- building control teams
- utilities companies
- community groups
- environmental bodies
- specialist interest groups
- insurance and warranty providers

They generally have no contractual relationships with the project team. As such, anticipating, managing and responding to the range of opinions or requests can be challenging. Preparing a **Project Stakeholder** plan can help to: clarify who the key stakeholders are; how they are being managed, who is the key contact within the project team; whether information is required for sign-off or consent; and how constraints or risks are to be managed. In certain instances, the client might include key **Project Stakeholders** as project partners or develop another means of better managing their involvement and contributions.

# Industry Feedback on the RIBA Plan of Work

## 3 CHAPTER THREE

# Industry feedback on the RIBA Plan of Work

Following the substantial update of the RIBA Plan of Work in 2013, the RIBA maintained a schedule of common queries arising from its use. The schedule recorded the day-to-day enquiries and issues encountered in the application and interpretation of the RIBA Plan of Work. Comments were received from a wide range of users, including clients, industry bodies, other designers and, of course, architectural practices.

This intelligence-gathering and listening exercise revealed several areas where tweaks to the Plan and the accompanying guidance were deemed necessary, to bring greater clarity to certain topics and resolve ambiguities about how the Plan of Work is used. In most instances, more detailed guidance on these topics is available from other sources; however, these sources are not as widely used as the RIBA Plan of Work. In response to this feedback, this publication provides comprehensive guidance on the application of the RIBA Plan of Work, to ensure there is consistency across the construction industry.

This chapter presents the key observations arising from the feedback received on the use of the RIBA Plan of Work. Some of the trends observed – for example, the scheduling of specialist subcontractors' design work at Stage 5 – are a consequence of the RIBA Plan of Work 2013 being interpreted differently than intended. Others – such as submitting a planning application at the end of Stage 2 – have required additional guidance for clients, to make sure the best project outcomes can still be achieved when industry deviates from the RIBA Plan of Work core tasks.

This chapter has been placed towards the beginning of this publication to allow these key observations to be understood, and so make it clear why the RIBA Plan of Work has been updated. It is essential that those who have been using the RIBA Plan of Work read this chapter to see where they may have misinterpreted the Plan and what measures they might take if they are not using it as intended.

## Stage 0

Stage 0 is about determining the best means of achieving the client's requirements. An open mind is required because a building might not be the most appropriate solution.

### Common misapplication 1

Certain clients use Stage 0 to prepare a detailed brief.

#### Recommendation

Stage 0 should be strategic in nature, defining the **Business Case** and **Client Requirements**. Depending on the circumstances, the stage can range from being a very quick review to being a long and protracted process involving many consultants. For Stage 0 to deliver the best outcome for the client, the crucial consideration for the client is what skills need to be brought to the client team. Different projects, each with a unique site and brief, bring different challenges and so require different skills. Developing the **Business Case** might require strategic thinking, management consulting expertise, whole life analysis, sustainability guidance, financial modelling or design thinking. Selecting the right team to deal with the strategic considerations is crucial. Once the outputs from the stage proceed to Stage 1, a building project has been set up and different skills will be needed.

### Common misapplication 2

Design team services regularly commence at Stage 0.

#### Recommendation

The Stage 0 team should be very different in composition to the Stage 1 team. The design team should not generally be appointed until Stage 2 as design work does not commence until then. On some projects, however, design thinking might be required to help address strategic considerations. If the client needs design thinking to unlock a project's strategic challenges, they might consider employing an RIBA Client Adviser to provide strategic advice, to help them navigate the early stages and provide continued support throughout the project.

### Common misapplication 3

In many scenarios, high-level spatial requirements are set that are not affordable within the envelope of the **Project Budget**.

#### Recommendation

It is important that the **Client Requirements** are aligned with the **Project Budget** during this stage. If the likely accommodation required to deliver the outcomes is unaffordable, there is no point in proceeding to Stage 1.

## Stage 1

Stage 1 is about developing the detail of the brief and making sure that everything needed for the design process is in place before Stage 2. This includes ensuring that the brief can be accommodated on the site.

### Common misapplication 1

**Feasibility Studies** undertaken at Stage 1 are seen as the start of the design process.

#### Recommendation

**Feasibility studies** are carried out as part of the briefing process to verify whether a site can accommodate the client's needs, or to test a particular aspect of the brief, allowing the brief to be honed as required. Where a number of options demonstrate that a number of approaches are feasible for a given site, they should not be narrowed down or appraised at this stage. Instead, the feasible options should be subjected to the more detailed rigor of the design process that commences at Stage 2. If the client has appointed an RIBA Client Adviser, they will be able to carry out the **Feasibility Studies**. This creates a cleaner boundary between the client team's work at Stage 1 and the commencement of the design work at Stage 2. If the client team does not have the skills required to conduct **Feasibility Studies**, they might consider appointing a designer early, to carry out the **Feasibility Studies**, as part of the client team. This can bring continuity to Stage 2. While design thinking may be applied at Stage 1, this is not in the creation of the design of the building; that starts at Stage 2.

### Common misapplication 2

The briefing process is often rushed, to allow Stage 2 to commence earlier.

#### Recommendation

An inadequate briefing process can result in delay during Stage 2, as the design team will have to undertake additional iterations of the design to tease out and resolve briefing issues. It is usual for the brief to iterate at Stage 2, in response to the design proposals. However, it is essential that, at the end of Stage 1, the brief covers any topics that the client wishes the design team to consider, including **Project Outcomes**, exemplar projects, **Spatial Requirements** and how these link to the **Project Budget**, and any topic or objective that would better inform the design process. The better the brief, the more engaged the design team can be in developing the best solution. RIBA Client Advisers can support the client in developing a clear and robust **Project Brief** in Stage 1, that will provide the design team in stage 2 with all the project requirements.

### Common misapplication 3

Clients are framing information requirements for projects around traditional 2D deliverables. Increasingly, this adds waste to the design process and may discourage design teams from leveraging more value from their federated model or other innovative ways of working.

#### Recommendation

The new challenge for Stage 1 is to define the **Information Requirements** for each project stage. This includes considering the use of new digital survey techniques that might assist the design process, the need for **Asset Information** at handover, and how new technologies might create better and faster design processes. Experienced clients might have the skills to set these new deliverables themselves. Less experienced or one-off clients can look to the design teams bidding for the project to suggest optimum proposals or might appoint the lead designer, an RIBA Client Adviser or an information manager to assist them during the development of the brief. As digital transformation takes hold in the construction industry, there is no right or wrong approach. However, if this topic is not considered at the start, the design process can easily become inefficient and less productive than traditional ways of working, when the converse should be true.

## Stage 2

Stage 2 is about getting the design concept right and making sure that the look and feel of the building is proceeding in line with the client's vision, brief and budget. The key challenge of this stage is to make sure that the tasks that are undertaken are geared to meeting the stage objectives. Going into too much detail too early can pivot the design team's effort away from setting the best strategy for the project; but if there is too little detail, Stage 3 becomes inefficient.

### Common misapplication 1

An increasing number of private sector clients are submitting planning applications near the beginning of Stage 3; developers often need to understand at an early stage what the costs of developer contributions required from the local authority will be - as they may affect the viability of a project.

#### Recommendation

While submitting an early planning application may bring clarity regarding developer contributions including section 106 or community infrastructure levy obligations, it creates several **Project Risks**. The RIBA recommends this approach is only followed by experienced clients who are aware of the risks and can manage them effectively.

### Common misapplication 2

Focus has been on what level of detail is required in the BIM (building information modelling) model during this stage, rather than on the tasks required to underpin the detail in the model.

#### Recommendation

Determining where the boundary between Stages 2 and 3 lies is one of the most complex tasks for a project team. The RIBA Plan of Work requires a robust **Architectural Concept** to be produced. However, this can be done in different ways. A core challenge at Stage 2 is determining what tasks and **Information Requirements** are required to achieve the stage outcomes. In some instances, the intuitive skills of the designer will be enough to develop an **Architectural Concept**. In other situations, a detailed analysis may be required to test the design that has been produced. For example, some clients may be satisfied by 'rule of thumb' calculations for the stairs and toilets of an office building and for light touch engineering inputs. Others may wish greater certainty in the design, requiring detailed calculations for these elements. There is no right or wrong approach. It is essential that the lead designer focuses the design team on the tasks that support and underpin the stage goals and which will make the design as resilient as possible as it progresses into Stage 3, when the level of work by the engineering teams and any specialists needs to accelerate.

### Common misapplication 3

Many clients request comprehensive BIM models, along with detailed 2D information and other data-driven outputs, during this stage, without considering whether it is the right information to deliver the stage outcomes.

#### Recommendation

Clients need to consider what information is required to deliver the stage outcomes. Will their outcomes be best served by the production of large quantities of 2D information during this stage? 3D technologies, including VR and augmented reality, are no longer gimmicks. They are valid ways of undertaking **Design Reviews** and their use should be considered alongside the need for traditional deliverables. Part 4, chapter Nine: *Setting Information Requirements* looks at the complexities of defining what information should be produced for each project stage.

## Stage 3

The purpose of Stage 3 is to spatially coordinate the design before the focus turns to preparing the detailed information required for manufacturing and constructing the building. The information at the end of this stage needs to be coordinated sufficiently to avoid all but the most minor of iterations at Stage 4 and to make sure that the planning application is based on the best possible information.

### Common misapplication 1

It is commonplace for the concept design to continue to be iterated during Stage 3. This diverts the design team from undertaking the core tasks for the stage.

#### Recommendation

The **Architectural Concept** should be concluded and signed off at Stage 2, along with the **Project Brief**. The project should not proceed to Stage 3 if any **Spatial Requirements** or room adjacencies remain inconclusive. During Stage 3, **Change Control Procedures** should be used to manage functional changes to the **Project Brief** and the **Architectural Concept**. Minor aspects of the scheme may need to be adjusted in response to the design tasks being undertaken. For example, a core might have to be rearranged to suit the final toilet and riser layouts.

### Common misapplication 2

It is common to start Stage 4 before the design is **Spatially Coordinated**; for example, where the engineering design is one step behind the architect's information.

#### Recommendation

The Stage 3 design needs to be **Spatially Coordinated** to allow each design team member to work independently at Stage 4, or for the design of specialist subcontractors to be integrated into the coordinated design. Similarly, all of the **Project Strategies** and any other project information should be coordinated.

### Common misapplication 3

The number of specialists being used on projects is increasing, but in many instances the timing of their contributions are not timed properly. The right contributions are produced, but at the wrong stage.

#### Recommendation

The majority of **Project Strategies** (produced by specialist consultants) should be coordinated and concluded by the end of Stage 3, ready to be embedded into the Stage 4 design information. Allowing work on **Project Strategies** that do not require further development for construction or **Facilities Management** purposes to stray into Stage 4 can be disruptive to the Stage 4 design process. The lead designer should review the schedules of services for specialist consultants and comment on what tasks are proposed and when these will be undertaken, being alert to any tasks that may disrupt the Stage 4 design process.

### Common misapplication 4

Under some procurement routes, Stage 3 deliverables are being used for tender purposes. However, while this information is coordinated, it is unlikely to contain sufficient detail to allow robust tenders to be prepared. For example, specifications will not be ready, the scope of work might be incomplete and detailed drawings will not have been prepared.

### Recommendation

The project team should consider what adjustments to the design process, including the early delivery of Stage 4 information, might improve the design team's effectiveness for procurement purposes. For example, being able to provide the scope for a particular work package or the detail design for a complex aspect of the project, such as the cladding, will reduce the contractor's need for assumptions, providing a more accurate tender return.

## Stage 4

Stage 4 is about developing the information required to manufacture and construct the building. This requires information from the design team and the specialist subcontractors employed by the contractor, regardless of which procurement route is used.

### Common misapplication 1

There is a tendency for design work by specialist subcontractors to be allocated to Stage 5, including any reviews of this information by the client team.

### Recommendation

Specialist subcontractors' design work should be allocated to Stage 4. The intention of the RIBA Plan of Work is that Stage 5 comprises solely the manufacturing and construction of the building, along with any associated inspections and reporting and the resolution of **Site Queries**. On the majority of projects, Stage 4 and Stage 5 will run concurrently and a contractual 'firewall' will occur midway through Stage 4. For example, on a two-stage design and build project, the client may be content to sign the **Building Contract** after the major packages have been secured; however, on a traditional project, the design team's work should be substantially complete prior to the **Building Contract** being signed, with the specialist subcontractor design completed after the contractor has been appointed. By keeping all design work within Stage 4, the lead designer is able to prepare a Stage 4 Design Programme that covers all elements of the design team's and specialist subcontractors' design work.

### Common misapplication 2

Setting boundaries between the design team's and the specialist subcontractors' design responsibilities is not considered at the outset. As a result, there may be ambiguities in what the design or construction teams have allowed for in their pricing.

### Recommendation

Where to position the interface between the design team and the specialist subcontractors is a core project decision. However, this is not the same as selecting the procurement route and the two must not be confused. It is possible for a traditional project to include a number of performance-specified (descriptive) elements, as opposed to the more expected prescriptive specification on traditional projects, and for a design and build project to have predominately descriptive specifications. The value brought by the design team delivering **Prescriptive Information** will vary depending on the building type and the outcomes the client is seeking to achieve. Many clients will prefer products visible on completion to be specified by the design team, allowing others to be selected by the contractor. Many specialist subcontractors have design skills beyond those of traditional designers and so can add value to the design process. With this in mind, the **Responsibility Matrix** needs to be set up at Stage 1, acknowledging that it can be updated if necessary as the design progresses.

### Common misapplication 3

The use of offsite manufacturing and other modern methods of construction is only being considered first at Stage 3 or even Stage 4.

#### Recommendation

The RIBA is witnessing an increased interest in offsite manufacturing and other modern methods of construction. However, these technologies need to be considered at Stage 2 and be embedded into the design from the outset. The RIBA recommends that if a client wishes the design team to embrace a specific modern method of construction, this should be implicit in the **Project Brief**. Where this is not a specific requirement, the RIBA suggests that the design team, perhaps in consultation with a construction adviser, considers different ways of building when preparing the Stage 2 **Construction Strategy**.

## Stage 5

Stage 5 is when the building is manufactured and constructed.

### Common misapplication 1

Design activity undertaken after construction has started is being considered Stage 5 design activity, or Stage 4 design work is delayed until Stage 5.

### What should happen/recommendation

With the exception of resolving **Site Queries**, there is no design activity at Stage 5. It is likely that Stages 4 and 5 will overlap, as dictated by the **Project Programme** and the **Procurement Strategy**. However, it should be clear in the professional services agreements that the production of information required for manufacturing and constructing the building, including the design work of the design team and the specialist subcontractors (including the review of this information), is a Stage 4 activity.

### Common misapplication 2

The information that will be handed over at the end of Stage 5 is not considered at the outset.

### Recommendation

The information handed over at the end of Stage 5 is changing. It can now range from 2D general arrangement information (perhaps derived from the design team's latest federated model through to a multi-disciplinary model containing specialist subcontractor information and a wealth of data for asset management, maintenance or in-use purposes. Those setting the **Information Requirements** need to consider what information is required for the effective use of the building. Even the smallest of projects has **Building Systems** that need to be operated effectively to enable the building to perform as expected. It can be difficult to define these **Information Requirements** at the outset, when standards and software are moving at pace, and it may be necessary as the project progresses to check that the contractual commitments will meet the client's information needs.

### Common misapplication 3

Although alternative models to traditional procurement model have been in use for some time, they do not necessarily provide clarity on who is to inspect the ongoing construction works.

### Recommendation

The client needs to consider how much inspection is required on a project. Exactly who is responsible for inspecting the building for compliance with the **Building Contract** will vary from project to project, as will the need for the design team to respond to **Site Queries**. These relationships need to be properly considered and necessary roles identified during Stage 1.

## Stage 6

By Stage 6 the building will be in use and the emphasis of the project team will have switched to closing out any defects and completing the tasks required to conclude the **Building Contract**.

### Common misapplication 1

As a project nears completion, there is a tendency for the construction team to be focused on finishing the physical aspects of the building, and on certifying **Practical Completion** in order to conclude Stage 5, possibly at the expense of handover activities to ensure that the client can use the building optimally.

### Recommendation

For the handover of the building to be successful, and to ensure that the building performs as planned, the Plan for Use Strategy should be considered in greater detail at each stage. Handover activities set out in the Plan for Use Strategy might occur during Stage 5, to ensure that the objectives are met. The end of Stage 5 continues to be defined as when the **Practical Completion** certificate is issued: the point where the building is legally ready for occupation. However, it is acknowledged that handover activities need to start before this date and continue beyond it. These include activities to help the client move in, such as the preparation of a **Building Manual**. Making sure that the building is performing as anticipated after occupation requires a light touch **Post Occupancy Evaluation** to be undertaken.

### Common misapplication 2

**Post Occupancy Evaluation** come in different guises and the term is being used to describe very different types of activity leading to confusion; collecting feedback from the project team is very different to assessing whether the building's energy performance is as planned.

### Recommendation

At Stage 1, the Plan for Use Strategy needs to be clear regarding expectations. Immediately after **Practical Completion**, it is essential to hold a **Project Performance** session with the project team, to gather their views before they disappear to their next projects. The **Aftercare** tasks that will help the building perform as planned have a different timeline – the building needs to have been in use for some time before seasonal **Commissioning** can take place or the data required to analyse performance outcomes can be collated.

## Stage 7

This is the period when the building is in use, lasting until the building reaches the end of its life.

### Common misapplication 1

It is common to see Stage 7 referenced in professional services contracts. However, by the end of Stage 6, those involving in briefing, designing, manufacturing and constructing the building will have completed their tasks.

### Recommendation

The work of the project team concludes with the closing out of the **Building Contract**. If tasks are to be undertaken beyond the end of Stage 6, they need to be properly set out in separate professional services contracts. Appointments to complete the **Aftercare** activities, such as detailed **Post Occupancy Evaluation**, or providing longer term client advice should be in place.

### Common misapplication 2

There are different views on how the end of a building's life relates to the circular processes of the RIBA Plan of Work. In certain industries, the work required at the end of a building's life is extensive and prolonged, justifying an additional project stage beyond Stage 7.

### Recommendation

When the client is considering what to do when a building no longer fulfils the client's needs or at the end of a building's life, they are, in essence, commencing a new Stage 0 process. For example, the client might first assess whether refurbishment, repurposing or extension of the building is possible. If they conclude that none of these is viable, then the building will be disassembled, with its constituent parts reused or recycled. With the end of Stage 7 in mind, some clients may include relevant considerations in the **Project Brief**. For example, they may ask the design team to produce test fits for other possible uses, or to make sure that the means of disassembling the building are clear in the **Construction Strategy** at Stage 2. These tasks will become more commonplace as circular economy principles take hold in the construction industry.

PART

RIBA  
Plan of  
Work  
2020

# 4 CHAPTER FOUR

## Using the RIBA Plan of Work

The RIBA Plan of Work comprises eight stages, which are designed to act together to inform the briefing, design, construction, handover and use of a building. The RIBA Plan of Work can be used by a client at the outset of a project, to help them set up their project, or by any project team member during the project, as a constant point of reference – to remind them of the core tasks that should be undertaken at any particular stage. In addition to understanding the outcomes of each stage, it is crucial to recognise how the RIBA Plan of Work facilitates the progression of several priorities, defined here as **Project Strategies**, through the RIBA stages.

Part 1 of this publication has explained the background to the RIBA Plan of Work and outlined some key changes made to the stages in this edition. Part 2 provides more detail on the structure and content of the Plan and the associated **Project Strategies**.

The majority of the RIBA stages work on a standalone basis. However, achieving successful outcomes at one stage relies on achieving successful outcomes at the stage before. It is foolhardy to believe that where the outcomes from one stage are poor, they can be recovered in the next stage. For example:

- a poor **Project Brief** is likely to lead to poor design outcomes
- a poor design will not achieve exemplary **Project Outcomes**
- designs that are not **Spatially Coordinated** in Stage 3 will result in unnecessary iterations in Stage 4
- poor information in Stage 4 will create an unnecessary volume of **Site Queries**
- lack of foresight on maintenance in the early stages will make maintenance difficult.

In many instances, there will be cross-cutting issues that flow from one stage to another, or information produced by one party that is crucial to another at the next stage. In this regard, while each stage acts independently, the RIBA Plan of Work has been constructed as a whole. Anyone using it should be cautious about changing the strategic tasks in any stage as this will potentially have an impact on the outcomes of the next.

### Capitalised terms

The RIBA Plan of Work contains a number of capitalised terms. These are the core procedures, processes and tools. As crucial aspects of the RIBA Plan of Work, their intentions and purposes need to be clear – the glossary in Part 4 of this publication defines in greater detail the meaning of each term.

# 5

## CHAPTER FIVE

# The RIBA Plan of Work task bars

Running across the RIBA Plan of Work stages are a number of tasks bars that explain the key aspects of each stage.

It should be noted that the **Project Strategies** that need to be worked thorough on most projects are covered in detail in chapter Six.

The RIBA Plan of Work tasks bars now comprise the following.

## Stage Outcome

The stage outcomes are high-level statements of the core outcomes to be expected at the end of each stage.

## Core Tasks

The core tasks are key activities that should be completed if the stage outcomes are to be achieved. The lists are neither exhaustive nor chronological, but are high-level summaries of the tasks. Supported by the capitalised terms (set out in detail in Part 4), the core tasks explain the thrust of activities that can be expected during each stage.

The tasks in this task bar are undertaken by the project team, having been distributed among the client team, design team or construction team as appropriate, under professional services contracts or the **Building Contract**.

## Core Statutory Processes

Any construction project must adhere to statutory requirements set out in planning and health and safety legislation, and the **Building Regulations**. This task bar lists the core statutory tasks that would be expected to be carried out at each project stage. Clients who are undertaking their first construction project will need members of the project team to provide detailed explanations of these requirements.

Crucially, this task bar acts as a reminder that engagement with external stakeholders is a crucial part of the project process. The **Project Programme** needs to be clear regarding any statutory requirements, such as the proposed date for submitting a **Planning Application**.

## Procurement Strategy

The **Procurement Strategy** task bar underlines that the RIBA Plan of Work is procurement neutral. There are two reasons for this. First, a number of different procurement routes are followed in the UK: while traditional procurement is still widely used, design and build forms of building contract are common amongst developers. Second, each **Procurement Strategy** engages with the design process differently during Stages 2 to 4.

It is, therefore, not possible to include specific procurement tasks in the RIBA Plan of Work. However, this task bar illustrates strategically when the construction team would be expected to become involved in the project for each typical procurement route. Procurement does not impact on the core tasks that need to be undertaken as part of the RIBA Plan of Work. However, it may require adjustments to the **Information Requirements** and will certainly be influential in determining the **Project Programme**. It can also have a major impact on the **Design Programme** for Stage 4, and how it overlaps with the **Construction Programme** of Stage 5. These topics are all covered in detail Part 3, chapter Nine.

It should be noted that the **Procurement Strategy** also determines how the design team will be appointed. However, the design team always need to be appointed before the start of Stage 2, regardless of the procurement route or who employs them.

Further guidance on the Procurement Strategy is included in chapter Eight.

## Information Exchanges

During each stage a large quantity of information will be exchanged between project team members and with external stakeholders. However, a crucial goal at each project stage is to ensure that, at the end of the stage, all information required for a client to sign off a stage is captured properly within a set of documentation. This serves two purposes. First, the information delivered at the end of one stage becomes the basis for the next stage, so it needs to be clear at the end of the stage what information will be used by the relevant project team members at the next stage. Second, the information produced at the end of a stage represents a wide range of decisions, made by the client, that will influence how the next stage progresses. These range from the agreement of the **Procurement Strategy** and determination of the **Information Requirements**, to decisions deriving from **Design Reviews** by the client team or external stakeholders, such as planners. As such, it is crucial that the information exchanged at the end of a stage not only includes the information required for the next stage, but also records the basis on which this information was determined.

## Project Strategies

**Project Strategies** are a crucial component of any project. As well as helping to tease out specific briefing issues, they enable design team members and, where necessary, specialist consultants to contribute effectively to the design process by allowing the lead designer to coordinate their contributions within the development of the broader design. They are an effective way of ring-fencing core aspects of the project, allowing the decision-making processes for each aspect to be clearly defined. **Project Strategies** can be appended to the **Stage Reports**, with a summary included within the main body of the text and, if necessary, a higher level statement in the executive summary.

**Project Strategies** need to be coordinated with the design work of the design team as a whole. Because of this, most **Project Strategies** need to be concluded at the end of Stage 3. This will allow their contents and recommendations to be absorbed into the Stage 4 information for each **Building System**. However, where specialist consultants have produced such **Project Strategies**, they might still be available to assist in honing the Stage 4 information.

Some **Project Strategies** will continue to evolve through and beyond Stage 4. It is crucial to understand how each **Project Strategy** will be developed during this stage and by whom, noting that the **Procurement Strategy** will determine who employs the design team.

In chapter Six, key tasks relating to the following **Project Strategies** are set out next to the main descriptions of each of the RIBA Plan of Work stages:

## Conservation Strategy

For use on conservation projects of any size or complexity the Conservation Strategy helps to map the approach that the project team can take when dealing with historic buildings, with an emphasis on managing the effect of the heritage protection measures that currently apply to 'designated assets', such as listed buildings, buildings in a conservation area and scheduled monuments. Each case and situation will be different and there is no set of hard and fast rules - it is more important to adopt an attitude of respect for the past, based on an open-minded approach to the variety of opportunities and problems that will be encountered.

## Cost Plan Strategy

The **Cost Plan** represents the anticipated construction cost of the building and, as such, it represents only a portion of the **Project Budget**. The **Cost Plan** used to be prepared at the end of Stage 2 or Stage 3. At the outset, the **Cost Plan** can be based on industry norms for similar building types adjusted to take account of market conditions, project abnormalities, Project Risks and contingencies. As design information is developed, an elemental **Cost Plan** is prepared. Essentially, this breaks down the cost for the building into the different **Building Systems**.

## Fire Safety Strategy

The Fire Safety Strategy forms an integral part of the design and must be integrated from the point at which a building project is identified and will continue through the ongoing **Asset Management** of the building, providing a golden thread of fire safety information. A high-level **Site Appraisal** to determine the fire safety suitability against the **Client Requirements** informs the viability of the project through **Feasibility Studies**. Layers of fire safety are integrated into the design as the project develops then constructed and managed in use in accordance with the Fire Safety Strategy and maintenance requirements.

## Health and Safety Strategy

The Health and Safety Strategy needs to be considered early on in the project because it is key to securing the safe construction, occupation, maintenance and future re-use or demolition of the project. The client's role is fundamental to this, to establish and maintain a health and safety-conscious approach to delivery of the project from the outset. The Health and Safety Strategy should set clear health and safety objectives.

## Inclusive Design Strategy

Accessibility and inclusion for people with disabilities is a firm policy of Government and the aspirations and expectations of the general public. Its achievement is dependent upon

the availability of barrier free environments and supportive mechanisms in delivering content and managing resources. The sooner that inclusion is considered the more effective and more cost effective it becomes. Alongside meeting Part M of the Building Regulations, buildings must also comply with the Equality Act, which gives legal protection from discrimination in the workplace and in wider society, on the grounds of age, disability, gender reassignment, marriage and civil partnership, pregnancy and maternity, race, religion or belief, sex, sexual orientation, also known as the protected characteristics. The Inclusive Design Strategy should consider all of these and be developed at the outset and implemented over the building's useful life.

## Planning Strategy

Planning legislation, policy and procedure is an ever increasingly complex part of the development process. Good planning is inseparable from good design and vice versa. Assessing planning issues should not be left to Stage 3 but be evaluated from the outset of every commission. For example, will the Client Requirements be acceptable under planning policy? If not, there is no value in developing design solutions for a proposal that is unlikely to gain consent. The Client Team must ensure adequate resources are allocated and appointments are made to managing planning issues throughout the project. This applies to both pre and post planning submission.

## Plan for Use Strategy

Plan for Use is the RIBA's interpretation of the Soft Landings Framework produced by the Usable Buildings Trust and BSRIA. Its aim is to encourage a more outcome-based approach to briefing, design, construction, handover and aftercare throughout the construction industry. The Plan for Use Strategy is central to this focal shift. Plan for Use has three basic components:

- Set realistic and measurable targets
- Complete Plan for Use activities
- Evaluate building performance and feed back lessons learned

Additional guidance on the Plan for Use Strategy can be found in the RIBA Plan for Use Guide (2020), created for this version of the RIBA Plan of Work.

## Sustainability Strategy

The Sustainability Strategy acts as a guide to the delivery of sustainable buildings. It provides a framework that can help project teams to take ownership of their buildings' performance. The onus is on project teams to develop targets through the **Sustainability Outcomes** and deliver verified building performance through the Plan for Use Strategy.

This approach embeds key sustainability principles into the overall RIBA Plan of Work, while allowing the targets, benchmarks and **Sustainability Outcomes** to evolve and intensify in their ambition and urgency, as they must over the coming years.

Additional guidance on the Sustainability Strategy and **Sustainable Outcomes** can be found in chapter Seven.

# 6

## CHAPTER SIX

# The RIBA Plan of Work Stages and Project Strategies

The eight stages of the RIBA Plan of Work have been devised to help anyone involved in a building project, from an experienced designer through to a client undertaking their first project. While the RIBA Plan of Work acts as the basis for professional services or building contracts, it is not intended to be contractual; it does not set out in detail who does what at each stage, nor does it define the detail around the many topics covered in this publication. However, anyone undertaking a building project should be alert to the strategic aims and broad outcomes of each stage set by the RIBA Plan of Work, which are based on industry consensus.

The RIBA Plan of Work focuses on the briefing, design, manufacturing, construction, handover and use of a building project. However, it is procurement neutral reflecting the diversity of procurement routes used today and acknowledging that procurement requires tweaks, not transformation, of the design process.

The RIBA Plan of Work also acknowledges that tasks undertaken during any stage might have an impact on the performance of the building and on the successful delivery of the requirements set out by the client. For this reason, Stage 7 reflects the activities carried out after the handover of the building and well into a building's life, even though on the majority of projects the Building Contract and the involvement of design team and the contractor will have concluded at the end of Stage 6. Stage 7 is arguably the most important stage in a building's life. During this stage, its performance impacts on whole life costs and, importantly, on the environment. The performance of future buildings can only be improved if feedback is gathered from buildings in use. Regardless, the project team designing and constructing the project increasingly need to deliver information for asset or facilities management purposes.

While the RIBA acknowledges that major transformations in the way buildings are briefed, designed and constructed are upon us, it is not anticipated that future innovations will alter the RIBA Plan of Work methodology. The RIBA Plan of Work is proving resilient to the changes happening around it. The refinements made in this version make the stages clearer and, regardless of the innovation happening around it, the RIBA Plan of Work will continue to be an invaluable tool for those involved in the briefing, design, manufacturing, construction, maintenance and use of buildings.

There is no standard timescale for a project and project teams will need to set out a project programme appropriate to the scale and complexity of the project. Figure 2 below illustrates a timeline of the stages and likely overlaps of certain stages, this should be read in conjunction with the RIBA Plan of Work 2020 Template which sets out when the tendering activities take place on different procurement routes. In this example the planning application takes place at the end of stage 3 and work has paused during this process.

Figure 2: Example Project Programme for each stage of the RIBA Plan of Work 2020

# RIBA Plan of Work 2020 Template

# RIBA Plan of Work 2020

The RIBA Plan of Work organises the process of briefing, designing, delivering, maintaining, operating and using a building into eight stages. It is a framework for all disciplines on construction projects and should be used solely as guidance for the preparation of detailed professional services and building contracts.

### Stage Boundaries:

Stages 0-4 will generally be undertaken one after the other.

Stages 4 and 5 will overlap in the **Project Programme** for most projects.

Stage 5 commences when the contractor takes possession of the site and finishes at **Practical Completion**.

Stage 6 starts with the handover of the building to the client immediately after **Practical Completion** and finishes at the end of the **Defects Liability Period**.

Stage 7 starts concurrently with Stage 6 and lasts for the life of the building.

### Planning Note:

**Planning Applications** are generally submitted at the end of Stage 3 and should only be submitted earlier when the threshold of information required has been met. If a **Planning Application** is made during Stage 3, a mid-stage gateway should be determined and it should be clear to the project team which tasks and deliverables will be required. See **Overview** guidance.

### Procurement:

The RIBA Plan of Work is procurement neutral - See **Overview** guidance for a detailed description of how each stage might be adjusted to accommodate the requirements of the **Procurement Strategy**.

- Employer's Requirements
- Contractor's Proposals

### Stage Outcome

at the end of the stage

### Core Tasks

during the stage

**Project Strategies** might include:

- Conservation (if applicable)
- Cost
- Fire Safety
- Health and Safety
- Inclusive Design
- Planning
- Plan for Use
- Procurement
- Sustainability

See **RIBA Plan of Work 2020 Overview** for detailed guidance on **Project Strategies**.

### Core Statutory Processes

during the stage:

Planning  
Building Regulations  
Health and Safety (CDM)

### Procurement Route

Traditional  
Design & Build 1 Stage  
Design & Build 2 Stage  
Management Contract  
Construction Management  
Contractor-led

### Information Exchanges

at the end of the stage

	0 Strategic Definition	1 Preparation and Briefing	2 Concept Design
<b>Stage Outcome</b> at the end of the stage	The best means of achieving the <b>Client Requirements</b> confirmed  If the outcome determines that a building is the best means of achieving the <b>Client Requirements</b> , the client proceeds to Stage 1	<b>Project Brief</b> approved by the client and confirmed that it can be accommodated on the site	<b>Architectural Concept</b> approved by the client and aligned to the <b>Project Brief</b>  The brief remains "live" during Stage 2 and is derogated in response to the <b>Architectural Concept</b>
<b>Core Tasks</b> during the stage	Prepare <b>Client Requirements</b> Develop <b>Business Case</b> for feasible options including review of <b>Project Risks</b> and <b>Project Budget</b> Ratify option that best delivers <b>Client Requirements</b> Review <b>Feedback</b> from previous projects Undertake <b>Site Appraisals</b>	Prepare <b>Project Brief</b> including <b>Project Outcomes</b> and <b>Sustainability Outcomes</b> , <b>Quality Aspirations</b> and <b>Spatial Requirements</b> Undertake <b>Feasibility Studies</b> Agree <b>Project Budget</b> Source <b>Site Information</b> including <b>Site Surveys</b> Prepare <b>Project Programme</b> Prepare <b>Project Execution Plan</b>	Prepare <b>Architectural Concept</b> incorporating <b>Strategic Engineering</b> requirements and aligned to <b>Cost Plan</b> , <b>Project Strategies</b> and <b>Outline Specification</b>  Agree <b>Project Brief Derogations</b>  Undertake <b>Design Reviews</b> with client and <b>Project Stakeholders</b>  Prepare stage <b>Design Programme</b>

## Stage 0: Strategic Definition

**Outcome:** The best means of achieving the **Client Requirements** confirmed.

The primary goal of Stage 0 is strategic – to ratify that a construction project, or otherwise, is the best means of achieving the **Client Requirements**. For example, a client wishing to expand its workforce has a range of options for accommodating the additional staff, including implementing new ways of working, adopting a more efficient space plan, subleasing premises or desk spaces close by, carrying out a refurbishment, building an extension or commissioning a new building.

Stage 0 is not about design or the practical details. It focuses on making the right strategic decisions and capturing them in a **Business Case**. The stage involves considering the pros and cons, **Project Risks** and **Project Budget** for a range of options and, where necessary, carrying out **Site Surveys** and corresponding planning appraisals, before undertaking a comparative analysis and recommending and ratifying the best option for delivering the **Client Requirements**.

The **Project Risks** consider any circumstances which would affect the delivery of the **Client Requirements** for each option, taking into account that, beyond this stage, substantive costs could be incurred. Examples might include onerous stakeholder constraints that could delay the delivery date, or a costly services diversion that could make an option unviable. The **Project Budget** – the funds the client has available for all aspects necessary to achieve the **Client Requirements** – will need to be considered for each option. This will include professional fees and, where relevant, land acquisition costs. The high-level **Spatial Requirements** relevant to any option may need to be determined as these can significantly influence the estimated construction cost, rents or other costs.

Increasingly, Stage 0 is about gleaning **Feedback** from previous similar projects and gathering insight from **Project Stakeholders**, making sure that lessons are learned. Knowledge gained in this way can help the briefing process, improve design quality and make the building perform better.

Stage 0 should not be regarded only as a first step – it is also the logical next step after Stage 7 in the circular RIBA Plan of Work process. When the end of a building's life is reached, it must be refurbished, repurposed for another use or deconstructed.

Detailed tasks for Stage 0 need to align with the complexity of the challenge and the diversity and demands of the options being considered for the **Business Case**.

---

**Who:** Only the client team is involved at this stage. The client team may seek advice from a wide range of professional advisers, such as RIBA Client Advisers to help them develop the **Client Requirements** and **Business Case** that will achieve these.

**Recommendations:** The process of developing the **Client Requirements** and the corresponding **Business Case** should involve all key **Project Stakeholders** within the client body.

## Stage 0: Strategic Definition

### Project Strategies Tasks

<b>Conservation</b>	<p>Identify <b>Project Outcomes</b> and define <b>Client Requirements</b> in relation to conservation. (e.g. minimising harm to historic fabric, preservation or conservation or bring into active use).</p> <p>Begin initial <b>Site Appraisals</b> including investigations and research, to identify significance, sensitivity, and conservation-related <b>Project Risks</b> (for example, protected wildlife, materials containing lead and asbestos) which may affect the delivery of the <b>Client Requirements</b>. This may include establishing historic status (conservation area, listed building or scheduled ancient monument), meeting statutory authorities and reviewing the existing conservation management plan.</p> <p>Define whether any specialist conservation expertise is needed in the client team.</p>
<b>Cost</b>	<p>Prepare a rough order of cost estimate, which captures a very high-level calculation of the <b>Project Budget</b> to meet the <b>Client Requirements</b> including high level <b>Spatial Requirements</b>, taking into consideration any <b>Project Risks</b>. The estimated construction cost might only be stated in terms of estimated cost per square metre or by reference to the estimated cost of a functional type (school place, bed space, etc.) and taking account of <b>Feedback</b> from previous similar projects. The estimated construction cost may be used to form the initial <b>Project Budget</b> figure as part of the <b>Business Case</b>, with the addition of professional fees and land acquisition costs.</p> <p>Define whether any specialist cost consultancy expertise is needed in the client team.</p>
<b>Fire Safety</b>	<p>Undertake <b>Site Appraisals</b> to determine the high level fire safety suitability of the site against the <b>Client Requirements</b> including high level <b>Spatial Requirements</b>, particularly in relation to access and facilities for the fire service and means of escape.</p> <p>Identify relevant current and emerging global, European, national and local fire-related trends, policy and legislation.</p> <p>Review <b>Feedback</b> from previous projects.</p> <p>Define whether the client team require any specialist fire safety expertise.</p>
<b>Health and safety</b>	<p>Gather existing health and safety information about a site or existing building, including relevant information from the <b>Health and Safety File</b> for existing buildings, to identify any significant risks to health and safety (e.g. the presence of asbestos or confined spaces).</p> <p>Take account of client duties under the Construction (Design and Management) Regulations 2015 (CDM Regulations) and their essential role in securing the safe delivery of a project to ratify the best means of achieving the <b>Client Requirements</b>.</p> <p>Review <b>Feedback</b> from previous projects (e.g. the efficacy of the cleaning and maintenance strategy or provisions for work at height).</p> <p>Define whether any specialist health and safety expertise is needed in the client team.</p>

<b>Inclusive design</b>	<p>Identify <b>Project Outcomes</b> and <b>Client Requirements</b> in relation to inclusive design.</p> <p>Undertake an access and inclusion audit of the existing site or environment to identify any <b>Project Risks</b> which may affect the delivery of the <b>Client Requirements</b> for inclusive design.</p> <p>Identify relevant current and emerging global, European, national and local inclusive design-related trends, policy and legislation.</p> <p>Review <b>Feedback</b> from previous projects.</p> <p>Define whether any specialist inclusive design expertise is needed in the client team.</p>
<b>Planning</b>	<p>Undertake a strategic planning appraisal of the site and its immediate and wider context, identifying the planning policy context, site designations, site history, an existing building's listed or scheduled status and related <b>Project Risks</b> which may affect the acceptability and viability of the <b>Client Requirements</b> including high level <b>Spatial Requirements</b> to <b>Project Stakeholders</b> including the planning authority and statutory consultees.</p> <p>Review <b>Feedback</b> from previous Planning history (i.e. any previous applications, refusals and approvals).</p> <p>Define whether any specialist planning expertise is needed in the client team to provide strategic advice on planning considerations.</p>
<b>Plan for Use</b>	<p>Explore opportunities for links to other projects or programmes to achieve economies of scale and improve efficiency, and review the implications for the scope of the <b>Client Requirements</b> and the <b>Business Case</b>.</p> <p>Review opportunities and <b>Project Risks</b> associated with potential future changes of use, operating hours and specific user or tenant requirements that might affect in-use performance.</p> <p>Review <b>Feedback</b> from previous or similar projects or the existing asset.</p> <p>Integrate operation, maintenance and whole life cost considerations into both the <b>Client Requirements</b> and the <b>Business Case</b>.</p>
<b>Sustainability</b>	<p>Develop high level, measurable, ambitious and unambiguous project <b>Sustainability Outcomes</b> to define the <b>Client Requirements</b>, following initial consultation with internal <b>Project Stakeholders</b>.</p> <p>Undertake a <b>Site Appraisal</b> of sustainability opportunities and constraints of potential sites and building assets.</p> <p>Identify relevant current and emerging global, European, national and local sustainability-related policy and legislation.</p> <p>Review relevant <b>Post Occupancy Evaluation Feedback</b> from previous projects (e.g. energy use).</p> <p>Review whether development is necessary to deliver the <b>Client Requirements</b> as one of the <b>Business Case</b> options considered.</p>

## Stage 1: Preparation and Briefing

**Outcome:** **Project Brief** approved by the client, and confirmed that it can be accommodated on the site.

If Stage 0 has determined that a building project is the best means of achieving the **Client Requirements**, the client team begin the briefing process during Stage 1. The **Client Requirements** for the project are considered in more detail, in connection with a specific site or sites, and the outcomes recorded in the **Project Brief**.

The **Project Brief** will contain guidance on the **Project Outcomes**, **Sustainability Outcomes** and **Quality Aspirations**. These may influence how the client, design and construction teams are assembled to form the project team, as part of the **Procurement Strategy**, and may dictate the core milestones in the **Project Programme**. Some clients give detailed, prescriptive briefing guidance, while others leave such considerations to the design team.

This stage is about developing the information that the design team will need to commence the design process at Stage 2. **Feasibility Studies** might be required in order to tease out the full range of briefing considerations and to demonstrate that the **Spatial Requirements** can be accommodated on the site. In some instances, several options might be prepared, but these options should not be vetted and appraised at this stage. **Feasibility Studies** are not part of the design process. For example, illustrative masterplan visions might be prepared in order to determine and shape the brief, and to tease out decisions that will be required on certain topics, but they are not part of the design process itself. As there is a direct correlation between cost and a building's area, the **Spatial Requirements** do need to be tested against the **Project Budget**.

The design team, with appropriate knowledge, skills and experience to deliver the **Project Outcomes**, needs to be selected, ready for Stage 2 to commence. On smaller projects, this team may already have been appointed to develop the **Project Brief**.

As the construction industry uses more digital tools and nudges towards greater uptake of whole life considerations, the information landscape is becoming more complex. The **Information Requirements** are therefore set at Stage 1, including whether the design team will deliver **Prescriptive Information** or **Descriptive information** in Stage 4. A **Responsibility Matrix** also needs to be prepared so that it is clear what tasks will underpin the production of information and who will undertake them. The matrix needs to focus on the boundaries between Stage 2 and Stage 3 tasks, and between the design team and any specialist subcontractors at Stage 4. A **Project Execution Plan** should be prepared, and a **Digital Execution Plan** will allow the design team to set out how they will produce the information.

A comprehensive set of **Site Information** needs to be sourced, including **Site Surveys**, ready for Stage 2 to commence.

---

**Who:** Stage 1 involves only the client team. The skills required will vary depending on the specific needs of the client and the project. Developing the **Project Brief** and the other outputs of this stage are skills that can be provided by specialists, such as RIBA Client Advisers who can also assist on selecting the design team. The **Feasibility Studies** might need architectural skills, and engineers or surveyors may be necessary to assess key **Project Risks**

**Recommendations:** It is important to recognise that Stage 1 is not a design stage. This stage is about layering detail and requirements into the **Project Brief**, before the design process commences at Stage 2.

## Stage 1: Preparation and Briefing Project Strategies

<b>Conservation</b>	<p>Undertake specialist <b>Site Surveys</b> and appraisal of conservation area and research historic <b>Site Information</b> and assess the building's listed or scheduled status.</p> <p>Identify specialist conservation <b>Project Stakeholder</b> interest, undertake consultation and respond to <b>Feedback</b> in the <b>Project Brief</b>.</p> <p>Use <b>Feasibility Studies</b> to test the <b>Client Requirements</b> in relation to conservation and discuss options with the local authority, Historic England and amenity societies.</p> <p>Assess the impact of the project on significance and draft a statement of significance to inform the <b>Quality Aspirations, Project Brief, Procurement Strategy</b> and <b>Project Programme</b>.</p> <p>Identify the conservation knowledge, skills and experience required in the design team (e.g. conservation architect), include it within the <b>Responsibility Matrix</b> and appoint specialist consultants.</p>
<b>Cost</b>	<p>Prepare order of cost estimates to test the feasibility of achieving the emerging <b>Project Brief</b> including the <b>Quality Aspirations</b> and <b>Project Strategies</b> when carrying out <b>Feasibility Studies</b>.</p> <p>Breakdown the cost of elements or categories to highlight any areas which may cause significant cost-related <b>Project Risks</b>. (e.g. likely foundation type) and consider the risk profile of potential market changes and inflation impact.</p> <p>Agree the <b>Project Budget</b>.</p> <p>Identify the cost consultant expertise required in the design team, include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>
<b>Fire Safety</b>	<p>Identify <b>Project Stakeholders</b> including building users, residents, building managers and facilities managers and seek <b>Feedback</b> on access requirements, occupant behaviour, and building use and maintenance requirements to inform the development of the <b>Project Brief</b> (as well as technical requirements to qualify for insurance and warranties).</p> <p>Develop overarching fire safety requirements to inform the <b>Project Brief</b>, including initial fire safety measures such as access and facilities for the fire service, and the number and location of cores.</p> <p>Source <b>Site Information</b> relating to fire safety including fire strategies for existing buildings (e.g. existing compartmentation arrangements).</p> <p>Use <b>Feasibility Studies</b> to confirm that the <b>Project Brief</b> can be accommodated on the site in accordance with the overarching fire safety requirements.</p> <p>Identify whether specialist fire safety expertise is required in the design team, include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>
<b>Health and safety</b>	<p>Research and communicate Health and Safety <b>Site Information</b> (e.g. asbestos) and coordinate it with <b>Feasibility Studies</b>.</p> <p>Initiate the collation, review and distribution of <b>Pre-Construction Information</b>, and establish design risk management processes.</p> <p>Define health and safety aspirations and incorporate these objectives within the <b>Project Brief</b>.</p> <p>Agree resource requirements, including time, fees and competence for CDM duty holders, and appoint the designers and the principal designer.</p> <p>Identify whether specialist health and safety advice is required in the design team, include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>

<b>Inclusive design</b>	<p>Identify Inclusive design needs from <b>Project Stakeholders</b>, consultation groups, site audits, design standards and obligations from legislation and incorporate these into the <b>Project Brief</b>.</p> <p>Source <b>Site Information</b> including <b>Site Surveys</b> relevant to inclusive design (e.g. topography, historic building).</p> <p>Use <b>Feasibility Studies</b> to verify that the inclusive design needs can be accommodated on the site within the <b>Project Budget</b>.</p> <p>Identify whether specialist inclusive design expertise is required in the design team, include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>
<b>Planning</b>	<p>Undertake a <b>Site Appraisal</b> (urban design analysis or character appraisal as appropriate).</p> <p>Source pre-design <b>Planning Advice</b> to identify local planning policy <b>related Project Risks</b> to be considered in <b>Feasibility Studies</b>.</p> <p>Use <b>Feasibility Studies</b> to test the <b>Project Brief</b> against the planning constraints of the site and to verify that <b>Quality Aspirations</b> can be achieved.</p> <p>Confirm the requirement for, and scope of, an Environmental Impact Assessment, listed building consent, required consent formats (outline or full), and appropriateness of a planning performance agreement.</p> <p>Develop a planning brief incorporating planning policy principles, the planning strategy, and <b>Project Stakeholder</b> consultation methodology, to inform the <b>Project Brief</b>.</p> <p>Identify planning expertise required (e.g. planning consultant, landscape architect, ecologist, archaeologist, transport consultant), include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>
<b>Plan for Use</b>	<p>Incorporate <b>Feedback</b> from lessons learned on previous projects or from the existing building's <b>Facilities Management</b> team into the <b>Project Brief</b>.</p> <p>Establish measurable targets for environmental performance, amenity and comfort in the <b>Project Brief</b> (e.g. metered energy and water consumption).</p> <p>Set out the requirements for <b>Post Occupancy Evaluation</b>, handover and <b>Aftercare</b>, maintenance and <b>Facilities Management</b> within the <b>Project Brief</b>, taking whole-life costs into consideration.</p> <p>Agree a schedule of <b>Project Stakeholder</b> engagement for Stages 2 and 3, as part of the <b>Project Execution Plan</b>.</p> <p>Identify a consultant within the <b>Responsibility Matrix</b> to take on the role of Plan for Use champion to maintain the focus on <b>Project Outcomes</b> throughout the project.</p>
<b>Sustainability</b>	<p>Use <b>Feedback</b> from <b>Post Occupancy Evaluation</b>, precedent review data, <b>Site Surveys</b>, and past experience of the client's <b>Facilities Management</b> team (if applicable) to state clear, deliverable and ambitious <b>Sustainability Outcomes</b> in the <b>Project Brief</b>.</p> <p>Use <b>Feasibility Studies</b> to verify that the <b>Sustainability Outcomes</b> can be achieved on the site within the <b>Project Budget</b>.</p> <p>Verify local authority sustainability requirements (e.g. enhanced regulatory requirements or assessment methods to be used).</p> <p>Define certification requirements, including timetable for assessor appointments and early stage client actions.</p> <p>Identify sustainability expertise required, include it within the <b>Responsibility Matrix</b> and appoint consultants.</p>

## Stage 2: Concept Design

Outcome: **Architectural Concept** approved by the client and aligned to the **Project Brief**.

Stage 2 sets the **Architectural Concept** for a project. Proposals that align with the **Site Information** and the **Project Brief**, including the **Spatial Requirements**, are prepared. Regular **Design Reviews** are used to seek comments from the client and other **Project Stakeholders** and the design is iterated in response. Any **Project Brief Derogations** are agreed, or the **Project Brief** is adjusted to align with the **Architectural Concept**.

The **Architectural Concept** proposals must also be iterated to accommodate inputs from the design team and from specialist consultants, including the **Strategic Engineering** requirements (building services, civil and structural engineering). The proposals must also be coordinated with the **Project Strategies**, and everything captured in a **Stage Report**. The **Cost Plan** should demonstrate that the proposals and **Outline Specification** are aligned to the **Project Budget**.

A core challenge is to determine what detailed tasks need to be undertaken at this stage. Although Stage 2 is more about rules of thumb than detailed analysis, calculations may be required to progress specific aspects, such as calculating stair or riser sizes. However, if the **Architectural Concept** is not certain, or does not have sufficient buy-in from the client, carrying out detailed supporting tasks now can result in abortive design work. There is no right or wrong approach. A pragmatic review of what tasks should be undertaken to make the **Architectural Concept** as robust as possible before Stage 3 commences is required.

The proposals should demonstrate that the **Spatial Requirements** are being achieved, along with any adjacency requirements. Any non-briefed areas, such as cores, must be developed sufficiently to coordinate with the **Architectural Concept**. Externally, the building must meet the vision of the client, as well as the demands of the local context and environment. The client may seek pre-application **Planning Advice** on the suitability of the initial proposal from a planning adviser or the relevant planning department. The **Architectural Concept** must also be reviewed against the **Quality Aspirations**, and the route to **Building Regulations** compliance needs to be clarified and agreed.

A Stage 2 **Design Programme** must be prepared, in line with the **Project Programme** and **Responsibility Matrix**, to guide the design process and to ensure that the **Information Requirements** are included in the **Stage Report** signed off by the client.

---

**Who:** The client team and the design team are the key players in this stage, along with any specialist consultants, whose contributions are required to achieve an **Architectural Concept** that is both robust and aligned with the **Project Brief**. Under some procurement routes, the construction team may also be engaged in this stage.

**Recommendations:** The crucial consideration at this stage is to determine which tasks and **Project Strategies** will contribute to the development of the **Architectural Concept**. The extent and nature of the tasks to be undertaken, and who should undertake them, will vary from project to project and from client to client.

## Stage 2: Concept Design Project Strategies

<b>Conservation</b>	<p>Evaluate <b>Site Information</b> to date the historic fabric and identify sensitivity, significance, condition and threats.</p> <p>Produce measured and condition surveys, and historic development drawings, and develop an historic building analysis to inform the <b>Architectural Concept</b>.</p> <p>Review the <b>Architectural Concept</b> options and <b>Outline Specification</b> against the statement of significance, conservation management plan, input from specialist consultants and <b>Feedback</b> from the client and other <b>Project Stakeholders</b>, using formal Design Reviews where appropriate.</p> <p>Source pre-application <b>Planning Advice</b> including on <b>Conservation Area</b> and listed building consent.</p> <p>Establish required specialist subcontractors, conservators' and suppliers' capabilities and associated lead-in times.</p>
<b>Cost</b>	<p>Prepare an initial formal <b>Cost Plan</b>, which takes account of initial design parameters established by the <b>Architectural Concept</b> and <b>Strategic Engineering</b> requirements, and which includes an elemental analysis of the various significant elements of cost and initial bulk quantities of key items set out in the <b>Outline Specification</b>.</p> <p>Review the cost implications of iterations of the <b>Architectural Concept</b>, taking into account the <b>Project Outcomes</b>, the <b>Procurement Strategy</b>, <b>Project Programme Implications</b> and <b>Project Risks</b>.</p> <p>Demonstrate that the <b>Architectural Concept</b> and <b>Outline Specification</b> are aligned to the <b>Project Budget</b> in the <b>Cost Plan</b>.</p>
<b>Fire Safety</b>	<p>Develop the <b>Architectural Concept</b> to align with the fire safety strategy and the <b>Project Brief</b>, incorporating input from Project Stakeholders (end users, facilities managers, specialist consultants, building control bodies and the fire and rescue authority where appropriate), to identify and address the fire safety measures relating to means of warning and escape, external fire spread and access and facilities for the fire service.</p> <p>Include a record of key fire safety design decisions in the fire safety strategy as part of the <b>Stage Report</b>.</p>
<b>Health and safety</b>	<p>Implement design risk management processes: identify, record and analyse significant and/or unusual foreseeable health and safety hazards (e.g. electricity and chemicals).</p> <p>Eliminate or reduce health and safety risks if possible, or record control measures, and coordinate matters relating to health and safety in the <b>Architectural Concept</b> and <b>Outline Specification</b>, aligned with the other <b>Project Strategies</b> and the <b>Project Brief</b>.</p> <p>Update <b>Pre-Construction Information</b> in line with relevant design development of the <b>Architectural Concept</b>.</p> <p>Initiate the <b>Health and Safety File</b>, and update the design risk management process if necessary.</p> <p>Include a record of key health and safety design decisions as part of the <b>Pre-Construction Information</b> in the <b>Stage Report</b>.</p>

<b>Inclusive design</b>	<p>Develop the inclusive design concept and review against the <b>Project Brief</b>, input from specialist consultants, <b>Project Stakeholder</b> consultation <b>Feedback</b> and local planning authority accessibility needs.</p> <p>Incorporate the inclusive design concept into the <b>Architectural Concept</b> and <b>Outline Specification</b>, and <b>Strategic Engineering</b> requirements.</p> <p>Include a record of key inclusive design decisions in the <b>Stage Report</b>.</p>
<b>Planning</b>	<p>Obtain pre-application <b>Planning Advice</b> on the suitability of the initial proposal from a planning adviser or the relevant planning department.</p> <p>Consult <b>Project Stakeholders</b> and use <b>Design Reviews</b> (as appropriate to the scale, complexity and sensitivity of the project) to seek comments on the <b>Architectural Concept</b> proposals, including the impacts on immediate neighbours, the local context and environment.</p> <p>Iterate the <b>Architectural Concept</b> proposals to accommodate inputs from specialist consultants (e.g. transport/highways consultant, ecologist, archaeologist).</p> <p>Draft a design and access statement (if required), and assess possible section 106 contributions and community infrastructure levy requirements.</p> <p>Option: Submit an outline <b>Planning Application</b> to establish whether the scale and nature of the proposed development would be acceptable to the local planning authority before a fully detailed proposal is put forward.</p>
<b>Plan for Use</b>	<p>Undertake a <b>Feedback</b> exercise to gather lessons learned from key <b>Project Stakeholders</b> and produce a record of performance risks.</p> <p>Finalise requirements for <b>Post Occupancy Evaluation</b>, handover and <b>Aftercare</b>.</p> <p>Review the <b>Architectural Concept</b> against end-user, operation and maintenance building performance requirements and whole-life costs.</p> <p>Align the Plan for Use Strategy with the Sustainability Strategy, <b>Cost Plan</b>, metering, site waste and other <b>Project Strategies</b>.</p> <p>Confirm that <b>Facilities Management</b> plans are in place, appropriate to the project.</p>
<b>Sustainability</b>	<p>Consider benchmarking and quality assurance requirements in initial design work.</p> <p>Incorporate lessons learned from <b>Post Occupancy Evaluation Feedback</b> and the review of precedents in developing the <b>Architectural Concept</b>.</p> <p>Carry out sufficient energy and other modelling to test and refine the <b>Architectural Concept</b>, Sustainability Strategy and delivery of <b>Sustainability Outcomes</b>.</p> <p>Review the <b>Architectural Concept</b> against the intended <b>Sustainability Outcomes</b> and report and mitigate any deviations.</p> <p>Include a record of key design decisions to deliver the <b>Sustainable Outcomes</b> in the <b>Stage Report</b>.</p>

## Stage 3: Spatial Coordination

**Outcome:** Architectural and engineering information **Spatially Coordinated**.

Stage 3 is fundamentally about testing and validating the **Architectural Concept**, to make sure that the architectural and engineering information prepared at Stage 2 is **Spatially Coordinated** before the detailed information required to manufacture and construct the building is produced at Stage 4.

Detailed **Design Studies** and **Engineering Analysis** are undertaken to ratify the assumptions made during Stage 2 and to layer more detail onto the design. Stage 3 is not about adjusting the **Architectural Concept**, which should remain substantially unaltered, although detailed design or engineering tasks may require adjustments to make sure that the building is **Spatially Coordinated**. Changes to the **Architectural Concept**, for whatever reason, should be agreed via the **Change Control Procedure**.

**Design Studies** should be aligned to **Cost Exercises** and the development of the **Outline Specification** – iterations of the design may be required to ensure the **Cost Plan** aligns with the **Project Budget**. Product suppliers and specialist subcontractors might be consulted to test or conclude specific aspects of the design. A **Spatially Coordinated** design allows each designer, including specialist subcontractors, to finalise their information at Stage 4 (except for minor tweaks at interfaces) without further major iterations of the design.

The **Project Strategies** need to be updated and additional detail added, and a **Building Regulations** review undertaken. A Stage 3 **Design Programme** is created to make sure that the right tasks are undertaken at the right time. At the end of Stage 3, once the client has signed off a **Stage Report** that captures all the design development work undertaken during the stage, a **Planning Application** can be submitted.

**NOTE:** When a **Planning Application** before the end of Stage 3 is being considered, it is important to set a mid-stage gateway and focus on the tasks necessary to ensure that the threshold of information required for an application is achieved, and that the design is robust enough for development once planning consent has been obtained.

**NOTE:** On some projects, **Employer's Requirements** might be issued at the end of Stage 3 rather than in Stage 4. This documentation may require some elements of the design to be drawn to a higher level of detail, or require schedules or detailed specifications to be produced, to help remove risk from the procurement process and set the **Quality Aspirations**. This is a drawdown from Stage 4 activity, and might be undertaken at the end of Stage 3, after the **Stage Report** has been signed off.

---

**Who:** The lead designer and design team are key to this stage. The client team are involved where Stage 3 coordination requires client decisions. The construction team may also be involved if the selected procurement route requires early contractor or specialist subcontractor inputs.

**Recommendations:** Stage 3 results in a **Spatially Coordinated** design. It is crucial that the client team and design team understand the stage outcomes and the tasks required to achieve them, as well as the impact that preparing **Employer's Requirements** or a **Planning Application** might have on the **Information Requirements** and tasks to be undertaken.

## Stage 3: Spatial Coordination Project Strategies

<b>Conservation</b>	<p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b> to test technical solutions for building conservation (e.g. to minimise harm to historic fabric), informed by specialist subcontractors and conservators, analysis, surveys and theory, and develop the building conservation aspects of the design in more detail.</p> <p>Undertake a <b>Building Regulations</b> review and recognise any <b>Building Regulations</b> exemptions.</p> <p>Integrate building conservation principles into a <b>Spatially Coordinated</b> design aligned to <b>Project Stakeholder</b> consultation Feedback.</p> <p>Identify and record any risks to significance, sensitivity, and conservation principles and mitigate any deviation from the conservation <b>Project Outcomes</b> (e.g. to accommodate inclusive design requirements).</p> <p>Establish the input and responsibilities of specialist subcontractors and conservators required, and the availability and lead-in times of specialist materials, to inform the <b>Procurement Strategy</b>.</p> <p>Prepare and submit a <b>Planning Application</b> and application for listed building or scheduled monument consent at the end of Stage 3.</p>
<b>Cost</b>	<p>Carry out <b>Cost Exercises</b> to allow more detailed aspects of the design, <b>Project Strategies</b> and <b>Outline Specification</b> to be tested, using <b>Design Studies</b> and involving suppliers or specialist subcontractors if necessary to determine affordability, and taking into consideration the cost implications of achieving the <b>Project Outcomes</b> including compliance with statutory requirements.</p> <p>Update the formal <b>Cost Plan</b> iteratively with increasing levels of cost certainty as greater detail of the architectural proposal is developed to align with the <b>Project Budget</b>; greater certainty allows any cost increases to be balanced by reductions in the project contingency.</p>
<b>Fire Safety</b>	<p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b>, with input from end users, facilities managers, specialist consultants (e.g. access consultant, subcontractors and the contractor if appointed, to test the design for fire safety and develop the fire safety measures in more detail).</p> <p>Undertake a <b>Building Regulations</b> review of Part B, Part A, Part M and Regulation 7 requirements, with input from the building control body and fire rescue authority where appropriate.</p> <p>Integrate the fire safety measures into a <b>Spatially Coordinated</b> design, aligned to <b>Feedback</b> from the fire service, and building insurers if required.</p> <p>Identify and record any risks to fire safety and mitigate any deviation from the Fire Safety Strategy and include key design decisions relating to fire safety in the <b>Stage Report</b>.</p> <p>Establish the input and responsibilities of specialist subcontractors required (e.g. fire stopping) to inform the <b>Procurement Strategy</b>.</p>
<b>Health and safety</b>	<p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b> to eliminate or reduce residual and additional risks to health and safety, informed by specialist subcontractors and the contractor if appointed.</p> <p>Integrate design risk management considerations into a <b>Spatially Coordinated</b> design, record control measures and update <b>Pre-Construction Information</b> in line with relevant design development.</p> <p>Include <b>Pre-Construction Information</b> in the <b>Stage Report</b>.</p> <p>Establish the input and responsibilities of specialist sub-contractors required (e.g. façade access and maintenance) to inform the <b>Procurement Strategy</b>.</p>

<b>Inclusive design</b>	<p>Undertake a review of Part M of the <b>Building Regulations</b> and the Equality Act.</p> <p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b> to test and develop the inclusive design requirements in more detail with input from <b>Project Stakeholders</b> (e.g. end users and access consultants).</p> <p>Integrate inclusive design considerations into a <b>Spatially Coordinated</b> design aligned to <b>Project Stakeholder</b> consultation <b>Feedback</b>.</p> <p>Identify and record any <b>Project Risks</b> to inclusive design and mitigate any deviation from the Inclusive Design Strategy for inclusion in the <b>Stage Report</b>.</p> <p>Prepare and submit the design and access statement as part of the <b>Planning Application</b> at the end of Stage 3.</p>
<b>Planning</b>	<p>Undertake a <b>Building Regulations</b> review of the <b>Spatially Coordinated</b> Design before submitting a <b>Planning Application</b>.</p> <p>Undertake <b>Design Studies</b> to test in more detail the impacts of the proposals on immediate neighbours, the local context and environment - informed by specialist consultants as required (e.g. transport/highways consultant, ecologist, archaeologist).</p> <p>Integrate pre-application <b>Planning Advice</b> into a <b>Spatially Coordinated</b> design aligned to other <b>Project Strategies</b>, <b>Project Stakeholder</b> consultation <b>Feedback</b> and information produced by specialist consultants.</p> <p>Prepare the environmental impact assessment, heritage statement, design and access statement (if required) and supporting planning documents.</p> <p>Establish likely <b>Planning Conditions</b>, including pre-commencement and post completion operational <b>Planning Conditions</b>, and confirm section 106 contributions and community infrastructure levy requirements with planning consent.</p> <p>Submit the <b>Planning Application</b> once the design is <b>Spatially Coordinated</b> sufficiently for development, with only minor iterations required once planning consent has been obtained.</p>
<b>Plan for Use</b>	<p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b> to test the building performance requirements and conclude <b>Design Reviews</b> with input from end users, facilities managers, specialists, design consultants and the contractor (if appointed), to ratify the design from an end-user perspective.</p> <p>Integrate the building performance requirements into a <b>Spatially Coordinated</b> design aligned to <b>Project Stakeholder</b> consultation <b>Feedback</b>.</p> <p>Embed the requirements for <b>Post Occupancy Evaluation</b>, handover and <b>Aftercare</b> in the Procurement Strategy.</p> <p>Update the record of performance risks to inform Stage 4 tasks and deliverables.</p>
<b>Sustainability</b>	<p>Undertake <b>Design Studies</b> and <b>Engineering Analysis</b> to test the <b>Sustainability Outcomes</b>, including carrying out a building performance assessment following <b>Plan for Use</b> protocol, and develop the design in more detail.</p> <p>Submit a <b>Building Regulations Application</b> and any interim certification applications (e.g. BREEAM).</p> <p>Integrate <b>Sustainability Outcomes</b> into a <b>Spatially Coordinated</b> design aligned to <b>Project Stakeholder</b> consultation <b>Feedback</b> incorporating lessons learned from <b>Post Occupancy Evaluation Feedback</b> and the review of precedents, and record new lessons learned.</p> <p>Identify and update record of performance risks to inform Stage 4 tasks and deliverables, and mitigate any deviation from the <b>Sustainability Outcomes</b>.</p> <p>Embed the requirements for <b>Post Occupancy Evaluation</b> in the <b>Procurement Strategy</b>.</p> <p>Include a record of key design decisions to deliver the <b>Sustainable Outcomes</b> in the <b>Stage Report</b>.</p>

## Stage 4: Technical Design

**Outcome:** All design information required to manufacture and construct the project completed.

Stage 4 involves the preparation of all information required to manufacture and construct a building. The core documents at the start of Stage 4 are the **Responsibility Matrix**, the **Information Requirements** and the **Stage 4 Design Programme**, which is heavily influenced by the **Procurement Strategy**.

The **Responsibility Matrix**, produced in Stage 1, defines whether the design team will deliver **Prescriptive Information** or **Descriptive Information** (including **Final Specifications**) for each **Building System**. **Prescriptive Information** can be used for construction purposes, with **Descriptive Information** issued where a specialist subcontractor will design a **Building System** for manufacturing and/or construction. While the **Procurement Strategy** influences who takes ultimate responsibility for **Manufacturing Information** and **Construction Information**, it is a common misconception that it also determines who is to produce it. However, a client on a design and build project may wish the design team's information to be as prescriptive as possible, keeping the need for specialist subcontractor design of **Building Systems** to a minimum. Conversely, a client using traditional procurement may require several specialist subcontractors to design **Building Systems**.

The **Procurement Strategy** does, however, influence when the **Building Systems** will be designed, dictating how the **Stage 4 Design Programme** will be structured. The **Procurement Strategy** might require Stage 4 to be undertaken in two parts. For example, on a traditional project, specialist subcontractors will design **Building Systems** after the **Building Contract** has been awarded.

The **Procurement Strategy** may also influence the structure of the project team. For example, the design team may be novated to the construction team. With this in mind, it is important that the **Procurement Strategy** is clear about project roles, including who will direct the work of the design team and who will review the design work of specialist subcontractors.

A **Building Regulations Application** should be made during Stage 4, before work commences on site. It will also be necessary to discharge any pre-commencement **Planning Conditions**.

Cost control measures applied during this stage will vary from project to project. These might include the preparation of an updated **Cost Plan**, bills of quantities or pricing schedules, as defined by the **Procurement Strategy**. The **Building Contract** needs to be agreed and signed at some point during the stage, to allow Stage 5 to commence. The majority of **Project Strategies** developed by the design team will be embedded in the **Manufacturing Information** and/or **Construction Information**, but some will continue into this stage and beyond. It is not usually necessary to produce a **Stage Report** for Stage 4.

---

**Who:** The design team and the specialist subcontractors employed by the contractor complete the design in this stage. Under some forms of procurement, a client monitoring team may be appointed to review the information that is produced.

**Recommendations:** All the design work required to manufacture and construct the building is undertaken in Stage 4, regardless of the **Procurement Strategy**. It is crucial to review the **Responsibility Matrix** before Stage 4 commences so it is clear who will be producing the **Manufacturing Information** and **Construction Information** and whether the design team will produce **Prescriptive Information** or **Descriptive Information**.

## Stage 4: Technical Design Project Strategies

<b>Conservation</b>	<p>Complete practicable intrusive surveys, and identify future surveys necessary.</p> <p>Undertake technical design, including <b>Final Specifications</b> and material sourcing, for building conservation.</p> <p>Prepare and coordinate specialist subcontractors' and conservators' information including <b>Final Specifications</b>, embedding the Conservation Strategy.</p> <p>Discharge any pre-commencement listed building consent and <b>Planning Conditions</b> (e.g. submit a conservation method statement), and submit a <b>Building Regulations Application</b>, recognising any exemptions.</p> <p>Include the conservation requirements in tender information or <b>Employer's Requirements</b> and review tender returns or <b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, and against Conservation Strategy outcomes.</p> <p>Identify <b>Project Risks</b> and uncertain areas of work where provisional sums are required (e.g. when it has not been possible to fully analyse the structure or building fabric).</p>
<b>Cost</b>	<p>Update the formal <b>Cost Plan</b> iteratively – to a level of detail defined by the Procurement Strategy – with a detailed elemental analysis of cost, together with a full bills of quantities, unit cost items or pricing schedules; the final <b>Cost Plan</b> becomes a pre-tender cost estimate.</p> <p>Review tender returns or <b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, against the <b>Cost Plan</b>, <b>Quality Aspirations</b>, <b>Building Regulations</b> and <b>Project Strategies</b>. Monitor and report the cost of any variations to the technical design between the point that the tenders are invited and up to the point that the contractor has been appointed.</p> <p>Identify <b>Project Risks</b> and uncertain areas of work where provisional sums are required.</p>
<b>Fire Safety</b>	<p>Undertake technical design, including <b>Final Specifications</b>, to manufacture and construct a fire safe building, including passive and active fire protection measures, means of warning and escape, and access and facilities for firefighting.</p> <p>Prepare and coordinate fire safety technical design information including <b>Final Specifications</b> required to manufacture and construct the building, and review against any insurer/warranty provider requirements, and building use, management and maintenance requirements.</p> <p>Identify and contact suitable contractors, and name or nominate specialist fire protection and fire safety subcontractors.</p> <p>Include the fire safety requirements in tender information or <b>Employer's Requirements</b> and review tender returns or <b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, against fire safety outcomes.</p> <p>Close down design risks in relation to the fire safety in use by the end of Stage 4.</p> <p>Address <b>Building Regulations</b> Part B, Part A, Part M and Regulation 7 requirements in full and submit a <b>Building Regulations Application</b>.</p>
<b>Health and safety</b>	<p>Identify, record and analyse, and eliminate or reduce, any Stage 3 or final residual risks to health and safety in undertaking the technical design.</p> <p>Integrate information identifying residual risks and record control measures in the final <b>Pre-Construction Information</b> handed over to the principal contractor.</p> <p>Include health and safety requirements in tender information or <b>Employer's Requirements</b> and review tender returns or <b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, against the requirement to secure the health and safety of any person affected by the project.</p> <p>Prepare the <b>Construction Phase Plan</b>, and update the <b>Health and Safety File</b>. Submit Form F10 to the HSE if required.</p>

<b>Inclusive design</b>	<p>Undertake technical design, including <b>Final Specifications</b>, to manufacture and construct an inclusive building.</p> <p>Coordinate design team and specialist subcontractors' <b>Manufacturing Information, Construction Information</b> and <b>Final Specifications</b>, embedding the inclusive design requirements and other <b>Project Strategies</b>.</p> <p>Include the inclusive design requirements in tender information or <b>Employer's Requirements</b> and review tender returns or <b>Contractors</b>, including any alternatives proposed to reduce costs, against inclusive design outcomes.</p> <p>Address the Equality Act (2010) and <b>Building Regulations</b> Part M requirements and submit a <b>Building Regulations Application</b>.</p>
<b>Planning</b>	<p>Develop and prepare any necessary supplementary design information to confirm details required before the planning permission can be implemented (e.g. large scale construction details) and submit an application to discharge any pre-commencement <b>Planning Conditions</b>.</p> <p>Negotiate and prepare any applications for non-material or minor material amendments if required, submit to the local planning authority; submit a new <b>Planning Application</b> if material amendments are required.</p> <p>Include list of <b>Planning Conditions</b> in tender information/<b>Employer's Requirements</b> and review tender returns/<b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, against the <b>Planning Conditions</b>.</p>
<b>Plan for Use</b>	<p>Regularly review the record of performance risks against the technical design with the design team, design out or control as many performance risks as possible, and identify strategies for managing those that remain.</p> <p>Include appropriate instructions for <b>Plan for Use</b> activities for the remaining stages in tender information or <b>Employer's Requirements</b>, including a handover strategy and Aftercare plan, and a requirement for <b>Facilities Management</b> information to operate the building effectively and enable it to perform as expected.</p> <p>Review tender returns or <b>Contractors Proposals</b>, including any alternatives proposed to reduce costs, against the record of performance risks, <b>Project Outcomes</b> and <b>Sustainability Outcomes</b>.</p> <p>Coordinate design team and specialist subcontractors' <b>Manufacturing Information, Construction Information</b> and <b>Final Specifications</b> with the record of performance risks.</p>
<b>Sustainability</b>	<p>Undertake technical design, including <b>Final Specifications</b> and material sourcing, to manufacture and construct the building to achieve the target <b>Sustainability Outcomes</b>.</p> <p>Coordinate design team and specialist subcontractors' <b>Manufacturing Information, Construction Information</b> and <b>Final Specifications</b>, embedding the target <b>Sustainability Outcomes</b> and the Plan for Use Strategy.</p> <p>Update any target commitments (e.g. to reduce carbon, energy or water use, and improve health and wellbeing).</p> <p>Include the Sustainability Strategy in tender information or <b>Employer's Requirements</b> and review tender returns or <b>Contractors Proposals</b> – including any alternatives – against <b>Sustainability Outcomes</b>.</p> <p>Mitigate or control as many building performance and climate change impact <b>Project Risks</b> as possible and identify strategies for managing those that remain.</p> <p>Address the <b>Sustainability Outcomes</b> targets – and Part F, G and L <b>Building Regulations</b> requirements – and submit a <b>Building Regulations Application</b>.</p>

## Stage 5: Manufacturing and Construction

**Outcome:** Manufacturing, construction and **Commissioning** completed.

Stage 5 comprises the manufacturing and construction of the **Building Systems** in accordance with the **Construction Programme** agreed in the **Building Contract**. Increasingly, digital technologies are being used to rehearse different construction activities, allowing Stage 5 to be faster and safer. As the construction industry moves towards greater uptake of offsite manufacturing, greater emphasis is also placed on the logistics of getting materials and large-scale components to site on time, and on the management of supply chain partners.

It should be clear from the outset who is responsible for responding to **Site Queries**, for regularly reporting on **Construction Quality**, for inspecting the works and monitoring progress, and for producing the **Defects List** prior to **Practical Completion** being certified. This may be the design team, who have produced the Stage 2, 3 and 4 information, or it may be a separate standalone role or client team. A separate team may have delivered the Stage 4 information, and the design team members might be allocated different roles at Stage 5. There is no right or wrong way to assemble the project team at this stage. However, which options have been chosen and who is responsible for what require clarification in the **Responsibility Matrix**.

Stage 5 concludes with the issue of a **Practical Completion** certificate, which allows a building to be handed over. The Plan for Use Strategy requires several tasks and activities to be undertaken before and after **Practical Completion**. Approaching **Practical Completion**, the construction team are focused on completing the manufacturing and construction of the project, so it is important that a project team member is allocated the role of planning for handover at Stage 6. On larger projects, a team might be formed to focus on the tasks that will deliver effective performance and operation of the building in use, rather than on completing the construction works.

Preparations for handover will include compilation of the **Building Manual** and the completion of **Verified Construction Information**, and maybe the delivery of **Asset Information**. Even the simplest of projects requires a **Building Manual**. For example, on a residential project, information on how to use appliances or set thermostats to operate effectively needs to be provided. What information will be required to use and operate the building needs to be considered at the outset, so that it can be collated at each project stage. The requirements can, however, be reviewed closer to completion, to make sure the client team receive the best possible information for the effective performance and management of their asset.

**NOTE:** It is likely that Stages 4 and 5 will overlap. The extent of overlap will be dictated by the **Procurement Strategy** and the **Project Programme**.

---

**Who:** The construction team take centre stage at Stage 5. The contributions from the client team and design team will depend on the Procurement Strategy, and on how the client decides to review Construction Quality as construction progresses.

**Recommendations:** It is crucial that it is clear who is to inspect **Construction Quality**, so that the client can be sure the building will be delivered in line with the requirements of the **Building Contract**.

## Stage 5: Manufacturing and Construction Project Strategies

<b>Conservation</b>	<p>Implement any requirements for protecting the historic or sensitive building fabric during construction including temporary works and commissioning of the building.</p> <p>Undertake building conservation works; inform operatives of the building's significance, and work to specialists' and conservators' requirements, refined through samples and exemplars.</p> <p>Record and manage discoveries and resolve <b>Site Queries</b>.</p> <p>Inspect the <b>Construction Quality</b> of the building conservation works and quality of materials regularly (e.g. by through samples and examples).</p> <p>Comply with and discharge <b>Planning Conditions</b> related to conservation works, and listed building consent conditions (e.g. replace or conserve an element of the fabric as set out in a conservation method statement).</p> <p>Produce the conservation <b>Defects List</b> prior to <b>Practical Completion</b> being certified.</p> <p>Update the conservation management plan.</p>
<b>Cost</b>	<p>Monitor and report the cost of any variations to the <b>Building Contract</b>, against the relevant sections and/or individual items of cost using the <b>Cost Plan</b> control document as the basis of the contractor's pricing document, based on the expected out-turn cost, agreed and anticipated changes, and the release strategy for any contingency funds.</p> <p>Prepare and issue interim valuations for payment for works completed as agreed in the <b>Building Contract</b>.</p> <p>Manage the cost of items outside the <b>Building Contract</b> which form part of the overall project (e.g. furniture, fittings and equipment).</p>
<b>Fire Safety</b>	<p>Manufacture and construct fire safety measures, informing operatives of the importance of proper workmanship, regularly inspecting the <b>Construction Quality</b>; insurers/warranty providers may be required to review and validate the works. No fire safety measures should be outstanding in the <b>Defects List</b> prior to <b>Practical Completion</b> being certified.</p> <p>Resolve fire safety <b>Site Queries</b>.</p> <p>Undertake <b>Commissioning</b> of fire protection and life safety systems, including fire detection, alarm and ventilation systems.</p> <p>Update fire safety information for inclusion in the <b>Building Manual</b>, including fire safety specific <b>Commissioning</b> and <b>Facilities Management</b> requirements (e.g. testing of ventilation systems).</p>
<b>Health and safety</b>	<p>Install welfare facilities according to the <b>Construction Phase Plan</b>.</p> <p>Manufacture, construct and commission the building in accordance with the <b>Construction Phase Plan</b>, and involve operatives in developing, promoting and checking the effectiveness of measures to ensure health, safety and welfare.</p> <p>Resolve <b>Site Queries</b>, and update information for inclusion in the <b>Health and Safety File</b>, including relevant specific commissioning and <b>Facilities Management</b> requirements.</p> <p>Complete the <b>Health and Safety File</b> and include it in the <b>Building Manual</b>.</p>

<b>Inclusive design</b>	<p>Manufacture, construct and commission inclusive design measures, informing operatives of the importance of proper workmanship, regularly inspecting the <b>Construction Quality</b>.</p> <p>Resolve inclusive design <b>Site Queries</b>.</p> <p>Prepare appropriate access information for end users and occupiers for inclusion in the <b>Building Manual</b>.</p>
<b>Planning</b>	<p>Submit information needed to comply with any <b>Planning Conditions</b> relating to any restrictions on the work/<b>Site Logistics</b> before work commences on site (e.g. details of cabin and hoarding layouts or procedures for washing down trucks before they leave site).</p> <p>Manufacture and construct the building to comply with the planning permission and any <b>Planning Conditions</b>.</p> <p>Inspect <b>Construction Quality</b> for compliance with <b>Planning Conditions</b>.</p> <p>Prepare and submit applications to discharge remaining <b>Planning Conditions</b>, and provide the client with copies of any consent notices.</p>
<b>Plan for Use</b>	<p>Manufacture, construct and commission the building to deliver effective performance and operation of the building in use.</p> <p>Commission the equipment required for monitoring energy, water consumption and building comfort and other <b>Project Outcomes</b>, and check that data being received in the correct format as defined during Stage 3.</p> <p>Consider the impacts of any variations to the design or <b>Specification</b> on building performance and whole life cost.</p> <p>Review and update the record of performance risks on site, and use it to identify and avoid potential defects.</p> <p>Plan for a smooth handover through careful planning of pre-completion activities, to focus the client, contractor and facility managers on the tasks that will deliver effective performance and operation of the building in use.</p> <p>Compile the <b>Asset Information</b> and data required for the effective performance and management of the building for the <b>Building Manual</b> (e.g. the Part L log book).</p>
<b>Sustainability</b>	<p>Manufacture, construct and commission the building to meet the target <b>Sustainability Outcomes</b> (e.g. to reduce carbon, energy or water use, and improve health and wellbeing).</p> <p>Commission all the equipment required for monitoring the <b>Sustainable Outcomes</b>.</p> <p>Review any construction stage changes, and report and mitigate any deviation from the <b>Sustainability Outcomes</b>.</p> <p>Compile construction stage information required for certification and demonstrate compliance with the <b>Sustainability Outcomes</b>.</p> <p>Submit final information for statutory approval and certification, and performance in use verification.</p> <p>Review and update the record of performance risks on site, and use it to identify and avoid any defects.</p> <p>Implement handover and <b>Aftercare</b> procedures, as outlined in the Plan for Use Strategy.</p> <p>Compile the <b>Asset Information</b> required for the effective performance and management of the building for the <b>Building Manual</b>.</p>

## Stage 6: Handover

---

**Outcome:** Building handed over, **Aftercare** initiated and **Building Contract** concluded.

Stage 6 starts with the building being handed over to the client, with **Aftercare** initiated and the **Building Contract** concluded.

After the building has been handed over, the construction team rectify any residual defects as promptly as possible. Usually twelve months after **Practical Completion**, the **Final Certificate** will be issued, which concludes the contractual involvement of the design and construction teams. Although Stage 6 commences after the building has been handed over, several tasks may need to commence during Stage 5 to ensure that the handover of the building is as efficient and effective as possible, such as training the users on how to use the **Building Systems**.

In addition to the core contractual obligations to rectify **defects**, certify **Practical Completion** and close out the **Building Contract**, other tasks need to be undertaken. A **Project Performance** session needs to be facilitated, so that the project team can share their experiences for the benefit of future projects.

Initial **Aftercare** tasks need to be initiated and completed. The project team will be interested in the **Feedback** from a light touch **Post Occupancy Evaluation**, conducted once any seasonal **Commissioning** has been completed, so they can understand how the building is performing and whether the building and its systems are being used as planned. Client, design and construction teams undertaking repeat building types can gain enormously from this process, by identifying trends across several projects.

---

**Who:** The construction team and those responsible for administering and closing out the **Building Contract** complete the project in Stage 6. The project team will be required for a **Project Performance** session.

**Recommendations:** Make sure that any **Feedback on Project Performance** is sought as soon as possible after **Practical Completion**, before the project team move on to new projects and knowledge is dissipated and lost. Do not underestimate the value of **Aftercare** in achieving successful building performance.

## Stage 6: Handover Project Strategies

<b>Conservation</b>	<p>Label spare materials and store scheduled historic pieces suitably in situ.</p> <p>Update the conservation management plan.</p> <p>Gather information for reports, archives, specialist journals, amenity societies or dossiers, where appropriate/required.</p> <p>Compile surveys and records of discoveries and works to include in the <b>Building Manual</b>.</p> <p>Hand over the updated conservation management plan to the client and <b>Facilities Management</b> team, including maintenance and training requirements.</p> <p>Implement any requirements for protecting the historic or sensitive building fabric during any <b>Seasonal Commissioning</b>.</p> <p>Undertake a review of <b>Project Performance</b> and a light touch <b>Post Occupancy Evaluation</b>, and revise or improve master conservation specifications based on lessons learned from the <b>Feedback</b> gathered.</p>
<b>Cost</b>	<p>Calculate and agree the adjusted contract sum as a progression from the <b>Cost Plan</b> control document/contractor's pricing document and original contract sum at the end of the defects period to settle the final account and allow the <b>Final Certificate</b> to be issued.</p> <p>Undertake a <b>Project Performance</b> session so that the final cost information can be used as <b>Feedback</b> for benchmarking the estimating and planning of costs on future projects.</p>
<b>Fire Safety</b>	<p>Hand over the fire safety information in the <b>Building Manual</b> to the client.</p> <p>Review <b>Project Performance</b> to learn lessons on design and construction for fire safety from the <b>Feedback</b> gathered (e.g. on the management of fire information between members of the project team).</p> <p>Identify relevant fire safety training and maintenance requirements, and provide induction and training of building users and facilities managers.</p> <p>Close out any new defects that arise during the defects liability period as they relate to fire safety.</p> <p>Undertake an initial fire risk assessment to gather <b>Feedback</b> on the operation of fire safety design measures and management systems, and building user behaviour.</p>
<b>Health and safety</b>	<p>Initiate <b>Aftercare</b> for the health and safety of <b>Facilities Management</b> team and building users.</p> <p>Hand over the <b>Health and Safety File</b> to the client.</p> <p>Identify relevant health and safety training and maintenance requirements, and provide induction and training of building users and <b>Facilities Management</b> team.</p> <p>Review <b>Project Performance</b> to learn lessons on design and construction for health and safety from the <b>Feedback</b> gathered (e.g. the efficacy of the cleaning and maintenance strategy).</p> <p>Identify relevant health and safety training and maintenance requirements, and provide induction and training of building users and facilities managers.</p> <p>Close out any new defects that arise during the defects period in accordance with the arrangements for managing health and safety on the project.</p> <p>Undertake <b>Seasonal Commissioning</b> of the new building in accordance with the arrangements for managing health and safety on the project.</p> <p>Gather <b>Feedback</b> on how <b>Facilities Management</b> and building maintenance is being undertaken in accordance with the Health and Safety file, and update information as required.</p>

<b>Inclusive design</b>	<p>Hand over the inclusive design information in the <b>Building Manual</b> to the client including the inclusive design principles and measures (e.g. the requirement to maintain and retain manifestation, materials, lighting or signage).</p> <p>Review <b>Project Performance</b> to learn lessons from <b>Feedback</b> gathered on design and construction to meet the needs of all building users.</p> <p>Provide induction and training for building users and <b>Facilities Management</b> team with reference to the inclusive design strategy, including disability awareness and access auditing.</p> <p>Close out any new defects that arise during the defects period relating to inclusive design.</p> <p>Undertake light touch <b>Post Occupancy Evaluation</b> to gather <b>Feedback</b> on the how the building is performing to meet the needs of all building users.</p>
<b>Planning</b>	<p>Discharge any pre-occupation <b>Planning Conditions</b> before handover.</p> <p>Provide the client with copies of any <b>Planning</b> consent notices and advise of any specific in use restrictions.</p> <p>Hold a <b>Project Performance</b> session with the project team to gather their views on the planning process for the benefit of future projects.</p>
<b>Plan for Use</b>	<p>Complete an effective transfer to <b>Facilities Management</b>, including user training, a user friendly <b>Building Manual</b> and any outstanding <b>Asset Information</b>.</p> <p>Hold a <b>Project Performance</b> session with the project team to gather their views on the handover and integrating <b>Facilities Management</b> thinking from the start for the benefit of future projects.</p> <p>Review the progress of defect rectification, maintenance and energy monitoring at periodic <b>Aftercare</b> meetings with the design team, contractor and <b>Facilities Management</b>.</p> <p>Begin gathering <b>Feedback</b> through light touch <b>Post Occupancy Evaluation</b> of the <b>Project Outcomes</b> in use.</p> <p>Hand over the <b>Building Manual</b> to users.</p> <p>Calibrate the as-built energy model with the commissioned building.</p> <p>Fine tune operational systems during <b>Seasonal Commissioning</b>, with reference to the <b>Sustainability Outcomes</b>.</p> <p>Close out any new defects that arise during the defects period relating to achieving the <b>Sustainability Outcomes</b>.</p>
<b>Sustainability</b>	<p>Hold a <b>Project Performance</b> session with the project team to gather their views on the process of embedding the <b>Sustainability Outcomes</b> in briefing, design and construction and handover for the benefit of future projects.</p> <p>Provide induction and training of building users and facilities managers, with reference to the Sustainability Strategy.</p> <p>Begin gathering <b>Feedback</b> through light touch <b>Post Occupancy Evaluation</b> of the <b>Sustainable Outcomes</b> in use.</p>

## Stage 7: Use

**Outcome:** Building used, operated and maintained efficiently.

On the majority of projects, the design team and construction team will have no Stage 7 duties to undertake. However, both teams will be interested in receiving ongoing **Feedback**, to help them understand how they might improve the performance of future buildings.

**Post Occupancy Evaluation** services are commissioned to determine how the building is performing in use to help fine tune the building and inform future projects.

Some client teams will continue to be closely involved during the life of a building, implementing **Facilities Management** or **Asset Management** strategies over the course of the building's lifetime. **Asset Information**, the **Building Manual** and these strategies may be updated on a regular basis. In the future, a **Digital Twin** might be used to optimise the operation and maintenance of the building and to compare predicted performance with actual performance.

In some **Building Contracts**, maintenance obligations might extend beyond Stage 6. Where this is not the case, a new standalone maintenance contract might be set up. This would require continuity of knowledge about how the building operates, therefore the **Asset Information** would need to be kept live and relevant throughout the life of the building.

At the end of a building's life, Stage 0 commences again. In line with circular economy principles, a refurbishment might prolong the life of the building or facilitate a new use. Where neither is possible, the deconstruction of the building will be undertaken after a new use for the site, and perhaps a new building, has been commissioned. Regardless of the outcome, the circular process of the RIBA Plan of Work moves the site towards its next meaningful use.

**NOTE:** Stage 7 starts concurrently with Stage 6.

---

**Who:** Those involved in ongoing **Asset Management** and **Facilities Management** will support the users of the building. The design team and construction team will no longer be involved, but design team members may be appointed separately to carry out **Post Occupancy Evaluation** tasks and some clients may require longer term strategic advice from specialists such as RIBA Client Advisers.

**Recommendations:** Handing over a building is just the beginning for those responsible for ensuring its successful operation and maintenance, that it performs as intended and achieves optimal outcomes for its users until the end of its life.

## Stage 7: Use Project Strategies

<b>Conservation</b>	<p>Put in place appointments to maintain historic fabric and execute conservation management plan.</p> <p>Complete obligations under licences (e.g. bat licence).</p> <p>Carry out ongoing quadrennial and quinquennial inspections as required.</p> <p>Carry out regular maintenance of the building fabric.</p> <p>Review and update the conservation management plan and continue monitoring repairs and survey requirements.</p> <p>Retain a conservation lead or team (e.g. surveyor to the fabric or cathedral architect).</p>
<b>Cost</b>	<p>Embed final cost data from the completion of the construction phase into a <b>Facilities Management</b> operating model, for use in building maintenance, repair or renewal, as required.</p> <p>Identify cost for any necessary detailed diagnostic or forensic <b>Post Occupancy Evaluation</b> services.</p> <p>Monitor operational costs for inclusion in whole life cost assessment and provide <b>Feedback</b> on in use costs as part of <b>Post Occupancy Evaluation</b> undertaken.</p>
<b>Fire Safety</b>	<p>Implement <b>Facilities Management</b> of building as set out in the Fire Strategy.</p> <p>Undertake regular fire risk assessments to gather <b>Feedback</b> on the operation of fire safety measures and management systems, and building user behaviour, to inform any subsequent management, maintenance or refurbishment works.</p> <p>Review and update the <b>Fire Safety Information</b> to reflect any management, maintenance and refurbishment works and updates to the fire risk assessment.</p>
<b>Health and safety</b>	<p>Implement the management and maintenance of the building in a way that secures the health and safety of <b>Facilities Management</b> team and building users</p> <p>Undertake <b>Post Occupancy Evaluation</b> of the health and safety of maintaining and using the building.</p> <p>Review and update the <b>Health and Safety File</b> throughout the life of the building and pass the file on to subsequent building owners.</p>
<b>Inclusive design</b>	<p>Implement the management and maintenance of the building in a way that meet the needs of all building users.</p> <p>Identify and implement any adjustments or improvements required to the building, day-to-day operations or policies to meet the needs of all building users.</p> <p>Undertake <b>Post Occupancy Evaluation</b> of inclusive performance and review the asset in operation for inclusivity needs.</p>
<b>Planning</b>	<p>Comply with <b>Planning Conditions</b> on use as required (e.g. operating hours or use of external space)</p>

<b>Plan for Use</b>	<p>Implement <b>Facilities Management</b> or <b>Asset Management</b> in accordance with the Plan for Use Strategy over the course of the building's lifetime.</p> <p>Implement the findings of the light touch <b>Post Occupancy Evaluation</b>, to fine-tune <b>Building Systems</b> and <b>Facilities Management</b> to optimise comfort and performance.</p> <p>Undertake more detailed <b>Post Occupancy Evaluation</b> as required, after putting in place separate professional services contracts. Compare predicted performance with actual performance to optimise the operation and maintenance of the building.</p> <p>Disseminate findings of <b>Post Occupancy Evaluation</b> activities in electronic format to the client, users, design and construction team members and, where possible, the wider construction industry.</p> <p>Maintain live <b>Asset Information</b> for <b>Facilities Management</b>, including regularly updating the <b>Building Manual</b>, throughout the life of the building.</p>
<b>Sustainability</b>	<p>Comply with in use <b>Planning Conditions</b> in relation to sustainability (e.g. meeting ongoing renewable energy use requirements).</p> <p>Use observations from the light touch <b>Post Occupancy Evaluation</b> to fine tune and improve and <b>Sustainable Outcomes</b> performance against the <b>Sustainability Outcomes</b> targets, and keep the <b>Building Manual</b> up to date.</p> <p>Undertake more detailed <b>Post Occupancy Evaluation</b> as required, after putting in place separate professional services contracts, to test delivery of the in use <b>Sustainability Outcomes</b>.</p> <p>Report and mitigate any deviation from the <b>Sustainability Outcomes</b>.</p> <p>Share <b>Feedback</b> from lessons learned with the client, users, design and construction team members and with <b>Project Stakeholders</b>.</p>

## 7 CHAPTER SEVEN

# Sustainability Strategy – detailed tasks

Climate change is the greatest challenge facing us. We are likely to reach an average global temperature increase of 1.5°C by 2030. To avoid exceeding this (relatively) 'safe' upper limit, the Intergovernmental Panel on Climate Change (IPCC) stated in its report *Global Warming of 1.5°C* (2019) that this would require rapid and far-reaching transitions in energy, land, urban and infrastructure (including transport and buildings) and industrial systems.

Buildings and construction contribute 40% of all carbon dioxide emissions. In the past 40 years, there has been a 60% decline in animal populations across the planet. According to the Living Planet Index, habitat loss, pollution and climate change have been key to this reduction.

The construction industry generally, and the architectural profession in particular, is in a key position to reduce further contributions to the causes of climate change and to mitigate its impacts. We are in the grips of an environment and climate emergency and our profession must do all it can to reduce the impact of the built environment. It is in this context that the Sustainability Strategy for the RIBA Plan of Work is written.

The **Sustainability Strategy** does not provide targets in itself. It is neutral in terms of methodologies, assessment tools and certification types, as it must work for all scales of project, all types of client and all levels of expertise.

The Sustainability Strategy acts as a guide to the delivery of sustainable buildings, to help deliver buildings that both meet clients' requirements and address the climate and biodiversity emergency. It provides a framework with actions, checks and stage outcomes, that can help project teams to take ownership of their buildings' performance. The onus is on project teams to develop targets through the **Sustainability Outcomes** and deliver verified building performance through the **Plan for Use Strategy**.

This approach embeds key sustainability principles into the overall RIBA Plan of Work, while allowing the targets, benchmarks and **Sustainability Outcomes** to evolve and intensify in their ambition and urgency, as they must over the coming years.

The eight **Sustainable Outcomes** are taken from the *RIBA Sustainable Outcomes Guide (2019)* when guidance can be found on setting measurable targets, designing to meet these targets and evaluating them in use by undertaking **Post Occupancy Evaluation**.

## 0 Strategic Definition

### Actions

Develop high level, measurable, ambitious and unambiguous project **Sustainability Outcomes** to define the **Client Requirements**, following initial consultation with internal **Project Stakeholders**.

Undertake a **Site Appraisal** of sustainability opportunities and constraints of potential sites and building assets.

Identify relevant current and emerging global, European, national and local sustainability-related policy and legislation.

Review relevant **Post Occupancy Evaluation Feedback** from previous projects (e.g. energy use).

Review whether development is necessary to deliver the **Client Requirements** as one of the **Business Case** options considered.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Review options for formal assessment of sustainability and/or energy performance.

Asses implications of net-zero carbon target, in line with the UK government's 2050 commitment and the RIBA 2030 Climate Challenge.

Assess the climatic context and consider passive potential for conditioning strategies

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Prioritise total or partial reuse of existing facilities, buildings, components or materials.

Consider the scope of new build elements and set ambitious embodied energy targets. Be mindful of the relationship between operational and embodied energy.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Prioritise proximity to public transport when selecting a site.

Create a comprehensive green travel plan in response to an assessment of existing conditions.

#### Sustainable Water Cycle (litres/person/day)

Define storm water management and site discharge requirements.

Develop strategies to minimise potable water use.

Explore on-site water recycling through rain, grey and black water harvesting.

### Sustainable Land Use and Biodiversity (increase in species)

Prioritise brownfield site selection and sustainable remediation of any site pollution.

Integrate aims for biodiversity, sustainable land use, improved ecological value and habitats into the **Project Brief**.

### Good Health and Wellbeing (various)

Identify and understand final occupants' needs to help to establish appropriate health and wellbeing metrics.

Consider connection to external spaces, occupancy, daylight and thermal comfort, air quality (including healthy materials), user needs and operational energy when selecting the site or developing the **Project Brief**.

### Sustainable Communities and Social Value (various)

Identify opportunities to enhance existing social and community structures through the development. Including place making, community involvement, amenity and opportunities for meanwhile use in the developing design.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Develop high level whole life **Cost Plan** incorporating the value of **Sustainability Outcomes**.

Consider building longevity in the context of climatic and functional adaptability. Prioritise passive design principles.

Set responsible sourcing agenda for all materials.

## Stage outcome

A sustainability champion is in place and a Sustainability Strategy relevant to the **Client Requirements** is integrated into the **Business Case** and **Project Brief**, which includes ambitious and unambiguous targets for each of the **Sustainability Outcomes**.

## 1 Preparation and Briefing

### Actions

Use **Feedback** from **Post Occupancy Evaluation**, precedent review data, **Site Surveys**, and past experience of the client's **Facilities Management** team (if applicable) to state clear, deliverable and ambitious **Sustainability Outcomes** in the **Project Brief**.

Use **Feasibility Studies** to verify that the **Sustainability Outcomes** can be achieved on the site within the **Project Budget**.

Verify local authority sustainability requirements (e.g. enhanced regulatory requirements or assessment methods to be used).

Define certification requirements, including timetable for assessor appointments and early stage client actions.

Identify sustainability expertise required, include it within the **Responsibility Matrix** and appoint consultants.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Operational energy use and CO<sub>2</sub> targets should include regulated and unregulated energy.

Use predicted in-use energy calculations (such as TM54) alongside compliance assessment.

Define seasonal climatic design energy strategies, prioritising passive principles.

Include options for renewables and implications on building and site design (e.g. form, orientation, façade details, control strategies and likely plant space).

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Assess site or existing buildings for reusable parts or components.

Define embodied energy and carbon target outcome, including the boundaries of the assessment with regard to net-zero carbon and certification methodologies.

Consider the relationship between embodied and operational energy.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Create a comprehensive green travel plan in response to an assessment of existing conditions.

Define outcome targets for connectivity and transport, including active travel, minimising car-use and encouraging walking and cycling.

#### Sustainable Water Cycle (litres/person/day)

Define water use target outcomes, including potable, rain and recycled water targets.

Define sustainable drainage and surface water retention requirements.

Explore on-site water recycling through rain, grey and black water harvesting.

Outline implications for the design, including tank sizes, permeable surfaces, fittings, etc.

### Sustainable Land Use and Biodiversity (increase in species)

Commission necessary surveys to understand existing ecology.

Develop strategies to enhance biodiversity and create new habitats.

Consider diversification of land use, meanwhile uses and productive landscaping.

### Good Health and Wellbeing (various)

Include requirements for internal environmental conditions, including thermal comfort and overheating, visual and acoustic comfort, spatial needs, ventilation type, control strategies and relationships to external environments.

Consider health and wellbeing alongside the energy strategy.

Include an approach to active circulation.

### Sustainable Communities and Social Value (various)

Consider place making, privacy, social interaction, mixed use places, community, amenity, involvement and inclusion. Plan for community consultation.

Include outcome targets for social value in the **Project Brief**.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Define an outcome target for life cycle value for key **Building Systems**.

Determine scope of life cycle assessment.

Specify measurable outcomes and targets for whole life carbon, whole life costs, building life span, refurbishment rates, end of life and circular economy.

Develop responsible sourcing targets.

Consider strategies for climate and functional adaptation.

## Stage outcome

A site specific Sustainability Strategy is included in the **Project Brief**.

**Sustainability Outcomes** are defined, ambitious and measurable and are shared across the project team.

Requirements for **Post Occupancy Evaluation** and handover and **Aftercare** defined.

## 2 Concept Design

### Actions

Consider benchmarking and quality assurance requirements in initial design work.

Incorporate lessons learned from **Post Occupancy Evaluation Feedback** and the review of precedents in developing the **Architectural Concept**.

Carry out sufficient energy and other modelling to test and refine the **Architectural Concept, Sustainability Strategy** and delivery of **Sustainability Outcomes**.

Review the **Architectural Concept** against the intended **Sustainability Outcomes** and report and mitigate any deviations.

Include a record of key design decisions to deliver the **Sustainable Outcomes** in the **Stage Report**.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Develop an operational energy strategy, considering the impact of complexity of form on thermal performance, orientation, glazing proportions, airtightness and building physics.

Develop seasonal energy strategies for the site, considering opportunities for passive systems, the impact of complexity of controls and management on energy consumption, comfort and occupant satisfaction.

Check that the materials and construction approach will provide a level of thermal mass that is appropriate to the environmental design strategy.

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Review the embodied energy and carbon of materials and construction processes in the context of the building's lifespan and operational strategy.

Minimise high embodied energy materials. Prioritise low carbon and recycled materials.

Avoid inefficient/wasteful use of materials. Design out waste where possible.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Incorporate the aspects of the green travel plan into the emerging design.

Encourage active and low carbon travel. Minimise private car use through connections to public transport and provision of alternatives.

#### Sustainable Water Cycle (litres/person/day)

Incorporate water use target outcomes, include potable, rain and recycled water targets.

Maximise storm water attenuation through permeable paving, planted areas and storage and attenuation tanks.

### Sustainable Land Use and Biodiversity (increase in species)

Develop the design against targets, including biodiversity enhancement and linked ecosystems.

Aim for long term diversification of land use, incorporating different functions, green spaces and economic models.

Incorporate water cycle targets into biodiversity strategy where possible.

### Good Health and Wellbeing (various)

Develop a plain English description of the internal environmental conditions and seasonal occupant control strategies.

Review the design against outcomes, including daylight, controls, social spaces and inclusivity.

### Sustainable Communities and Social Value (various)

Incorporate strategies for place making, privacy, social interaction, safety, mixed use places, community involvement, inclusion and amenity and opportunities for meanwhile use into the developing design.

Consider the need for and scale of private, semi-private and public external space.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Incorporate outcomes for whole life carbon, whole life costs, building life span, refurbishment rates and circular economy principles into the **Architectural Concept**.

Optimise the relationship between operational and embodied energy.

Consider resilience to future changes in climate through adaptation strategies.

Include future deconstruction, disposal and recycling in the design.

Incorporate a strategy to avoid toxic supply chains, practices and pollution.

## Stage outcome

The **Architectural Concept** design integrates the Sustainability Strategy with the **Project Brief**.

**Sustainability Outcomes** are included in the **Outline Specification** and **Cost Plan**.

## 3 Spatial Coordination

### Actions

Undertake **Design Studies** and **Engineering Analysis** to test the **Sustainability Outcomes**, including carrying out a building performance assessment following **Plan for Use** protocol, and develop the design in more detail.

Submit a **Building Regulations Application** and any interim certification applications (e.g. BREEAM).

Integrate **Sustainability Outcomes** into a **Spatially Coordinated** design aligned to **Project Stakeholder** consultation **Feedback** incorporating lessons learned from **Post Occupancy Evaluation Feedback** and the review of precedents, and record new lessons learned.

Identify and update record of performance risks to inform Stage 4 tasks and deliverables, and mitigate any deviation from the **Sustainability Outcomes**.

Embed the requirements for **Post Occupancy Evaluation** in the **Procurement Strategy**.

Include a record of key design decisions to deliver the **Sustainable Outcomes** in the **Stage Report**.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Audit design against operational energy outcome target, including seasonal conditioning strategies, form and orientation and details for airtightness, continuity of insulation.

Assess coordinated consultant information, including any subcontractor packages.

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Use embodied energy and carbon assessment to test relative impacts of design options as part of whole life costs.

Prioritise low carbon materials.

Consider the relationship between embodied and operational energy and carbon emissions.

Create a baseline carbon budget as an outcome target.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Incorporate the aspects of the green travel plan into the emerging design.

Encourage active travel, including walking and cycling. Coordinate space for deliveries, car clubs and connections to public transport.

#### Sustainable Water Cycle (litres/person/day)

Coordinate design to deliver outcomes for reduced water use, recycled waste water and incorporated sustainable drainage.

Coordinate the sustainable drainage with the biodiversity strategy where possible.

### Sustainable Land Use and Biodiversity (increase in species)

Consider ecological health in procurement strategy to help avoid toxic supply chain practices, air, water and soil pollution.

Include biodiversity design enhancements to local ecosystems, habitat and productive landscaping in design documentation.

### Good Health and Wellbeing (various)

Coordinate proposals to deliver **Sustainability Outcomes** for health and wellbeing including daylighting, indoor air quality (including healthy materials), responsive controls and visual, thermal and acoustic comfort.

Consider the artificial lighting and daylighting strategy. Review environmental controls, ensuring that they are simple and intuitive and supportive of the wider Sustainability Strategy and **Sustainability Outcomes**.

Encourage active circulation and travel.

### Sustainable Communities and Social Value (various)

Coordinate proposals to deliver **Sustainability Outcomes** for social and economic aims, including place making, privacy, social interaction, safety, mixed use places, community involvement, inclusion and amenity and opportunities for meanwhile use in to the developing design.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Review the expected building lifespan against capital and operational energy, carbon and financial costs.

Check the environmental and human impacts of materials and the **Construction Strategy**.

Consider risks of short and long term damage to retained traditional building fabric.

Refine the climate adaptation strategy and make provision for future climatic and functional adaptations.

## Stage outcome

**Spatially coordinated** design checked against the **Sustainability Outcomes**.

Services, structural and architectural design coordinated with the Sustainability Strategy, which is made explicit and included in **Statutory Submissions** and the **Stage Report**. Include a plain English description of the internal environmental conditions, seasonal control strategy and systems.

**Sustainability Outcomes** included in the **Cost Plan, Planning Application** and **Outline Specification**.

## 4 Technical Design

### Actions

Undertake technical design, including **Final Specifications** and material sourcing, to manufacture and construct the building to achieve the target **Sustainability Outcomes**.

Coordinate design team and specialist subcontractors' **Manufacturing Information, Construction Information** and **Final Specifications**, embedding the target **Sustainability Outcomes** and the Plan for Use Strategy.

Update any target commitments (e.g. to reduce carbon, energy or water use, and improve health and wellbeing).

Include the Sustainability Strategy in tender information or **Employer's Requirements** and review tender returns or **Contractors Proposals** – including any alternatives – against **Sustainability Outcomes**.

Mitigate or control as many building performance and climate change impact **Project Risks** as possible and identify strategies for managing those that remain.

Address the **Sustainable Outcomes** targets – and Part F, G and L **Building Regulations** requirements – and submit a **Building Regulations Application**.

### Delivering outcomes

– refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Illustrate how the Sustainability Outcomes will be delivered for operational energy through drawings, details, specifications and strategy drawings. Detail seasonal strategies, passive and active measures and controls. Include details for continuity of insulation, mitigation of point and linear cold bridges and airtightness.

Include in subcontractors' packages and in the **Building Manual**.

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Integrate and communicate detailed design strategies to deliver outcomes for embodied energy and carbon. Include materials, construction, manufacturing and supply decisions. Describe the relationship with operational energy and conditioning strategies.

Update the carbon budget and included in the specification.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Coordinate aspects of the green travel plan into the technical design.

Confirm measures to encourage active travel in the specification and the **Building Manual**.

#### Sustainable Water Cycle (litres/person/day)

Coordinate technical design to deliver outcomes for reduced water use, including fittings and appliances and recycled waste water, and incorporating sustainable drainage. Integrated into biodiversity strategy where possible.

Leak detection and other technical requirements coordinated.

### Sustainable Land Use and Biodiversity (increase in species)

Integrate and communicate detailed design strategies to deliver sustainable land use outcomes, including diversification and meanwhile uses.

Integrate actions for avoiding toxic supply chain practices and air, water and soil pollution. Specify enhancements to local biodiversity and productive landscaping.

### Good Health and Wellbeing (various)

Illustrate how the proposals deliver **Sustainability Outcomes** for health and wellbeing, including daylighting, indoor air quality (through healthy materials and other means), responsive controls and visual, thermal and acoustic comfort.

Develop the **Building Manual**, illustrating user interaction with the building.

### Sustainable Communities and Social Value (various)

Integrate social and economic aims into the technical design, including outcomes for place making, privacy, social interaction, safety, mixed use places, community involvement, inclusion and amenity, and opportunities for meanwhile use.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Integrate and communicate strategies to deliver the expected building lifespan, incorporating capital and operational costs, material use, operational and embodied energy and environmental impacts.

Develop specification of sustainable materials and products that balances life cycle assessment, maintenance regime, durability, adaptability and cost.

Integrate responsible sourcing strategy into developing specification.

Adaptation strategy included in the **Building Manual**.

## Stage outcome

The Sustainability Strategy and verified **Sustainability Outcomes** are included in **Manufacturing Information** and **Construction Information**, including specification, drawings and the **Sustainability Outcomes** performance parameters.

## 5 Manufacturing and Construction

### Actions

Manufacture, construct and commission the building to meet the target **Sustainability Outcomes** (e.g. to reduce carbon, energy or water use, and improve health and wellbeing).

Commission all the equipment required for monitoring the **Sustainable Outcomes**.

Review any construction stage changes, and report and mitigate any deviation from the **Sustainability Outcomes**.

Compile construction stage information required for certification and demonstrate compliance with the **Sustainability Outcomes**.

Submit final information for statutory approval and certification, and performance in use verification.

Review and update the record of performance risks on site, and use it to identify and avoid any defects.

Implement handover and **Aftercare** procedures, as outlined in the Plan for Use Strategy.

Compile the **Asset Information** required for the effective performance and management of the building for the **Building Manual**.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

#### (Net zero) Operational Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Visit the site to check that **Construction Quality** meets with **Sustainability Outcomes** for operational energy.

Review testing and monitoring of construction, particularly airtightness and continuity of insulation.

#### (Net zero) Embodied Energy and CO<sub>2</sub> (kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Update embodied energy and carbon assessment.

Review impact of the construction process against the carbon budget.

#### Sustainable Connectivity and Transport (kgCO<sub>2</sub>e/km/person/year)

Check the green travel plan is implemented during the construction process and that site-based transport measures are implemented.

#### Sustainable Water Cycle (litres/person/day)

Check installations meet sustainable water cycle outcomes.

Include measures to reduce water use, including fittings and appliances, recycling grey and rainwater, and sustainable urban drainage.

### Sustainable Land Use and Biodiversity (increase in species)

Check that quality and installation are in line with **Sustainability Outcomes** for sustainable land use and biodiversity, including, air, water and soil pollution, enhancing and creating habitats and productive landscaping.

### Good Health and Wellbeing (various)

Check that quality and installation are in line with **Sustainability Outcomes** for health and wellbeing, inclusivity and accessibility.

Include visual, acoustic and thermal comfort measures. Verify location, type and function of controls and M&E installations.

### Sustainable Communities and Social Value (various)

Check the sustainable communities strategy is delivered on site, including place making, privacy, social interaction, safety, mixed use places, community involvement, inclusion and amenity.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Prepare for commissioning of controls to meet operational energy and comfort outcomes.

Monitor waste, energy and water use on site and update life cycle assessment to incorporate construction stage changes.

## Stage outcome

Interim testing and monitoring used to verify the **Sustainability Outcomes**.

Any deviation from the **Sustainability Outcomes** reported and mitigated.

Check that adequate commissioning and maintenance contracts are in place. Identify **Aftercare** representative(s) and when they will be available on site. Complete the plain English **Building Manual**, setting out the Sustainability Strategy.

**Asset Information**, including Sustainability Strategy and **Building Manual**, complete and disseminated.

## 6 Handover

### Actions

Hold a **Project Performance** session with the project team to gather their views on the process of embedding the **Sustainability Outcomes** in briefing, design and construction and handover for the benefit of future projects.

Provide induction and training of building users and facilities managers, with reference to the Sustainability Strategy.

Begin gathering **Feedback** through light touch **Post Occupancy Evaluation** of the **Sustainable Outcomes** in use.

### Delivering outcomes

– refer to the *RIBA Sustainable Outcomes Guide*

Assess **Sustainability Outcomes** by undertaking light touch **Post Occupancy Evaluation**

**(Net zero) Operational Energy and CO<sub>2</sub>**  
(kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Review the seasonal **Commissioning** process and assess the **Sustainability Outcomes** for operational energy use using in use data. Begin collection of in-use data for initial light touch **Post Occupancy Evaluation**.

**(Net zero) Embodied Energy and CO<sub>2</sub>**  
(kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Assess the **Sustainability Outcomes** for embodied energy and carbon through final assessment of the **Asset Information** model to compare to initial carbon budget.

**Sustainable Connectivity and Transport**  
(kgCO<sub>2</sub>e/km/person/year)

Support the assessment of the **Sustainability Outcomes** for sustainable transport and connectivity.

**Sustainable Water Cycle**  
(litres/person/day)

Assess the **Sustainability Outcomes** for sustainable water cycles using in use data.

### Sustainable Land Use and Biodiversity (increase in species)

Support the assessment of the **Sustainability Outcomes** for sustainable land use.

Observe new green spaces and planting, mixed uses and productive landscaping.

### Good Health and Wellbeing (various)

Support the assessment of **Sustainability Outcomes** for wellbeing, including assisting with user training and dissemination of the Building Manual.

### Sustainable Communities and Social Value (various)

Support the assessment of **Sustainability Outcomes** for social value. Ensure aspects of place making, space for social interaction, inclusion, etc are in place.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Support the assessment of the **Sustainability Outcomes** for life cycle value.

Review controls and adaptable aspects.

Review seasonal performance and update the **Building Manual** to reflect any changes.

## Stage outcome

Induction and training of building users and managers with reference to the Sustainability Strategy.

**Building Manual** issued to facilities managers and building users.

**Aftercare** including light touch **Post Occupancy Evaluation** carried out as per Plan for Use protocols.

**Project Feedback** gathered and reported to project team to help improve their organisational performance on future projects.

## 7 Use

### Actions

Comply with in use **Planning Conditions** in relation to sustainability (e.g. meeting ongoing renewable energy use requirements).

Use observations from the light touch **Post Occupancy Evaluation** to fine tune and improve and **Sustainable Outcomes** performance against the **Sustainability Outcomes** targets, and keep the **Building Manual** up to date.

Undertake more detailed diagnostic or forensic **Post Occupancy Evaluation** as required, after putting in place separate professional services contracts, to test delivery of the in use **Sustainability Outcomes**.

Report and mitigate any deviation from the **Sustainability Outcomes**.

Share **Feedback** from lessons learned with the client, users, design and construction team members and with **Project Stakeholders**.

### Delivering outcomes

- refer to the *RIBA Sustainable Outcomes Guide*

Evaluate **Sustainability Outcomes** and building performance using diagnostic (and forensic) **Post Occupancy Evaluation** and **Feedback** provided to client and **Facilities Management** team.

**(Net zero) Operational Energy and CO<sub>2</sub>**  
(kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Gather **POE** data to evaluate the energy use for the building.

Disaggregated energy data used where possible for zone-by-zone and/or system-by-system analysis of energy use and CO<sub>2</sub> emissions.

**(Net zero) Embodied Energy and CO<sub>2</sub>**  
(kWh/m<sup>2</sup>/year and kgCO<sub>2</sub>/m<sup>2</sup>/year)

Gather **POE** data to evaluate, for example, the appropriateness of thermally massive elements.

**Sustainable Connectivity and Transport**  
(kgCO<sub>2</sub>e/km/person/year)

Gather **POE** data to evaluate, for example, the expected levels of car use and bicycle storage and use. Occupant survey can gather information on transport choices.

**Sustainable Water Cycle**  
(litres/person/day)

Gather **POE** data to evaluate the use of potable water, **Sustainable** recycling and reuse rates and attenuation.

### Sustainable Land Use and Biodiversity (increase in species)

Gather **POE** data to evaluate the establishment of ecosystems and success of new biodiversity.

### Good Health and Wellbeing (various)

Gather occupant **Feedback** data to measure subjective aspects. Monitoring equipment used for quantitative metrics, such as daylight.

### Sustainable Communities and Social Value (various)

Gather **POE** data to test the social value performance. The Social Value Toolkit or similar can be used to quantify efficacy of measures.

### Sustainable Life Cycle Value (£/m<sup>2</sup>)

Gather operational cost data to assess life cycle value and consider life cycle impacts (costs, resource use, etc) of services and fabric maintenance and repair regimes.

## Sound outcome

**POE** derived lessons learned fed back to all stakeholders.

Knowledge shared and performance outcomes published where possible.

**Feedback** used to drive performance in use improvements to optimise building performance.

Any deviation from the **Sustainability Outcomes** reported and mitigated.

## Procurement Strategy

The **Procurement Strategy** needs to be considered from an early stage in a project as it has a fundamental impact on how a project is organised. The **Procurement Strategy** influences:

- who employs the design team, particularly during Stage 4
- when the construction team are appointed
- when the construction team's involvement begins
- who might inspect the building works as they progress
- how the **Project Programme** is structured and how it manages risk
- who is contractually responsible for **Project Risks**
- who is responsible for the design
- when the specialist subcontractors become involved in the design work
- what information is required for inclusion in the **Building Contract**.

The choice of **Procurement Strategy** does not fundamentally alter the design process during Stages 2 and 3. However, the information that will be produced at each stage needs to be carefully considered to ensure the best value is delivered by the design team and construction team. In particular:

- comprehensive information to minimise the **Project Risks**
- detailed information to lock down key aspects of the design critical to the quality of the outcome before tendering
- a balance of **Descriptive Information** and **Prescriptive Information** to optimise best value: ensuring that the products crucial to the design intent and design quality are specified by the design team, and that the construction team are able to influence the selection of others
- coordination between the different core design disciplines, including the cost consultant
- clear and coordinated **Project Strategies** that explain the background to each aspect of the project and minimise the need for changes at Stage 4.

The choice of **Procurement Strategy** has its biggest impact on Stage 4, as it dictates when specialist subcontractor design work will be undertaken. It can also affect who employs the design team, and whether the design team will be novated to the contractor or the contractor will appoint their own. The impact for each **Procurement Strategy**, including the impact on the **Design Programme**, is as follows:

### Traditional

Under traditional **Building Contracts**, the design team's technical design information will be issued for tender to a number of contractors. This will usually comprise **Prescriptive Information**. However, it may also include **Descriptive Information** (often referred to as the Contractor's Design Portion in the **Building Contract**), where specialist subcontractors are to design discrete aspects of the building. Once the Building Contract has been awarded, the construction team can appoint specialist subcontractors to complete their design work, requiring pre- and post-contract **Design Programmes** to be developed. How the design team will manage the design work of specialist subcontractors, including the review of their information and how any tweaks required to the design team's information will be dealt with needs to be clearly defined. This will require the **Change Control Procedures** to be followed and an architect's instruction to be issued.

### One-stage design and build

Once the **Building Contract** has been awarded, the lead designer or the contractor's design manager will prepare a **Design Programme** which confirms when the design information from the design team and/or specialist subcontractors will be produced. A core consideration for this type of procurement is the amount of **Manufacturing and Construction Information** that will be produced by the client team as part of the **Employer's Requirements**. There should be sufficient detail to give clarity on areas of complexity, provide an accurate scope of work and define the detail for core aspects of the design and/or the production of **Final Specifications**.

### Two-stage design and build

The design team produce a concept design which forms the bases for the **Employer's Requirements** at the end of Stage 2. With the contractor appointed under a pre-contract design services agreement during Stage 3, the lead designer or the contractor's design manager can prepare a single **Design Programme** that confirms when the design information from the design team and/or specialist subcontractors will be produced. The core consideration with this type of procurement is whether this information will be produced before or after the **Building Contract** has been signed. Producing more information beforehand will give the client certainty of the detail, but this requires more time and might delay the start of work on site.

### Management contracting

Management contracting achieves the shortest **Project Programme** duration by maximising the overlap between design, procurement and construction. A number of packages for crucial **Building Systems** which need to be designed before work starts on site are likely to have been tendered and contracts awarded earlier in Stage 4. An integrated **Design Programme** can be created that includes the design work of both the design team and the specialist subcontractors. To bridge the gap between the **Design Programme** and **Construction Programme**, a procurement programme will be created and monitored. The timescale between issuing information for tender and issuing information

for manufacturing or construction will be shorter for **Prescriptive Information** than for **Descriptive Information**, because in the latter case a specialist subcontractor is required to produce the information for manufacturing or construction.

### Contractor led

Contractors provide a design team to develop then submit their concept design at the end of stage 2 as proposals for the tendering process, typically leading to two teams proceeding to Stage 3. The lead designer or the contractor's design manager will prepare a **Design Programme** that confirms when the design information from the design team and/or specialist subcontractors will be produced. During Stage 3, assessments will be finalised, and one construction team will be appointed preferred bidder. The preferred bidder will continue tendering core packages to finalise their contract sum. A 'shadow' design team may be part of the client team that review this information for compliance with the requirements of the **Building Contract**. The timing of the contract award will depend on the planning process.

### Procurement – Stage 5

The complexity of the overlap between Stages 4 and 5 has been considered at Stage 4. For all forms of procurement, awarding the **Building Contract** – so that construction, and therefore Stage 5, can commence – is a priority. However, this is sometimes not feasible, in which case the contractor may be appointed under a pre-contract services agreement. This might be to allow the contract sum or other contractual aspects to be concluded while allowing the design work of core specialist subcontractors to commence, or other aspects, such as **Site Logistics**, to be progressed.

The client team needs to be clear about who will be monitoring **Construction Quality** and progress and producing a regular quality report.

The only other procurement tasks during Stage 5 might relate to tenders for maintaining and/or operating the building before it is handed over. The **Information Requirements** for **Facilities Management** or **Asset Management** might need to be reviewed before tender documents are issued, to make sure that the information scoped at the outset of the project is still aligned with current best practice (the lag between commencing a project and the end of Stage 5 can be a number of years and so technology is likely to have moved on).

### Procurement – Stage 6

During Stage 6, the construction team will focus on rectifying any outstanding items on the **Defects List**, with the client team focused on **Aftercare** tasks. The issue of the **Final Certificate** closes out the **Building Contract**, ending the project team's involvement.

Any separate procurement activities required for the **Facilities Management** or **Asset Management** of the building are Stage 7 tasks.

## Employer's Requirements (ERs)

The **Employer's Requirements** are contractual. They can range from a copy of the **Project Brief** to a completed **Spatially Coordinated Design** with substantially completed technical design and specification information. They will generally include the professional services contracts of the design team members that will be novated, to ensure that the necessary services are carried out.

## Contractor's Proposals (CPs)

The **Contractor's Proposals** are the contractor's response to the **Employer's Requirements**. Where the **Employer's Requirements** consist of only the **Project Brief**, the contractor will need to complete a design, usually in competition with others. At the end of Stage 3 (or early in Stage 4) when more information is included in the **Employer's Requirements**, it is common for the **Contractor's Proposals** to include the same information as the **Employer's Requirements**. However, contractors may propose alternatives (frequently referred to as 'value engineering') in order to arrive at a more competitive tender. The information in the **Contractor's Proposals** supersedes the **Employer's Requirements**, although clauses in the **Employer's Requirements** will remain relevant to cover the final information to be completed by the contractor. A mechanism for reviewing the final **Manufacturing and Construction Information** also needs to be incorporated into the **Building Contract**.

## Novation

Under some forms of procurement, the employer of the design team changes from the client to the construction team, using a mechanism called novation. This allows the design team to work directly for the client during Stages 2 and 3 up until a **Spatially Coordinated Design** has been produced, and then for the construction team when preparing the **Manufacturing Information** and **Construction Information** at Stage 4.

PART

# Changing Processes

## 9

## CHAPTER NINE

## Setting Information Requirements

The task of setting the **Information Requirements** for a project is becoming ever more challenging due to changes in the way buildings are briefed, designed, manufactured, constructed and used. The **Information Requirements** for each stage perform two crucial functions. First, they allow the client to review and sign off the design development that has been undertaken during that stage, with an emphasis on capturing the key decisions made. Second, the information produced at the end of one stage drives the activities carried out during the next. Put another way, the **Information Requirements** need to consider not just the outcomes of the stage in which they are produced, but also how successful they will be in delivering the outcomes of the next stage. For example, an inadequate **Project Brief** at the end of Stage 1 may result in a sub-optimal **Architectural Concept** at Stage 2, or poor Stage 4 information might delay or hinder progress on site during Stage 5.

### Stage 0: Strategic Definition

The **Information Requirements** for Stage 0 will be dictated by the possible solutions for achieving the **Client Requirements** and the information required to build the **Business Case**. The diversity of options possible these are not considered in this publication.

### Stage 1: Preparation and Briefing

It is crucial at Stage 1 to consider the **Information Requirements** for Stages 2 to 5 inclusive, because the professional services contracts and **Building Contract** must clearly define what information the design team and the contractor are required to deliver at the end of each of these stages. This depends on the choice of procurement and planning routes, which might not change who produces the information required but will affect the timing and the contractual chain of responsibility.

Setting the **Information Requirements** is a core Stage 1 requirement, regardless of a project's scale or complexity. The challenge in defining what information is required is becoming ever more complex for a range of reasons:

- The use of digital tools is shifting the balance away from 2D information and towards 3D and data.
- Digital **Site Surveys** can enable 3D working from the outset.
- The timing of the **Planning Application** during Stage 3, and information required to make a submission, can vary.
- Different **Procurement Strategies** will have different **Information Requirements** at different stages.
- Both **Descriptive Information** and **Prescriptive Information** can be required at Stage 4.
- Modern methods of construction are changing how buildings are designed, manufactured and assembled.
- Information produced at handover can be used for **Asset Management** or **Facilities Management**.

These trends are considered in detail in this chapter of the Overview Guide, along with the factors that are driving further change.

With the range of information possibilities increasing, it is important that the **Information Requirements** are agreed with the client at the outset. On larger projects, the client team needs to set the **Information Requirements**, perhaps with the assistance of an information manager. On smaller projects, clients will rely on their professional advisers to recommend what information will add value to the process, such as a virtual reality model to help the client better understand the concept design.

## Site Information

While an Ordnance Survey (OS) map and some site photographs can often provide enough information to allow the design process to begin, digital survey techniques are providing more options for gathering **Site Information**. A wealth of recent innovations, including point cloud surveys, photogrammetry, lidar, the ability to mount cameras on drones, and even city-wide infrastructure models, have made it possible for accurate and detailed 3D **Site Surveys** to be carried out cost effectively on projects of all sizes, from the smallest refurbishment to the largest of greenfield sites. As a result, planning how the project information is set up, and ensuring that everyone will be using compatible digital tools, is becoming of greater importance to the success of projects.

For design teams shifting away from using 2D information, such as OS and topographical surveys, and towards 3D working, there are a number of considerations to be discussed with the client:

- How will the survey information be integrated into a federated model? It is commonplace for surveys to be converted into BIM models by the survey company; however, some will use native survey information which will require some additional resource to convert.
- How accurate does the information need to be? This will be dictated by how the survey information is to be used, and will determine what type of camera needs to be used, the survey time and the data file sizes.
- How extensively will the survey information be used during the design process? For example, will Manufacturing Information and Construction Information that relies on survey information be in 2D or 3D?

3D scans are particularly useful for unlocking the value of BIM on refurbishment projects. However, consideration needs to be given to exactly how **Site Surveys** are to be used. In some instances, survey work may need to be incremental; for example, to record aspects of a building as it is stripped out. On other projects, it might not be necessary to record every detail, such as the ductwork above a ceiling. A listed building may need to be surveyed to a greater level of accuracy, to ensure that key features are captured and to avoid the need for site measurements, such as for cabinetry and other work.

### Client considerations in Stage 1

- Deciding whether to adopt a BIM approach or leave the choice of methodology to the design team.
- Requiring access to the model or just the 2D outputs if a BIM approach is to be used.
- Defining which activities will use BIM e.g. site analysis, design, engineering analysis, construction information and asset management.
- Defining the minimum 2D information requirements.
- Identifying responsibility across the client, design and construction teams for for effective information management.
- Identifying any new tools to enable the client to support design team efficiency.
- Determining the value of using digital survey processes and data, and requiring a BIM as a deliverable model, including how accurate the survey information needs to be (e.g. a point cloud, lidar or photogrammetric survey).
- Assessing the BIM competence of the design team e.g. whether they have the experience to use a 3D scan .
- Clarifying whether the contractor can use the design team's information. e.g. for digital fabrication or verified construction information.

## The design stages: Stages 2, 3 and 4

Although each stage of the RIBA Plan of Work has its own unique purpose and outcomes, a complexity for setting the **Information Requirements** is that the design process spans three stages. Design work begins at the start of Stage 2, when the initial ideas are created, and runs through to the end of Stage 4, when all of the design information required for manufacturing and constructing the building is completed.

The aim of Stage 2 is to ensure that the **Architectural Concept** is robust, incorporates appropriate **Strategic Engineering** aspects and has been signed off by the client, before the work of the design team and the level of coordination increases in complexity at Stage 3. The RIBA Plan of Work emphasises that Stage 3 is about producing a **Spatially Coordinated** design.

During this period, the project must also be navigated through the planning and procurement processes. The timing for submitting the **Planning Application** and the timing for producing tender information (as determined by the **Procurement Strategy**) will vary from project to project. For this reason, planning and procurement are not included as RIBA Plan of Work stages. It has become common for the terms 'Stage 3 plus' or 'Stage 3 minus' to be used by the construction industry, but the RIBA Plan of Work stages cannot be adjusted in this way and remain consistent. The outcomes for each stage – set out in the Plan of Work Template and Stage Descriptions in Chapter Six – must always be completed and signed off before progressing to the next stage for a project is to be successful. However, these terms do recognise that it is sometimes necessary to extract information from the design process part way through a stage; for example, when submitting a **Planning Application** midway through Stage 3, or when using some technical

design information as part of the **Employer's Requirements** (for a one-stage design and build project) at the end of Stage 3.

Extracting information from the design process midway through a stage does not impact on the thrust of the design activity, but it does create risks and needs to be used with caution. While individual elements of information can be extracted during a stage, it is not possible for this information to be fully coordinated with the rest of the design information. Although the information might seem complete, it is likely to require further design iterations, to conclude the engineering aspects (including **Engineering Analysis** in Stage 3), coordinate it with **Project Strategies** and align it with the **Cost Plan**. It is simply not possible for information issued mid-stage to be fully coordinated; any client using such information needs to be aware of this.

In defining the information for a mid-stage gateway, it needs to be clear what information is to be produced, what tasks will underpin it and for what purposes it is required. Crucially, using information mid-stage does not remove the need to conclude the formal stage milestone, which is required to deliver the stage outcome before progressing to the next stage.

The **Project Programme** is a crucial tool for determining when **Information Requirements** are required outside the formal stage gateways. Once these mid-stage gateways are understood, the **Information Requirements** for each can be developed, the risks associated with issuing information early determined, and any mitigation measures put in place.

## Stage 2: Concept Design

There are no fixed **Information Requirements** for Stage 2. The specific **Information Requirements** need to be determined by the project team. These will vary depending on the complexity and scale of the project, the challenges of the brief and site, the views of the client team and, of course, what information most efficiently conveys that the stage outcome has been achieved.

The information challenge at Stage 2 is determining the contents of the **Stage Report**. Traditionally, a set of general arrangement drawings (plans, sections and elevations of the building at an appropriate scale) would be created to support the **Stage Report**, usually appendices in PDF format. With the use of BIM becoming more prevalent a new approach is being employed to produce **Stage Reports**: using 3D images (including 3D visualisations), cutaways and extracts derived from the BIM model to explain design decisions, and 2D views to demonstrate how the **Spatial Requirements** are being achieved.

Some architects may still work traditionally and wish to use sketches to convey the **Architectural Concept**. Others may wish to use virtual reality to walk the client around the proposals, and to issue a video of what the client has agreed to – as the core deliverable. The amount of supporting information required from other design team members will depend on the size and scale of the project. However, the **Stage Report** can be used to corral everyone's efforts, and to record the decision making that has influenced this information.

A core task during Stage 2 is to undertake **Design Reviews**. It is important that these involve all **Project Stakeholders**, so that their views are incorporated into the **Stage Report**. The **Project Strategies** set out in chapter Six provide more detail on how **Design Reviews** can be used to engage **Project Stakeholders** on key issues.

## Stage Report

The **Stage Report** records all of the relevant decision making during the stage for the future. On larger projects it is not uncommon for project team members to come and go, and for new team members to question the basis of the design. The **Stage Report** acts as a reminder of what decisions were made in relation to the design and the Project Strategies, why they were made and who was party to them, recording what options that were examined and why one was chosen over another. For example, if the sign-off process includes a formal **Design Review**, the **Stage Report** might include a section recording any comments made and the design team's responses, so that everything is captured in the single document.

The sign-off period can be standalone, or it might occur in parallel with the start of the next stage. On larger projects, it may be inefficient to stand down a large design team between stages, while waiting for the **Stage Report** to be signed off. The client and design teams should therefore agree if any work should progress into Stage 3 before the Stage 2 **Stage Report** is signed off.

A **Stage Report** is not usually produced at the end of Stage 4. However, some clients may request or require a report to record the decisions made during the stage.

## Tasks

Information is only as good as the data and tasks that underpin it. Failing to undertake certain tasks during Stage 2 can make Stage 3 more difficult. Conversely, undertaking too many tasks (which is easy to do) can divert effort away from achieving the stage outcomes. The tasks required at Stage 2 to underpin the **Information Requirements** should be clear in the **Responsibility Matrix** developed at Stage 1. These tasks should ensure that the **Architectural Concept** is as robust as possible and is aligned to the Cost Plan.

It is beyond the remit of this Overview Guide to consider what these tasks might be. A core consideration is whether rules of thumb can be used rather than detailed calculations. For example, a practice which has delivered many office buildings might not need to calculate stair sizes or toilet numbers as they can draw on their experience to determine what is likely to be required. They may also be able to take a view on likely riser sizes and plant locations, and have an understanding of structural grids that work, requiring fewer contributions from engineers and less BIM information as a result. Conversely, a client may wish these matters to be unambiguous and require the architect to calculate stair sizes and toilet numbers, and the engineers to confirm column sizes, bracing strategies and plant room and riser schedules, underpinned by calculations. There is no right approach. However, it is important that the project team understands the basis of the concept design information and the tasks underpinning it, and that the lead designer is confident that the tasks being undertaken are sufficient to deliver the stage outcomes.

## Specialist Consultants

The increasing number of specialist consultants involved in projects, including acoustics, fire and façade engineers, further complicates the challenge of task setting. A range of industry innovations, including the circular economy, lifecycle costing and offsite construction, now require new expertise within the team. It is therefore important for designers to identify when they are at the limit of their expertise in a particular area and when additional experts are required, either as specialist consultants or as new/newly trained staff within design consultancies.

Determining the need for specialist consultants is a key task at Stage 1. For example, the appointment of an acoustician might be essential for a school next to a railway line.

At Stage 2, specialist consultants should develop their **Project Strategies**, focusing on, as a minimum, any aspects impacting on the **Architectural Concept** or the **Cost Plan**.

## Information Requirements and the Procurement Strategy

The **Procurement Strategy** determines when the contractor will become involved in the project and who employs the design team. It has no impact on the Stage 2 **Information Requirements**, which confirm that the **Architectural Concept** meets the requirements of the **Project Brief**. However, on some projects, information confirming buildability, **Site Logistics** and other construction-related matters, such as the adoption of modern methods of construction in the **Construction Strategy**, will be more comprehensive and robust if the contractor is appointed and involved at Stage 2.

## Client considerations in Stage 2

- Deciding whether the client or design team will determine how tasks are split between Stage 2 and Stage 3
- Determining how innovative the workflow will be – whether it will be ground breaking or traditional - and how experienced the design team are in new ways of working,
- Establishing whether 2D and/or 3D information formats are required to inform client decision-making.
- Determine the need for specialist consultants on the project and whether light touch or comprehensive involvement is required.
- Identifying what tasks are needed to ensure the **Architectural Concept** is coordinated with the **Strategic Engineering** requirements and aligned with the **Cost Plan**.
- Deciding who will produce the **Construction Strategy** at Stage 2.

## Stage 3: Spatial Coordination

The focus for Stage 3 information, after the **Architectural Concept** is approved by the client, pivots towards **Engineering Analysis** – developing the detail of the architectural proposal via **Design Studies**, developing the **Project Strategies** and testing the **Cost Plan** further. At this stage, the engineering output is geometric, such as column and beam dimensions or ductwork sizes, and calculations or analyses are not usually required.

The **Planning Application** is usually submitted at the end of this stage, based on **Information Requirements** set by the local authority. The timing of the **Planning Application**, particularly where this is undertaken using information from a mid-stage gateway is one of the main information considerations at Stage 3. Another key consideration is whether the **Procurement Strategy** needs **Employer's Requirements** to be produced and, possibly, some technical design information to be created in tandem, as part of this documentation.

### Submitting a Planning Application during Stage 3

The optimal time for submitting a **Planning Application** is at the end of Stage 3, once design information is **Spatially Coordinated** and at the level of detail expected by a planning authority, the **Stage Report** has been signed off and the **Planning Application** documents have been prepared. A comprehensive and coordinated application will facilitate an efficient planning process. At the end of Stage 3, for example, energy analysis, daylighting calculations and other aspects, such as plant room requirements, will be coordinated.

It is common for **Planning Applications** to be submitted midway through Stage 3, in order to gain early clarity on a proposal's feasibility, including the scope of any section 106 contributions. When a **Planning Application** is being submitted at a mid-stage gateway, there are a number of questions that need to be considered:

- What **Design Studies** need to be completed? For example, detailed studies of the elevations.
- What **Engineering Analysis** might be required to underpin the proposal? For example, an energy strategy.
- What contributions from specialist consultants are required? For example, from a sustainability adviser.
- How will the increasing amount of multi-disciplinary information required be integrated into the Stage 3 **Design Programme**?
- How does the mid-stage **Planning Application** submission date relate to the completion of Stage 3 in the **Project Programme** when the assembling of information may take some time?

A poorly managed mid-Stage 3 **Planning Application** can result in amendments being required later in the **Project Programme**, after Stage 3 is completed. This option is therefore only recommended for experienced clients who know what information is required, and for seasoned design teams who know empirically what design development needs to be undertaken. Ultimately, a mid-Stage 3 design is not **Spatially Coordinated**, and while risks to the deliverability of the project can be mitigated, they cannot be eliminated entirely.

### Client considerations in Stage 3

- Establishing whether the cost circumstances or programme certainty requiring a **Planning Application** to be submitted before the end of Stage 3.
- Determining whether the project team have the experience necessary to submit a mid-stage **Planning Application** and to split the Stage 3 tasks accordingly.
- Identifying which tasks need to be undertaken and information gathered to provide a robust **Planning Application**.
- Establishing how the **Procurement Strategy** influences the interface between Stages 3 and 4, how this is defined in the **Project Programme**, and whether any early **Information Requirements** are clear.

### Stage 4: Technical Design

Although the Stage 4 outcome is clear and unambiguous (i.e. all design information required to manufacture and construct the project completed), this stage presents the biggest information challenges. There are a number of complexities that need to be considered when defining the Stage 4 **Information Requirements**:

- Will the design team produce **Descriptive Information** or **Prescriptive information**?
- What modern methods of construction will be used?
- How will the shift towards digital design impact on the information required?
- How will the **Procurement Strategy** impact on the **Design Programme**?

#### Prescriptive Information vs Descriptive Information

As the design information develops, the level of **Prescriptive Information** increases as shown in Figure 3 below. During Stage 4, the design team must produce **Prescriptive Information** for use in construction on site, or **Descriptive Information** for use by specialist subcontractors in the design and manufacturing or construction of particular **Building Systems**. When deciding whether the design team should deliver **Prescriptive Information** or **Descriptive Information** for a particular **Building System**, the following factors should be taken into account:

- **Descriptive Information** is already industry standard for many **Building Systems** (including piling and aspects of building services, such as building management systems).
- **Prescriptive Information** is essential where the contractor must adhere to a specific design, perhaps as a requirement of a **Planning Condition** (such as the use of a specific brick or window system) or because the client and/or design team wish to determine design quality (for example, the balustrading, doors and finishes in an entrance lobby).
- Some **Building Systems** tend towards **Descriptive Information**, including façades and mechanical services, to allow a specialist subcontractor to generate an innovative solution.
- There are a small number of **Building Systems** where the design team produce **Prescriptive Information**, but where the **Manufacturing Information** then needs to be produced by a supplier. For example, the architect might specify and set out the cubicles in a toilet, with the supplier requiring shop drawings for the elements of the cubicles to be made.

- For some **Building Systems** for which **Prescriptive Information** has traditionally been used, **Descriptive Information** can also be issued at Stage 4. This provides the contractor with a degree of flexibility within clear quality and safety parameters when determining the final product supplier.

Figure 3 Descriptive and prescriptive information.

Guidance on **Information Requirements** for structural engineering is being developed by the Institution of Structural Engineers. For building services engineering, BSRIA has produced a comprehensive document, *BG 6: A Design Framework for Building Services* (5th edition, 2018), that sets recommendations for level of design detail for each stage of the RIBA Plan of Work. There is currently no authoritative guidance on the use of descriptive specifications in architecture.

A common misconception is that **Descriptive Information** is used by the design team to limit workload. This may be the case where the design team's commission ends at a particular stage. However, where the design team are appointed through all of the design stages the decision to produce **Descriptive Information** is likely to be time neutral. This is because the scope for the specialist subcontractor's design needs to be defined, interfaces drawn and a specification produced. Furthermore, meetings must be held with those tendering for the work, workshops conducted with those who are successful, and the designs of the successful tenderer reviewed. However, the use of **Descriptive Information** will increase the challenge of coordination for the lead designer, particularly if two descriptive packages interface with each other. The specialist subcontractors' design costs, which will be built into their tender returns, also need to be considered.

## Transforming construction

As contractors increasingly adopt modern methods of construction, Stage 4 deliverables are changing. Some of the more progressive new methods, such as volumetric modular, need to be embedded into the design and transform **Information Requirements** from Stage 2. The RIBA Plan of Work acknowledges this shift by encouraging the preparation of a **Construction Strategy** at Stage 2. This allows the design team to consider at an early stage which modern methods of construction will be appropriate for the project, given that, in many instances, the contractor may not be part of the project team until a later stage.

Many clients are embracing design for manufacture and assembly (DfMA). Organisations such as the Supply Chain Sustainability School are sharing knowledge and skills across the industry to those who are interested in this methodology.

See: <https://www.supplychainschool.co.uk/topics/offsite/design-manufacture-assembly/>

## Changing deliverables

Stage 4 is set to evolve over the coming years – the project team needs to be alert to the depth and breadth of the disruption that will occur. In the future, the core decisions around Stage 4 **Information Requirements** will shift beyond the 2D/3D debate and setting the **Construction Strategy**. The construction industry is starting to use programme approaches drawn from the manufacturing industries geared towards repetition, including different software and more stringent change control processes and product lifecycle management. This way of working is starting to be used for manufacturing whole **Building Systems**, not just individual construction products, leading to increased standardisation and repetition in large parts of buildings, although not in every sector. The increasing use of robotics for assembling buildings, both in factories and on site, also raises new considerations and information requirements, including the kinematic studies required to analyse robotic assembly.

### Client considerations in Stage 4

- Defining which **Building Systems** will be specified by the design team to **Descriptive Information** and which to **Prescriptive Information**.
- Determining the most appropriate modern methods of construction for the project and establishing who has the experience to advise on and/or determine which should be adopted.
- Establishing what type of information is required: traditional 2D details and setting out, or 3D data-rich information?

## Stage 5: Manufacturing and Construction

### Handover information

One of the biggest transformations driven by BIM level 2 has been the ability to extract data that can be used for maintaining and operating an asset from the **Manufacturing Information** and **Construction Information**. This has primarily been driven by the Construction Operations Building information exchange (COBie) schema, which sets the data attributes for each project stage. Further developments in using data for **Asset Management** are transforming project handover information well beyond the traditional

'as-constructed' information and the health and safety file and fire safety information required to comply with CDM and Building Regulations.

Project team members must now consider what **Asset Information** is required at handover; those receiving it are not always ready to use it effectively, and those delivering the information required to construct a building often do not have expertise in providing the information that will transform **Asset Management** or **Facilities Management**. Information deliverables must therefore be defined at the outset, so that the relevant information can be incrementally developed as the project progresses. The information produced at the end of the design and construction process can provide significant benefits throughout the period the building is in use. However, in order to achieve the outcomes required, the delivery requirements for **Asset Information** need to be defined accurately and specifically.

**Information Requirements** in the RIBA Plan of Work at Stage 5 include:

### **Building Manual**

A **Building Manual** provides the means for a building's owner and/or user to maintain the building effectively and safely. It might include guides to using equipment effectively; for example how to operate the heating system and any energy devices, such as photovoltaics. By law, it must include the **Health and Safety File** and **Fire Safety Information**.

### **Health and Safety File**

The preparation of a **Health and Safety File** is a requirement under CDM 2015 that must be handed over to the client before the client occupies the building. It must contain relevant information about the project which should be taken into account when any construction work is carried out on the building after the current project has finished. Information included should only be that which is needed to plan and carry out future work safely and without risks to health. See the Health and Safety Executive's guide to CDM L153 for more information: <https://www.hse.gov.uk/pubns/books/l153.htm>

### **Fire Safety Information**

Under Regulation 38 of the Building Regulations, **Fire Safety Information** must be handed over to the responsible person not before the completion of the construction work, or the date of occupation of the building or extension, whichever is the earlier. This information relates to the design and construction of the building or extension, and the services, fittings and equipment provided in or in connection with the building or extension which will assist the responsible person (owner/client) to operate and maintain the building or extension with reasonable safety.

### **Verified Constructed Information**

A complete set of the **Manufacturing Information** and **Construction Information** is not typically issued at handover, instead, the design team issues **Asset Information** (sometimes known as 'as-constructed' information) for the building. This comprises the last set of information that the design team issued to the contractor for construction. 'As-constructed' information is a misleading term as it is unusual for the information issued to have been verified against what was actually built on site, covered up works in particular. Floor area is sometimes checked post-handover in the commercial sector, so that the surveyors' measurements can be used to calculate the

rent to be charged to tenants. Laser measurement devices allow these spot checks to be undertaken easily, and point cloud surveys can be used to compare the completed building against what should have been built.

Inspections throughout Stage 5 are required to confirm that the contractor is meeting **Construction Quality** requirements. At the end of Stage 5, there are a number of means of verifying construction information, including a visual inspection to determine that the building has broadly been built as per the last set of information issued, a dimensional survey to ratify that it has been constructed as modelled (this might necessitate adjustments to the model if this is not the case), through to a 3D laser scan that can be compared with the federated model. Clearly, the costs associated with the different options vary and each client needs to determine how accurate they need this information to be, and who will undertake the work. Circular economy principles point towards more information being required at the end of a building's life, so that its **Building Systems** can be repurposed effectively.

### CAFM Systems

Computer-aided facilities management (CAFM) systems allow those responsible for the maintenance of a building to manage maintenance and repairs, both reactively and pre-emptively. Many CAFM systems are not currently capable of managing BIM information, but this will happen in time. CAD information derived from the model can be used to manage changes to the building, such as partition alterations or furniture moves. To be effective, this information needs to be updated as changes are made. Clients need to consider who will provide this resource during the life of the building.

### Asset Management information

In CAFM systems, building assets need to be tagged to record the information required to manage them, ranging from serial numbers through to manufacturers' maintenance cycles. It is crucial for the client to consider which building assets need to be tagged, and whether a particular classification or referencing system will be used, perhaps to align with an existing estate.

### Digital Twin

A **Digital Twin** is a digital replica of a building or part of a building, that can mirror the way the actual building performs. A **Digital Twin** might be a simple model of the electrical or mechanical systems that can be digitally tested or could be a complete working digital building. A **Digital Twin** should be updated over the course of a building's life, whenever changes are made to the building – perhaps to enable new uses or in line with **Asset Management** tasks. The core goal of a **Digital Twin** is to enable the actual performance of the building to be assessed against the predicted performance, allowing **Building Systems** to be honed appropriately or **Feedback** to be provided for future projects. Predictive analytics can be used to determine when plant is operating poorly, allowing pre-emptive maintenance. Gathering data from a number of **Digital Twins** allows connected networks to be considered, enabling broader networks to be improved and allowing design criteria to be adjusted for future projects across a programme or estate.

### Client considerations in Stage 5:

- Considering how the building will be maintained and operated.
- If so, determining what **Asset Information** needs to be delivered at Stage 5 in order to do so.
- Deciding whether data is required for **Asset Management** or **Facilities Management** or to demonstrate that better outcomes have been achieved.
- Establishing what data is required at the handover of the project.

## Beyond level 2: from BIM to digital

It was always anticipated that once level 2 BIM had been assimilated and absorbed, the next target, level 3, would be conceived by the UK government, creating a new objective for the construction industry to work towards.

However, as level 2 BIM matures, the UK government has moved its support away from the concept of BIM level 3 to enabling a Digital Built Britain. The Centre for Digital Built Britain has identified a number of digital construction technologies and processes beyond BIM such as AI, the Internet of Things, **Digital Twins** and offsite manufacturing initiatives as future trends to be investigated. As these technologies mature at their own pace, clients will need to keep abreast of developments to understand how to define the workflow of the design team and contractors, and use their asset efficiently. ([www.cdabb.cam.ac.uk/](http://www.cdabb.cam.ac.uk/)).

The design team are also innovating. The use of virtual reality during Stage 2 to review design ideas and processes is becoming business as usual, reducing the requirement for 2D information as a contractual deliverable. The use of parametric and generative design is increasing, allowing options to be tested more rigorously, with rules-based design becoming more commonplace. Those undertaking the lead designer role are shifting away from clash detection, towards using digital for proactively coordinating the design. The planning system still requires **Planning Applications** to include traditional 2D deliverables, but this too may change in time.

As many in the industry contemplate how to embrace and adopt these transitions from traditional design and construction processes, the next wave of technologies is already upon us. The challenge for those considering how to incrementally develop their workflow in future will be in determining which of the many digital tools and technologies will be most appropriate for how they want to work. Rates of innovation and adoption will vary between project and design team members. Not every architect wants to leverage the power of parametric modelling and not every client requires **Asset Information**, although every client would welcome better performance of their buildings.

As the choice increases, the challenge will be to select the tools that will create the most immediate - and whole-life - benefits for those involved in the process. At some point, disruption will occur. Every other industry has seen pending disruption drive greater urgency in developing new business models to unlock value from new processes.

It is likely that the coming change will be focused around the following technologies:

- **Rules-based design**  
Design automation is possible where detailed rules for spaces, adjacencies and building systems can be determined by repeat clients. If designers can conceive how to utilise this technology for faster and smarter design processes, the efficiency gains may be

returned to design teams, allowing them to invest resources in providing more valuable outcomes-focused advice to their clients.

- **Generative design**

By using complex coding scripts, it is possible to generate a multitude of design options instantly. The challenges when using this approach are how to develop software that considers the correct project drivers and quality aspirations, and how to filter a potentially infinite number of design options down to a handful, that can then be developed and concluded using a traditional design workflow.

- **4D**

Today, 4D (3D plus time) tools are primarily being used by contractors during the tender process to unlock the most efficient way of manufacturing and constructing the building, giving them an edge over their competitors. 4D tools also enable contractors to convince the client team that their proposals are robust and realistic. It is likely that as lower cost 4D software becomes available, 4D reviews will be commonplace at Stage 2, at the point when the design team can demonstrate how their proposals can be constructed. How procurement reacts to this change will be central to unlocking the value of contractors and their supply chains.

- **5D**

5D enables the addition of the cost dimension to 4D information. Although BIM has shifted Cost Plans towards a revival of bills of quantities (generated from the federated model), a more manufacturing-based workflow points to a future where bills of materials can also be extracted from the federated model.

- **Integrated system analysis**

At present, one of the biggest challenges for the lead designer is the time lag between the current design proposals and some aspects of engineering analysis. For example, daylighting and energy calculations cannot provide real-time feedback from the architect's model. When available, engineering analysis software that provides real-time contributions to the architectural development will make the design process more accurate, saving design time and, crucially, allowing design decisions to be based on high-quality data.

- **Manufacturing workflow**

Designing for manufacturing and assembly (DfMA) is rapidly being seen by clients as the way to transition towards faster and more effective ways of making buildings, and by contractors as a way to lower the costs of delivery and reduce risks. However, construction has many years of momentum behind it, being underpinned by suppliers and product manufacturers who have evolved together over a long period of time. Shifting towards greater use of manufacturing requires suppliers to consider the products of the future, designers to look at manufacturing-oriented tools and software and consider transformative design workflows, and clients to be open to innovation, before a track record of case studies exists.

- **Artificial intelligence**

Artificial intelligence (AI) is unlikely to drive disruption in building construction in the short term due to the disaggregation of information. Machine learning in particular, needs huge volumes of information to detect patterns for supervised learning. Holding large databases of projects will enable clients or designers to begin to use their models and information more effectively, but consistent classification and other factors will be crucial in making AI work. In the long term, it is inevitable that AI will drive new ways of designing, and of making the connections necessary to drive better client outcomes.

Other technologies, such as blockchain, are also emerging as innovations that will transform how the industry will work in the future. However, if new solutions simply continue to be plugged into traditional design and procurement models, disruption is unlikely. Disruption requires a step change in how project teams brief, design and make their building, resulting in better outcomes, such as faster design, faster manufacturing and construction, smarter ways of designing and better information at all project stages.

Everyone in the project team needs to be alert to the trends and nascent technologies that will result in better **Project Outcomes**. Determining when a technology or tool is sufficiently robust to be used is a core challenge, as it is difficult to integrate new tools into live projects. At the start of a project, it is worth considering how new tools or technologies might improve the **Information Requirements** for each stage. A training programme might be required to bring everyone up to speed before Stage 2 commences, but the time needed for this will be offset by better **Project Outcomes**.

Towards a  
Transformed  
Construction  
Industry:  
Programmes,  
Practice and  
Research, by  
Dale Sinclair

## 10

## CHAPTER TEN

# Towards a Transformed Construction Industry: Programmes, Practice and Research, by Dale Sinclair

As clients become better informed – as a result of the UK government's level 2 BIM strategy, the world wide web and in house experts to deal with sustainability or modern methods of construction – their expectations are also increasing. Although the RIBA Plan of Work was established to make individual projects more effective, professional clients now expect greater consistency of outcomes between one project and the next by using programme approaches to drive further efficiencies where required, such as on reducing energy costs or improving the user experience.

The demands of the well-informed client are compounded by a wave of new trends and innovations gathering momentum by the day.

In this context, those who fail to undertake **Research and Development** initiatives to enable them to embrace innovations – to transform their design process, become more efficient or build their knowledge base – risk finding it increasingly difficult to compete against peers who are transforming the way they work.

The wide range of trends currently influencing the design of buildings that project teams should be abreast of include:

- **Post Occupancy Evaluation** and the need to improve building performance
- the circular economy and the drive to minimise the use of the planet's resources
- DfMA and other modern methods of construction that are transforming traditional construction methodologies
- BIM, which is progressing beyond a narrow focus on the geometry in the federated model towards the use of digital tools that will leverage data more effectively as part of an evidence-based design process
- new information focused on the more effective operation, maintenance and use of buildings
- parametric and generative design processes driven by the scripting skills of many recent graduates to develop new ideas for their projects
- ethical project considerations which might range from the source of construction materials to ensuring that the local community is properly engaged on a project from the start
- the myriad of digital trends, including artificial intelligence in its various guises, such as machine learning.

The breadth and depth of knowledge required to keep up with these trends can require **Research and Development** resources and initiatives. But when the market for fees is competitive and client expectations are high, it is difficult to allocate the resource for **Research and Development** at the same time as improving design efficiency and

the bottom line – even though it might be the differentiator that wins more work. The commitment to **Research and Development** requires a leap of faith.

Practices and clients must consider the following aspects of **Research and Development** carefully:

- Which trends are client groups interested in?
- How can these be incorporated into proposals?
- What digital tools can add value to the design process and how might they be used on specific projects?
- Are new skills required in the practice to increase knowledge or promote the use of state-of-the-art tools?

Deciding whether investment in **Research and Development** should be made on- or off-project is a core consideration. Introducing innovation into projects can help to offset investment costs. However, the demands of delivering designs, and the corresponding information, to the required **Construction Quality** and to increasingly fast-paced **Project Programmes** can mean that the time and resources for **Research and Development** activity must be undertaken and resourced outside projects.

Trends that clients and practices might consider from a programmatic perspective are detailed below.

## Project Outcomes

Buildings have been delivered for clients for centuries, but the process and focus has evolved over time. Design teams were formed in the early twentieth century as **Building Systems** became more complex. Project managers brought greater focus on the **Project Programme** at the end of the last century and, at the beginning of the twenty-first century, BIM placed greater emphasis on improving **Asset Management** and **Facilities Management** outcomes. Now, the overarching focus for building projects is better **Project Outcomes**; that is how buildings perform for their users – making people happier at home, achieving better exam results in schools or facilitating faster recoveries in hospitals.

See the *RIBA Sustainable Outcomes Guide* for further advice on building performance related **Project Outcomes**.

At this point in time, **Building Contracts** are framed around the delivery of the physical work. However, the increasing focus on **Project Outcomes** suggests that, in future, obligations to meet key metrics for the building, such as improving on a specified energy target, may be included.) In the future, if rent is calculated, not by the square metre, but by how building performance enhances productivity then client's may pass this requirement down to the project team in their contracts. **Project Outcomes** will increasingly blur the contractual boundaries between handover and the effective use and positive impact of a building on its users.

## Quality Aspirations

The three principles of procurement have always been time, cost and quality. Convention has always dictated that two of these drivers can be delivered by the **Procurement Strategy**, but not all three. The ability of design and build forms of procurement to deliver favourable time and cost outcomes is now a deep-rooted belief for many clients. One issue is that the definition of quality covers a wide range of factors from the materials and

**Building Systems** that shape the look and feel of building, to ensuring that the construction has been carried out in accordance with the relevant standards and codes, and ensuring that the building performs as required. Who is responsible for each aspect of design quality is a key consideration. A number of recent project failures, including the Edinburgh schools failures and the Grenfell Tower tragedy, have brought the quality agenda back into sharp focus and there is an urgent imperative to achieve better **Quality Aspirations** with all forms of procurement.

The following measures for the project team to improve **Quality Aspirations** are currently under consideration:

- establishing a 'golden thread' that runs through the whole design process so that it is clear who is responsible for each aspect of the design and for the **Final Specifications** for each **Building System**
- considering the use of **Prescriptive Information** for core quality aspects to avoid any ambiguities in relation to quality and safety, particularly for core **Building Systems** (this may need to be a contractual requirement in any case to ensure that materials scheduled in the **Planning** consent are used)
- reviewing and commenting on the design work of the construction team, including the **Final Specifications** of products
- undertaking inspections of construction throughout the duration of the project
- defining quality beyond the constraints of cost, to encompass sustainability and health and safety considerations.

## Project Programme

One of the four core goals of Construction 2025, the UK government's Industrial Strategy for Construction, was to reduce the time taken to deliver projects by 50%. This target is difficult to achieve with current design and construction workflows and current planning processes. However, it may be possible to reduce **Project Programme** timescales by implementing the following measures while carefully considering their risks:

- The timescale for achieving the **Planning** consent necessary to allow a start on site can be in excess of six months from submission of a **Planning Application**. A means of giving clients greater clarity regarding the acceptability of the proposals prior to achieving consent needs to be found to reduce these timescales. For example, agreement in principle to the proposals for the site (including areas and uses) and to the level of developer contributions would offer the client greater certainty in commissioning the design team to prepare more detailed information or allowing enabling works to commence.
- Ways to reduce the number of iterations of the design team's model by better integrating the federated model with **Engineering Analysis** software must be developed. The development of software may also allow more accurate data to be produced at Stage 2, rather than relying on information generated by rule of thumb, further reducing Stage 3 timescales as a result.
- A reduction in Stage 4 timescales could also be made possible by a shift towards object-based modelling or the ability to integrate construction and/or fabrication information into the model at an earlier stage. Clients therefore need to consider how the effective application of more accurate information might improve the procurement process.

- The shift from construction towards manufacturing-based processes has the potential to significantly reduce the overall project programme, especially on groups of projects, but will require new, larger sub-assemblies to be conceived and the existing off-site industry provision to be scaled up.

There are no right or wrong approaches to reducing **Project Programmes**; however, these measures do require design and construction teams with the right collaborative behaviours and willingness to reduce project timescales.

## Design Programme

**Design Programmes** will evolve in the future to reflect improvements in the integration of the design team's digital information as more effective **Design Review** processes, geared to real-time viewing of the design team's model, make the design process more efficient.

Workflow geared towards a more effective synthesis of **Engineering Analysis** software with the architect's model will reduce the number of design iterations, for example, by allowing architects to make more accurate and earlier judgements on the requisite percentage of glazing. Object-based modelling will transform the way in which projects are integrated into workflow.

## Digital Execution Plan (DEP)

The **DEP** represents an evolution of the BIM execution plan (BEP) promoted by UK BIM level 2. The **DEP** is the core document for setting out how the design team will use digital tools on a project. A BEP has two focal points: first, it allows the design team to demonstrate that they have the relevant experience, skills, software and hardware to produce the **Information Requirements**; and second, it sets out how they will use these tools to undertake the project, including details on collaborative workflow and file naming.

The **DEP** begins to consider issues beyond the modelling strategies, looking at the connectivity of all of the software used on projects, including that employed in **Engineering Analysis**. The ultimate goal for the lead designer is to reach the point where **Engineering Analysis**, or other software used by the design team, is integrated seamlessly into the federated model, giving real-time feedback on proposals as they are developed.

Significant benefits will result as the design team improve the connectivity of their models and their software packages. It is also crucial for the client and construction teams to consider how they might change their working methodologies to make the project workflow more efficient. For example, the client team might undertake **Design Reviews** using 3D rather than 2D information, which would require training in how to use new tools. Many construction teams are ahead of the digital curve but, given the current speed of change, more can always be done; for example including using new software tools to allow setting-out dimensions to be taken directly from the design team's model (avoiding the need for dimensions to be added onto a separate 2D layer), or employing robotics for use cases, such as demolition, MEP first fix or setting out of partitions.

Critically, no one in the project team will be immune to the extensive changes that will take place in the future, although some clients may fight to keep existing processes in place until more pilot projects or processes have been tested and verified. This underlines the increasing need to agree the **DEP** at the outset of a project so that it is clear which digital tools will be used, allowing workflow diagrams to be created to inform all parties.

## Construction Strategy

While many infrastructure and public sector clients are leveraging the benefits of early contractor engagement, private sector clients tend to value the benefits for the **Quality Aspirations** of managing the design team and the design process through Stages 2 and 3 until Planning consent is secured. This approach allows different construction teams to tender on the basis of one- or two-stage design and build tenders, bringing value to a number of **Building Systems**, where they might have a technical advantage over their competitors, or can bring more effective logistics that will reduce the **Construction Programme**, without diminishing quality and performance.

With greater uptake of modern methods of construction, a core future dilemma for clients will be determining the most appropriate form of construction. For example, volumetric construction requires early decisions and discussions with potential fabricators who may have manufacturing constraints such as wall thicknesses or unit sizes. Similarly, the increasing use of offsite manufacturing points to larger sub-assemblies being used on buildings in the future, from the increased use of toilet pods to pre-manufactured building services modules. Where a specialist subcontractor is required to develop these aspects, a 'chicken and egg' scenario is created: the design team is unable to complete their **Architectural Concept** until the fabricator is known and the client team is not prepared to enter into a **Building Contract** until the **Architectural Concept** has been concluded. Finding an effective means of resolving this sequencing conundrum will be crucial to the future of procurement.

There are major challenges to be overcome in creating the construction materials of the future. Many architects are looking to use new materials on their projects to deliver better performance or a new design language. However, under a design and build contract, the construction team may be unwilling to take responsibility for a new and untested material. **Research and Development** must be undertaken to develop a new generation of materials that are lighter, have good insulating properties yet are resistant to heat absorption, are safe to install and maintain and resistant to fire while proving, that they will remain robust for the life of the building.

## Cost Plan

Most design teams are well versed in producing a federated model of projects but, for some reason, the uptake of 5D BIM (cost) linked to these models has been slow. Those undertaking the lead designer and cost consultant roles need to consider how to use the data from the federated model more effectively in creating the **Cost Plan**. A core issue with 5D BIM is that any software tools can only read the data from the aspects of the project that have been modelled. In the short term, until workflow incorporating 5D BIM is better established, those wishing to use such technologies will need to consider how the **Cost Plan**, federated model, **Outline Specification** and the modelling of the different **Building Systems** can best work together as the design progresses.

## Outline Specification

An **Outline Specification** fulfils a number of purposes. First, it conveys to the client team the quality of the proposed finishes, presented via sample boards at a client's Design Review. Second, it allows the cost consultant to align the **Cost Plan** with the level of specification appropriate to the design team's **Quality Aspirations** for each **Building System**.

Many **Building Contracts** have been shifting away from **Prescriptive Information** and towards **Descriptive Information** in recent years. This approach offers the construction team maximum flexibility in determining the products to be used on a project and how these products can be brought together. Conversely, it pushes a great deal of coordination work to the end of the design process. The client therefore needs to be certain that the construction team has the requisite experience to specify products that will meet the demands of the **Descriptive Information**; for example, the compatibility of a fire door with its specified ironmongery.

As designers begin to use object-based modelling more and more widely, a return to **Prescriptive Information** in specifications is emerging. This programmatic and pragmatic approach to specification can be effectively leveraged by repeat clients and design teams alike. Consistent use of products from one project to the next has the following advantages:

- allows greater cost certainty
- minimises interface issues between different **Building Systems**
- ensures that the best possible digital information can be leveraged from the outset
- reduces time spent researching materials for individual projects
- reduces maintenance issues due to **Feedback**
- minimises the possibility of errors when materials are used together for the first time.

Once the comprehensive specification work has been undertaken and the right products with the optimum balance between cost, aesthetics, sustainability, safety, buildability and maintainability have been chosen, they can be locked down and specified at an earlier stage. 5D technologies can schedule quantities earlier than industry norms, giving clients a clear understanding of costs earlier in the process. This approach raises the question of who takes responsibility for the products – the design team on the project or those who have developed the programme-wide library of products? Clients need to consider whether the benefits of repeatable and consistent products outweigh the benefits of the construction team specifying later in the design process, paying particular attention to where whole life criteria such as better safety, energy use and maintenance, as well as the visible products on a project, would take precedence over reducing capital costs.

## Building Systems

The architecture of any project focuses on a building's spaces and how they effectively come together to form a cohesive whole that delivers the best functional relationships and, in due course, the best **Project Outcomes**. While certain **Building Systems**, such as wall linings, ceilings and lighting systems are easily visible, many **Building Systems**, usually building services such as ducts, risers and major elements of plant, are unseen by a building's user. Those easily visible systems will likely need an enhanced level of detail if a client is reviewing a concept design in a virtual reality walkthrough in Stage 2. Some **Building Systems** can be designed independently; others have numerous interfaces and relationships with other **Building Systems**. Some can be designed in isolation; others require iterations of the architecture and **Engineering Analysis**; for example, the building façade design and the specification and percentage of glazing can require a number of iterations to balance energy needs with aesthetics and fire safety.

## Facilities/Asset Management

Bridging the gap between information used for construction and the information required for **Facilities Management** or **Asset Management** purposes has proved challenging, with

COBie, an American schema, used as a short term vehicle to secure a consistent structure and attributes for this data. However, software systems are now creating more seamless systems to allow information to progress from its project-related (manufacturing and construction) purposes to fulfil **Asset Management** functions. Crucially, these systems now allow both geometry and data to be integrated within a single system. Furthermore, the advent of the **Digital Twin** is not far away. **Digital Twins** have been used in a number of advanced manufacturing industries for several years and allow project simulations for energy performance purposes, and other factors, for comparison with live 'in use' information. These real time feeds allow those using the building to understand where a building's performance is deviating from what was planned, permitting adjustments to be made. In addition, this feedback loop allows designers to gain a clearer understanding of how their buildings are working in practice, and to hone the design process accordingly. Crucial building maintenance, aligned to predictive analytics, can be undertaken proactively rather than allowing a sub-par item of building plant to underperform until failure.

## Conclusion

By understanding the **Project Documents** and **Project Strategies** that are core to the RIBA Plan of Work, it is possible for client, design and construction teams to consider ways of developing templates for these documents that can be rolled out from one project to the next. At present, a core challenge is the pace of change. Many clients have their own **Responsibility Matrix** or **Information Requirements**, but at what point would they be comfortable changing the balance of **Descriptive** or **Prescriptive information** provided by the design team and when might they shift away from 2D deliverables to place greater emphasis on the model and its data? Clients can draw the line on how progressive they seek to be, design teams can choose how far to push and promote their innovative workflow and construction teams can feel confident that modern methods of construction will be embraced by the project team.

Innovation can only be fostered if the construction industry shares experiences, both good and bad, with illustrative case studies to promote the ever changing line that indicates best practice as more design automation takes place and technologies such as machine learning become more prevalent.

The notion that we will reach a new steady-state environment in the future is ill-founded. The breadth and depth of the trends that will influence the future point to an era of continuous improvement. Improvements to the project process and information deliverables that bring about true step changes in how buildings are designed, manufactured and constructed. Improvements to design that result in better outcomes for users. **Research and Development** will be crucial in this era of whole life learning. Those who acknowledge these facts will prosper. Those who strive to maintain the status quo, without making significant efficiency improvements elsewhere, will find it difficult to engage with new initiatives.

In this environment, the RIBA will continue to monitor how the RIBA Plan of Work is being used. The RIBA believes that this updated version of the Plan of Work will bring greater consistency of use on current projects, while allowing clients and practices to focus on the efficiency improvements that will gradually result in a transformed construction industry.

**Dale Sinclair, Director – Architecture, Technical Practice, AECOM**

PART

# Glossary

# Glossary and guidance on RIBA Plan of Work terms

Term/task	Definition (guidance is included in grey boxes)
<b>Aftercare</b>	Initiatives aimed at making the use of the building, or subsequent buildings, more effective, including improving the performance of the <b>Building Systems</b> . Tasks may include gathering <b>Feedback on Project Performance</b> and building performance from <b>Post Occupancy Evaluations</b> .
<b>Approved Plans</b>	Plans of a building that have been approved as part of a <b>Building Regulations Application</b> .
<b>Architectural Concept</b>	<p>The architectural vision for the project, developed in Stage 2, which may start as several options that are tested against the <b>Project Brief</b>. As the initial ideas solidify, following <b>Design Reviews</b> with the client and other stakeholders, <b>Strategic Engineering</b> aspects are incorporated into the <b>Architectural Concept</b> before it is concluded and forms part of the <b>Stage Report</b> at the end of Stage 2.</p> <p>The <b>Architectural Concept</b> is the backbone of the Stage 2 design process. The architect conceives and creates ideas in response to the <b>Project Brief</b>, according to the <b>Project Budget</b> and the demands of the site, including its setting, topography, ecology, shape and historic context. These ideas, which might comprise a number of options, need to be tested at <b>Design Reviews</b> with the client and developed by the design team in parallel. Once an idea begins to solidify, engagement with other <b>Project Stakeholders</b> can commence. However, the <b>Architectural Concept</b> cannot exist in isolation. It must incorporate <b>Strategic Engineering</b> considerations, respond to <b>Project Strategies</b> and be tested against the <b>Project Budget</b> by producing a <b>Cost Plan</b>.</p> <p>The lead designer must strike a balance between the need to have an <b>Architectural Concept</b> that is acceptable to the client and other <b>Project Stakeholders</b> while coordinating the <b>Strategic Engineering</b> aspects or a <b>Project Strategy</b> that impacts on the development of the <b>Architectural Concept</b> or the <b>Cost Plan</b>.</p>
<b>Asset Information</b>	<p>Information that can be used for <b>Asset Management</b> and/or <b>Facilities Management</b> purposes.</p> <p>Traditionally, information provided by the design team to the contractor has been solely for the purposes of manufacturing and constructing a building. However, in order to maintain their asset, the client team requires further information that covers many different aspects, such as product numbers and manufacturers' details, replacement procedures and timing, serial numbers of air handling units or specifically allocated asset numbers. The most effective means of collating this information is to make sure that the BIM model includes the relevant data structure from the outset and that the information is added as the design progresses. However, some of this information may not be obtained until Stage 5, as subcontractors complete their installations. The client needs to clearly specify their requirements so that the necessary data are compiled as the design and construction phases progress.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Asset Management</b>	<p>The process of developing, operating, maintaining, upgrading and disposing of an asset using the most efficient and effective means.</p> <p><b>Asset Management</b> provides a further overlay to <b>Facilities Management</b>, formalising the maintenance regimes for the building. To achieve this, some of the components of the <b>Building Systems</b>, such as doors and items of plant, are given asset tags and unique identifiers, allowing maintenance planning to be optimised. Examples of asset management in practice include identifying when smoke seals on doors need to be inspected or when the batteries in escape signage need to be replaced, as well as recording when the requisite work was undertaken.</p>
<b>Building Contract</b>	<p>The contract between the client and the contractor for the construction of the project. In some instances, the <b>Building Contract</b> may contain design duties for specialist subcontractors and/or design team members.</p> <p>On some projects, more than one <b>Building Contract</b> may be required – for example, one <b>Building Contract</b> for shell and core works and another for furniture, fitting and equipment (FF&amp;E) aspects.</p>
<b>Building Manual</b>	<p>A summary of all key information about a building, including the <b>Health and Safety File</b> and <b>Fire Safety Information</b>, which are regulatory requirements. The <b>Building Manual</b> is used to ensure that <b>Asset Management</b> and <b>Facilities Management</b> are effectively implemented and might contain tasks that the users must consider in order to get the most out of the building.</p> <p>Historically, the <b>Building Manual</b> was produced in response to statutory requirements and the need to produce an Operations and Maintenance Manual. Typically, this comprised a large amount of design information, supplemented by information added by the specialist subcontractors responsible for designing the various <b>Building Systems</b>, compiled in various volumes and handed over to the client. In many instances, this information was unwieldy or poorly structured and difficult to use. Digital approaches allow the creation of a <b>Building Manual</b> that can offer links to information on all of the incorporated products and <b>Building Systems</b>, providing useful information on how to maintain them and how to source replacement parts. The client needs to consider what the <b>Building Manual</b> should look like and what information will be required beyond the statutory requirements. The design and construction teams must consider how this information can be effectively accessed and stored using digital tools.</p>
<b>Building Regulations</b>	<p>Minimum standards for design, construction and alteration of buildings. See <a href="http://www.legislation.gov.uk/ukxi/2010/2214/contents/made">www.legislation.gov.uk/ukxi/2010/2214/contents/made</a>.</p>
<b>Building Regulations Application</b>	<p>An application to a building control body (local authority or approved inspector) to check that the proposals for a building meet the requirements of the <b>Building Regulations</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Building Systems</b>	<p>The constituent parts of a building, including, but not limited to, structural systems, mechanical and electrical systems, façade, ceiling, floors and wall systems.</p> <p>At Stage 4, the emphasis shifts from the building as a whole to the information required to define each <b>Building System</b>. Every building is composed of a series of building systems, each allocated to a member of the design team in the <b>Responsibility Matrix</b>. The role of the lead designer involves ensuring that this information is coordinated by directing the Stage 4 design and reviewing and coordinating the work of the design team. On some projects, the design team will issue their <b>Building System</b> information as a whole. On others, the construction team will break this information down into 'packages', with a number of <b>Building Systems</b> tendered together.</p> <p>In Stage 4 the contractor also sends out tenders to subcontractors as packages, which broadly follow the <b>Building Systems</b>' breakdown. Some may be amalgamated, others let as a single item. The design team might issue the 'packages' as a whole or in line with a tender event schedule, which should be clearly set out in the <b>Responsibility Matrix</b>. The interfaces between the <b>Building Systems</b> will be defined by the contractor.</p> <p>See Uniclass 'Systems' (SS) table for a list of many Building Systems: <a href="http://www.thenbs.com/our-tools/uniclass-2015">www.thenbs.com/our-tools/uniclass-2015</a></p>
<b>Business Case</b>	<p>The rationale behind the initiation of a new building project. The <b>Business Case</b> examines and appraises possible approaches or options against the <b>Project Outcomes</b> (social, environmental and economic considerations) defined in the <b>Client Requirements</b>. On a small project, the <b>Business Case</b> might comprise a few pages; however, on larger projects it can run to several comprehensive volumes, prepared by a wide range of consultants and advisers. On some larger projects, the <b>Business Case</b> is reviewed and updated beyond Stage 0 until the project is given final approval.</p> <p>It is necessary to understand the client's <b>Business Case</b> for a project, because <b>Feasibility Studies</b> may identify several possible approaches in response to a client's needs. For example, a client may want to increase the desk count in their existing buildings, but studies may show that space rationalisation, an extension or a combination of the two options is more effective than relocating to a new-build project. Conversely, undertaking a financial appraisal to obtain site values may conclude that a new building is a justifiable business approach, although this may conflict with the Sustainability Strategy. The <b>Business Case</b> should tease out the pros and cons of different approaches, considering the <b>Project Risks</b> and <b>Project Budget</b> of each. The criteria for selecting the most appropriate way forward must be considered and different topics might be weighted differently depending on the <b>Client Requirements</b>. For example, on one project, adhering to the <b>Project Budget</b> might be the overriding criterion, while, on another, design quality might outweigh other considerations.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Change Control Procedures</b>	<p>Procedures for controlling changes to the design and construction following the sign-off of the Stage 2 <b>Concept Design</b> and the final <b>Project Brief</b>.</p> <p>During Stage 3, the design continues to be developed with <b>Design Studies</b>, <b>Engineering Analysis</b> and <b>Project Strategies</b>. This work is termed 'design development' and might involve tweaks to the <b>Architectural Concept</b>. Functional changes – for example, relocating a space or changing its size – are not design development and should be dealt with under the <b>Change Control Procedures</b>.</p> <p>The RIBA Plan of Work recommends that <b>Change Control Procedures</b> formally commence at the start of Stage 3. This allows any proposed changes to the <b>Architectural Concept</b> to be properly considered before they are implemented, noting that changes can impact different members of the design team in different ways.</p> <p>It should also be noted that any substantive changes to the <b>Project Brief</b> during Stage 2 also require client instructions. Examples of substantive changes would be increasing the area of office space required by 20% or adding a new lecture theatre to the <b>Project Brief</b>. The impact of these changes, including the need for additional fees or an extension to the Stage 2 <b>Design Programme</b>, will depend on when they are instructed and how significantly they impact on the design work undertaken to date.</p> <p>As the project progresses into Stage 4 and towards construction at Stage 5, the cost of change increases as more design information needs to be updated and, ultimately, there is a point where change impacts on work that is under way on site, as figure 4 illustrates.</p>

Figure 4 Cost and opportunity for change

Term/task	Definition (guidance is included in grey boxes)
<b>Client Requirements</b>	<p>A statement or document that defines the <b>Project Outcomes</b> and sets out what the client is seeking to achieve. It is used to develop the <b>Business Case</b>, which examines any viable options that meet the <b>Client Requirements</b>.</p>
	<p>The <b>Client Requirements</b> set out what the client is trying to achieve. For example, two residential clients might have the same <b>Spatial Requirements</b> (say, a new kitchen and an extra bedroom); however, one might be about to sell their property and is looking to increase its sale price while the other has a new baby and wants to consolidate their position close to good local schools. While the <b>Spatial Requirements</b> for both clients are the same, it is unlikely that their desired <b>Project Outcomes</b> will be the same, so a different <b>Business Case</b> and <b>Project Budget</b> is required for each. The <b>Client Requirements</b> allow the project team to explore viable options, determine the pros and cons for each and, ultimately, recommend the option best suited to deliver the <b>Client Requirements</b>. When this recommendation constitutes a building project, and it is signed off by the client, the more nuanced and detailed <b>Project Brief</b> can be prepared.</p>
<b>Commissioning</b>	<p>A number of <b>Building Systems</b> will need to be commissioned before the building can be handed over. <b>Commissioning</b> involves calibrating and adjusting the relevant systems until they are working as specified, with test results reviewed to confirm that they are satisfactory.</p>
	<p>Prior to <b>Commissioning</b>, the work of a number of subcontractors might have to be completed; for example, controls systems are normally installed separately from the mechanical systems they regulate. A crucial consideration is the time frame available. It is common for <b>Commissioning</b> to be delayed for various reasons, resulting in pressure on commissioning engineers to undertake their work quickly. <b>Commissioning</b> is increasingly becoming a requirement for every building. For example, as residential projects incorporate more complex <b>Building Systems</b>, from photovoltaics to integrated sound systems, it is important to ensure that these all function as planned.</p> <p>Seasonal <b>Commissioning</b> can take be undertaken during Stage 6 to help bed in the mechanical <b>Building Systems</b>, allowing them to work more efficiently throughout the year.</p>
<b>Construction Phase Plan</b>	<p>A statutory requirement under the CDM Regulations. The <b>Construction Phase Plan</b> must set out the arrangements for securing health and safety during the construction phase (the period that construction work is carried out). See HSE publication L153: <i>Managing Health and Safety in Construction</i> (HSE Books, 2015) for more information.</p>
<b>Construction Information</b>	<p>Information used to construct the <b>Building Systems</b> on site. This information can be prepared by the design team or by a specialist subcontractor and must comprise <b>Prescriptive Information</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Construction Programme</b>	<p>The period specified in the <b>Project Programme</b> and the <b>Building Contract</b> during which <b>Building Systems</b> can be manufactured and the project will be constructed, commencing on the site mobilisation date and ending at <b>Practical Completion</b>.</p> <p><b>Construction Programmes</b> differ from <b>Project Programmes</b> and <b>Design Programmes</b>. The <b>Construction Programme</b> is a detailed and granular programme that sets out when each <b>Building System</b> will be constructed. The high-level <b>Construction Programme</b> can be distilled into a programme for each 'package' to inform subcontractor tenders. It also highlights the critical path for the project. Increasingly, 4D BIM (time) tools are used to link the design team's federated model to the <b>Construction Programme</b>. This improves health and safety and programme outcomes by allowing a number of options to be rehearsed in good time before work begins on site. As more modern methods of construction exert an increasing influence on how buildings are made, it is likely that these tools will be used earlier and earlier in the design process, making concept designs more robust from a construction perspective.</p> <p>The critical path indicates the optimum methodology for constructing a building, where the immediate impact of a delay to one task is a delay to the next. Achieving the fastest <b>Construction Programme</b> requires the critical path to be determined and optimised.</p>
<b>Construction Quality</b>	<p>The quality of workmanship (and other factors, such as tolerances) defined in the <b>Employer's Requirements</b> and/or <b>Final Specifications</b> and <b>Building Regulations</b> that the construction team must comply with. To confirm that the contractor is meeting these <b>Construction Quality</b> requirements, it is common for regular inspections to be carried out.</p> <p>A regular (usually monthly) report on <b>Construction Quality</b> might be produced for the client team, detailing whether the ongoing manufacturing and construction on the project are compliant. Appropriate inspection requirements need to be clearly determined at the outset of a project and the appropriate fees included in the <b>Project Budget</b>.</p> <p>Inspections should be undertaken by individuals with experience of similar construction technologies. If the design team remains with the client, its members are the most likely candidates to conduct these inspections. However, if the design team is novated to the contractor, a shadow design team may be appointed to monitor construction.</p> <p>In addition to 'walking the site' to inspect the ongoing works, those undertaking this role typically produce a monthly quality report to record issues identified and to monitor progress. While the contractor might produce their own report, it is prudent and commonplace for the client team to review progress against the <b>Construction Programme</b>. The increasing use of digital surveying tools allows real-time comparisons of actual progress against planned progress, providing indisputable and granular information. On smaller projects, a more hands-on approach might be required with frequent site visits and immediate identification of areas where <b>Construction Quality</b> is not being achieved.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Construction Strategy</b>	<p>A strategy that considers specific aspects of the design that may affect the buildability or logistics of constructing a project or that may impact health and safety aspects.</p> <p>The <b>Construction Strategy</b> comprises items such as the craneage strategy, site access and accommodation locations, reviews of the supply chain and sources of materials, and specific buildability considerations, such as the choice of frame (steel/concrete) or the installation of larger items of plant.</p> <p>On a smaller project, the <b>Construction Strategy</b> may be restricted to the location of site cabins, welfare provisions and storage, and the ability to transport materials up an existing staircase. However, health and safety considerations should still be applied in full.</p>
<b>Cost Exercises</b>	<p>Exercises used to develop the <b>Cost Plan</b> and to verify that the <b>Outline Specification</b> for the <b>Building Systems</b> meets the available <b>Project Budget</b>.</p> <p>The goal at Stage 3 is to carry out <b>Cost Exercises</b> that allow more detailed aspects of the design to be tested. <b>Design Studies</b> are a good means of developing specific aspects of <b>Building Systems</b> and determining their affordability. In some instances, suppliers or specialist subcontractors might get involved in conversations and, indeed, this dialogue will be vital to certain procurement routes. The <b>Outline Specification</b> and <b>Project Strategies</b> can also be tested further during Stage 3. Although these exercises might result in increased costs, these should be balanced by a reduction in the project contingency included in the <b>Cost Plan</b> as greater certainty regarding the detail allows the contingency to be reduced accordingly.</p>
<b>Cost Plan</b>	<p>The estimate of the construction, or capital, costs for a building, aligned with the <b>Project Budget</b>, unless otherwise agreed with the client team. The <b>Cost Plan</b> may also include, or be linked to, whole life cost information.</p> <p>When undertaking cost estimating and cost planning at any Stage of the project, due reference should be made to the high-level cost classification system set out in the International Construction Measurement Standards (ICMS) (<a href="https://icms-coalition.org">https://icms-coalition.org</a>) and the provisions of the RICS Professional Statement on Cost Prediction, which provides a combination of best practice guidance and rules in respect of initial cost estimating (prediction) and subsequent cost planning.</p> <p>See section Seven: <i>Project Strategies – Cost Plan Strategy</i> for guidance on how the <b>Cost Plan</b> develops during each stage.</p>
<b>Defects List</b>	<p>A list of items that do not comply with the requirements of the <b>Building Contract</b> when the <b>Practical Completion</b> certificate is issued.</p> <p>A building should be free of defects when it is handed over. However, the majority of clients do not wish minor defects to delay handover and it is therefore common for a <b>Defects List</b> to be appended to the <b>Practical Completion</b> certificate to allow the building to be used. These defects are rectified as quickly as possible during Stage 6.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Descriptive Information</b>	<p>The means by which the design team describes a <b>Building System</b> in a manner that allows a specialist subcontractor to design the system.</p> <p><b>Descriptive Information</b> is issued by the design team to allow a specialist subcontractor to prepare <b>Manufacturing Information</b> for a <b>Building System</b>. <b>Descriptive Informative</b> is commonly referred to as 'design intent' as it frames the scope of work, describing what is required and any specific details that must be adhered to, and includes a performance specification that specifies the standards that must be met.</p> <p>See chapter Nine: <i>Setting Information Requirements</i> for more guidance on <b>Descriptive Information</b>.</p>
<b>Design Programme</b>	<p>The duration of the design tasks of each member of the design team, overseen by the lead designer and usually agreed before each design stage commences. The <b>Design Programme</b> is derived from the <b>Project Programme</b>.</p> <p><b>Design Programmes</b> vary substantially from <b>Project Programmes</b> or <b>Construction Programmes</b>. With the views of clients, and other stakeholders, difficult to predict and the complexity of projects creating new dynamics involving topics or interfaces that may not have been encountered before, it is essential that the lead designer creates a simple, flexible <b>Design Programme</b> that works alongside other design management tools. A detailed <b>Design Programme</b> is doomed to fail unless key <b>Project Stakeholders</b> agree with the design approach from the outset. The following points are vital to a successful <b>Design Programme</b>:</p> <ul style="list-style-type: none"> <li>• a clear understanding of the key dates for the client's <b>Design Reviews</b> (there is little point in developing a design if the client will be away when it needs to be approved)</li> <li>• considering when key <b>Project Stakeholders</b> might engage with the design process (noting that meetings could take months to arrange)</li> <li>• establishing a strategy for developing key <b>Strategic Engineering</b> aspects and coordinating them with the <b>Architectural Concept</b></li> <li>• considering when key <b>Project Strategies</b> might be developed for discussion with the client.</li> </ul> <p>Crucially, the lead designer needs to use their experience to decide when each team member should become more involved in the design process. Too many tasks undertaken too early in the process can result in abortive design work. Conversely, tasks tackled too late in a stage can result in iterations of the design that impact on an <b>Architectural Concept</b> that the client has already approved.</p> <p>The <i>Lead Designer's Handbook: Managing design and the design team in the digital age</i> (RIBA Publishing, 2019) contains tips and tools that can be used by design teams to progress the design from its early, embryonic stages to the final set of information for manufacturing and construction purposes and beyond, into the in-use stage for <b>Asset Management</b> or <b>Facilities Management</b> purposes.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Design Reviews</b>	<p>Reviews of the <b>Architectural Concept</b> by the client and other <b>Project Stakeholders</b> to obtain comments and determine whether it meets the requirements of the <b>Project Brief</b>. More experienced clients may also review the <b>Strategic Engineering</b> aspects or the <b>Project Strategies</b> and, during Stage 3, the outputs from <b>Design Studies</b> or <b>Engineering Analysis</b>.</p> <p>Design is not a linear process in which one task flows naturally from another. The design process is influenced by many different aspects. In the early project stages, <b>Design Reviews</b> by <b>Project Stakeholders</b> might be a primary driver for refining, or iterating, the design. However, as the building services and structural engineers and other specialist consultants progress their work, the design will be iterated on a regular basis until it is complete.</p> <p><b>Design Reviews</b> are an essential part of the design process. At Stage 2, <b>Design Reviews</b> are likely to focus on the client's review of the <b>Architectural Concept</b>. A core challenge in developing the <b>Design Programme</b> during the early design stages is determining when the client team is able to meet for <b>Design Reviews</b> with a broad range of <b>Project Stakeholders</b>.</p> <p>As well as the more obvious and design-oriented aspects of the design process, the client may wish to understand the engineering aspects or <b>Project Strategies</b> in detail. The lead designer and client team need to determine the level of detail that the client team wish to review so that the <b>Design Reviews</b> for these aspects can be incorporated into the <b>Design Programme</b>.</p>
<b>Design Studies</b>	<p>Detailed studies that develop aspects of the building further during Stage 3. For example, looking at the façade of the building in greater detail or developing the detail of a core space, such as the entrance lobby. <b>Design Studies</b> consider how the engineering aspects (for example, lighting and structural options for the entrance lobby) can be successfully coordinated into the design.</p> <p>The <b>Design Studies</b> undertaken at Stage 3 represent the next stage in the development of the <b>Architectural Concept</b>. They might comprise detailed studies of a façade system, an atrium roof or a key area of a building, such as a loading bay. On larger projects, <b>Design Studies</b> might be undertaken by multidisciplinary teams which analyse all aspects of a specific topic. For example, for an atrium roof the team would scrutinise fire engineering, structural solutions, acoustics, heat gain and glare as well as access and maintenance, testing the assumptions made in the <b>Architectural Concept</b>.</p> <p><b>Design Studies</b> are not intended to change the <b>Architectural Concept</b>. They focus on developing greater detail to inform the <b>Cost Plan</b> and to allow more comprehensive and in-depth coordination exercises to be undertaken.</p>
<b>Digital Execution Plan (DEP)</b>	<p>A document (also commonly called the BIM execution plan) that sets out how the design team will deliver the <b>Information Requirements</b> for the project, considering the tools to be used at each stage. The construction team might prepare a separate <b>DEP</b> to confirm how the <b>Asset Information</b> and <b>Verified Construction Information</b> will be produced.</p>
<b>Digital Twin</b>	<p>A digital representation (replica/model) of a building that allows simulations of its predicted performance to be reviewed against the actual performance, and its operation and maintenance to be optimised. A <b>Digital Twin</b> provides useful <b>Feedback</b> on areas where a building is not performing as planned, facilitating the process of optimising both the current building's performance and future projects.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Employer's Requirements</b>	A description of the <b>Client Requirements</b> with the specific purpose of providing the basis for tender of a <b>Building Contract</b> .
	See chapter Eight: Procurement Strategy for more information.
<b>Engineering Analysis</b>	The detailed calculations and analysis required to progress each engineering aspect of the project. During Stage 3, this analysis needs to focus on ensuring that the building is <b>Spatially Coordinated</b> by the end of the stage. Where <b>Engineering Analysis</b> does not impact on the Stage 3 design, it can be undertaken at Stage 4, when each <b>Building System</b> is detailed.
	<p>Once the <b>Architectural Concept</b> has been signed off, the engineering teams can begin more detailed calculation and analysis exercises at Stage 3, confident that the direction of design travel is robust. With the increasing complexity created by topics such as the circular economy and growing demands to reduce buildings' contributions to climate change, it is useful for the design team to have a space in which to undertake their work, confident that a further iteration of the design will not require calculations to be reworked or strategies to be revised. In addition, the increasing numbers of specialist consultants on a project require the lead designer to oversee a large number of <b>Project Strategies</b>, many of which have overlapping themes, and coordinate everyone's efforts for the <b>Stage Report</b>.</p> <p>In this sense, Stage 3 is the lead designer's space. Any client involvement should be minimal, with an emphasis on the <b>Design Reviews</b> generated by the <b>Design Studies</b>, as the design team bridges the gap between the <b>Architectural Concept</b> and the production of <b>Manufacturing Information</b> and <b>Construction Information</b> at Stage 4.</p>
<b>Facilities Management</b>	The tasks undertaken to enable the effective running of a building.
	<p>Every building needs some form of <b>Facilities Management</b>. For example, residential buildings must accommodate recycling facilities, provide somewhere for mail to be delivered and meters to be inspected or read, as well as considering how cisterns, rainwater pipes and other items will be accessed for repairs or replacement over the life of the building. On larger projects the principles are the same; however, the tasks will be more comprehensive and may be carried out by a third party. They are typically divided into hard or soft <b>Facilities Management</b>.</p> <p>Hard <b>Facilities Management</b> relates to the building itself, including maintenance of the façade, lighting, mechanical, plumbing and fire safety aspects. Tasks include regular replacement of items, such as bulbs in light fittings or filters in air handling units, as well as scheduled and recommended maintenance. One current trend in <b>Facilities Management</b> is predictive analytics, in which the data from key items of plant is used to determine when plant is underperforming and likely to need attention ahead of schedule. Soft <b>Facilities Management</b> relates more to the functionality of the building, providing the interface between the building and the user experience; for example, manning the reception desk, window cleaning, day-to-day cleaning, mail and waste management or catering.</p>

Term/task	Definition (guidance is included in grey boxes)
Feasibility Studies	<p>Studies undertaken to test the feasibility of the <b>Client Requirements</b> and emerging <b>Project Brief</b> against a specific site/context, and to consider how to deal with site-wide issues.</p>
	<p>Producing a <b>Project Brief</b> can sometimes be counterproductive if it is not tested against the constraints of a particular site. The RIBA recommends that, where making the brief fit a given site might be challenging, <b>Feasibility Studies</b> are undertaken to prove that the <b>Spatial Requirements</b> can be accommodated. <b>Feasibility Studies</b> can benefit from the skills of a designer, but this exercise is purely to test the potential project's fit. It is not meant to be the beginning of the design process, which commences at Stage 2. Where a number of options are proposed, these should not be assessed or vetted except to inform the briefing process or this exercise may risk undermining the start of the design process. <b>Feasibility Studies</b> might also include engineering aspects; for example, undertaking searches for utilities or considering the stability of an existing building. This work might help to inform and test the <b>Project Budget</b>. The <b>Feasibility Studies</b> should also consider the <b>Project Risks</b> and any issues likely to result in abnormal costs; such as high utility costs. It is always possible that, as the <b>Project Brief</b> is developed, a situation arises that prevents the project from progressing. This is, of course, best discovered before design work commences.</p>
Feedback	<p>Knowledge derived from previous similar projects, often used to inform dialogue at Stage 0. <b>Feedback</b> might comprise <b>Post Occupancy Evaluation</b> feedback, building visits, case study information or discussions with the project teams involved.</p>
	<p><b>Feedback</b> from previous projects is an essential part of the briefing process and can help to inform the <b>Client Requirements</b>. <b>Feedback</b> can relate to any aspect of a previous project, such as energy performance, how a specific space in the building performed or other functional features or it might cover the structure of the team, the information provided or a specific aspect of the design process.</p> <p>Increasingly, the core goal of Stage 6 is to make a building work as efficiently as possible – e.g. the building services working optimally and consuming the minimum amount of energy. Comparison of the planned with the actual energy and water use is a good starting point.</p> <p>Seasonal <b>Commissioning</b>, undertaken before closing out the <b>Building Contract</b>, also helps to bed in the mechanical <b>Building Systems</b>, ensuring that they work efficiently throughout the year.</p> <p>However, it is not just the building's consumption of resources that can offer scope for improvement. The building's use and maintenance can be observed. For example, are blinds included to reduce heat gain and glare? Are resource-saving devices being used as planned, such as low flush devices on toilets? Is the waste strategy working? Examining these items might point to the need to train and educate users in how they can refine the way in which the building is used, improving outcomes for all.</p>
Final Certificate	<p>A contractual document that formally concludes the <b>Building Contract</b> and Stage 6, winding up the construction team's involvement in the building's life. Many professional services contracts are aligned with the <b>Building Contract</b>, meaning that the issue of this document also concludes the work of the design team, except where a separate appointment requires <b>Aftercare</b> activities beyond the end of Stage 6.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Final Specifications</b>	<p>The specifications issued at Stage 4 by the design team. These specifications can be descriptive or prescriptive.</p> <p>The <b>Final Specification</b> for each <b>Building System</b> is produced by the design team and sets the contractual requirements, directing the subcontractors employed by the contractor in terms of the products to be used, confirming workmanship, tolerances or other aspects that must be adhered to. The <b>Final Specification</b> can include <b>Descriptive Information</b> or <b>Prescriptive Information</b>. The contents of the <b>Final Specifications</b> might be influenced by which party is employing the designer creating them.</p>
<b>Fire Safety Information</b>	<p>Information relating to the design and construction of the building or extension, and the services, fittings and equipment provided in, or in connection with, the building or extension, which will assist the Responsible Person (under the Regulatory Reform (Fire Safety) Order 2005) to operate and maintain the building or extension with reasonable safety. It must be handed to the client prior to occupation, as required by Regulation 38 of the Building Regulations 2010.</p>
<b>Health and Safety File</b>	<p>All project information that may be relevant to any subsequent work on the building to ensure the health and safety of any person. It must be handed over to the client at the end of the project and passed on to any subsequent owners as required by the Construction (Design and Management) Regulations 2015.</p> <p>See L153: Construction (Design and Management) Regulations 2015. Guidance on Regulations for more guidance: <a href="https://www.hse.gov.uk/pubns/books/l153.htm">https://www.hse.gov.uk/pubns/books/l153.htm</a></p>
<b>Information Requirements</b>	<p>The formal issue of information for review and sign-off by the client at key stages of the project. The project team may also have additional formal information exchanges as well as the many informal exchanges that occur during the iterative design process.</p> <p>See chapter Nine: <i>Setting Information Requirements</i> for more guidance.</p>
<b>Manufacturing Information</b>	<p>Information prepared for the manufacture of <b>Building Systems</b> during Stage 4. This detailed information will usually be prepared by a specialist subcontractor using <b>Descriptive Information</b> from the design team with the resultant <b>Manufacturing Information</b> submitted for comment and approval prior to manufacturing. <b>Manufacturing Information</b> feeds into computer-aided design and manufacturing (systems in factories to facilitate effective manufacturing processes).</p> <p>See chapter Nine: <i>Setting Information Requirements – Prescriptive Information vs Descriptive Information</i> for more guidance on <b>Manufacturing Information</b>.</p>
<b>Outline Specification</b>	<p>Sufficient information to allow the client to understand what is proposed for each <b>Building System</b>. The <b>Outline Specification</b> might include, for example, the door or floor finishes, the extent or specification of the engineering <b>Building Systems</b> or the type of frame proposed. The <b>Outline Specification</b> also assists in the preparation of the <b>Cost Plan</b>.</p> <p>See chapter Nine: <i>Setting Information Requirements</i> for guidance on <b>Outline Specifications</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Planning Advice</b>	<p>Early advice sought to determine any planning risks, such as policy constraints or height restrictions. Advice can be obtained from architects, planning advisers or the local planning authority, although this may incur a fee. <b>Planning Advice</b> obtained during Stage 1 will be more strategic in nature, and during Stage 2 might comprise a <b>Design Review</b> to inform the project team about the suitability of the proposals being developed.</p> <p>The local planning authority is a key <b>Project Stakeholder</b> on any project. Its opinions and approaches are outside the control of the project team and therefore planning represents a core <b>Project Risk</b>.</p> <p>Pre-design <b>Planning Advice</b> helps to manage this risk by allowing the early views of the planners to inform the briefing and/or design process and can be invaluable in shaping the direction of the design.</p> <p>During Stage 2 and into Stage 3 it may be prudent to obtain formal pre-application <b>Planning Advice</b> on the <b>Architectural Concept</b> as it develops and matures. This advice might come from an architect, a planning consultant or might be sourced directly from the relevant planning department. Planning departments have recognised the value that these meetings can add to the process and many have started to charge pre-application fees, formalising these early engagements to allow them to be recognised as part of the planning process. On larger projects it may also be prudent to arrange a community consultation or to undertake a formal <b>Design Review</b> as part of the design process.</p> <p>The project team need to consider the scale and location of project and any specific sensitivities that are likely to influence the choice of the most appropriate way forward. Ultimately, the planning risk cannot be considered resolved until a <b>Planning Application</b> has been submitted and approved.</p>
<b>Planning Application</b>	<p>An application to the local authority for permission to erect a particular building on a specific site. The RIBA Plan of Work recommends that the <b>Planning Application</b> be submitted at the end of Stage 3.</p> <p>A set period after Stage 3 is completed might be specified in the <b>Project Programme</b> to allow the final assembling of the planning information prior to submission of the <b>Planning Application</b>. The increasing complexity of these submissions, covering detailed topics such as energy use and accessibility, makes the end of Stage 3 the optimal point for submission. This timing allows a number of the <b>Planning Application Information Requirements</b> to be absorbed into the Stage 3 <b>Design Programme</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Planning Conditions</b>	<p>A set of conditions attached to a planning consent that must be met. Many conditions must be discharged prior to work commencing or the building being occupied. Other conditions apply for the life of the building.</p> <p>Planning consent is likely to come with a number of <b>Planning Conditions</b>, which could require supplementary information to be submitted and approved, such as more detailed information on the façades. This might involve the production of additional Stage 4 information or, if this information has been pre-emptively prepared, revision of the information. Similarly, it is likely that the contractor will have to submit information before work commences on site (for example, details of cabin and hoarding layouts or procedures for washing down trucks before they leave site). The <b>Project Programme</b> must include sufficient mobilisation time to allow the appointed contractor to meet these conditions. In addition, the <b>Planning Conditions</b> might include ongoing obligations for the contractor, such as limiting the timing of the works or setting maximum permitted noise levels. The client must ensure that these requirements are embedded into the <b>Building Contract</b>. In addition, the client team may wish to monitor whether the contractor is adhering to the requirements.</p>
<b>Post Occupancy Evaluation (POE)</b>	<p>Evaluation undertaken once the building is occupied to determine whether the <b>Project Outcomes</b> and <b>Sustainability Outcomes</b> set out in the <b>Project Brief</b>, or later design targets for <b>Building Systems</b>, have been achieved. There are three progressive levels and the RIBA recommends that all <b>POE</b> starts with the first level:</p> <ul style="list-style-type: none"> <li>• Light touch <b>POE</b>: Simple but meaningful rapid evaluation undertaken post occupancy, before the <b>Building Contract</b> is concluded. This information may not reflect the final building performance due to seasonal <b>Commissioning</b> being incomplete or other <b>Building Systems</b> not being fully bedded in. However, it can provide useful insights for the client and act as <b>Feedback</b> for other projects.</li> <li>• Diagnostic <b>POE: Feedback</b> from light touch <b>POE</b> might identify the need for more detailed evaluation. This may be undertaken by independent evaluators during the second year of occupation, to verify performance and review any issues discovered, including those identified in the light touch <b>POE</b>.</li> <li>• Detailed (forensic) <b>POE</b>: Investigations, if necessary, by independent evaluators, to identify and, where possible, resolve any significant and persistent performance issues. These can start at any time but should ideally be completed by the end of the third year of occupation.</li> </ul>
<b>Practical Completion</b>	<p>The point in the process when the construction work is certified as practically complete under the <b>Building Contract</b>.</p> <p>A <b>Practical Completion</b> certificate may be used as a contractual document that allows the client to take possession of and to use a building. It requires the <b>Building Contract</b> administrator to confirm that the building has been completed in accordance with the <b>Building Contract</b>, including the issue of any information for <b>Asset Management</b> or <b>Facilities Management</b> as well as the <b>Building Manual</b> and any <b>Verified Construction Information</b>. It may also be necessary to consult with <b>Project Stakeholders</b> to confirm that the building meets with the relevant standards and is suitable for occupation.</p>
<b>Pre-construction Information</b>	<p>A statutory requirement under the CDM Regulations for health and safety information in the client's possession or which is reasonably obtainable by or on behalf of the client, which is relevant to the construction work and is of an appropriate level of detail and proportionate to the risks involved. See HSE publication L153: <i>Managing Health and Safety in Construction</i> (HSE Books, 2015) for more information.</p>

Term/task	Definition (guidance is included in grey boxes)
Prescriptive Information	<p>Complete, instructive information used to manufacture and construct the <b>Building Systems</b>, produced by the <i>design team</i> or the construction team.</p> <p>See chapter Nine: <i>Setting Information Requirements</i> for guidance on <b>Prescriptive Information</b>.</p>
Procurement Strategy	<p>The strategy that sets out the process for tendering and entering into a <b>Building Contract</b> with the contractor. On certain projects, this will include early contractor involvement.</p> <p>See chapter Eight: <b>Procurement Strategy</b></p>
Project Brief	<p>Detailed requirements for the design and management of the project, included in design team professional services contracts, to enable the <i>design team</i> to begin design work in Stage 2.</p> <p>An effective <b>Project Brief</b> is crucial for the efficient design of any building. It is a tool to that helps to take the <b>Client Requirements</b> to the next level of detail and includes the following elements:</p> <ul style="list-style-type: none"> <li>• <b>Project Outcomes</b> – Defining <b>Project Outcomes</b> is still a relatively new briefing topic. However, determining these at an early stage can provide a useful tool for the design team. The challenge for the design team is how to obtain the information necessary to achieve the <b>Project Outcomes</b> and, more importantly, how success can be measured. This requires objective data, but any information-gathering exercise is likely to yield highly subjective responses. Nevertheless, regardless of how <b>Project Outcomes</b> are measured, they are a useful briefing tool that provide a focus beyond the provision of the <b>Spatial Requirements</b></li> <li>• <b>Sustainability Outcomes</b> – The client's wishes with regard to their building's level of sustainability need to be clearly conveyed to the design team. A client may wish simply to comply with the <b>Building Regulations</b> or they may want to achieve a particular BREEAM award rating. They may also wish to embrace specific subjects, such as circular economy principles, create a zero carbon building or use specific materials. These objectives need to be teased out during the briefing process.</li> <li>• <b>Quality Aspirations</b> – Quality comes in many guises. It can relate to the building, a space, or materials and finishes or to the quality of construction. Some clients base their <b>Quality Aspirations</b> on value. Regardless of the client's particular views on the subject, it is a crucial briefing topic. <b>Quality Aspirations</b> can be conveyed by written statements but are better expressed using images from similar exemplar projects.</li> <li>• <b>Spatial Requirements</b> – Defining the spaces in the <b>Project Brief</b> is a useful way of setting out precisely what is required on a project. Establishing the <b>Spatial Requirements</b> gives the architect the necessary information to start the design process and allows the <b>Project Budget</b> to be meaningfully tested. It is important that any <b>Spatial Requirements</b> are tested against industry norms or client expectations and that allowances for circulation and plant spaces are included</li> </ul>

Term/task	Definition (guidance is included in grey boxes)
<b>Project Brief Derogations</b>	<p>A record in the <b>Stage Report</b> of Stage 2 used to identify and agree where aspects of the design do not need to comply with the <b>Project Brief</b>.</p> <p>As the <b>Architectural Concept</b> is developed, it is sometimes necessary to revisit the <b>Project Brief</b>. For example, the design team might identify a better way of achieving the end result or the massing might dictate a change in the size of a number of spaces. In some sectors, such as healthcare, where briefing guidance documents exist, it is customary to agree derogations from these standards. In other sectors, it is more common to update the <b>Project Brief</b> so that it is aligned with the <b>Architectural Concept</b> at the end of Stage 2. On a design and build project, the <b>Stage Report</b> at Stage 2 and the <b>Project Brief</b> might be issued as <b>Employer's Requirements</b> and it is preferable to avoid any contradictions. On a smaller project, the <b>Project Brief</b> might be superseded as soon as the <b>Architectural Concept</b> is produced, having served its purpose to kick-start the design process.</p> <p>The RIBA Plan of Work advocates that the project team should consider how the <b>Project Brief</b> and Stage 2 <b>Stage Report</b> need to interact, if at all, and set tasks accordingly. The briefing process is concluded at the end of Stage 2 as the design process enters a more detailed phase. The <b>Project Brief</b> is superseded by the <b>Architectural Concept</b> as it moves into Stage 3. However, some <b>Procurement Strategies</b> may require the <b>Project Brief</b> to form part of the <b>Employer's Requirements</b>, to reinforce aspects that are required in the <b>Building Contract</b> but have not yet been designed. In these circumstances, the <b>Project Brief</b> will remain a live project document and all members of the project team should regularly confirm that any <b>Building Contract</b> documentation is checked against its requirements.</p>
<b>Project Budget</b>	<p>The client's budget for the project, which includes the construction cost, the cost of the professional services and the cost of certain items required post completion and during its operational use.</p> <p>A crucial task at Stage 1 is determining the <b>Project Budget</b>. This must be based on the <b>Spatial Requirements</b> set out in the <b>Project Brief</b> and needs to take into account the <b>Quality Aspirations</b> of the client, which may dictate a high level of specification for fittings and finishes. The <b>Project Budget</b> should also allow for professional fees and, where a construction project is proposed, financing or land costs, planning and <b>Building Regulations</b> submission costs, contingencies and any other anticipated project costs.</p>
<b>Project Execution Plan</b>	<p>The plan, produced with contributions from the project team, that sets out the processes and protocols to be used during each stage of the project.</p> <p>As project teams transition from traditional ways of working to more digitally integrated working methods, the <b>Project Execution Plan</b> becomes a core project tool. It allows the project team to agree how they will communicate with each other, what tools will be used for <b>Design Reviews</b>, how information will be transmitted, how queries will be raised and monitored, and other day-to-day considerations. Consider the case of a client who is not keen on using technology working with a progressive digital design team, or vice versa, and it is easy to understand why the <b>Project Execution Plan</b> is an essential project document.</p> <p>There is a correlation between the <b>Project Execution Plan</b> and the <b>Information Requirements</b>, as well as with the BIM execution plan or <b>Digital Execution Plan</b> that specifically sets out how the design team will work together.</p>
<b>Project Outcomes</b>	<p>The desired outcomes for the project, including <b>Sustainability Outcomes</b>, set out in Stage 0 to inform the <b>Client Requirements</b>. For a hospital, a reduction in recovery times might be a key <b>Project Outcome</b>. The outcomes may include operational aspects, as well as a mixture of subjective and objective criteria, and will influence the preparation of the <b>Project Brief</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Project Performance</b>	<p>The performance of the project process and project team, determined using <b>Feedback</b> following completion of a building.</p> <p>The RIBA Plan of Work is a circular process and at the end of each building project cycle it is recommended that a <b>Feedback</b> exercise is undertaken with the project team to gather lessons learned on <b>Project Performance</b>. With the majority of the project team leaving the project prior to, or at the end of, Stage 5, the timing for undertaking this needs to be carefully considered.</p>
<b>Project Programme</b>	<p>The overall period for the briefing, design, manufacturing, construction and post-completion activities of a project.</p> <p>Setting the <b>Project Programme</b> is a crucial project task and one of the biggest challenges for the client team. The programme determines the time required for each project stage as the brief is prepared, the design developed and manufacturing and construction undertaken. These periods vary depending on the size and complexity of the project. The timing of the <b>Planning Application</b> needs to be considered, along with how the <b>Procurement Strategy</b> will shape the programme. Key drivers of the durations for the <b>Project Programme</b> include the following:</p> <ul style="list-style-type: none"> <li>• The complexities of the briefing process at Stage 1 – speeding up these activities can prove counterproductive.</li> <li>• The need, at Stage 2, to create the <b>Architectural Concept</b>, incorporate <b>Strategic Engineering</b> aspects and undertake <b>Design Reviews</b> with key <b>Project Stakeholders</b>.</li> <li>• The complexities of coordination at Stage 3.</li> <li>• Deciding when to submit a <b>Planning Application</b> and the period for determining the application.</li> <li>• The timing of Stage 4 design, as dictated by the <b>Procurement Strategy</b>.</li> <li>• The impact of modern methods of construction.</li> <li>• The timing and process of a <b>Building Regulations</b> application.</li> </ul> <p>At present, with traditional design and construction models still prevalent, there are limited opportunities to shorten the <b>Project Programme</b> timescales. BIM has not delivered faster projects because it is still plugged into traditional methods of designing. At present, there are only two ways to reduce time: by compressing the time allocated to a stage or by overlapping stages. Either strategy creates risk to the project and, while that risk may be contractually accepted by one party, compressing time does make it less likely that the project team will be able to deliver the <b>Project Outcomes</b> that the client is seeking to achieve.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Project Risks</b>	<p>Issues that cannot be fully determined at a particular time/stage that may impact on the design, cost or delivery of a project. Lack of clarity regarding <b>Project Risks</b> can necessitate a redesign or result in cost overruns or programme delays.</p> <p>Some <b>Project Risks</b> may be deal-breakers that prevent the project from proceeding past the end of Stage 0. For example, the costs of providing energy to the building, the risk of failing to obtain planning consent for the areas required to make the scheme viable or a key <b>Project Stakeholder</b> who is unlikely to support the proposals. Determining the <b>Project Risks</b> at Stage 0 is therefore a crucial task. Should the project proceed, identified risks should be actively managed throughout each project stage, with each risk allocated to, and managed by, a member of the project team.</p>
<b>Project Stakeholders</b>	<p>Parties outside the project team that may have an influence on the design development. <b>Project Stakeholders</b> include any party with a vested interest in a project, such as local authorities, planning departments, statutory consultees, non-statutory consultees, specialist amenity groups, building users, local community groups, neighbours, utility companies and transport bodies.</p> <p><b>Project Stakeholders</b> might include, for example, a local community that may have concerns about parking or amenity spaces, utility companies that can provide information on their networks' ability to accommodate a new building or a conservation group that might have specific comments in relation to how a building sits in its context.</p> <p>As it can take time to arrange meetings with some <b>Project Stakeholders</b>, the project team need to consider each <b>Project Stakeholder</b> individually and determine when an approach might be appropriate, although this can be a difficult task when the design process has just started and the issues and challenges have yet to be identified. Discussing a design which has not been sufficiently developed can be counterproductive and, conversely, discussions entered into too late in the design process may result in significant iterations of the design.</p> <p>The project team need to be alert to the risks posed by <b>Project Stakeholders</b>. At the commencement of a project it is important to map out who those stakeholders are. On larger projects it is common to have a stakeholder engagement plan or to include the risks flagged in early discussions with each stakeholder in a record of <b>Project Risks</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Project Strategies</b>	<p>Strategies to support the design process, generally developed in parallel with the design stages (Stage 2-3) and to respond to the <b>Business Case</b> or <b>Project Brief</b> before they are concluded or support the use of the building. These strategies typically include the following:</p> <ul style="list-style-type: none"> <li>• Conservation Strategy</li> <li>• Cost Strategy</li> <li>• Fire Safety Strategy</li> <li>• Health and Safety Strategy</li> <li>• Inclusive Design Strategy</li> <li>• Planning Strategy</li> <li>• Plan for Use Strategy</li> <li>• Procurement Strategy</li> <li>• Sustainability Strategy</li> </ul> <p>These strategies are usually prepared in outline at Stage 2 and in detail at Stage 3, with the recommendations absorbed into the technical design and information exchanges. The strategies are not typically used as <b>Construction Information</b> but may inform the construction process.</p> <p>Guidance and stage specific tasks for the above <b>Project Strategies</b> are covered in detail in chapter Six.</p>
<b>Quality Aspirations</b>	<p>The objectives that set out the quality aspects of a project. The objectives may comprise both subjective and objective aspects.</p> <p><b>Quality Aspirations</b> can relate to the building, a space, or materials and finishes or to the quality of construction. Some clients base their <b>Quality Aspirations</b> on value. Regardless of the client's particular views on the subject, it is a crucial briefing topic. Quality Aspirations can be conveyed by written statements but are better expressed using images from similar exemplar projects.</p>
<b>Research and Development</b>	<p>Project-specific <b>Research and Development</b> in response to the <b>Project Brief</b> or the <b>Concept Design</b> as it is developed.</p>
<b>Responsibility Matrix</b>	<p>A matrix determining who is responsible for the different tasks to be undertaken at each stage. It can set out which project team member should lead on each task and who should provide support. It can be broken down by <b>Building System</b> and will be closely aligned to the <b>Information Requirements</b>. This document sets out the extent of any performance specified design. The <b>Responsibility Matrix</b> is created at a strategic level at Stage 1 and fine tuned in response to the <b>Architectural Concept</b> at the end of Stage 2 in order to ensure that there are no design responsibility ambiguities or omissions at Stages 3 and 4.</p> <p>A robust <b>Responsibility Matrix</b> is a core project document. It ensures that everyone is aware of what they have to do and the stage during which they have to do it, allowing those tendering for professional services to set their fees appropriately. A <b>Responsibility Matrix</b> can work at project level, bringing clarity to the tasks to be undertaken by the client, design and construction teams. It can also be used to assign design responsibility for the different <b>Building Systems</b> to members of the design team – and for determining whether the design team will prepare <b>Descriptive Information</b> or <b>Prescriptive Information</b> at Stage 4, establishing the boundary between the design team and any specialist subcontractors.</p> <p>A key challenge is who should set the <b>Responsibility Matrix</b>. In the case of a client who is appointing the design team independently, the client would be responsible for preparing the document. However, if the client is appointing the whole design team as a single entity, the <b>Responsibility Matrix</b> might be set by the lead designer in response to the <b>Information Requirements</b>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Site Appraisal</b>	A review of the site or potential sites, which may include an existing building or collection of buildings, to determine the viability of the <b>Client Requirements</b> .
<b>Site Information</b>	<p>Specific project information in the form of surveys or reports relating to the particular site/context for a project, including <b>Site Surveys</b>.</p> <p>See chapter Nine: <i>Setting Information Requirements</i> for guidance on <b>Site Information</b>.</p>
<b>Site Logistics</b>	<p>Site and construction supply chain management items prepared by the contractor for consideration as part of a tender and, if successful, prior to starting on site.</p> <p><b>Site Logistics</b> may include the following aspects:</p> <ul style="list-style-type: none"> <li>• Understanding how materials will arrive and be unloaded on site. A small residential site down a narrow lane will have different issues to a city centre site where just-in-time deliveries are required.</li> <li>• How to move materials around the site, including the use of cranes, hoists and other mechanical equipment.</li> <li>• Location of site cabins providing management and welfare facilities for site operatives.</li> <li>• Fencing to mark the boundaries of the site, for security and health and safety purposes.</li> <li>• Measures to minimise issues with neighbours; for example, where generators might best be positioned or how the wheels of trucks are to be washed before leaving site.</li> </ul>
<b>Site Queries</b>	<p>Questions directed to the design team by the contractor (sometimes more formally called 'a request for information') to clarify information in the <b>Building Contract</b> documentation or requesting information that was not complete when the <b>Building Contract</b> was agreed.</p> <p>Construction on site using <b>Prescriptive Information</b> from the design team commonly generates <b>Site Queries</b>. While it is usual for the designer responsible to respond to such queries, this designer may not be part of the construction team, or the contractor might wish to handle queries in a different way. The design team should be clear about any ongoing commitments when they submit their proposals. Similarly, the client may wish to establish who will deal with <b>Site Queries</b> as this may impact <b>Construction Quality</b>. The frequency of site visits should also be considered. Although it is possible to deal with <b>Site Queries</b> remotely, in many instances there is no substitute for communicating directly with the construction team on site.</p>
<b>Site Surveys</b>	Surveys of sites carried out before design work starts. As the construction industry moves towards more 3D, data-centric methods of working, it is becoming common for 3D <b>Site Surveys</b> to be undertaken. Point cloud or photogrammetric surveys are the most common types. Some surveys might need to be converted into a model that can be used by the design team. The type of survey undertaken is determined by how the information will be used and the level of accuracy required.
<b>Spatial Requirements</b>	A schedule of rooms and/or spaces that will achieve the <b>Client Requirements</b> . The <b>Spatial Requirements</b> for the building as a whole are set at Stage 0. By the end of Stage 1, the <b>Spatial Requirements</b> will have been developed in detail and incorporated into the <b>Project Brief</b> .

Term/task	Definition (guidance is included in grey boxes)
Spatially Coordinated	<p>Design in which the client's <b>Spatial Requirements</b> and the spaces required for any <b>Building Systems</b> – such as structural and building services engineering aspects, including grids, risers and plant rooms – have been determined and fixed to allow Stage 4 to progress without any further iterations.</p> <p>Stage 3 provides a bridge between the strategic outputs of Stage 2 and the significant detail produced at Stage 4. During Stage 3, further layers of detail are added to the design. The core goal of Stage 3 is a design that is <b>Spatially Coordinated</b>. This stage has two key aims. First, it allows each <b>Building System</b> to be developed independently at Stage 4. Second, a <b>Planning Application</b> can be made with the certainty that changes will not be required once planning consent has been granted.</p> <p>Coordination is a continual process throughout all of the design stages. This might involve coordinating the client documents with the emerging design; for example, adjusting the <b>Project Brief</b> to align with an aspect of the design. However, <b>Spatial Coordination</b> principally relates to the ongoing coordination of the design by the lead designer, and includes the tasks of coordinating the <b>Project Strategies</b> and designs of the different design team members.</p> <p>The lead designer needs to coordinate design efforts and the direction of the design team throughout every design stage, and individual designers must also coordinate their own efforts. For example, at Stage 4, the building services engineer must ensure that the various services installed above the ceilings have been correctly coordinated in the zone set out for all services during Stage 3 as part of the <b>Engineering Analysis</b> contributions.</p> <p>Defining <b>Spatially Coordinated</b> is difficult; however, it is fundamentally about ensuring that every space in a building is conclusively defined, from the client's functional spaces, such as living rooms, classrooms, operating theatres or departure lounges, to the spaces required for building services including plant rooms and risers. Simply put, if all of a building's spaces are not determined during Stage 3 it can cause a great deal of disruption during Stage 4, as designers discover that areas of a building are in a state of flux precisely when they are undertaking the detailed design of every <b>Building System</b>.</p>
Stage Report	<p>A report produced at the end of Stage 2 and Stage 3 to capture decision making during the stage and record the outcome of the design process as reviewed by the client. The <b>Stage Report</b> will also contain the <b>Project Strategies</b> and other useful project information. The <b>Stage Report</b> is signed off by the client at the end of the stage.</p> <p>For more information on the <b>Stage Report</b>, see chapter Nine: <i>Setting Information Requirements</i>.</p>

Term/task	Definition (guidance is included in grey boxes)
<b>Strategic Engineering</b>	<p>Engineering information which is crucial to the development of the <b>Architectural Concept</b>, including plant room or riser information, or required to develop the <b>Cost Plan</b> or for the consideration of <b>Project Risks</b>.</p> <p>During Stage 2, a core challenge for the civil, structural and building services engineers is to refrain from undertaking detailed <b>Engineering Analysis</b> and instead to provide more general, 'rule of thumb' <b>Strategic Engineering</b> contributions to the development of the <b>Architectural Concept</b>. Aspects to consider include agreeing the floor-to-floor heights, the structural grid, the locations of plant rooms or risers and any issues that might influence the <b>Cost Plan</b>, from the need for new road junctions or new utility connections to the complexity of the energy strategy. The depth of engineering contributions at Stage 2 will depend on the robustness of the <b>Architectural Concept</b>. There is a great deal to be gained by ensuring that any proposed options are robust and considered. In addition, some engineering aspects will be capable of development in isolation. For example, developing an energy or security strategy.</p> <p>It is crucial that everyone in the project team understands that there is no point in dogmatically adhering to a <b>Design Programme</b> if the <b>Architectural Concept</b> is still undergoing iterations in response to conflicting and contradictory comments from the client team and other <b>Project Stakeholders</b>.</p>
<b>Sustainability Outcomes</b>	<p><b>Project Outcomes</b> related to sustainability. These start as the client's aspirations for sustainability, then will be developed into detailed target metrics as the design progresses. The Sustainability Strategy is prepared in response to the <b>Sustainability Outcomes</b>.</p> <p>See section Seven – Sustainability Strategy and the <i>RIBA Sustainable Outcomes Guide</i> (2019) for more advice on <b>Sustainability Outcomes</b>.</p>
<b>Verified Construction Information</b>	<p>An option for enhanced <b>Asset Information</b> based on post construction surveys of the works. If this information is required, the project team must determine what tasks are required during Stage 5 to generate the specific <b>Verified Construction Information</b> needed for each project.</p> <p>More information on <b>Verified Construction Information</b> can be found in section Eight: <i>Setting Information Requirements</i>.</p>

# RIBA Plan of Work 2020

The RIBA Plan of Work organises the process of briefing, designing, delivering, maintaining, operating and using a building into eight stages. It is a framework for all disciplines on construction projects and should be used solely as guidance for the preparation of detailed professional services and building contracts.

### Stage Boundaries:

Stages 0-4 will generally be undertaken one after the other.

Stages 4 and 5 will overlap in the **Project Programme** for most projects.

Stage 5 commences when the contractor takes possession of the site and finishes at **Practical Completion**.

Stage 6 starts with the handover of the building to the client immediately after **Practical Completion** and finishes at the end of the **Defects Liability Period**.

Stage 7 starts concurrently with Stage 6 and lasts for the life of the building.

### Planning Note:

**Planning Applications** are generally submitted at the end of Stage 3 and should only be submitted earlier when the threshold of information required has been met. If a **Planning Application** is made during Stage 3, a mid-stage gateway should be determined and it should be clear to the project team which tasks and deliverables will be required. See **Overview** guidance.

### Procurement:

The RIBA Plan of Work is procurement neutral - See **Overview** guidance for a detailed description of how each stage might be adjusted to accommodate the requirements of the **Procurement Strategy**.

- Employer's Requirements
- Contractor's Proposals

### Stage Outcome

at the end of the stage

### Core Tasks

during the stage

**Project Strategies** might include:

- Conservation (if applicable)
- Cost
- Fire Safety
- Health and Safety
- Inclusive Design
- Planning
- Plan for Use
- Procurement
- Sustainability

See **RIBA Plan of Work 2020 Overview** for detailed guidance on **Project Strategies**.

### Core Statutory Processes

during the stage:

Planning  
Building Regulations  
Health and Safety (CDM)

<b>Procurement Route</b>	Traditional
	Design & Build 1 Stage
	Design & Build 2 Stage
	Management Contract
	Construction Management
	Contractor-led

### Information Exchanges

at the end of the stage

**0**

**Strategic Definition**

**1**

**Preparation and Briefing**

**2**

**Concept Design**

The best means of achieving the **Client Requirements** confirmed

If the outcome determines that a building is the best means of achieving the **Client Requirements**, the client proceeds to Stage 1

Prepare **Client Requirements**

Develop **Business Case** for feasible options including review of **Project Risks** and **Project Budget**

Ratify option that best delivers **Client Requirements**

Review **Feedback** from previous projects

Undertake **Site Appraisals**

No design team required for Stages 0 and 1. Client advisers may be appointed to the client team to provide strategic advice and design thinking before Stage 2 commences.

Strategic appraisal of **Planning** considerations

	Appoint client team		
		Appoint design team	
			Appoint contractor
			ER

**Client Requirements**

**Business Case**

**Project Brief** approved by the client and confirmed that it can be accommodated on the site

Prepare **Project Brief** including **Project Outcomes** and **Sustainability Outcomes**, **Quality Aspirations** and **Spatial Requirements**

Undertake **Feasibility Studies**

Agree **Project Budget**

Source **Site Information** including **Site Surveys**

Prepare **Project Programme**

Prepare **Project Execution Plan**

Source pre-application **Planning Advice**

Initiate collation of health and safety **Pre-construction Information**

**Project Brief**

**Feasibility Studies**

**Site Information**

**Project Budget**

**Project Programme**

**Procurement Strategy**

**Responsibility Matrix**

**Information Requirements**

**Architectural Concept** approved by the client and aligned to the **Project Brief**

The brief remains "live" during Stage 2 and is derogated in response to the **Architectural Concept**

Prepare **Architectural Concept** incorporating **Strategic Engineering** requirements and aligned to **Cost Plan**, **Project Strategies** and **Outline Specification**

Agree **Project Brief Derogations**

Undertake **Design Reviews** with client and **Project Stakeholders**

Prepare stage **Design Programme**

Obtain pre-application **Planning Advice**

Agree route to **Building Regulations** compliance

Options: submit outline **Planning Application**

**Project Brief Derogations**

**Signed off Stage Report**

**Project Strategies**

**Outline Specification**

**Cost Plan**

Core RIBA Plan of Work terms are defined in the RIBA Plan of Work 2020 Overview glossary and set in **Bold Type**.

<p>3</p>  <p><b>Spatial Coordination</b></p>	<p>4</p>  <p><b>Technical Design</b></p>	<p>5</p>  <p><b>Manufacturing and Construction</b></p>	<p>6</p>  <p><b>Handover</b></p>	<p>7</p>  <p><b>Use</b></p>
<p>outcome of Stage 0 may be the decision to initiate a project and Stage 7 covers the ongoing use of the building →</p>				
<p>Architectural and engineering information <b>Spatially Coordinated</b></p>	<p>All design information required to manufacture and construct the project completed</p> <p>Stage 4 will overlap with Stage 5 on most projects</p>	<p>Manufacturing, construction and <b>Commissioning</b> completed</p> <p>There is no design work in Stage 5 other than responding to <b>Site Queries</b></p>	<p>Building handed over, <b>Aftercare</b> initiated and <b>Building Contract</b> concluded</p>	<p>Building used, operated and maintained efficiently</p> <p>Stage 7 starts concurrently with Stage 6 and lasts for the life of the building</p>
<p>Undertake <b>Design Studies, Engineering Analysis</b> and <b>Cost Exercises</b> to test <b>Architectural Concept</b> resulting in <b>Spatially Coordinated</b> design aligned to updated <b>Cost Plan, Project Strategies</b> and <b>Outline Specification</b></p> <p>Initiate <b>Change Control Procedures</b></p> <p>Prepare stage <b>Design Programme</b></p>	<p>Develop architectural and engineering technical design</p> <p>Prepare and coordinate design team <b>Building Systems</b> information</p> <p>Prepare and integrate specialist subcontractor <b>Building Systems</b> information</p> <p>Prepare stage <b>Design Programme</b></p> <p>Specialist subcontractor designs are prepared and reviewed during Stage 4</p>	<p>Finalise <b>Site Logistics</b></p> <p>Manufacture <b>Building Systems</b> and construct building</p> <p>Monitor progress against <b>Construction Programme</b></p> <p>Inspect <b>Construction Quality</b></p> <p>Resolve <b>Site Queries</b> as required</p> <p>Undertake <b>Commissioning</b> of building</p> <p>Prepare <b>Building Manual</b></p> <p>Building handover tasks bridge Stages 5 and 6 as set out in the <b>Plan for Use Strategy</b></p>	<p>Hand over building in line with <b>Plan for Use Strategy</b></p> <p>Undertake review of <b>Project Performance</b></p> <p>Undertake seasonal <b>Commissioning</b></p> <p>Rectify defects</p> <p>Complete initial <b>Aftercare</b> tasks including light touch <b>Post Occupancy Evaluation</b></p>	<p>Implement <b>Facilities Management</b> and <b>Asset Management</b></p> <p>Undertake <b>Post Occupancy Evaluation</b> of building performance in use</p> <p>Verify <b>Project Outcomes</b> including <b>Sustainability Outcomes</b></p> <p>Adaptation of a building (at the end of its useful life) triggers a new Stage 0</p>
<p>Review design against <b>Building Regulations</b></p> <p>Prepare and submit <b>Planning Application</b></p> <p>See <b>Planning Note</b> for guidance on submitting a <b>Planning Application</b> earlier than at end of Stage 3</p>	<p>Submit <b>Building Regulations Application</b></p> <p>Discharge pre-commencement <b>Planning Conditions</b></p> <p>Prepare <b>Construction Phase Plan</b></p> <p>Submit form F10 to HSE if applicable</p>	<p>Carry out <b>Construction Phase Plan</b></p> <p>Comply with <b>Planning Conditions</b> related to construction</p>	<p>Comply with <b>Planning Conditions</b> as required</p>	<p>Comply with <b>Planning Conditions</b> as required</p>
<p>Pre-contract services agreement</p> <p>Preferred bidder</p>	<p>Tender</p> <p>Appoint contractor</p> <p>ER CP</p> <p>Appoint contractor</p> <p>CP</p> <p>Appoint contractor</p> <p>CP</p> <p>Appoint contractor</p>			<p>Appoint <b>Facilities Management</b> and <b>Asset Management</b> teams, and strategic advisers as needed</p>
<p>Signed off <b>Stage Report</b></p> <p><b>Project Strategies</b></p> <p>Updated <b>Outline Specification</b></p> <p>Updated <b>Cost Plan</b></p> <p><b>Planning Application</b></p>	<p><b>Manufacturing Information</b></p> <p><b>Construction Information</b></p> <p><b>Final Specifications</b></p> <p><b>Residual Project Strategies</b></p> <p><b>Building Regulations Application</b></p>	<p><b>Building Manual</b> including <b>Health and Safety File</b> and <b>Fire Safety Information</b></p> <p><b>Practical Completion</b> certificate including <b>Defects List</b></p> <p><b>Asset Information</b></p> <p>If <b>Verified Construction Information</b> is required, verification tasks must be defined</p>	<p><b>Feedback on Project Performance</b></p> <p><b>Final Certificate</b></p> <p><b>Feedback</b> from light touch <b>Post Occupancy Evaluation</b></p>	<p><b>Feedback</b> from <b>Post Occupancy Evaluation</b></p> <p>Updated <b>Building Manual</b> including <b>Health and Safety File</b> and <b>Fire Safety Information</b> as necessary</p>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
1.1	<p><b>To demonstrate evaluation of changes detailed from previous KSAR</b></p> <ul style="list-style-type: none"> <li>Assessment of any substantive changes in highlighted areas from previous review stage and all actions have been implemented</li> </ul>
1.2	<p><b>To demonstrate verification that CIG recommendations have been implemented with respect to prescribed in scope areas</b></p> <ul style="list-style-type: none"> <li>Review of the implementation of all CIG recommendations. Evaluation of any deviation from previous submissions or reviews.</li> </ul>
1.3	<p><b>To demonstrate cross-referencing with NDAP and AEDET recommendations have been implemented</b></p> <ul style="list-style-type: none"> <li>An assessment if there is full compliance with the applicable recommendations and actions from the preceding step.</li> </ul>
1.4	<p><b>To demonstrate service / clinical input into design decisions based on a current and comprehensive knowledge of patient cohorts</b></p> <ul style="list-style-type: none"> <li>Recorded and updated input taken from service lead(s) / clinician(s) about relevant patient cohort characteristics and their typical needs in terms of the accommodation's environment, safety and infection control standards.</li> <li>Demonstrable expertise of service lead(s) / clinician(s) in providing this advice.</li> </ul>
1.5	<p><b>To demonstrate a unified and recorded understanding of needs of main users and patient cohorts of the proposed accommodation and how this has influenced the design of critical building, engineering and infection prevention and control quality and safety standards</b></p> <ul style="list-style-type: none"> <li>Updated and current list available of all stakeholders, service users and patient cohorts impacted by this project, plus the identification of any high risk groups and their specialist needs</li> <li>Updated and recorded engagement on these design issues having taken place between the project team and service lead(s) / clinician(s), infection prevention and control team, and other key stakeholders (e.g. Estates, Medical Physics, IPC, the AEDET, NDAP or other design briefing workshops)</li> <li>Details available of how service users / patient cohort needs and their expected use of the accommodation are influencing the design brief, including critical building, engineering and infection prevention and control quality and safety standards.</li> </ul>
1.6	<p><b>To demonstrate the planned approach towards determining the necessary standards for this accommodation</b></p> <ul style="list-style-type: none"> <li>Updated and current list of the relevant NHS and non-NHS guidance that is being used and adopted (see previous section of workbook FBC KSAR (Page 9) for examples of appropriate guidance).</li> <li>Updated and current list of all proposed derogations from NHS guidance with a detailed technical narrative on each derogation and/or list of known gaps in guidance that will need to be resolved in order to meet the needs of the patient / user cohort</li> <li>Knowledge of the role of infection prevention and control advisors (IPCN and ICD) to be used throughout the final design stages, and details of the resource plan in place to ensure continuity into the construction phase</li> </ul>
1.7	<p><b>To demonstrate there is an effective infection prevention and control management structure in place and how it relates to the development of the project, as well as, demonstrate leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation, and that there is an effective IPC structure in place and how it relates to the design development</b></p> <ul style="list-style-type: none"> <li>Evidence IPC and clinical teams have been integrated into all decisions regarding any derogations through the design process and are satisfied this will not impact on patient safety such as, specific sign off, supporting meeting minutes, risk assessments, risk registers relating to IPC with evidence of escalation through the agreed NHS board governance process</li> </ul>
1.8	<p><b>To demonstrate implementation of evidence based infection prevention and control measures</b></p> <ul style="list-style-type: none"> <li>The Health Board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this. (Ask staff)</li> </ul>
1.9	<p><b>To demonstrate the Infection Prevention and Control Strategy</b></p> <ul style="list-style-type: none"> <li>Assessment of the Health Boards approach to all IPC related matters in relation to the development of the design, HAISCRIBE etc.</li> </ul>
1.10	<p><b>To demonstrate monitoring and records</b></p> <ul style="list-style-type: none"> <li>Evidence that the Health Board integrating this project with wider IPC requirements within the context of the FBC. For example, evidence that the proposals for equipping incorporate IPC requirements?</li> </ul>

# FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
1.11	<p><b>To demonstrate the planned approach for managing the design process to ensure successful compliance with agreed and approved standards</b></p> <ul style="list-style-type: none"> <li>The project governance arrangements and resource plan in place to ensure that the necessary decision making authority and technical expertise is available to take responsibility for and deliver the project as planned and agreed.</li> <li>Details of how gaps in expertise are being filled.</li> <li>Details of how compliance with the appropriate guidance, design brief and other standards are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated throughout the design, construction and commissioning stages.</li> <li>Details of how all stakeholders' interests are being agreed, signed off, monitored, reported against and if necessary escalated / adjudicated throughout the design, construction and commissioning stages.</li> </ul>
1.12	<p><b>To demonstrate the approach on the procurement journey with evidence of the plans on how the Board will provide assurance, particularly emphasis on the critical system identified earlier</b></p> <ul style="list-style-type: none"> <li>Evidence on how this requirement is being managed and how it fits with the project governance arrangements</li> <li>Plans to identify any gaps in the procurement approach that may require to be addressed.</li> <li>Evidence on how Infection Prevention and Control are involved with the conceptual procurement approach to the design stage and future plans for project.</li> <li>Evidence that the Health Boards selected procurement route has gone through the Board's Governance channels.</li> </ul>
1.13	<p><b>To demonstrate the approach on those areas of design that the procurement route has provided identification as possibly being Contractors Designed Portions (CDP's).</b></p> <ul style="list-style-type: none"> <li>Evidence that the procurement of the lead designer will encompass these areas in their oversight and sign off of the complete design</li> <li>Evidence that a clear demarcation of design responsibility is being developed.</li> </ul>
1.14	<p><b>To demonstrate evaluation of the commissioning plan</b></p> <ul style="list-style-type: none"> <li>Evidence that the Health Board has recorded plans that are comprehensive and adequate to address the needs of the project and that they are fully resourced.</li> </ul>
1.15	<p><b>To demonstrate evaluation of the duty holder matrix</b></p> <ul style="list-style-type: none"> <li>Evidence that the Health Board have a fully recorded matrix of the required roles and responsibilities and have a clear governance structure that is fully resourced together with plans in place for the implementation.</li> <li>Evidence that Health Boards have appropriate number of competent, qualified staff to carry out specific duties throughout the life cycle of the project e.g., IPC, Engineers, Estates staff etc. The number of competent, qualified staff will depend on the type and size of the Build Project.</li> </ul>
Water and Internal Plumbing / Drainage Systems	
2.1	<p><b>To demonstrate completed competency checks on the water and drainage consultant designers</b></p> <ul style="list-style-type: none"> <li>Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards.</li> <li>Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers?</li> <li>Recorded evidence that input from the Health Authorising Engineer for Water (AE(W)) has been requested.</li> <li>Evidence that all contractors and sub-contractor competency checks have been completed and signed off</li> </ul>
2.2	<p><b>To demonstrate how the Health Board ensures that water services are designed in a fashion which will retain space for minor additions and modifications to services in the future</b></p> <ul style="list-style-type: none"> <li>Evidence that the engineers are presented their co-ordination drawings (B M model), with space for future flexibility identified, to the Board.</li> <li>Evidence that the Design Consultant has considered and agreed with the Board, space for future flexibility in the service installations.</li> <li>Evidence that the designers have presented each of the main service runs plus plant rooms to the Board's FM team, to highlight space for future flexibility.</li> <li>Evidence that the Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design.</li> <li>Are plant/tank rooms, IPS sections, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance.</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
2.3	<p><b>To demonstrate how the Health Board assures itself that all variations / derogations which may be required to water systems are investigated and agreed by all parties before they are incorporated in the design</b></p> <ul style="list-style-type: none"> <li>Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their water management group clinical, engineering, Estates, infection prevention and control and FM teams</li> </ul>
2.4	<p><b>To demonstrate the Water Management Strategy</b></p> <ul style="list-style-type: none"> <li>Assessment of Health Board proposed water management strategy and how this relates to the specification, guidance and project requirements.</li> <li>What involvement has there been from the water management group?</li> </ul>
2.5	<p><b>To demonstrate water governance arrangements</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded how it will ensure appropriate numbers of trained staff (AP and CP) and AE(W) will be appointed, is there an established project water management group that ensures the water management strategy is adhered to for the Board and is it clear how this project will interface with this existing group?</li> </ul>
2.6	<p><b>To demonstrate the development of commissioning proposals</b></p> <ul style="list-style-type: none"> <li>Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient to meet the requirements of the project, guidance and the design of the system.</li> <li>Evidence that the design has considered the commissioning of the water system including:               <ul style="list-style-type: none"> <li>Safe storage of materials</li> <li>Agreed type of chemical (to avoid warranty and corrosion issues)</li> <li>Adequate time scale</li> <li>Competency checks on all contractors</li> <li>Water sampling scope</li> </ul> </li> <li>Water sampling test results and approval process.</li> </ul>
2.7	<p><b>To demonstrate evaluation of the planned preventative maintenance (PPM) proposals</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes, including:               <ul style="list-style-type: none"> <li>Adequate numbers of staff</li> <li>Water management PPM including all outlets, TMT &amp; TMV, plumbing and drainage systems, etc?</li> </ul> </li> </ul>
Ventilation	
3.1	<p><b>To demonstrate completed competency checks on the ventilation consultant designers</b></p> <ul style="list-style-type: none"> <li>Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards.</li> <li>Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers?</li> <li>Recorded evidence that input from the Health Boards Authorising Engineer for Ventilation (AE(V)) has been requested.</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
3.2	<p><b>To demonstrate how the Health Board ensures that ventilation services are designed in a fashion which will retain space for minor additions and modifications to services in the future and there is an appropriate plant access strategy</b></p> <ul style="list-style-type: none"> <li>- Evidence that the design engineers have presented their co-ordination drawings (BIM model), with space for future flexibility identified, to the Health Board.</li> <li>- Evidence that the design consultant has considered and agreed with the Board, space for future flexibility in the service installations.</li> <li>- Evidence that the design engineers have presented each of the main service runs plus plant rooms to the Health Board's Estates team and / or FM team, to highlight space for future flexibility</li> <li>- Evidence that the ventilation solution has been agreed with clinical and IPC colleagues.</li> <li>- Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance to be incorporated into the design.</li> <li>- Are plant rooms, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe adequate maintenance?</li> <li>- Evidence that a plant access strategy for the entire ventilation system has been provided to ensure safe, adequate access, including access for cleaning.</li> </ul>
3.3	<p><b>To demonstrate how the Health Board assures itself that all variations / derogations which may be required to the ventilation systems are investigated and agreed by all parties before they are incorporated in the design</b></p> <ul style="list-style-type: none"> <li>- Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Health Board and agreed with their ventilation safety group, clinical, engineering, Estates, infection control and FM teams.</li> </ul>
3.4	<p><b>To demonstrate a strategy for ventilation (for rooms where this is permitted within the SHTM/SHPN guidance)</b></p> <ul style="list-style-type: none"> <li>- Evidence of agreed environmental matrix.</li> <li>- Evidence that the Dynamic thermal modelling confirms what the design must include (e.g. structure, solar shading/protection, orientation, equipment optimisation, etc.) to ensure that room temperatures comply with SHTM guidance, in naturally ventilated rooms.</li> <li>- Floor plans with associated plant locations highlighted plus simple schematic of strategy. This must also identify the air intake and exhaust strategy / locations.</li> </ul>
3.5	<p><b>To demonstrate evidence of stakeholder input to ventilation strategies</b></p> <ul style="list-style-type: none"> <li>- Addition to or supplement to the Environmental Matrix which confirms the following, on a room by room basis: <ul style="list-style-type: none"> <li>- a) the type of ventilation (to SHTM 03-01) b) patient group and / or function related to the space.</li> <li>- c) name of the Consultant, Clinical Lead or Department Lead who has agreed to the room requirements.</li> <li>- d) name of the Infection Prevention and Control Doctor or equivalent who has agreed to the room requirements.</li> <li>- e) name of the Infection Prevention and Control Nurse who has agreed to the room requirements.</li> <li>- f) name of the Estates / FM team representative who has agreed to the room requirements.</li> <li>- g) name of the NHS Project Manager who has agreed to the room requirements.</li> <li>- h) name of the Decontamination Manager who has agreed to the room requirements (where this is part of the project).</li> </ul> </li> </ul>
3.6	<p><b>To demonstrate development of Ventilation Commissioning Proposals</b></p> <ul style="list-style-type: none"> <li>- Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient do they meet the requirements of the project, guidance and the design of the system?</li> <li>- What plans have been made for independent validation of the ventilation systems?</li> <li>- What plans have been made for independent verification of the ventilation system?</li> <li>- What plant and ductwork cleaning has been specified?</li> <li>- What safe adequate access has been allowed for access to dampers?</li> </ul>
3.7	<p><b>To demonstrate development of ventilation governance arrangements</b></p> <ul style="list-style-type: none"> <li>- Has the Health Board commenced its planning and recorded how it will ensure appropriate numbers of trained staff (AP and CP) staff and appointment of AE(V) for the project and is it clear how this project will interface with the Health Boards existing arrangements for management of the ventilation installations?</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
3.8	<p><b>To demonstrate evaluation of the planned preventative maintenance (PPM) proposals</b></p> <ul style="list-style-type: none"> <li>- Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes?</li> </ul>
Electrical	
4.1	<p><b>To demonstrate completed competency checks on the electrical consultant designers</b></p> <ul style="list-style-type: none"> <li>- Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards.</li> <li>- Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the Consultant Designers?</li> <li>- Recorded evidence that input from the Health Boards Authorising Engineer for Electrical (AE(E)) has been requested.</li> </ul>
4.2	<p><b>To demonstrate how the Health Board ensures that electrical services are being designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future</b></p> <ul style="list-style-type: none"> <li>- Evidence that the designers have presented their co-ordination drawings (BIM model) to the Health Board</li> <li>- Evidence that the designers have presented each of the main service runs plus plant rooms to the Health Board's FM team.</li> <li>- Evidence that the Health Board has agreed a strategy (percentage) for spare capacity and a documented allowance has been incorporated into the design.</li> <li>- Are sub stations, switch rooms, distribution board cupboards, horizontal distribution runs and risers appropriately sized for the equipment being installed and facilitate safe, adequate maintenance?</li> </ul>
4.3	<p><b>To demonstrate how the Health Board assures itself that all variations / derogations which may be required to electrical systems are investigated and agreed by all parties before they are instigated</b></p> <ul style="list-style-type: none"> <li>- Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their electrical safety group, clinical, Estates, infection prevention and control and FM teams</li> </ul>
4.4	<p><b>To demonstrate availability of adequate supply from the local utility infrastructure</b></p> <ul style="list-style-type: none"> <li>- Confirmation from the Regional Electricity Company as to how the supply will be provided from their network and if single or dual supplies are being made available.</li> <li>- What is the Health Board's resilience strategy for the electrical infrastructure (including dual supplies, renewables, generators, UPS, etc.)?</li> </ul>
4.5	<p><b>To demonstrate provisions for emergency supplies during loss of the utility incoming supply</b></p> <ul style="list-style-type: none"> <li>- Floor plans with standby generator locations highlighted plus simple schematic.</li> </ul>
4.6	<p><b>To demonstrate a strategy for locating substations</b></p> <ul style="list-style-type: none"> <li>- Floor plans with substation locations highlighted plus simple schematic of strategy.</li> </ul>
4.7	<p><b>To demonstrate a strategy for locating switchrooms</b></p> <ul style="list-style-type: none"> <li>- Floor plans with switchroom locations highlighted plus simple schematic.</li> </ul>
4.8	<p><b>To demonstrate a strategy for locating Medical IT distribution equipment</b></p> <ul style="list-style-type: none"> <li>- Floor plans with Medical IT board locations highlighted plus simple schematic.</li> <li>- Compliance with BS7671 section 710</li> <li>- Compliance with SHYM 06-01</li> </ul>
4.9	<p><b>To demonstrate a strategy for distribution</b></p> <ul style="list-style-type: none"> <li>- Floor plans with containment distribution routing (horizontal and vertical).</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
4.10	<p><b>To demonstrate the development of electrical commissioning proposals</b></p> <ul style="list-style-type: none"> <li>Evaluation of the suitability of the proposed plans in the context of the FBC, are these sufficient do they meet the requirements of the project, guidance and the design of the system?</li> <li>Has sufficient time been allocated for a full commissioning program?</li> </ul>
4.11	<p><b>To demonstrate early thinking for the electrical governance arrangements for the operational phase</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded how it will ensure appropriate trained staff and appointment of AE for the project and is it clear how this project will interface with the Health Board existing arrangements for management of the electrical installations, inclusive of third party providers?</li> </ul>
4.12	<p><b>To demonstrate evaluation of the planned preventative maintenance (PPM) proposals</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes, inclusive of third party providers?</li> </ul>
Medical Gases	
5.1	<p><b>To demonstrate completed competency checks on the medical gases consultant designers</b></p> <ul style="list-style-type: none"> <li>Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards.</li> <li>Where anyone does not have a record of extensive health care experience what recorded plans are to be put in place by the consultant designers?</li> <li>Recorded evidence that input from the Health Boards Authorising Engineer for Medical Gases (AE(MG)) has been requested.</li> <li>Evidence that all contractors and sub-contractor competency checks have been completed and signed off.</li> </ul>
5.2	<p><b>To demonstrate how the Health Board assures itself that all variations / derogations' which may be required to medical gas systems are being investigated and agreed by all parties before they are instigated</b></p> <ul style="list-style-type: none"> <li>Evidence that the each variation / derogation has a detailed technical analysis and has been referred to the Board and agreed with their medical gases management group, clinical, Estates, infection control and FM teams.</li> </ul>
5.3	<p><b>To demonstrate how the Health Board ensures that medical gas services are designed in a fashion which will provide ease of access for future maintenance and which will retain space for minor additions and modifications to services in the future</b></p> <ul style="list-style-type: none"> <li>Evidence that the designers have presented their co-ordination drawings (BIM model) to the Board.</li> <li>Evidence that the designer has presented each of the main service runs to the Board's FM team.</li> </ul>
5.4	<p><b>To demonstrate development of medical gases commissioning proposals</b></p> <ul style="list-style-type: none"> <li>Evaluation of the suitability of the proposed plans in the context of the FBC are these sufficient do they meet the requirements of the project, guidance and the design of the system?</li> </ul>
5.5	<p><b>To demonstrate development of medical gases governance arrangements for the operational phase</b></p> <ul style="list-style-type: none"> <li>Is the Health Board considering how it will ensure appropriate numbers of trained staff (AP and CP) and AE(V) for the project? And is it clear how this project will interface with the Board existing arrangements for management of the medical gases installations?</li> </ul>
5.6	<p><b>To demonstrate a strategy for bulk gas and bottle gas storage</b></p> <ul style="list-style-type: none"> <li>Floor plans with vacuum insulated evaporator (VIE) locations highlighted plus simple schematic of strategy.</li> <li>Confirmation that the medical gas strategy is adequate.</li> <li>Floor plans with pipework distribution routing and manifold locations.</li> </ul>
5.7	<p><b>To demonstrate evaluation of the planned preventative maintenance (PPM) proposals</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded the PPM requirements and approach to ensure appropriate levels of maintenance, comprehensive statutory compliance and robust management processes?</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan	
0	Provide the current, completed Action Plan
Response to KSAR Workbook - Evidence Expected	
Project Governance and General Arrangements	
Fire	
6.1	<p><b>To demonstrate completed competency checks on the Fire Engineering consultant designers</b></p> <ul style="list-style-type: none"> <li>Recorded evidence that the design team are experienced and have a comprehensive knowledge of the relevant design standards applicable to healthcare premises.</li> <li>Recorded evidence that input from the Health Boards Fire Advisors has been requested.</li> <li>Evidence that all contractors and sub-contractor competency checks have been completed and signed off.</li> </ul>
6.2	<p><b>To demonstrate a completed written fire strategy, which provides evidence, where there is a variance from statutory and mandatory guidance, that an equivalent level of safety has been achieved by alternative means.</b></p> <ul style="list-style-type: none"> <li>Is there documented evidence that fire suppression systems have been considered for life safety and property protection?</li> <li>Is progressive horizontal evacuation available for all patient areas that continuously moves away from the fire area?</li> <li>Does the design considerations of the fire and detection system, for in-patient facilities, provide L1 coverage including voids?</li> <li>Does the design provide for a compliant emergency lighting system?</li> <li>Are free swing arm self-closers fitted to all leafs of doors serving sleeping accommodation?</li> <li>Have escape lifts been considered for the evacuation of patients and others with mobility issues?</li> <li>Are multi sensor fire detectors installed to reduce the occurrence of unwanted fire alarm signals?</li> <li>Are there adequate storage facilities to ensure escape routes are not used for this purpose?</li> <li>Are measures in place to provide safe charging of electrical and personal electronic equipment?</li> <li>In addition to the prescribed list in the Building Standards Technical Handbook have fire hazard rooms been designated based on fire load?</li> <li>Where there is a mechanical ventilation system - have all compartments, sub-compartments and corridors serving sleeping accommodation been designed to be fitted with fire and smoke dampers?</li> </ul>
6.3	<p><b>To demonstrate how the Health Board assures itself that all variations / derogations which may be required to fire systems are investigated and agreed by all parties before they are instigated.</b></p> <ul style="list-style-type: none"> <li>Evidence that the each variation / derogation and any fire engineering proposals are being referred to the Board and agreed with their fire safety advisors, NDAP group, clinical, engineering, Infection Prevention and Control, FM teams and regulatory authorities.</li> </ul>
6.4	<p><b>To demonstrate how the Health Board assures itself that all fire dampers and fire/smoke dampers are designed to allow for inspection, resetting and maintenance</b></p> <ul style="list-style-type: none"> <li>Safe and adequate access has been allocated on both sides of all fire dampers for maintenance.</li> </ul>
6.5	<p><b>To demonstrate how the Health Board assures itself that any smoke control and/or clearance systems are fit for purpose</b></p> <ul style="list-style-type: none"> <li>Evidence that the smoke system is being designed by an accredited Fire Engineer.</li> <li>Evidence that Building Control are being consulted.</li> <li>Confirmation that the Health Boards fire advisors and NDAP team are satisfied with the design proposal.</li> </ul>
6.6	<p><b>To demonstrate the development of the fire system outline commissioning proposals</b></p> <ul style="list-style-type: none"> <li>Is there an established fire management group that will ensure the fire strategy is adhered to?</li> </ul>
6.7	<p><b>To demonstrate early thinking for the Fire Safety arrangements for the operational phase</b></p> <ul style="list-style-type: none"> <li>Has the Health Board commenced its planning and recorded how it will ensure appropriate trained staff and appointment of Fire Officers for the project in the operational phase and is it clear how this project will interface with the Health Boards existing arrangements for management of the Fire Safety?</li> </ul>
IPC Built Environment	

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
7.1	<p><b>To demonstrate that there is an effective infection prevention and control management structure in place, and leadership and commitment to infection prevention and control to ensure a culture of continuous quality improvement throughout the organisation and that there is an effective IPC structure in place: inputting into the design process</b></p> <ul style="list-style-type: none"> <li>• The Health Board provides evidence that there is an IPC Management Structure with the necessary expertise and leadership skills to support the design work</li> <li>o The Health Board provides evidence that there is an IPC Management Team with the necessary expertise and leadership skills to support the project.</li> <li>o Executive board reports or minutes, Risk registers or equivalent, Minutes from operational and governance groups, (and action points)</li> <li>o Structure of infection prevention and control team (IPCT) and qualifications held, previous experience supporting new build projects.</li> <li>o Evidence IPC and clinical teams have been involved with any derogation through the design process and are satisfied this will not impact on patient safety. This can be meeting minutes, risk assessments, and risk registers. There is IPC evidence of escalation through the agreed NHS board governance process.</li> <li>o Evidence the Executive Board Member assigned to lead on IPCT has been kept informed of IPC risks identified and associated with the project this can be demonstrated by the board</li> <li>o Evidence that fixtures fitting and equipment have not been proposed for the project that would represent an identified IPC risk</li> <li>o Evidence that all contractors and sub-contractor competency checks have been completed and signed off.</li> </ul>	
7.2	<p><b>To demonstrate implementation of evidence based infection prevention and control measures during the design process</b></p> <ul style="list-style-type: none"> <li>• The Health Board can demonstrate the current version of the National Infection Prevention and Control Manual has been adopted by the organisation and all staff are aware of how and where to access this and it is being referred to during the design process.</li> <li>• The Health Board can demonstrate IPC advisors have been included within the design phase and development of HAISCRIBE</li> </ul>	
7.3	<p><b>To demonstrate how the Health Board assures itself that the designers have a proper understanding of the infection prevention and control procedures required</b></p> <ul style="list-style-type: none"> <li>• The Health Board evidences that:           <ul style="list-style-type: none"> <li>o All relevant staff within the designers' organisation are provided with clear guidance on roles and responsibilities in relation to infection prevention and control.</li> <li>o The contractors' organisation will provide evidence of education in relation to infection prevention in the built environment for all staff involved in the project.</li> </ul> </li> </ul>	
7.4	<p><b>To demonstrate how the Health Board assures itself that equipment being proposed meets the required IPC standard</b></p> <ul style="list-style-type: none"> <li>• The IPC Team are involved and IPC advice followed in all procurement decisions for new equipment prior to purchase. IPCT are satisfied that all equipment purchased can be decontaminated safely in line with National Guidance and manufacturers' instructions.</li> </ul>	
7.5	<p><b>To demonstrate evaluation of the planned preventative maintenance (PPM) proposals for equipment issues and the Built Environment in relation to IPC issues</b></p> <ul style="list-style-type: none"> <li>• Has the Health Board considered how they will undertake assessment of and report cleanliness of the proposed facility and equipment within the healthcare environment, this is inclusive of planned programmes of maintenance?</li> <li>• Does the Health Board plan to seek feedback from patients, staff and visitors for their views?</li> <li>• Is it clear how the work for this project will interface with the Health Board existing arrangements for management of the IPC in the Built Environment in the wider estate?</li> </ul>	
To support the KSAR Response and Technical Assessment - Deliverables Expected		
Item	Deliverables - including drawings, specifications, reports	Further Information
1	NHS Board Authority Construction Requirements (ACRs)	Noting any changes from OBC
2	PSCP/Design Team Contracts/Appointment Documents	
3	Evidence of Board Competency Checks on Design Team/Contractors	
4	Clinical Brief	Noting any changes from OBC
5	Project Brief	This document should be in place from IA and OBC Stages. Changes/departures from brief during FBC to be clearly identified. May be linked to ACRs if they are project specific.
6	Project Programme	To include key construction & commissioning milestones.

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
7	Responsibility/Duty Holder Matrix	Evidence that the Board have a fully recorded matrix of the required roles and responsibilities and have a clear governance structure that is fully resourced together with plans in place for the implementation. Evidence that Health Boards have appropriate number of competent, qualified staff (or have a strategy to procure) to carry out specific duties throughout the life cycle of the project e.g., IPC, Engineers, Estates staff etc. The number of competent, qualified staff will depend on the type and size of the Build Project.
8	Provide report(s) on building services issues as part of concept design report(s). The following topics must be covered as minimum:	
8.1	Stage 4 MEP Report - Outline system strategies to satisfy the clinical and project brief	<p>Include details of ventilation strategy (natural/mechanical); outline control strategy. Identify requirements for pressure cascades in clinical areas. Identify any specialist areas requiring dedicated/specialist ventilation services e.g. decontamination units, infectious diseases, etc. Evidence of dynamic modelling should be provided to support the strategies (e.g. TM52 all 3 criteria, TM59 for bedrooms, use 2020 High local weather data, plus test for 2030).</p> <p>Identify strategy for heating/cooling to each area/room including how temperatures and peak percentage relative humidity will match the level of control selected by the clinical team.</p> <p>Identify common design criteria including summer/winter external design criteria both for building loads and for plant selection.</p> <p>Primary plant strategies to be defined, including details on how loads have been assessed and indicative plant selections made.</p> <p>Provide a breakdown of water supply grade to be provided to each space. This should include details of any areas required to be provided with dedicated water supplies independent to the remainder of the main facility, as well as any specialist clinical/process requirements.</p> <p>Identify requirements for Medical IT systems to BS7671.</p> <p>Identify the safety systems &amp; resilience requirements.</p>
8.2	MEP Technical Specifications	<p>Provide detailed technical MEP specifications. Specifications should include reference to the following:</p> <ul style="list-style-type: none"> <li>Scope of works for all mechanical, electrical and public health engineering systems.</li> <li>Modifications/reurbishment/replacement works associated with existing systems. Include details of interfaces to existing infrastructure.</li> <li>Materials &amp; workmanship requirements.</li> <li>Description of controls systems and narrative for each controls algorithm.</li> <li>Generator/standby power systems sequence of operations.</li> <li>Fire detection &amp; alarm system cause &amp; effect.</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
8.3	Sustainability Strategy	<p>Document should include detail of:</p> <p>Sustainability targets – what does project brief entail and how is it satisfied?</p> <p>Net zero/carbon negative strategy/roadmap.</p> <p>Planning considerations detailed.</p> <p>How loads and load profiles have been assessed/benchmarked to inform strategy.</p> <p>Renewable and lowzero carbon technologies considered (LZCT Report). Where new and emerging technologies are considered, evidence should be provided to support their use in a healthcare environment, including impact on patient safety, HAI, resilience and maintainability/serviceability.</p> <p>Integration into site plant strategy, including resilience, control and seasonal/weather considerations (e.g. external design air temperatures, ground temperatures, demand profiles).</p> <p>A clear statement on the solutions which have been chosen and the logic behind their selection.</p>
8.4	Energy strategy	<p>Report should include finalised estimates of regulated in-use energy consumption. Report should state all assumptions made in relation to loads, how these have been benchmarked, etc. Dynamic thermal modelling outputs should be provided in support of strategy (e.g. NCM templates).</p> <p>Consideration of occupancy profiles and levels of unregulated electrical loads which have been agreed with the stakeholders.</p>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
0.5	Utility Report	<p>Document should include detail of:</p> <ul style="list-style-type: none"> <li>Anticipated demand/peak loads plus profiles for each utility (e.g. power/water/gas) (this should include details of any loads for medical equipment that have been agreed with the stakeholders).</li> <li>Connection point(s) to utility provider network, including review of resilience, single points of failure and reliability of supply (including any historical/seasonal variations in supply).</li> <li>Incoming water quality and evidence of variations which have been discussed with the supplier.</li> <li>Evidence of engagement with utility provider.</li> <li>Planning considerations.</li> <li>Site logistics, space planning and requirement for any wayleaves. Consideration to be given to service routes and co-ordination with site operation (e.g. blue light routes).</li> <li>Phasing considerations.</li> <li>Required diversions.</li> <li>The impact of any issues which have been determined through surveys or site works.</li> </ul>
8.6	Environmental assessments	HAI considerations should also be considered as part of FBC HAI-SCRIBE e.g. contaminated land, impact of surroundings/proximity to neighbouring buildings. Identify whether any site specific tests have been undertaken in support of natural ventilation - e.g. air quality monitoring, etc. Provide details of any mitigating measures which have been adopted.
8.7	Building control and planning approvals status, including Building Regulations Compliance - e.g. Section 6, fire protection measures, life safety systems, etc	Provide evidence of current approvals status, including details of any appeals.
8.8	Constraints arising from the brief or local authority policy	
8.9	Hierarchy of design standards	Detail applicable design standards to project. Updated from OBC
8.10	Daylight analysis	Climate Based Daylighting Modelling (CBDM) approach to test solutions. Provide details of the influence that the modelling has had on the building design.
8.11	Site selection & building form	Details on how building form/orientation/site selection have been considered to maximise energy performance of building.
8.12	Future-proofing strategy	Plant capacity, provision of spares, spatial co-ordination, services routes, adaptability of services to meet clinical brief, etc.
8.13	Optioneering/technical reports	Provide optioneering/technical reports to supplement/support engineering design and strategy decisions.

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
8.14	Research on/proposals for innovative solutions	For example digital services and technology to be adopted. Any specialist medical equipment e.g. robotics and impact on services. How have these been assessed for use in a healthcare setting e.g. maintenance, reliability, lifecycle considerations?
8.15	Considerations for offsite manufacture	HAI considerations should also be considered as part of GBC HAI-SCRIBE. Evidence should be provided of the measures to be implemented to ensure that domestic water components are not tested offsite or in the factory using water.
8.16	Limitations or considerations for future design development	This may be captured via project risk register, design development checklists or other documents. Processes should be clearly defined for monitoring purposes, including input from all key stakeholders (this should include limitations on the capacity of medical equipment that are imposed by the assumptions made). Stakeholders should be identified.
9	Resilience strategy	This should be prepared as a standalone document. Resilience strategy to be provided for all MEP systems in a single report. Evidence of stakeholder consultation should be provided. Generator/UPS provision. Redundancy of plant. Emergency protocols e.g. emergency water fill. Impact of maintenance shutdowns. Impact to facility on loss of essential MEP systems.
10	Water management strategy, including strategy for maintaining water temperatures	This should outline proposed control measures in relation to the project. Where in relation to an existing facility, control mechanisms should be detailed to take cognisance of existing facility water quality/supply. Strategy for maintaining hot and cold water at acceptable temperatures for control of legionella, plus how will system be monitored and escalated if temperature deviate from specified conditions? DSM modelling to support assumptions/proposals, including consideration of heat gain from void spaces and other areas/equipment. All of this information should be presented in the form of a report with risk assessment.
11	Designers risk assessment (Water)	
12	Environmental Matrix	Environmental matrix based on the NHS Scotland Assure Environmental Matrix template or technically equivalent.
13	Provide report on adequacy of existing building services to incorporate extended or refurbished works	<p>The report should consider resilience to existing and future works, impact of shutdowns and compliance with current guidance.</p> <p>The report should also detail how capacity within the existing systems has been assessed, including consideration of whether any spare capacity needs to be maintained for future works.</p> <p>It should identify how assurance is provided that systems are safe, suitable for re-use and how they will impact on compliance with current engineering best practice, standards and guidance. Cognisance of existing building O&amp;M/H&amp;S must be made, including where information is not available.</p> <p>Report should clearly detail tie-ins to existing infrastructure and include details of any tests/studies which have been completed or are required on the existing infrastructure.</p>
14	Provide specifications for final commissioning and handover	Including designers commissioning brief in accordance with SHTM 03-01 and SHTM 04-01
15	Detailed commissioning plan & programme	Document to clearly outline phasing requirements, control measures to be implemented, consideration of system or plant arrangements, sequencing of activities, testing & commissioning plan, define responsibilities, define deliverables for commissioning certification

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
16	Dynamic Thermal Modelling Outputs & Report	Including Section 6 compliance review, overheating & thermal comfort analysis and BRUKI.
17	Fire Strategy	Detailed strategy for fire safety (such as compartmentation, location of fire/evacuation lifts, fire detection and suppression philosophy, consultation with relevant authorities). Ensure strategies are supported by risk assessments where required. Ensure all key stakeholders required to input to the strategy are identified and provide evidence they have been consulted in creation of the fire strategy & any supporting risk assessments. Provide supporting drawings.
18	Fire and smoke control measures, with respect to building services	For example: locations selected for the use of fire rated ductwork or the provision of fire/smoke dampers, fire stopping methods, etc.
19	BREEAM Report & Scorecard	Particular focus on early stage credits & how these are evidenced.
20	Acoustic Report	Details should also be provided as to how plant has been designed to satisfy acoustic requirements (including the siting of plant relative to sensitive areas). This should consider both primary plant and distribution. Needs to identify whether any specialist requirements for the project e.g. specialist departments such as Audiology. Identify whether any site specific tests have been undertaken in support of natural ventilation - e.g. background noise, etc. Identify measures which have been taken in the design to ensure that the designs are in compliance with SHTM 08-01, including cross talk attenuation.
21	Provide technical design information model including appropriate geometric detail, defined level of clash detection and object information.	
22	Provide technical design drawings	<ul style="list-style-type: none"> <li>Plant Room Layouts</li> <li>Ventilation</li> <li>Heating &amp; Cooling</li> <li>Water Services</li> <li>Medical Gas</li> <li>Above Ground Drainage</li> <li>External Services</li> <li>Utility layouts</li> <li>External Lighting</li> <li>Lighting &amp; Emergency Lighting including controls</li> <li>IT/Comms Room Layouts</li> <li>Containment</li> <li>Small Power &amp; Data</li> <li>Earthing</li> <li>Fire Detection &amp; Alarm</li> <li>Intruder Alarm/Security/CCTV</li> <li>Nurse Call</li> <li>Lightning Protection</li> <li>Existing services diversions/modifications (if applicable to project).</li> </ul>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
23	Provide technical design schematics	They must be produced, as a minimum, for the following services - Water services plant Water services networks Ventilation plant Ventilation systems networks Above ground drainage Heating plant Heating networks Cooling plant Cooling networks HV Distribution LV Distribution UPS and Medical IT Distribution Systems Earthing & Bonding Lighting Controls Fire detection & alarms Intruder Alarm/Security/CCTV Nurse Call Fuel supply systems Fire suppression systems Medical gas plant and manifolds Dry Risers BMS controls CSFD controls architecture
24	Provide design calculations	Calculations including: 1. All Ventilation systems, including pressure cascades, air flow calculations, detailed theatre air flow rates to match doors, duct sizing. 2. Heating & Cooling calculations - may be linked to DSM 3. Electrical distribution calculations, including protection study (fault study & selectivity) 4. Lighting calculations 5. Electrical load calculations 6. MGPS Calculations 7. Domestic water pipework sizing 8. Fuel storage 9. Water storage 10. Drainage pipework sizing
25	Provide technical design builders work information as applicable	Provide evidence that the plant weights have been coordinated with the Structural Engineer.

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
26	Provide performance specifications & drawings for specialist/contractor designed elements of the works.	<p>Specialist/Contractor design portions should contain sufficient detail to provide assurance on spatial co-ordination including ceiling voids and plant rooms, as well as electrical loads.</p> <p>If PSCP/Contractor is already in place they should provide a delivery plan for when CDP's will be issued and how they will be monitored for compliance with the project brief. The Board should also identify what assurance measures they have in place for reviewing CDP's submitted post FBC. The CDP briefing specifications must give clear instruction on standards to be achieved and the method by which they will be verified.</p>
27.1	Provide mechanical & public health plant & equipment schedules.	<p>Detailed schedules to be provided for mechanical &amp; public health systems including but not limited to:</p> <ol style="list-style-type: none"> <li>1. Air Handling Units</li> <li>2. Pumps</li> <li>3. Chillers</li> <li>4. Boilers</li> <li>5. Fan Coil Units</li> <li>6. Heat emitters (e.g. radiant panels/radiators/etc).</li> <li>7. Heat Pumps</li> <li>8. Solar/PV</li> <li>9. Boilers</li> <li>10. BMS (including points list).</li> <li>11. Water filtration plant</li> <li>12. Cooling units</li> <li>13. Water chillers</li> <li>14. Power Factor Correction</li> <li>15. Louvres</li> <li>16. Fans</li> <li>17. Attenuators</li> <li>18. Grilles &amp; Diffusers</li> <li>19. Terminal heating &amp; cooling coils</li> <li>20. Terminal filters</li> <li>21. Fire/smoke dampers</li> <li>22. Booster sets</li> <li>23. Pressurisation and expansion units</li> </ol> <p>Schedules should provide information on equipment rating, type, configuration of components, etc</p>

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
27.2	Provide electrical plant & equipment schedules.	<p>Detailed schedules to be provided for electrical systems including but not limited to:</p> <ol style="list-style-type: none"> <li>1. Switchgear assemblies (low and high voltage)</li> <li>2. Distribution boards</li> <li>3. Cable schedules (for all main, sub-main and final circuits) and/or busbar schedules where applicable.</li> <li>4. Transformers</li> <li>5. Generators</li> <li>6. Luminaire schedule, including photometric performance information.</li> <li>7. Uninterruptible Power Supply (UPS) systems</li> <li>8. Fire detection &amp; alarm system</li> <li>9. Any other standby/emergency power systems including emergency lighting static inverter/central battery.</li> <li>10. Intruder alarm/security systems</li> <li>11. Power Factor Correction</li> </ol> <p>Schedules should provide information on equipment rating, type, configuration of components, etc.</p>
28	Provide coordinated reflected ceiling plans based on agreed architectural information for all components.	
29	Provide coordinated room elevations based on agreed architectural information for all components.	
30	Plant access, maintenance and replacement strategy	Report with drawings
31	Mitigation Strategy	
32	Provide report on any proposals or agreed outcomes following participation in any Soft Landings process	
33	Health and safety risk assessments for the technical/detailed design	Refurbishment or extension/expansions projects should take cognisance of any residual H&S risk assessments pertaining to the existing estate.
34	FBC HAI-SCRIBE	To be developed in accordance with SHFN 30. Input from all stakeholders to be identified, including all members of the DTM. Evidence of actions and integration of recommendations into design should be provided. This is an integral part of the design process that all parties have a responsibility to contribute to.
35	FBC Derogations Schedule	Evidence of stakeholder engagement/review/sign off to be provided. Mitigations must be described in full for all derogations and should identify how the mitigations achieve a standard no less than that achieved via compliance with guidance.
36	Design responsibility matrix	Including details of allocated Contractor Design Packages. Where a multi-stage procurement strategy is in place, this must be clearly reflected. Evidence of space planning associated with the GDPs should be shown and described.
37	Project Risk Register	
38	Equipping responsibility matrix	
39	Reviewable Design Data (RDD) schedule	

## FBC KSAR Deliverables List

Date: 17 December 2021

NOTE: This list must be read in conjunction with the FBC KSAR Workbook.

Action Plan		
0	Provide the current, completed Action Plan	
Response to KSAR Workbook - Evidence Expected		
Project Governance and General Arrangements		
40.1	Provide a report in consideration of any alternative plant, equipment, and component selections.	Report should clearly outline quality control measures in place by the Board, PSCP and design team to ensure that any alternatives meet the requirements of the respective technical specification/performance criteria.
40.2	Provide report on the specialist designers' proposals within the main contract.	As applicable dependant on procurement timelines.
40.3	Provide calculations and/or software files in support of specialist design proposals	As applicable dependant on procurement timelines.
41	Construction Phase Plan	This should be prepared prior to the project starting on site as per CDM regulations. Dependant on the timing of the KSAR this document may not yet be in place - if that is the case, assurance must be provided as to project protocols to ensure this document is provided within required programme timescales.
42	Draft Handover Checklist	Ensure requirements are identified prior to commencing construction. Phased handover and commissioning/system milestone requirements should be defined as applicable.
43	Evidence of client/key stakeholder consultation, review and approval of FBC documents	The Board must be able to demonstrate their internal governance and control measures, including input/review from suitably qualified/competent persons including Authorising Engineers, infection prevention and control team, the clinical team and a peer review of technical documentation

The above list has been developed based on a modified version of BSRIA (BG6/2018) Design Framework for Building Services 5th Edition, RIBA Plan of Work 2020, SCIM, various healthcare guidance documents and other lessons learned. It is not intended to be considered as an exhaustive list, rather it should be considered as the minimum information to be provided at the denoted workstage.

**BSRIA BG6 2018 Appendix A: Allocating Design Responsibility****PROJECT NAME:** RHCYP+DCN HVC107**SITE ADDRESS:** Little France Cres, Edinburgh EH16 4SA**Parties to the project:**

(The following letters are used as shorthand references in the completed proformas)

<b>A</b>	Hoare Lea
<b>B</b>	IMTECH
<b>C</b>	Architect
<b>D</b>	C&S Engineer
<b>E</b>	CDM Principal Designer
<b>Z</b>	Contractor (as-yet unknown team member)

**Notes:**

L, S and R indicate responsibility for leadership, support and review of the activity respectively.

Activities and deliverables not required for the project are either struck through or noted as "N/A" in the comments column.

The proformas are reproduced from BSRIA BG 6/2018 A Design Framework for Building Services 5th edition.

Text that has been changed or added to the BSRIA original are shown in red.

These pro-formas are to be read in conjunction with the relevant associated appointment / contract documents.

Reproduced from BSRIA BG 6/2018 A Design Framework for Building Services 5th edition

PROFORMA 2: CONCEPT (RIBA STAGE 2)								
Ref	Design activity in connection with building services	Allocated to .... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
<b>General obligations, external liaison (statutory bodies, utilities)</b>								
2.1.1	Consult local authorities about matters of principle in connection with the services design of the works including requirements over and above statutory requirements.	S	L					
2.1.2	Put known utility supplies or site-based utilities onto a model to support the engineering services philosophy for the project (energy generation/supply, water supply, waste removal, communications, fire-fighting).	L						
2.1.3	<del>Advise on the requirements for utilities and services diversions, based on desktop study and provided information.</del>							Not Required
2.1.4	Advise on regulatory compliance of MEP concept design.	L						
2.1.5	<del>Prepare initial strategy for fire safety (such as compartmentation, location of fire lifts, fire detection and suppression philosophy, consultation with relevant authorities).</del>							Not required
2.1.6	Establish impact of fire strategy on building services design.	L						
<b>Client liaison (briefing, handover, surveys)</b>								
2.2.1	Evaluate physical, environmental, functional and regulatory constraints from clients' brief, for potential schemes.	S	L	S				
2.2.2	Visit site(s) and/or example project(s) to assess physical restrictions that might influence the design philosophy or the development of the design.	S	L	S				
2.2.3	Advise the client on the need for arrangements to be made for and define the extent of special investigations or tests (could be intrusive or non-intrusive).	S	L					
2.2.4	Review and report on the condition/status of any existing services installations (usually only required for buildings being refurbished/extended).	S	L					Matterport Survey, Verification Surveys.
2.2.5	<del>Review feasibility of renewable technologies.</del>							Not Required for this project
2.2.6	Define performance metrics and design targets for the building.	L						
2.2.7	Give initial recommendations to the client in the development of an operating and maintenance strategy.	S	L					
2.2.8	<del>Establish targets for the post-occupancy review.</del>							
<b>Team liaison (builders' work, spatial coordination, energy targeting)</b>								
2.3.1	Undertake the role of lead project designer.	S	L					
2.3.2	Fulfil role of Principal Designer under CDM Regulations 2015.					L		
2.3.3	Discuss potential mechanical, electrical and public health schemes for the preferred solution selected in RIBA Stage 1, with the rest of the design team.	L						
2.3.4	Advise team members (architect, structural engineer) of significant implications (size, weight, access requirements for installation and replacement) of mechanical, electrical, public health systems including central plant.	L						
2.3.5	Agree builders' work philosophy (such as the treatment of structural openings) for principal mechanical, electrical and public health systems.	S	L					
2.3.6	Agree dimensional and other numerical tolerances to be applied to building services design and deliverables at different project stages.	S	L					E.g. weights, quantities of components
2.3.7	<del>Carry out or commission surveys relating to energy strategy options.</del>							
2.3.8	<del>Undertake energy strategy studies for the building fabric and engineering services to support the design – typically generic thermal simulation (and modelling) with simplified boundary conditions to give qualitative feedback.</del>							
2.3.9	Undertake generic daylight computer modelling required to support the design and obtain qualitative feedback (state particular requirements for the project).	L						Only required if the proposals were to impact on the daylight to existing rooms.
2.3.10	<del>Review architect's proposals for compliance with Building Regulations in relation to energy performance.</del>							
2.3.11	Develop and update BIM execution plan during project.	S	L					As per PAS 1192-2
2.3.12	Develop and update master information delivery plan during project.	S	L					As per PAS 1192-2
2.3.13	Develop and update building services task information delivery plan during project.	L						As per PAS 1192-2
2.3.14	Federate information models from separate task teams and oversee the clash avoidance process.	S	L					As per PAS 1192-2. See also 3.3.15
2.3.15	Remove critical clashes from the building services concept design.	L						See section 2.5 of BG 6
2.3.16	Prepare programme/Gantt chart for the design activities and schedule of design deliverables.	S	L					
2.3.17	Prepare risk assessments for the design, covering health and safety during construction, operation and end-of-life, and technical risks.	S	L	S	S			
2.3.18	Contribute to risk assessments for the design covering programme, cost and quality.	S	L	S	S			
2.3.19	Detailed review of existing health and safety file (for refurbishment projects or additional construction on an existing site).	S	L	S	S	R		
2.3.20	Team-wide design review to signal end of concept design stage.	S	L	S	S	S		See section 3.8 of BG 6
<b>Selection of plant and specialist designers</b>								
2.4.1	Identify activities needing early specialist design input by others.	S	L					E.g. lightning protection, earthing
2.4.2	Advise client on assessment and selection of specialist designers.	S	L					
2.4.3	Advise client on selection of Contractor Design Portions and plan for covering these topics until the relevant contractors are appointed.	S	L					
2.4.4	Advise on potential for off-site manufacture of building services plant and distribution equipment, including implications for construction strategy, project milestones and	S	L					Only external plantroom possibilities.
2.4.5	Agree initial off-site delivery strategy including programme milestones.	S	L					If deemed possible
2.4.6	Establish areas/zones for central plant in line with mechanical, electrical and public health design philosophies.	L						
2.4.7	Consider and define need for provisional sums.	S	L					
<b>Mechanical design</b>								
2.5.1	Determine mechanical systems philosophy.	L						
2.5.2	<del>Determine passive design philosophy.</del>							Not required
2.5.3	Undertake assessment of comfort conditions and overheating risk	L						
2.5.4	Design review.	L						See section 3.8 of BG 6
<b>Electrical design</b>								
2.6.1	Determine electrical systems philosophy (degree of system integration, redundancy, life-cycle, cross reference to lighting studies, etc).	L						
2.6.2	Design review.	L						See section 3.8 of BG 6
<b>Public health design</b>								
2.7.1	Determine water supply and waste-handling philosophy (recycling, storage).	L						
2.7.2	Design review.	L						See section 3.8 of BG 6
<b>Commissioning</b>								
2.8.1	Establish phased handovers, system configuration or plant arrangements to simplify commissioning.	S	L					
2.8.2	Prepare strategic commissioning plan.	L						
<b>Deliverables – including drawings, specifications, reports</b>								
2.9.1	Provide report on building services issues as part of concept design report. Specific considerations for this report include the items below. See BSRIA BG 71/2017 <i>Building Services Reports</i> for further details.							Usually as a desk study on matters affecting design options
2.9.1a	<del>recommendations for renewables,</del>							
2.9.1b	considerations for offsite manufacture,	L						
2.9.1c	environmental assessments,	L						
2.9.1d	building control requirements,	S	L	S				
2.9.1e	Building Regulations compliance (e.g. Section 6),	L						
2.9.1f	<del>Initial energy strategy.</del>							

Reproduced from BSRIA BG 6/2018 A Design Framework for Building Services 5th edition

PROFORMA 2: CONCEPT (RIBA STAGE 2)								
Ref	Design activity in connection with building services	Allocated to .... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
2.9.1g	noise and acoustic measures,	L						For MEP acoustics and architectural duties
2.9.1h	fire and smoke control measures,	S	L					
2.9.1i	future-proofing strategy,	L						
2.9.1j	<del>limitations or considerations for future design development,</del>							
2.9.1k	adequacy of utilities supplies,	L						
2.9.1l	constraints arising from the brief,	S	L					
2.9.1m	high-level metering strategy,	L						
2.9.1n	plant replacement strategy,	L						
2.9.1o	research on innovative solutions,	L						
2.9.1p	daylight analysis.	L						Only required of the proposals impact on the existing daylighting
2.9.2	<del>Provide MEP concept design information model including appropriate geometric detail and object information.</del>							BIM model will be a deliverable at a future stage.
2.9.3	Provide concept sketch drawings for preferred preliminary design(s).	L						
2.9.4	Provide concept schematics for preferred preliminary design(s).	L						
2.9.5	Provide information for early-stage life-cycle cost and life-cycle assessment studies.	S	L					
2.9.6	<del>Provide tender documentation for inclusion in a tender package if the procurement method requires it.</del>							See also 3.9.24 and 4.9.9
2.9.7	Provide outline cost plan for building services based on floor area / building type / system assumptions.	S	L					
2.9.8	<del>Provide COBie tables for BIM Level 2 Information Exchange 2.</del>							BIM model will be a deliverable at a future stage.
2.9.9	<del>Provide preliminary energy statement for planning submission, where required by the planning authority.</del>							
2.9.10	Provide concept design builders' work information as applicable.	L						
2.9.11	Provide report on adequacy of existing building services to incorporate extended or refurbished works.	L						
2.9.12	Provide preliminary estimate of regulated in-use energy consumption.	L						For the Isolation rooms only
2.9.13	<del>Provide report on any proposals or agreed outcomes following participation in any Soft Landings process.</del>							
2.9.14	Provide health and safety risk assessments for the concept design.	S	L	S	S	R		
2.9.15	Sign off the concept design report.							Usually by the client

PROFORMA 4: TECHNICAL DESIGN (RIBA STAGE 4)								
Some activities in RIBA Stage 4 may continue after the start of the project's construction stage.								
Ref	Design activity in connection with building services	Allocated to ... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
	<b>General obligations, external liaison (statutory bodies, utilities)</b>							
4.1.1	Carry out ongoing checks for compliance with regulations.	S	L	S	S			
4.1.2	<del>Advise on impact of any changes from scheme used to calculate the Building Emissions Rate for Building Regulations energy compliance and (if relevant) EPC.</del>							
4.1.3	Provide information for pre-site building control approval.	S	L	S	S			
4.1.4	<del>Obtain final quotations for incoming services based on final agreed building loads.</del>							
4.1.5	<del>Seek utility company comments on the spatial requirements and builders' work associated with the provision of incoming services.</del>							
	<b>Client liaison (briefing, handover, surveys)</b>							
4.2.1	Prepare the building services Employers Information Requirements in accordance with PAS 1192-2.						As per PAS 1192-2	
4.2.2	Prepare pre-contract BIM Execution Plan for building services installation (as required by procurement route).						As per PAS 1192-2	
4.2.3	Advise on an appropriate method of procuring maintenance expertise.							
4.2.4	Define the scope and content of operating and maintenance manuals appropriate for the project.						Already defined.	
4.2.5	Review the design against operational design targets, involving the future building manager(s) and update/reissue design reports, specifications and/or Soft Landings.							
4.2.6	Define the requirement for MEP handover information.						Already defined.	
4.2.7	Specify form of delivery and method of production of MEP handover information.						Take account of any phased handover or partial	
4.2.8	Prior to commencement of works, prepare method statement for the maintenance of existing services.		L					
	<b>Team liaison (builders' work, spatial coordination, energy targeting)</b>							
4.3.1	<del>Undertake checks in relation to Building Regulations energy performance compliance and (if relevant) EPC criteria.</del>							
4.3.2	<del>Review proposals from others in relation to Building Regulations energy performance compliance and (if relevant) EPC criteria.</del>							
4.3.3	Review dimensional and other numerical tolerances to be applied to building services design and deliverables at different project stages.	S	L					
4.3.4	Make submissions to obtain Building Regulations approval in relation to energy	S	L	S				
4.3.5	Design weatherproofing details for all services passing through external elements of the building.	S	L	S	S			
4.3.6	Provide typical details for all acoustic stopping for services penetrating builders' work elements.	L	S	S				
4.3.7	Develop and update BIM Execution Plan during project.		S				As per PAS 1192-2.	
4.3.8	Develop and update building services Task Information Delivery Plan.		L				As per PAS 1192-2.	
4.3.9	Develop and update Master Information Delivery Plan during project.		S				As per PAS 1192-2	
4.3.10	Federate information models from separate task teams and oversee the clash avoidance process.		S				As per PAS 1192-2	
4.3.11	Carry out project-wide design review of MEP feasible-generic design.	R	L				See section 3.8 of BG6	
4.3.12	Agree the principles relating to reflected ceiling plans.	S	S	L				
4.3.13	Carry out Stage 4 coordination between building services, structure and architecture prior to selection or procurement of actual equipment. (Feasible for building services contractor/ trade-contractor pricing and installation without major re-routing).	S	L	S			Major spaces: plant rooms, risers, ceiling and floor voids. Removal of critical clashes – see section 2.5 of BG 6	
4.3.14	Carry out Stage 4 coordination between different building services prior to selection or procurement of actual equipment. (Feasible for building services contractor/trade contractor pricing and installation without major re-routing).	S	L	S			Removal of critical clashes – see section 2.5 of BG 6	
4.3.15	Consider requirements for cable pulling (routes and anchor points).	S	L					
4.3.16	Review MEP design risk assessments incorporating specialist design input.	S	L				Specify extent of risk assessments (H&S, technical, commercial)	
4.3.17	Check the provision for and adequacy of builders' work information provided for specialist elements (including CDP).	S	L	S				
4.3.18	Select and detail sleeves, inserts, frames, and fixing anchors, and any other items required to be cast or built into the structures by others, including coordination of positions to such extent and accuracy to allow structural construction to proceed.		L		S			
4.3.19	Detail and coordinate all access platforms, stairs, rails and protection elements required for future maintenance and operation of plant/equipment.	S	L	S	S		Includes selecting proprietary platforms, access covers, gratings, ladders, walkways, balustrades, guardrails and all additional structural steelwork, associated with specific items of plant, where indicated in the Tender documentation.	
4.3.20	Carry out final detailed location and dimensioning of 2nd fix equipment based on architectural information.	S	L	S			State extent (luminaires, control devices, outlets, and grilles)	
4.3.21	Determine location of access panels.	S	L	S			For example, rodding eyes and pipework valves	
4.3.22	Carry out project-wide design review of coordinated-generic design.	S	L	S			See section 3.8 of BG6	
4.3.23	Confirm builders' work information for specified equipment or materials, or where alternatives to those provisionally or pre-selected are agreed.	S	L	S			Bases, supports and structurally significant holes	
4.3.24	Provide final details for all acoustic stopping for services penetrating builders' work	S	L	S				
4.3.25	Carry out Stage 4 coordination between all building services trade contractors after the selection or procurement of actual equipment.	S	L	S			Removal of critical clashes – see section 2.5 of BG 6	
4.3.26	Carry out Stage 4 coordination between the building services, structure and architecture after the selection or procurement of actual equipment.	S	L	S	S		Removal of critical clashes – see section 2.5 of BG 6	
4.3.27	Prepare detailed construction programme for installation and remaining design		L					
4.3.28	Carry out project-wide design review of coordinated-specific design.	R	L				See section 3.8 of BG6	
4.3.29	Design elements of the scheme to account for self-weight and other applied forces / loadings in reasonable use (eg the design of anchorage, encasement and foundations for buried tanks or buried piping).		L		S			
4.3.30	Design acoustic treatment (including attenuators, silencers, absorption materials, baffles, mutes, cladding and jacketing) or modification of equipment, to comply with the noise levels specified, including when all building engineering services systems and	S	L					
4.3.31	Chair drawing production / co-ordination workshops / meetings to resolve the effective production of the Co-ordinated Working Drawings, Installation Drawings, Builder's Work Information and Builder's Work Details for each and every discipline.	S	L	S	S			
4.3.32	Attend drawing production / co-ordination workshops / meetings as 4.3.31.	S	L	S	S			
4.3.33	Chair co-ordination meetings / workshops to resolve the effective production of the MEP Production Information Model and the MEP Installation Model and equivalent models for each and every discipline and to agree the resolution of any clashes	S	L	S	S		Main contractor to chair or nominate one of the sub-contractors to do so.	
4.3.34	Attend co-ordination meetings / workshops as 4.3.33.	S	L	S	S			
4.3.35	Undertake the responsibilities of "Lead co-ordinator" as defined in HL specification section A11 clause 200.		L				Main contractor to lead or nominate one of the sub-contractors to do so.	
4.3.36	<del>Designing thrust blocks associated with underground pipework installations.</del>							
	<b>Selection of plant and specialist designers</b>							
4.4.1	Develop initial technical design for systems to be procured as Contractor Design Portions (where building services contractor not already appointed).	S	L					
4.4.2	Advise of significant allowances or constraints incorporated in the main design that may affect the specialist design.	S	L					
4.4.3	Obtain indicative quotations for plant not requiring specialist design.		L					

Reproduced from BSRIA BG 6/2018 A Design Framework for Building Services 5th edition

**PROFORMA 4: TECHNICAL DESIGN (RIBA STAGE 4)**

Some activities in RIBA Stage 4 may continue after the start of the project's construction stage.

Ref	Design activity in connection with building services	Allocated to ... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
4.4.4	Review that all plant and equipment incorporated into the works can be safely maintained and accessed in compliance with current legislation.	R	L					
4.4.5	Check plant and system sizing once Stage 4 coordination of the works has been undertaken with selected or procured equipment (4.3.25).		L					Removal of critical clashes – see section 2.5 of BG 6
4.4.6	Select plant, equipment, components and material to meet the specified performance. Where items or manufacturers differ from provisional selections ensure they are fully compatible with all the other system parameters components and design		L					Includes the preparation and issue of technical submittals for each item or plant and equipment selected in line with HL specification section A11 clause
4.4.7	Advise whether the proposed alternative items or manufacturers comply with the selection criteria.		L					
4.4.8	Advise whether the proposed alternative items or manufacturers are acceptable.	R	L					
4.4.9	Re-evaluate all parts of the services design which may be affected by acceptance of alternative items or manufacturers.		L					
4.4.10	Re-evaluate all parts of the architectural or structural design which may be affected by acceptance of alternative items or manufacturers.		L					
4.4.11	Amend the building services design to incorporate agreed alternative items or		L					
4.4.12	Prior to confirming agreed final fixed costs with the client, agree final equipment selections and manufacturers.		L					
4.4.13	Monitor the specialist design input for compliance with the design intent.	R	L					
4.4.14	Evaluate the impact of the specialist design on those parts of the overall design that are provisional.		L					
4.4.15	Monitor the ongoing progress of the procurement, manufacture, installation and commissioning of all plant items.	R	L					
4.4.16	Review all plant and equipment incorporated into the works with respect to safe maintenance and access in compliance with current legislation.		L					
4.4.17	<del>Select the fire alarm system(s), and their components and cabling requirements, to meet the requirements of the particular manufacturer and the requirements of the specification. Ensure that the design of the fire alarm system(s) and voice alarm system(s) comply with the edition of BS 5839 current at the time of Tender.</del>							
4.4.18	<del>Size and design earthing and electromagnetic screening of electrical power systems and ensuring compliance with the appropriate EMC directives.</del>							
4.4.19	<del>Select plant, equipment and components from the UK Government's 'Energy Technology Product List' unless directed otherwise.</del>							
4.4.20	<del>Select plant, equipment and components from the UK Government's 'Water Technology List' unless directed otherwise.</del>							
4.4.21	<del>Design all temporary works, facilities and provisions required during construction, to meet the requirements of the Specification.</del>							
<b>Mechanical design</b>								
4.5.1a	<del>Determine parameters of boiler flues to incorporate the requirements of the plant manufacturer, building control, environmental health officer and current legislation such as the Clean Air Act, ensuring that the flue gas is discharged at the required velocity and altitude, and providing the Contract Administrator with a copy of the application for approval of the flue system under the Clean Air Act.</del>							
4.5.1b	<del>As 4.5.1a but for diesel generator flues</del>							
4.5.1c	<del>As 4.5.1a but for other flues (to be defined for each project)</del>							
4.5.2	Finalise detailed design calculations for all mechanical services being included in the technical design in accordance with recognised national standards.	L	R					See Appendix B for specific services
4.5.3a	<del>Determine detailed flue, duct and pipe sizes and routes (boiler flues).</del>							
4.5.3b	<del>As 4.5.3a but for diesel generator flues</del>							
4.5.3c	<del>As 4.5.3a but for other flues (to be defined for each project)</del>							
4.5.4	Following equipment procurement, modify distribution systems and equipment capacities as may be required as a result of coordination (4.3.25).		L					
4.5.5	Design all necessary facilities for flushing, and commissioning.		L					Includes providing all the facilities required (whether temporary or permanent), for pre-commissioning flushing and cleaning of water systems, all in accordance with the current edition of BSRIA Application Guide 'Pre-commission cleaning of pipework
4.5.6	Size, select and determine final locations of commissioning sets based on coordination of procured equipment (4.3.25).		L					
4.5.7	Carry out final sizing of sections of ductwork between terminal units and diffusers to ensure the specified acoustic criteria and duct velocities.		L					
4.5.8	Carry out final detailing and confirm the location and sizes of duct connections to external louvres.		L					
4.5.9	Carry out detailed design of anchors, guides and other provision for movement of services and systems due to thermal expansion and contraction and building movement.		L					Includes the provision of anchors, bellows, compensators, loops and bends, and for designing systems to safely and reliably accommodate and control their movement due to hydraulic pressures.
4.5.10	Check fan and pump system resistances based on coordination of procured equipment (4.3.25).		L					And based on the co-ordinated working drawings. Also includes checking natural gas pipework pressure drop downstream of meter, based on the final equipment selection and co-ordinated installation drawings, to ensure compliance with applicable regulations and guidance. Suggest checker is independent person from
4.5.11	Check system water capacities and quantities of chemical additives based on the final equipment selection.		L					And based on the co-ordinated working drawings. Suggest checker is independent person from selector
4.5.12	Carry out final detailing of drain and vent points.		L					
4.5.13	Carry out final selection of all terminal devices.		L					
4.5.14	Carry out final selection of pressurisation units and expansion vessels.		L					Based on the final equipment selection and co-ordinated working drawings. Includes calculating system water capacities based on the installation drawings and actual equipment intended for installation, in order to properly determine the required capacity of expansion vessels, expansion cisterns, pressure vessels and thermal inertia [buffer] vessels.
4.5.15	<del>Detailed design and sizing of refrigerant pipework between items of equipment provided under the contract works based on the final equipment selection and co-ordinated working drawings.</del>							
4.5.16	Select and confirm location of fire dampers and any other fire-stopping for mechanical systems.		L					
4.5.17	Select and confirm location of control dampers and control valves to achieve the specified function and to suit the characteristics of items served and final system configurations based on the final equipment selection and coordinated working		L					
4.5.18	Carry out final selection of control valves to suit pipework and authority of controls based on final installation drawings.		L					Includes calculating sub-circuit resistances based on the piping layouts shown on the installation drawings and taking into account items of plant and equipment selected for incorporation into the works, and selecting control valves based on the calculated sub-circuit
4.5.19	Carry out final selection of all anti-vibration mountings.		L					

Reproduced from BSRIA BG 6/2018 A Design Framework for Building Services 5th edition

**PROFORMA 4: TECHNICAL DESIGN (RIBA STAGE 4)**

Some activities in RIBA Stage 4 may continue after the start of the project's construction stage.

Ref	Design activity in connection with building services	Allocated to ... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
4.5.20	Design review.	R	L					See section 3.8 of BG 6
4.5.21	<del>Design and obtain certification of the sprinkler system, its components and configuration, to meet the particular and the performance requirements of the specification including submitting calculations and all other design information.</del>							
4.5.22	<del>Design the gaseous fire suppression system(s), its components and configuration, to meet the requirements of the specification.</del>							
4.5.23	Design and determine the required extent of the trace heating system(s) in accordance with section the specification.		L					
4.5.24	<del>Carry out stress calculations for steam and HTHW piping using the 'Caesar II' software (if applicable).</del>							
4.5.25	Design pump inertia bases to meet the specified vibration isolation requirements.		L					
4.5.26	Undertake bracket and support detailed design and the selection of appropriate locations for them taking account of any known restrictions on types or location of fixing. Detail, supply and install all sleeves, inserts, frames, fixing anchors etc, and any other items required to be cast or built into the structure by others, including co-ordination of positions to such extent and accuracy to allow structural construction to proceed. Declare all types, loads and locations ten working days prior to installation, for comment. Obtain approval from the structural engineer and / or architect of		L					
4.5.27	Design all secondary support steelwork required to support the engineering systems within installer's works package where not specifically detailed on the Structural Engineering drawings.		L					
4.5.28	Design and select attenuators to satisfy the particular and performance requirements of the specification, including spatial allowances shown on the Tender drawings.		L					
4.5.29	Determine exact locations of instruments, control sensors, detectors and thermostats.		L					
4.5.30	Carry out the final selection of fire rated ductwork systems and ductwork fire protection systems, including obtaining all necessary statutory approvals.		L					
4.5.31	<del>Undertake detailed design and sizing of underfloor heating pipework systems to achieve the specified heat outputs.</del>							
4.5.32	<del>Design of each Direct Expansion (DX) and Variable Refrigerant Flow (VRF) system. This includes the selection of indoor and outdoor units and other equipment as required, their mounting systems and all interconnecting pipework.</del>							
4.5.33	Carry out final detailed location and dimensioning of second fix equipment (including but not limited to: control devices etc.; grilles and diffusers) based on architectural		L					
4.5.34	<del>Carry out detailed design of laboratory and medical gases and bulk cryogenic storage systems and associated monitoring and alarm systems (including oxygen depletion monitoring and alarm).</del>							
	<b>Electrical design</b>							
4.6.1	Finalise detailed design calculations for all electrical services being included in the technical design in accordance with recognised national standards.	L						See Appendix B for specific services
4.6.2	Determine detailed cable and containment sizes, switchgear sizes and locations, control panel locations, user equipment sizes and locations, and sensor locations for small power, lighting, high voltage systems, and metering.	L						
4.6.3	<del>Determine approximate sensor locations, control panel locations for fire safety and security systems.</del>							
4.6.4	Design automatic controls systems as required to meet the operational, functional and spatial requirements of the specification.		L					
4.6.5	<del>Determine control strategy for lighting.</del>							
4.6.6	Design fixing, connection, earthing and bonding details as required for final installation of lightning protection systems.		L					
4.6.7	Modify distribution systems and equipment capacities as may be required as a result of Stage 4 coordination with intended or procured equipment.		L					
4.6.8	Verify spatial requirements for cable pulling and installation.		L					
4.6.9	Verify cable sizes for primary electrical supply based on coordination of procured equipment (4.3.25) and cable lengths.		L					Includes ensuring that the specified cable sizes are not invalidated by the selection of alternative cable routes.
4.6.10	Verify cable sizes for specialist systems based on coordination of procured equipment (4.3.25) and cable lengths.		L					Such as fire alarm, datacomms, CCTV, and access control. Includes ensuring that the specified cable sizes are not invalidated by the selection of alternative cable
4.6.11	Select and confirm location of fire-stopping for electrical systems.		L					
4.6.12	Check control panel cable entry and exits are possible in the final location and that safe operating and maintenance clearances are provided.		L					Includes designing cable and cable trunking terminations on to electrical equipment provided under the sub-contract and dimensioning of, and final installation details of, electrical switchgear.
4.6.13	Check compatibility of building services plant and equipment with the controls systems.		L					
4.6.14	Carry out design and incorporation of all interfaces (including relays or other devices or modifications to hardware or software).		L					
4.6.15	Incorporate final information for electrical systems into the design via schedules or BIM objects, including control addresses for lighting and fire alarm systems, BMS points.		L					
4.6.16	Design review.	R	L					See section 3.8 of BG 6
4.6.17	Design earthing and bonding requirements for electrical building engineering systems, mechanical building engineering systems, architectural elements and structural elements that require earthing and bonding		L					
4.6.18	Where there are interfaces (including relays or other devices or modifications to hardware or software), between equipment and the automatic control system, be responsible for their design and the incorporation of them.		L					
4.6.19	Carry out all electrical design activities, as detailed herein, relating to the automatic controls system.		L					
4.6.20	Ensure that control panel doors are not fouled by other plant, equipment, services or structural elements.		L					Applies to switchgear and control panels
4.6.21	Select the capacity, location and design of electrical conduits and containment systems smaller than 50mm.		L					
4.6.22	Select cable terminations on items of equipment provided by the installer to suit the cable sizes proposed by other Installers (including the electrical Installer, the automatic control system installer, etc.) or the specified cable sizes, as appropriate.		L					
4.6.23	<del>Ensure that the design of the lightning protection system components meets the particular manufacturer's and the specification's requirements.</del>							
4.6.24	<del>Ensure that the design of the security system(s) components and cabling requirements meet the particular manufacturer's and the specification's requirements.</del>							
4.6.25	<del>Undertake design of Photovoltaic systems including interconnecting wiring and fixings to meet the requirements of the performance specification.</del>

**PROFORMA 4: TECHNICAL DESIGN (RIBA STAGE 4)**

Some activities in RIBA Stage 4 may continue after the start of the project's construction stage.

Ref	Design activity in connection with building services	Allocated to ... L=Lead, S=Support, R=Review						Comments
		A	B	C	D	E	Z	
4.6.30	<del>Be responsible for the complete design, coordination, installation and testing of the converged network system by engaging a recognised specialist systems integrator to facilitate full operation of the building engineering systems in accordance with the tender drawings and the particular and performance requirements of the</del>							
4.6.31	Check software engineering and programming is completed so that systems function in the prescribed manner.		L					
<b>Public health design</b>								
4.7.1	Finalise detailed design calculations for all public health services being included in the technical design in accordance with recognised national standards.	L						See Appendix B for specific services
4.7.2	Determine detailed pipe sizes and routes for gravity and pumped drainage systems.	L						
4.7.3	Determine final positions of cast-in drainage gullies ensuring coordination with structural design and final mechanical plant locations.	L						
4.7.4	Finalise vent termination locations to coordinate around final AHU and air vent intake positions.	L						
4.7.5	Determine final power, BMS and Controls interface requirements from equipment.	L						
4.7.6	Coordinate all surface water domestic and waste water pipework rodding eye locations with other services, structural and architectural elements to ensure suitable maintenance access can be provided.	L						
4.7.7	<del>Verify storm water discharge flow rate satisfies planning and statutory authority requirements including SuDS.</del>							
4.7.8	Determine detailed routing of pipework and drainage to/from risers.	L						
4.7.9	Carry out detailed design of pipework gradients for builders' work and coordination.	S	L					Includes domestic and waste drainage (gravity/pumped), surface drainage and condensate runs. Includes designing drainage system to safely and efficiently dispose of condensate produce by plant and equipment, in accordance with the equipment manufacturers' recommendations and in compliance
4.7.10	Modify distribution systems and equipment capacities as may be required based on coordination of procured equipment (4.3.25).		L					
4.7.11	Make allowance for anchors, guides and provision for movement of services and systems due to thermal expansion and contraction and building movement.		L					
4.7.12	Select and confirm location of fire collars and any other fire-stopping for public health systems.		L					
4.7.13	<del>Check all surface water, domestic and waste drainage discharge flow rates with external civils interface package.</del>							
4.7.14	<del>Check all utility interface details (locations, pipe sizes and invert levels) with civils package to ensure internal and external services coordinate.</del>							
4.7.15	Design review.	R	L					See section 3.8 of BG 6
<b>Commissioning</b>								
4.8.1	Review all designs to ensure that systems are commissionable.		L					
4.8.2	Determine witnessing and commissioning requirements for items installed on site.	L						Other than those covered by 3.8.2
4.8.3	Identify and incorporate into system designs the essential components and features necessary to enable the proper commissioning of building services (including		L					For example, including test points
4.8.4	Review the commissioning plan.	R	L					
4.8.5	Update the commissioning plan.		L

## Executive Summary

---

Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' is published in two parts:

Part A: The concept, design, specification, installation and acceptance testing of healthcare ventilation systems.

Part B: The management, operation, maintenance and routine testing of existing healthcare ventilation systems.

The documents give comprehensive advice and guidance on the legal requirements, design implications, maintenance and operation of specialised ventilation in healthcare premises providing acute care. The use of these premises is very intense, the occupancy level high and the patients may be particularly susceptible to airborne infection risks. Their condition may also require close control of the environment.

The ventilation of non-healthcare facilities within the hospital curtilage should be designed to suit the application and specific guidance relating to the activity should be followed, for example pharmacy, central decontamination unit, etc. However, as they are on the hospital site, the means of providing ventilation should not adversely impact upon the hospital (for example, evaporative cooling towers should not be installed, sound levels should be appropriate and if the facility is within or attached to an area accessed by patients, their needs and the risk of airborne contamination should be considered).

In other types of healthcare facility that are outside of the hospital curtilage, for example GP practices, health centres, minor injuries units, dental, ophthalmic and podiatry clinics, mental health facilities, respite and long stay care homes and hospices, a risk assessment of the nature of the treatment being delivered, condition of the patients and intensity of use needs to be undertaken by those responsible for the facility in order to determine the extent to which this guidance will be applicable.

The guidance contained in Part A of this Scottish Health Technical Memorandum applies to new installations and major refurbishments of existing installations and should be considered as the standard to be achieved.

The guidance contained in Part B of this Scottish Health Technical Memorandum applies to all ventilation systems installed in healthcare premises irrespective of the age of the installation and should be considered as the standard to be achieved.

Scottish Health Technical Memorandum 03-01 (2022) supersedes all previous versions of Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' (2014). It also supersedes SHTM 2025 (1994) and DV4 (1983).

### Who should use this guidance?

This document is aimed at specifiers, designers, suppliers, installers, estates and facilities managers and operations. Elements of the document will also be relevant to

managers concerned with the day-to-day management of healthcare facilities and senior healthcare management.

### Main changes since the 2014 edition

- design information for specific healthcare applications has been revised and information on the reason for ventilation given. For example, endoscopy rooms may now be either negative (to contain and remove odours and manage airborne risks to staff) or positive pressure (to maintain a higher level of cleanliness where it is intended to puncture body membranes with the endoscope). These endoscopy-specific risks (i.e. waste anaesthetic gases and pathogenic material (for example, multi-drug-resistant tuberculosis) discharged by the patient during the procedure being undertaken) were identified prior to the SARS-CoV-2 pandemic. As with other elements in Part A, the application of this change is not retrospective but applies to new installations and major refurbishments (see Preamble above);
- the client's needs and legal requirements are more clearly explained;
- this edition of Scottish Health Technical Memorandum 03-01 introduces the concept of the Ventilation Safety Group in healthcare organisations (similar to the Water Safety Group in Scottish Health Technical Memorandum 04-01 and the Electrical Safety Group in Scottish Health Technical Memorandum 06-01). This is a multidisciplinary group whose remit will be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises;
- the SHTM introduces a standard method of identifying and labelling ventilation systems and the creation of an inventory of installed systems;
- the issues of resilience and diversity are addressed;
- guidance is provided on refurbishments or when changing the use of an existing installation;
- guidance is given on lifecycle and the updating of mid-life plant;
- design information for specific healthcare application has been extensively revised;
- issues around rooms where anaesthetic agents are used are addressed;
- airflow rates are more tailored to the applications to take advantage of new fan and control technology and so reduce energy consumption;
- revised air quality and filter standards are given;
- new and emerging technologies are catered for;
- advice is given on installation standards and the appointment of an independent validator;
- more detailed information is given on the commissioning process;
- validation acceptance standards and methodology has been completely revised;
- routine inspection and maintenance guidance has been revised and updated.

## Net Zero Carbon

Scottish Health Technical Memorandum 03-01 supports UK legislation to bring all greenhouse gas emissions to net zero by 2045, and promotes sustainable methods of ventilation in healthcare facilities.

SHTM's core principle is that the default method of ventilation should as far as possible be natural ventilation followed by mixed mode (natural with mechanical ventilation), with mechanical ventilation being the last option.

The energy consumption of ventilation systems should be further minimised by specifying solutions with the lowest lifecycle environmental cost. The basic objective of energy-saving strategies in this SHTM is to provide the required ventilation service using the minimum energy. To this end, Scottish Health Technical Memorandum 03-01 recommends switching a system "off" when not required to be the most energy-efficient policy. If the system is needed to maintain a minimum background condition, reducing its output by "setting back" to the minimum necessary to achieve and maintain the desired condition is the next best option.

Fans represent an enormous potential for energy savings to reduce carbon emissions, as they are among the largest single users of energy (they use approximately 40% of all electricity in ventilation systems). The European Regulation 1253/2014, implementing the Energy-related Products (ErP) Directive, has significantly reduced the power to drive fans. Accordingly, Scottish Health Technical Memorandum 03-01 recommends using electronically commutated fans, as these have been proven to be the most energy-efficient, while also advising that belt-driven fans should no longer be installed.

There have been many legislative changes aimed at reducing energy consumption and technical advances that have increased operational efficiency. This revised SHTM incorporates those changes and has amended many of the design parameters for healthcare ventilation. Designs that are simply repeated from previous installations designed to superseded standards and guidance will not meet the revised energy or operational standards and will not produce a compliant result.

# 1. Introduction

---

## The needs of the building occupants

- 1.1 Ventilation is used extensively in all types of healthcare premises to provide a safe and comfortable environment for patients and staff and control odours. More specialised ventilation is provided to help reduce airborne infection risks in areas such as operating departments, critical care facilities, isolation rooms and primary patient treatment areas.
- 1.2 The Health and Social Care Act places a duty of care on healthcare providers. Increased health risks to patients will occur if ventilation systems do not achieve and maintain the required standards. The link between surgical site infection and theatre air quality has been well established. If the ventilation plant has been installed to dilute or contain harmful substances, its failure may expose people to unacceptable levels of risk. Proven breaches of the statutory requirements can result in prosecution and may also give rise to a civil suit against the operators.

## The building environment

- 1.3 Healthcare buildings are visited and used by large numbers of people. Many will be unwell or anxious so a well-ventilated environment with a fresh feel and an absence of noxious odours is essential.
- 1.4 Ventilation may also be installed:
- to ensure compliance with highly regulated quality assurance requirements of items processed in pharmacies and central decontamination units;
  - to protect staff from airborne microorganisms and toxic substances (for example, in laboratories and anaesthetic rooms);
  - to contain the spread of smoke between fire compartments as part of the fire strategy.
- 1.5 Healthcare buildings are continuously occupied, intensively used and because of the specialised nature of the facilities it may be extremely difficult to provide the service elsewhere if the ventilation fails. In order to ensure continuity of service, ventilation systems should be designed and installed so that they can be quickly and easily maintained. The resilience of the proposed system in the event of service outage should also be considered.
- 1.6 The ventilation of healthcare facilities consumes a significant portion of their energy load, so wherever possible natural ventilation is the preferred option. Where mechanical ventilation is used, sustainable design concepts allied to good-quality installation and the provision of controls that maintain the desired environment when the facility is in use will result in the minimum energy input for the maximum benefit.

## Airborne risks to staff

- 1.7 Most healthcare staff are no more at risk from airborne hazards when at their workplace than they are when not in a healthcare environment; however, certain groups as detailed below may be exposed to a variety of airborne contaminants.
- staff who administer anaesthetic agents or who work in areas where they are routinely used will be at risk of casual exposure to these agents;
  - staff who routinely work in areas where they may come into close contact with patients who have respiratory symptoms will be at risk of exposure to the microorganisms causing the symptoms;
  - staff who routinely work in areas where they may come into close contact with patients that have skin lesions, an infectious disease or a dermatological condition will be at risk of exposure to the microorganisms causing the condition;
  - staff who routinely process pathology specimens;
  - staff who decant, mix and/or process chemicals used as reagents for the setting or processing of pathology specimens;
  - staff who harvest organs, tissues and specimens at a post-mortem;
  - staff who handle drugs or the components of drugs;
  - staff who pre-clean used scopes, surgical instruments and equipment prior to decontamination;
  - staff who may be routinely exposed to airborne hazards listed in EH40 issued under the Control of Substances Hazardous to Health Regulations (COSHH) (for example, woodworking dust, welding fumes, chemical vapours).
- 1.8 A well-designed ventilation system can mitigate the airborne risks to staff. It should:
- supply sufficient unvitiated air to dilute the possible contaminants;
  - have air terminals located to efficiently scour the ventilated space;
  - move the air from the clean to the less clean space and/or out of the building;
  - supply the air at high level and remove it at low level so that the breathing zone of staff is in a clean airflow path.
- 1.9 Adoption of these principles will be sufficient to control the general risk to the staff identified above in their particular working environment. More specific airborne hazards should be captured at source and removed by local exhaust ventilation (LEV) systems provided under the COSHH Regulations (see paragraphs 3.3–3.5).

## Airborne risks to patients

- 1.10 In general terms an environment that is satisfactory for staff will be satisfactory for patients. There are, however, exceptions as below:
- intensive treatment units of any type;
  - haematology/oncology units;

- transplant units and units treating patients that have had their immune system compromised;
- bone marrow transplant units (BMT);
- burns units;
- cystic fibrosis units;
- operating theatres.

Patients being treated in these areas will need an environment supplied with good-quality filtered air and that is maintained at a positive pressure with respect to surrounding areas

**Note:** Patients who are particularly at risk from airborne microorganisms will normally be placed in an isolation room or suite that is maintained at a positive pressure. Patients who have a condition that could be transmitted to others are normally placed in a negative pressure isolation suite. When the patient's exact condition is unknown they may be placed in a neutral pressure (PPVL) isolation suite (see Health Building Note 04-01 Supplement 1 – 'Isolation facilities for infectious patients in acute settings for detailed guidance).

- 1.11 A more general airborne risk will result from poorly designed and constructed air handling units (AHUs) that allow water to stagnate inside; they can then become a source of microorganisms such as Legionella. If their intake is badly sited or housekeeping in the area is poor, fungal spores such as aspergillus can be drawn in. The ventilation system will then become a means of spreading these microorganisms and fungal spores around the healthcare building.
- 1.12 All ventilation systems should conform to the principles set out in the Health and Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems' and Scottish Health Technical Memorandum 04-01 – 'Safe water in healthcare premises'.

### Specialist equipment environment

- 1.13 Imaging and other non-invasive scanning equipment will require stable environmental conditions to stay within calibration and provide accurate repeatable results. Health Building Note 06-01 and Health Building Note 10 (2021) give detailed guidance and the equipment manufacturers should be consulted.

**Note:** Health Building Note 26 – 'Facilities for surgical procedures' (2004) and Health Building Note 10-02 – 'Facilities for day surgery units' (2007) are under revision at the time of writing and will become Health Building Note 10-01 once updated.

Health Building Note 06-01 (2001) on diagnostic imaging and interventional radiology is also under revision at the time of writing.

## Medicinal products environment

- 1.14 Pharmacists are required to ensure that any manufacture or preparation activities involving medicinal products undertaken in their units conform with the requirements of the Medicine Act. Processes must be carried out in a suitable facility usually termed an aseptic preparation facility. The quality of air supply and design of the ventilation cascade are essential to ensure a suitable environment for the activities undertaken.

## Fire and smoke control fundamentals

- 1.15 Scottish Health Technical Memorandums 81 to 87 (including sub-parts) are the base documents for fire aspects. When designing a ventilation system, a fire and smoke control strategy should be developed that is relevant to the site and its function. The fire and smoke strategy should take account of the planned activity within the area, the type of patient present, staff-to-patient ratio and treatment being delivered (see also Chapters 5 and 7).
- 1.16 When ventilation systems are originally designed, they will conform to an agreed fire strategy. This will determine the compartmentation, provision of fire-rated ductwork, fitting of sprinklers, the siting of fire and smoke dampers and an agreed control action for the ventilation in the event of a fire. The agreed fire and smoke control strategy must be clearly set out as part of the design specification.
- 1.17 The fire regulations require that, if ventilation ductwork penetrates the fabric of a building, it should be designed and installed to contain the spread of fire (see Health Technical Memorandum 05-02 – 'Guidance in support of functional provisions for healthcare premises' for further guidance).
- 1.18 If a ventilation system is upgraded or altered to suit a change of use, it will be necessary to reassess the fire strategy.
- 1.19 It is management's responsibility to ensure that the fire strategy applied during the design and installation of a system is not reduced during the subsequent operation and maintenance of the equipment.
- 1.20 The number and location of fire and smoke dampers can be problematic. Fire-rated ductwork within fire zones will reduce the need for fire and smoke dampers. It will eliminate the need to provide access for routine damper testing and the infection control problems associate with reversed airflow paths resulting from damper failures and nuisance tripping (see also Chapter 7 for ventilation control in the event of fire).

**Note:** In developing a fire and smoke containment strategy the design of ventilation for infection control cannot be ignored. Over-compartmentation and poorly chosen fire lines can prevent air moving from clean to less clean areas and thus increase the infection risk. This can be a particular problem in operating departments where the desire to create a protected escape route can be at odds with the need to cascade air through a suite of rooms and out into a corridor in order to control the airborne infection risk.

## 2. The User Requirements

---

2.1 Patient treatment falls into four basic categories:

- surgical procedures – physical interventions to diagnose, repair, remove or rebuild damaged or infected tissue;
- medical care – the administering of drugs or various forms of practical, non-invasive treatment to diagnose, cure or reduce the severity of an infection or condition;
- mental health – the use of counselling, often in conjunction with drugs, to control or alleviate abnormal behavioural or false perception issues in patients;
- palliative care – treatment to temporarily or partially relieve or mitigate long-term conditions;

In all cases a patient may require treatment in one or more of the categories as either an in-patient or an out-patient.

### Surgical procedures

2.2 It is thought that up to 25% of infections that occur as a result of a surgical intervention are caused by the airborne route. The source of these infections are predominantly as a result of airborne microorganisms, typically skin scales, liberated during the surgical procedure becoming airborne and landing in the wound or on surgical instruments. These then become a means of inoculating the patient with the contaminant. There are five possible routes that may result in airborne infections:

- skin scales liberated by the surgical team during the procedure;
- organic material liberated from the patient as a result of the procedure;
- microorganisms remaining from a previous use of the space becoming airborne;
- airborne microorganisms liberated outside of the space entering during the procedure;
- microorganisms in the supply air from a ventilation system that has been contaminated with biological material.

2.3 The level of airborne organic material present or biological burden (bioburden) is typically defined in terms of the number of colony forming units (cfus) present at the wound site during the procedure. It will be dependent on:

- the number of persons present;
- the completeness and effectiveness of their gowning;
- the duration of the procedure;
- the type of procedure;
- the use of air-driven power tools;
- the extent to which a patient contributes to the bioburden in the space;

- the general cleanliness of the space;
- the discipline of the surgical team;
- the measures that have been taken to prevent or control contaminants from outside sources entering the space;
- the quality and volume of the incoming supply air;
- the efficiency of the incoming air to "scour" the space;
- the means of removing contaminated air from the space.

2.4 Good surgical discipline, effective patient preparation, the cleanliness of the space and control of the entry and exit of personnel during the procedure will all contribute to reducing the bioburden present.

2.5 A well-designed ventilation scheme that provides a suitable quality of air and efficiently scours the space will further reduce the bioburden. If the ventilation maintains the space at a positive pressure to adjoining areas, the risk of contaminants originating outside of the space entering will be reduced.

2.6 In addition to controlling the bioburden, the ventilation should provide comfortable conditions for the staff and patient.

2.7 The ventilation system should also control the risks to staff from anaesthetic agents and other hazardous fumes and emissions typically found in surgical facilities (see paragraphs 1.10–1.12).

2.8 Minor procedures may be carried out in a treatment room or at the bedside so surgical procedures are not exclusive to the operating department. (See Humphreys et al (2012) for further guidance on facilities for minor surgical procedures and minimal access interventions).

### Medical care

2.9 In general the main requirement will be to ensure that staff and patients are kept in comfortable conditions.

2.10 There are specific instances where staff can be at risk of contracting an illness by the airborne route from a patient. This is the case in infectious disease units where the ventilation will be designed to maintain the unit and individual patient rooms at negative pressure relative to adjacent areas. This will protect persons outside of the unit from infection by the airborne route but not staff entering and working in the unit, who may need to take additional precautions to protect themselves.

2.11 The opposite problem occurs when patients are neutropenic, that is, they have a reduced or extremely low resistance to infection. They are then at risk of infection by the airborne route from other persons such as staff and visitors. This will be the case in cancer/oncology units, critical care areas, and bone marrow and general transplant units. The ventilation in these areas will need a higher air quality and be set to maintain a positive pressure to adjacent areas.

## Mental health

- 2.12 Any specific patient needs should be assessed and addressed. The main requirement will be to ensure that staff and patients are kept in comfortable conditions (see comments on other types of healthcare facility in the Executive Summary).
- 2.13 The fire risk may be considered more likely and additional steps may need to be taken to control it.

## Palliative care

- 2.14 The main requirement is to ensure that staff and patients are kept in comfortable conditions. Temperature control may be more stringent for patients with long-term and/or end of life conditions (see the Executive Summary for further information).
- 2.15 Difficulties with evacuating patients in the event of fire may need to be considered.

## Diagnostic and support services

### Imaging and Interventional imaging

- 2.16 There are major advances in diagnosis and minimally invasive treatment involving imaging. It may be necessary during these invasive or non-invasive procedures to provide sedation or general anaesthesia to help with anxiety or pain. This may involve the use of inhaled anaesthetic agents and/or nitrous oxide (N<sub>2</sub>O). Staff working in these areas may be exposed to these anaesthetic agents when they are administered or subsequently when they are exhaled as the patient is recovered.
- 2.17 A similar situation occurs in maternity units, where a mixture of nitrous oxide and oxygen (N<sub>2</sub>O/O<sub>2</sub>) (Entonox) is used as an inhaled analgesic.
- 2.18 In both of the above cases ventilation should be designed to provide a clean airflow path and dilute any casual spillages of the gas. This approach will help control the casual exposure of staff to the anaesthetic agent (see paragraphs 3.3–3.5).

### Post-mortem and pathology

- 2.19 Staff who harvest organs and specimens at a post-mortem and place them into preservative solutions may be exposed to the microorganisms present and fumes from the preservative.
- 2.20 Staff who section organs and prepare specimens for analysis may be exposed to the microorganisms present and the chemicals used for staining and fixing the specimens.
- 2.21 In both of the above situations local exhaust ventilation (LEV) in the form of downflow benches, safety cabinets and fume cupboards need to be provided to control the risk.

## Pharmacy

- 2.22 Exposure to the active ingredients of drugs represents a hazard to pharmacy staff who are involved in their production. These activities are carried out in an aseptic

preparation facility to ensure that the drugs themselves are not contaminated. The actual production typically takes place inside an isolator so that there is a physical barrier between the hazard and the operator.

2.23 Alcohol sprays are used and staff exposure may be controlled by the provision of downflow LEV systems to remove the hazard.

2.24 Comfortable conditions are essential for staff working in preparation facilities as they need to be fully gowned, and entry and exit is restrictive.

#### **Decontamination facilities**

2.25 Staff may be exposed to airborne biological material and chemicals when handling and processing used scopes, surgical instruments and equipment as part of the decontamination process. The ventilation should provide a clean airflow path to control staff exposure. The quality, quantity and flow pattern of the air are also critical to the protection of the decontaminated items.

#### **Estates and facilities**

2.26 Staff may be engaged in welding, soldering, machining wood or paint- spraying. They may also decant chemicals in quantity (for example, for boiler treatment or hydrotherapy-pool dosage). LEV systems are routinely used to control the hazards arising.

## 3. Legal Requirements – Applicable Legislation

---

### Health and Safety at Work etc. Act

- 3.1 The Health and Safety at Work etc. Act 1974 is the core legislation that applies to ventilation installations. As these installations are intended to prevent contamination, closely control the environment, dilute contaminants or contain hazards, their very presence indicates that potential risks to health have been identified.
- 3.2 The Act places a duty of care on ALL to provide and maintain a safe workplace. This includes designers and suppliers of goods or services. Those trading as competent designers or suppliers are therefore liable to provide outcomes that meet the client's needs and are without hazard to staff, patients and others who may be affected by the work activity.

### Control of Substances Hazardous to Health Regulations

- 3.3 The Control of Substances Hazardous to Health (COSHH) Regulations 2002 place upon management an obligation to ensure that control measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and microbiological safety cabinets.
- 3.4 Where specialised ventilation plant is provided as part of the control measures, there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of COSHH requires that the system be examined and tested at least every 14 months by a competent person (P601 certified) and that management maintain comprehensive records of its performance, repair and maintenance.
- 3.5 Certain substances have workplace exposure limits (WELs) as set out in the Health and Safety Executive's (2005) Guidance Note EH40 – 'Workplace exposure limits'. This contains the list of workplace exposure limits for use with the Control of Substances Hazardous to Health Regulations 2002 (as amended). If specialised ventilation systems are provided in order to achieve these standards, they will be subject to the COSHH Regulations.

### Workplace (Health, Safety and Welfare) Regulations

- 3.6 These state that:
- all enclosed workplaces must be ventilated by natural or artificial means;
  - any plant provided under this legislation must include an effective device to give an audible or visual warning of plant failure where necessary for health and safety;
  - the Regulations require that ventilation systems are maintained in an efficient state, in efficient working order and in good repair.

## The Building Regulations

3.7 Approved documents L and F:

- apply to domestic and non-domestic buildings;
- clarify satisfactory methods of providing ventilation and give ventilation rates;
- set minimum standards for:
  - the protection of the supply position;
  - precautions against *Legionella*;
  - the purity of recirculated air;
  - access for service and maintenance;
  - documentation and proof of performance;
  - energy performance.

## Health and Social Care Act 2008 (Regulated Activities)

### Regulations 2014

3.8 Regulation 12(2)(h) of the Act decrees that registered providers must assess the risk of, and prevent, detect and control the spread of, infections, including those that are healthcare associated.

3.9 Appropriate standards of cleanliness and hygiene should be maintained in premises used for the regulated activity. DH (2015) issued 'The Health and Social Care Act 2008 Code of Practice on the prevention and control of infections and related guidance' (the HCAI Code of Practice), which contains statutory guidance about compliance with regulation 12(2)(h).

3.10 Regulation 15 of the Act states that:

All premises and equipment used by the service provider must be:

- clean;
- secure;
- suitable for the purpose for which they are being used;
- properly used;
- properly maintained; and
- appropriately located for the purpose for which they are being used.

The registered person must, in relation to such premises and equipment, maintain standards of hygiene appropriate for the purposes for which they are being used.

**Note:** The "registered person" means, in respect of a regulated activity, the person who is the service provider or a registered manager in respect of that activity. A "service provider" means a person registered with the CQC under Chapter 2 of Part 1 of the Health and Social Care Act 2008 as a service provider in respect of that regulated activity.

### **The Medicines Act 1968 and Human Medicines Regulations 2012**

- 3.11 Pharmacy aseptic preparation facilities should conform to the requirements of EudraLex – Volume 4 – Good Manufacturing Practice (GMP) guidelines or equivalent UK legislation, and the requirements of the UK Medicines Inspectorate (MHRA) if a licensed manufacturing unit.
- 3.12 There are specific requirements under the Medicines Act 1968 to maintain accurate records of plant performance, room conditions and maintenance events. Such records would need to be preserved for up to 25 years as part of a quality assurance audit trail.
- 3.13 Specialised ventilation plant installed in laboratories dealing with research, development or testing, whether involving drugs, animals or genetically modified microorganisms, may be subject to legislation regarding their operation in addition to that mentioned above.

### **Indoor air quality (IAQ)**

- 3.14 There is increasing awareness that IAQ has an important impact on health and well-being. The World Health Organization and the Royal College of Paediatrics and Child Health (2020) have produced papers on the importance of IAQ, and the National Institute for Health and Care Excellence (NICE) (2020) has issued guidelines for domestic environments. Indoor and outdoor sources of contaminants are important contributors to IAQ, and designers of ventilation systems should consider both. The Department for Environment, Food and Rural Affairs (Defra) gives data for outdoor air quality by postcode for the UK. This enables designers to choose suitable filter grades by location and application (see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02 – 'Change in air filter test and classification standards' for further information).

### **Other relevant standards and sources of guidance**

- 3.15 The Chartered Institution of Building Services Engineers (CIBSE) Guides and associated published documents (TMs) are the principal source of general ventilation specification and design guidance.
- 3.16 ISO 14644 and ISO 17141 provide basic information on cleanrooms used in pharmacy preparation facilities and inspection, assembly and packing (IAP) rooms for the processing of medical devices in central decontamination units.
- 3.17 BS EN 15780 applies to both new and existing ventilation and air-conditioning systems and specifies the assessment criteria of cleanliness and cleaning procedures of these systems.

- 3.18 HSG 258 issued by the Health & Safety Executive provides guidance on the design of local exhaust ventilation (LEV) systems.
- 3.19 Other relevant guidance is listed in the References.
- 3.20 The Board and their supply chain must ensure that the competence of all parties is considered at the point of their introduction and on an ongoing basis. The philosophies that are included in the HSE leaflet INDG368 (current revision), "Using Contractors" should be adopted. In addition, the outputs from the "Setting the Bar" report should be adopted as they are introduced through legislation. Evidence that the recommendations of "Setting the Bar" are being implemented in advance of the legislation would be considered to be good practice, particularly for high risk buildings. BSI Flex 8670 "Built environment. Core criteria for building safety in competence frameworks. Code of practice" should also form part of the project planning.

**Note:** In all cases the most recent version of any legislation, regulation, standard or guidance document should be consulted.

## 4. The Design and Specification Process

### Project brief

- 4.1 The ventilation aspects of a contract will normally form part of a wider project to provide, upgrade or replace a healthcare facility. It is important that the ventilation designer closely liaises with the architect, as the layout of the facility and the adjacency of spaces within it will have a major impact on the ability of the ventilation system to achieve the client's requirements. All new major projects are required to use building information modelling (BIM) in order to ensure a coordinated design and provide information for the subsequent operation and possible future development of the facility.
- 4.2 The Building Services Research and Information Association (BSRIA) has produced an approach to project delivery known as "Soft landings" (BSRIA, 2018). It aims to ensure that the client's success criterion is kept in focus during the inception and briefing, design, construction, pre-handover, initial aftercare and extended aftercare phases of a project. It is strongly recommended that the client and project contractor adopt this approach.

### Basis of design

- 4.3 This SHTM assumes that designers will be familiar with current CIBSE guidance and will use it as the basis for specifying and designing ventilation systems. However, the actual guidance contained in this SHTM may differ from the CIBSE guidance due to healthcare-specific issues and will take precedence over the CIBSE guidance where there are conflicts.

**Note:** Scottish Health Technical Memorandum 03- 01 Parts A and B need to be read and considered in their entirety when specifying and designing ventilation systems to ensure that the end result will comply with the client's needs.

### Ventilation Safety Group (VSG)

- 4.4 The management of the ventilation systems of a healthcare provider should be overseen by a Ventilation Safety Group (VSG). The VSG should have clearly defined roles and responsibilities, be part of a healthcare organisation's governance structure and report to the "Designated Person" at Board level. It should be led and chaired by a person who has appropriate management responsibility, knowledge, competence and experience (for example, the Designated Person). (See Chapter 2 in Part B of Health Technical Memorandum 03-01 for further information.)
- 4.5 The VSG should be a multidisciplinary group and should typically comprise:
- an Authorising Engineer/independent adviser for ventilation (AE(V));
  - an Infection Prevention and Control person;
  - the Authorised Person(s) for ventilation services (AP(V));
  - estates (operations and projects) staff;

- clinicians and specialist departments (for example, theatres, critical care areas, pharmacy, medical microbiology, nursing, decontamination);
- personnel from the finance department with accountability for capital and revenue evaluation;
- other stakeholders as appropriate;
- coopted expertise (for example, ventilation designers, consultants and suppliers).

4.6 The VSG remit should be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises. It should inform the following areas:

- the design process for new healthcare premises;
- the design process for modifications to existing premises;
- the commissioning and validation process;
- operational management and maintenance;
- annual verification and performance testing;
- prioritising the plant replacement programme;
- decommissioning and removal of redundant equipment.

**Note:** Where estates and facilities provider services are part of a contract (including PFI), it is essential that these providers participate fully in all those aspects of estate and facilities management that can affect patients. This includes responding to specific requests from the VSG, which may be in addition to relevant guidance and documentation.

4.7 It is important that decisions affecting the resilience, safety and integrity of the ventilation systems and associated equipment are not taken without the agreement of the VSG. The VSG should ensure that appropriate expertise and competence is available when making such decisions.

4.8 Whenever significant building work is undertaken, the VSG should consider its effects on the existing ventilation system air intakes. These may need to be protected from airborne dust during construction by the fitting of temporary additional filtration. There will also be a need to identify any risks to construction personnel who may be working in the vicinity of extract air discharges.

4.9 When construction or alteration work is undertaken inside an occupied building, its effects on the occupiers should be considered. The VSG should be consulted, and they may require that the area be sealed off from the occupied parts of the building and that a temporary extract be provided to maintain the worksite at a negative pressure to prevent the spread of dust into the rest of the building.

## Derogations and alternative design strategies

- 4.10 Any derogations or alternative design strategies from this guidance should be subject to the scrutiny and agreement in writing by the VSG. The reason for the derogation or alternative design strategy and limits to its application should be recorded.
- 4.11 Designers proposing a derogation or alternative design strategy should be able to supply a body of evidence that their proposal will provide a degree of safety no less than if the guidance in this document had been followed.

## Definition of clinical areas and critical systems

- 4.12 Healthcare ventilation may serve clinical or non-clinical areas of the estate:
- clinical areas are defined as spaces within the building where surgical or medical treatment is administered to patients. This includes patient bedrooms;
  - non-clinical areas are defined as spaces where patients may be present but are not under direct treatment. It also includes staff and healthcare services areas.
- 4.13 Certain clinical and non-clinical areas within a healthcare establishment are considered critical to its ability to provide healthcare. Typically, ventilation systems serving the following are considered critical:
- operating suites of any type including rooms used for image-guided surgical procedures and their recovery areas;
  - airborne isolation facilities, both source and protective;
  - critical care areas and neonatal units;
  - invasive treatment, endoscopy and bronchoscopy rooms;
  - containment level 3 laboratory;
  - pharmacy aseptic preparation facility;
  - inspection, assembly and packing (IAP) room in a central decontamination unit;
  - MRI, CAT and other types of emerging imaging technologies that require particularly stable environmental conditions to remain within calibration;
  - any system classified as an LEV system under the COSHH Regulations;
  - any other system that clearly meets the definition that “a loss of service from such a system would seriously degrade the ability of the premises to deliver optimal healthcare”.

**Note:** If any doubt exists about whether a system falls within this definition, the VSG should be consulted regarding the risk to patient safety and business continuity.

## Resilience and diversity

- 4.14 When planning the ventilation of healthcare facilities, it is important at the outset to consider how the service will be delivered if the installed ventilation system fails or the area served has to close due to the effects of fire, flood or an outbreak of

infection. The loss of power, primary heating or cooling medium, or an integrated control system can cause the loss of ventilation to an area, so subsystem resilience is an important consideration.

- 4.15 Resilience in critical healthcare areas can be provided by splitting the ventilation load between two or more AHUs and/or employing a design that allows two or more AHUs to feed a common plenum with isolation dampers on individual branches to each critical zone. (Note that it is not proposed that duplicate back-up units be provided.) As an example, a large critical care area (CCA) level 2 or 3 could be split into two sections with an AHU for each. A small CCA cannot easily be split, so a decant area with a suitable level of ventilation should be pre-designated.
- 4.16 Diversity can be achieved by having several facilities each served by its own AHU. As an example, in an operating department, if each theatre suite is fed from its own dedicated AHU, the loss of one suite, while inconvenient, will not shut the department. The same scenario applies to isolation rooms if several of them are each independently ventilated (see Health Building Note 04-01 for further information).

**Note:** Providing twin ventilation fans in an AHU delays the time at which the system needs to be completely shut down in the event of a fan failure. It does not in itself provide resilience in terms of delivering healthcare (see Chapter 9 for further guidance).

### New build facilities

- 4.17 New build healthcare facilities must be fully compliant with the requirements of all legislation in force at a date agreed when signing the contract. They should comply with the guidance contained in the current SHTM unless a derogation has been agreed with the VSG (see paragraphs 4.10 and 4.11).

### Assessment of service requirements: selection of design criteria

#### External design conditions

- 4.18 The most accurate data that is available for the summer and winter conditions at the site should be used. The Meteorological Office supplies data for the United Kingdom; data is also available from CIBSE and other sources. It is essential that the designer agrees with the client as to which source of data is used and the design risk associated with the chosen external design conditions.

**Note:** It is essential to design to future climate projection to ensure design temperatures are maintained even in the event of prolonged heatwave conditions. CIBSE (2014) publishes design summer year weather files morphed to reflect future climate change.

- 4.19 Local adjustments for height above sea level, exposure factor, or other local climate peculiarities should be made as appropriate.

#### Internal design conditions

- 4.20 The design conditions selected within patient areas should strike a balance between the comfort requirements of staff and patients, who often have very different levels of clothing and activity.

- 4.21 Recommendations for the operative temperature and humidity of individual spaces are given in Activity Data A-Sheets (see Chapter 8 for specific requirements). Particular departmental requirements are given in the respective SHPN/HBN and room data sheets. However, the determination of the room environment must be driven by the patient cohort plus the range of procedures envisaged for that room.

#### Minimum fresh air requirements

- 4.22 In general areas and wards within healthcare premises, odour control is the main reason for providing ventilation. In the absence of other guidance, 10 L/s/person should be taken as the minimum ventilation requirement. Healthcare ventilation systems will normally be "full fresh air" either by natural, mixed mode or mechanical means, with energy recovery from the extracted air.
- 4.23 In non-clinical areas recirculated air systems may be considered. At least 20% of the recirculated air should be fresh. Additional filtration will be required to remove airborne particulate contamination and, if necessary, odours. This will affect running and maintenance costs and, given the high ErP rating of heat recovery devices, it will be necessary to prove that recirculating the air will be more energy- efficient overall.

**Note:** Ultra clean ventilated (UCV) operating theatres use air recirculation. The fresh air requirements of this specific application are given in Chapters 8 and 9.

- 4.24 Smoking is generally not permitted in healthcare premises, so no allowance need be made. Reference should be made to local national policy guidance.
- 4.25 In treatment and support areas the overriding requirement may be due to airborne infection control, hazard containment, the stability of specialist equipment or relate to a specific department's function. Each case should be considered independently in order to determine the overriding minimum requirement for ventilation (see Chapter 8 for specific guidance).

#### Limiting supply air conditions

- 4.26 For most applications in healthcare buildings, it is the temperature differential between the supply and room air, rather than the actual temperature of the supply air, which is the critical factor. The maximum recommended supply-to-room air temperature differential is:
- summer cooling: 7 K
  - winter heating: 10 K
- 4.27 Room air humidity should be kept below 70% in order to minimise risks associated with condensation and mould growth. There is no lower limit in unoccupied spaces.
- 4.28 Some types of diagnostic imaging technologies require close control of both temperature and humidity as well as the rate of change of conditions to ensure clarity of the image and accuracy of the data generated. The manufacturer's guidance should be followed.

### Air purity

- 4.29 In healthcare premises, the standard of filtration will depend on the activities within the occupied spaces. Except for special areas (for example, manufacturing pharmacies), the requirement for aerobiological needs is not stringent and filtration is only required to:
- maintain hygienic conditions for the health and welfare of occupants, or for processes such as centralised food preparation facilities;
  - protect finishes, fabrics and furnishings – to reduce redecoration costs;
  - protect equipment either within the supply air system – to prevent blocking of coils – or in the space itself to prevent dust accumulation
- 4.30 Given that almost all viable particles will originate from the occupants of a space and not from the incoming air, dilution is the more important factor aerobiologically. Therefore, for general areas an ISO ePM 2.5  $\geq 55\%$  filter may be suitable. More critical areas would require an ISO ePM1  $\geq 50\%$  filter. Efficiency or high-efficiency (EPA or HEPA) filters will only normally be required in ultra-clean systems, designated “cleanrooms” (see Chapter 9 for specific information) or for some immune-suppressed patient areas
- 4.31 In some inner-city areas the local airborne particulate level may be particularly high. In those special cases filters to ISO ePM1  $\geq 50\%$  may be required to achieve the required indoor air quality. (See Defra's website and the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02 – ‘Change in air filter test and classification standards’.)

### Humidity control requirements

- 4.32 Close control of humidification was originally required for some healthcare applications (for example, operating theatres) in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased.
- 4.33 Providing humidification is expensive in terms of plant, running costs and maintenance, and therefore its use should be restricted to where it is necessary for physiological or operational reasons (see Chapter 8 and associated SHPNs/HBNs).
- 4.34 In general terms the humidity within an occupied building or space will naturally float between 30% and 70% RH (relative humidity). Humidity should not be allowed to rise above 70% at any time but there is no need to maintain a background minimum level when the building or space is unoccupied.

### Maximum noise levels

- 4.35 Noise will be generated in an air distribution system by the fan, ductwork fittings, dampers and grilles. The specified maximum noise level will depend on the activities within the occupied spaces.
- 4.36 Attenuation should be incorporated into the ductwork system or plant arrangement as necessary to reduce noise from fans and plant items in order to achieve the acceptable limits within the rooms at the design airflows.

- 4.37 Plant room noise level from fans when starting up or running should not be greater than 80 dB(A), and should be reduced where the plant is near to departments sensitive to noise.
- 4.38 Attention should be given to the reduction of tonal components. High tonal components from air diffusers etc. can seriously disturb concentration over longer periods even when the overall noise level is low. Broadband noise causes less annoyance.
- 4.39 The values recommended in Table 1 are for the total noise environment of space. In general, there will be noise transmitted into the space and noise generated within the space. The designer requires knowledge of the total hospital layout and operational policies, to assign acceptance magnitudes to all the possible noise sources, in order to arrive at the correct rating.
- 4.40 In Table 1 the overall noise level takes account of all internal and external noise sources. The noise level is the level measured with a sound-level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. The ventilation plant design noise level is that generated by the plant alone with no other noise source being considered. The levels suggested make recognised allowance for the ingress of environmental noise which will have to be considered in the overall design, that is, in specifying the attenuation of walls, partitions, ceilings, etc.

Table 1: Interior Noise Level

Area	Room: overall noise level – dB(A)	Ventilation design value – dB(A)
Operating department all rooms including preparation, anaesthetic, scrub and utility, interventional and diagnostic imaging departments – all rooms	48	Operating department all rooms including preparation, anaesthetic, scrub and utility, interventional and diagnostic imaging departments – all rooms
UCV operating theatre and adjacent open-plan scrub only	53	–
Treatment rooms Consulting rooms Sleeping areas/rooms Recovery rooms	35	Treatment rooms Consulting rooms Sleeping areas/rooms Recovery rooms
Sanitary facilities	45	40
Aseptic preparation facility	45	40
Industrial areas	50	45
Circulation waiting areas	50	45
Plantrooms	85	80

- 4.41 The recommended criterion is measured as the "A" weighted sound pressure level expressed in decibels, which should not be exceeded for more than 10% of the time. See Scottish Health Technical Memorandum 08-01 – 'Acoustics' for further information.
- 4.42 The designer should also consider noise escaping to the external environment and this should not be unacceptable to occupants of adjacent buildings.

## Calculation of building loads

### Air infiltration

- 4.43 Air infiltration occurs due to a complex combination of wind pressure, thermal effects, location relative to other features and the construction standard of the building. The infiltration rate is governed by the size and number of doors and other openings in the building envelope and the complexity of internal air paths.
- 4.44 CIBSE guide TM52 provides information and formulae for the calculation of air infiltration in buildings. In all cases the requirements of the appropriate section of the current Building Regulations Part L (airtightness minimum requirements) must be met.

### Summertime temperatures

- 4.45 To prevent overheating and avoid the future need for portable room air- conditioners, thermal modelling should be undertaken to ensure that internal temperatures in all areas do not exceed CIBSE Guide A guidance. Thermal modelling should be carried out whether the space is ventilated by natural, mixed mode or mechanical means. The modelling should be undertaken by a competent software user and take into account not only absolute values but also the time component.
- 4.46 Where thermal modelling indicates internal temperatures will exceed the recommended levels defined in CIBSE Guide A, additional measures should be explored to achieve compliance such as reducing solar and casual gains, improving building fabric performance, etc.

### Peak heating load

- 4.47 Peak heating local calculations are necessary on all mechanical supply systems to establish the size of heater-batteries and subsequently the central plant. Note that with the introduction of the requirement to fit energy recovery set out in EU 1253, the heater-battery size will be reduced. If the energy-recovery value is ignored, the heater-battery and its control valve will be oversized and the system when put to use will be unstable and liable to hunt.
- 4.48 Where ventilation systems provide tempered air to spaces which have supplementary low pressure hot water (LPHW) to offset the building fabric losses, the AHU heating load should be calculated based on the external winter design temperature, the design internal air temperature, and the calculated total air volume (including a suitable allowance for leakage).
- 4.49 Where the ventilation system is the only means of heating a space, an increase in load equivalent to the calculated fabric heat losses from the space should be added to the ventilation load. A check of supply temperature difference should be made. If it exceeds that recommended in paragraph 4.26 the ventilation supply volume should be increased to suit.

### Peak cooling load

- 4.50 In addition to the base data of airflow rates and temperatures, when calculating cooling loads, the designer should take into account:
- solar cooling loads;

- surface conduction cooling loads;
- internal gain cooling loads;
- air infiltration cooling loads;
- cooling loads due to high limit humidity control;
- method of control of internal conditions;
- fluctuations in internal temperatures.

Allowances must be made for all medical equipment in every space. Where the final item has not yet been selected, a unit that is reflective of the needs must be agreed with the stakeholders. A record must be included in the design documentation as to the unit which has been included in the design and the impact on all MEP systems of this unit. The stakeholders must have access to this data to ensure the compatibility of equipment and MEP systems can be checked against final medical equipment selections.

- 4.51 When the peak internal loads have been assessed and a suitable allowance made for non-coincidence, the supply temperature can be calculated.
- 4.52 Once the lowest required supply temperature of the air handling unit has been established, and an allowance made for temperature rise through the fan and ductwork (usually 1 K for low pressure systems), the off-plant enthalpy can be established from a psychrometric chart or table.
- 4.53 The cooling loads for all plant on the chilled water system should be calculated at each of the individual peak times in order to accurately establish the required (diversified) capacity of the chiller.

**Note:** Note that as with heating, the introduction of the requirement to fit energy recovery set out in EU 1253 means that the cooling-coil size will be reduced. If the energy-recovery value is ignored, the cooling coil and its control valve will be oversized and the system when put to use will be unstable and liable to hunt.

#### Annual energy consumption

- 4.54 The annual energy consumption of simple heating-only ventilation systems is simple to calculate, based on supply to external air temperature rise, and frequency of occurrence of external temperature data (see CIBSE Guide A).
- 4.55 Minimum air volumes are usually fixed by the room loads or fresh air requirements; however, the designer may increase airflow to some rooms or zones in order to balance loads, as detailed in paragraphs 4.63–4.68
- 4.56 The method of zoning and control can significantly influence energy consumption.
- 4.57 The nature of air-conditioning operation, that is, cooling and reheating for humidity or zonal temperature control, makes prediction of energy consumption very complex. It is imperative that these calculations are performed to ensure optimum energy efficiency.
- 4.58 The concept of load and plant operation charts is outlined in the CIBSE Guide TM52. The method requires the designer to establish the minimum and maximum loads on

all zones across the range of external temperatures between winter and summer design conditions. The total coil loads can be calculated taking account of the external air temperature and humidity plus the supply air conditions.

- 4.59 When all temperatures/enthalpies for all zones are plotted on the plant operation chart, set points and resetting schedules can be established. From this information, the outputs of individual heaters, coolers and humidifiers can be established at any given external condition. When those loads are computed against annual frequency of occurrence of external conditions as given in CIBSE Guide TM52, the annual energy consumption of individual elements, and thus the air-conditioning system, can be established.
- 4.60 In order to prevent surface condensation occurring, it is necessary to provide enough ventilation to maintain the maximum and ambient dew-point temperature below the lowest surface temperature, the coldest usually being the glazing.
- 4.61 Where this would require excessive ventilation levels, the designer should consider removal of the moisture at the source of the evaporation via an exhaust hood or similar device.
- 4.62 In intermittently heated buildings, it is necessary to consider the condensation risk at night set-back conditions as well as during normal operation. Calculation methods for this assessment are given in CIBSE Guide A.

### Calculation of plant requirements

#### Air supply volumes

- 4.63 The minimum air supply volume for a room is determined by the greatest of:
- the minimum fresh air requirement;
  - the air required to achieve the room differential pressure and provide open door protection at the key door;
  - the minimum supply volume for the room load as determined by the maximum heating or cooling supply temperature differential;
  - the desired air-change rate;
  - the make-up air for a local extract (for example, cooker hood or LEV system).

#### Plant sizing

- 4.64 Once the design airflow has been established, the cross-sectional area of the air-handling unit can be calculated based on values given in Commission Regulation EU 1253/2014.
- 4.65 The fan duty should be calculated by adding the resistances of all elements that contribute to the pressure drop of the index circuit.
- 4.66 In order to establish the length of the AHU, it will be necessary to refer to manufacturers' literature, ensuring all necessary access panels and components are included as detailed in Chapter 9.

- 4.67 The designer should ensure that an allowance has been made for "dirty filter" conditions and confirm whether the fan pressure quoted is the total or static pressure.
- 4.68 Upon completion of the resistance calculation exercise, the designer should make allowances for calculation and construction tolerances as indicated below:

Total pressure loss margin:

- for leakage and balancing requirement = +5%
- for uncertainties in calculation = +5%

Combined total pressure loss margin = +10%.

**Note:** All installed ductwork whether new or reused should be subject to a leakage test on site prior to the application of any insulation. The leakage test should be to BESA DW144 but with a permissible leakage rate of not greater than 3%.

### Refurbishment of existing facilities and fitting out shell schemes

- 4.69 When refurbishing existing facilities or fitting out "shell" schemes, every effort should be made to achieve full compliance with this SHTM and current Scottish Health Planning Notes (SHPNs). It is important that use of the space is revisited at this stage. Patient cohort, forms of treatment and all other stakeholder requirements must be compared to the capabilities of any existing system/plant and adjustments made to suit.
- 4.70 The physical constraints of the building may mean that some derogation in terms of layout and room dimensions are unavoidable, but it is vital that the infection control aspects, clean airflow paths, cascade of air from clean to less clean areas and fire and smoke requirements are not compromised and that the complete facility will be fit for purpose. The VSG should be consulted and agree in writing to any derogations.
- 4.71 A new AHU fully compliant with current standards will normally be required. The existing AHU should only be retained if it is not more than 10 years old and is (or can be made) fully compliant with current standards.

**Note:** The application of the ErP regulations may mean that new plant could be physically larger than that previously installed. If the replacement plant cannot be accommodated in the existing plant space, the plantroom may need to be expanded or a new plant space created. It may be that reconsidering how the ventilation load is determined, whether it can be shared, which type of AHU configuration will fulfill the design need, etc., will provide a satisfactory solution rather than just specifying like-for-like replacement plant.

- 4.72 The most commonly used original standard operating theatre design solutions from previous versions of this HTM have been revised and updated (see Appendix 7). They have been retained in this guidance as they will remain applicable to older theatre suites that are being refurbished within their original footprint. They may also be applicable where a pre-built "shell" is being fitted out.

### **Change of use of existing facilities**

- 4.73 When a change of use of existing facilities is contemplated, the ventilation requirement should be completely revised to suit the new use (see paragraphs 4.63 and 4.69). All requirements must be agreed with the Ventilation Safety Group.
- 4.74 A new AHU fully compliant with current standards will normally be required. The existing AHU should only be retained if it is not more than 10 years old and is (or can be made) fully compliant with current standards.
- 4.75 If the ventilation load is to be increased or reduced and the existing system is retained, its output should be adjusted to suit. This will necessitate a recalculation of the heater and cooler loads and resizing of the control valves to match the new loads. It may also necessitate a change in fan size. Failure to carry out this exercise will carry an energy penalty and loss of control function.
- 4.76 The area/zone fire strategy should be reassessed to suit the new layout and purpose.

### **Computer-aided design (CAD) and building information modelling (BIM)**

- 4.77 The design of new ventilation systems should be created using a CAD package, and the information generated should be incorporated into the BIM for the project. The client should have access to the BIM model as the project progresses; it will be transferred over to the client on completion (see paragraph 13.28 onwards)

## 5. Ventilation Strategies

---

5.1 In order to reduce energy costs and provide a more sustainable healthcare estate and support the declared zero- carbon target, ventilation selection should be as follows:

- first choice – natural ventilation;
- second choice – mixed mode ventilation;
- final option – mechanical ventilation.

### Natural ventilation

5.2 Natural ventilation is usually created by the effects of wind pressure. It will also occur if there is a temperature difference between the inside and the outside of a building. The “thermo-convective” effect frequently predominates when the wind speed is low, and will be enhanced if there is a difference in height between inlet and outlet openings.

5.3 Ventilation induced by wind pressures can induce high air-change rates through a building, provided air is allowed to move freely within the space from the windward to the leeward side. However, in most healthcare applications, internal subdivisions will restrict or prevent this effect.

5.4 Current guidance restricts the opening of windows for safety reasons; also, as many designs are top-hung, their ability to permit natural ventilation is limited. Some types of window (for example, vertical sliding) can enhance single-sided air change by temperature difference, and these will improve the overall rate of natural ventilation in protected or sheltered areas where the effect of wind pressure is likely to be minimal.

5.5 Current healthcare building design philosophy suggests that windows are provided to allow light into and a view out of a healthcare building. Ventilation should be provided by purpose-made openings with appropriate consideration for thermal comfort and air quality. The airflow may need to be controlled by motorised dampers linked to temperature and/or occupancy sensors in the ventilated space.

**Note:** Natural cross-flow ventilation can provide reasonable air distribution for a distance of up to 6 m inwards from the external facade, provided that reasonably clear air paths are maintained. Beyond this distance – in areas where clear air paths cannot be maintained and in areas where high minimum air-change rates are specified – mechanical ventilation should be provided.

If natural ventilation is single-sided, it will usually only be effective for a 3 m depth within the space. Beyond that it should be supplemented by mixed- mode or mechanical ventilation.

5.6 With natural ventilation, it is almost impossible to maintain consistent flow rates and ensure that minimum ventilation rates will be achieved at all times. However, this variability is normally acceptable in non-clinical spaces such as office accommodation, staff areas, library/seminar rooms and dining rooms, and some

clinical areas such as level 0 and 1 care spaces and waiting and consulting rooms where risk of airborne infections is likely to be low. The design must still aim to achieve agreed limits for room temperatures and, for clinical areas, achieve the desired room air change rate with "thermo-convective" effect (at peak room temperature coincident with summer external design temperature). Where it is essential to achieve a minimum ventilation rate at all times, mixed mode or mechanical methods will be needed.

- 5.7 Constraints caused by a building's shape and/or the functional relationships of specific areas will inevitably result in some measure of deep planning, thus reducing the opportunity for natural ventilation.
- 5.8 In all cases, for natural ventilation to be effective it will be necessary to take steps to reduce any solar gain to a minimum. Outdoor air-quality, excessive heat gain, indoor air-quality requirements or external noise are all factors that may limit or preclude the use of natural ventilation.
- 5.9 Further information can be found in Health Building Note 00-10 Part D – 'Windows', BS 5925 and CIBSE's Applications Manual AM10 – 'Natural ventilation in non-domestic buildings'.

### Mixed mode ventilation

- 5.10 Mixed mode ventilation is an assisted form of natural ventilation. Fans are fitted in purpose-made damper-controlled ventilation openings. Alternatively, a separate draw- or blow-through ventilation unit may be installed. In both cases the dampers and fans are controlled by temperature and occupancy sensors to ensure a minimum airflow rate while taking advantage of natural ventilation effects when present.
- 5.11 Where natural or mixed mode ventilation is adopted with complex air paths, the designer should produce an airflow diagram in order to ensure correct provision of air-transfer devices. CIBSE's Applications Manual AM13 – 'Mixed mode ventilation' gives guidance. Modelling of the airflows under a range of conditions should be undertaken to establish the airflow paths.

### Mechanical ventilation

#### Central versus local plant

- 5.12 Mechanical ventilation is expensive so it should only be provided when the space being served requires close control of its environmental conditions.
- 5.13 If the ventilation loads throughout a department or building are in phase, or are not significant, a central plant with single zone control may be adopted. However, this is rarely the case, so the condition or quantity of supply air to different areas or zones of the building will be varied accordingly. This may be achieved by either providing individual plant to each zone or providing separate controls for each zone such as provided by a variable air volume (VAV) system. Where there is a high density of rooms with similar ventilation requirements in an area of a building or department, it is usually economical to combine them into a central system; however, the operational resilience should be considered.

- 5.14 In large buildings, a choice between a small number of large ventilation systems located in centralised plant areas, or a larger number of smaller locally distributed systems, may arise
- 5.15 Large distribution systems and their plant can have the advantage of lower capital costs, but because they operate to a fixed supply condition, reheating or cooling may be locally required which will reduce energy efficiency. The distribution system will require more space for vertical shafts. In general, very long runs of ducting should be avoided to prevent undue heat losses or gains, excessive leakage and difficulties in balancing during commissioning. As the pressure losses in the long runs will be greater and a higher initial static pressure will be required, this may lead to a more expensive class of ductwork.
- 5.16 Decentralised AHUs feeding multiple smaller distribution systems may be more expensive in capital costs but as they avoid long runs, large ducts and vertical shafts, this may reduce overall costs. They can provide a more robust service, as the failure of an individual system does not prevent the use of the rest of the building. Future refurbishment or replacement of AHUs is also simpler. See also Chapters 4 and 9.

#### Horizontal and vertical AHUs

- 5.17 AHUs may be configured as horizontal or linear units that are single or double-stacked in the case of combined supply and extract units. They may also be configured more compactly as vertical or cabinet-style units. Selection will be dependent on the plant space available and where the unit is to be located. Whichever style is selected, good access for service and maintenance is essential. See legal requirements in paragraphs 3.6 and 3.10.

#### Chilled beams

- 5.18 Active chilled beams can provide an energy-efficient means of controlling environmental conditions. They are, however, subject to increased maintenance requirements due to the need for regular cleaning if they are to remain working efficiently. Access for this will not pose problems in non-clinical and office areas, but in clinical areas and patient bedrooms, routine access will be a major problem in an operational hospital.
- 5.19 Chilled beams should not be installed in clinical areas without the agreement in writing of the VSG.

**Note:** Patient bedrooms are classed as clinical areas as treatment is often delivered at the bedside rather than in a designated treatment room.

- 5.20 Where chilled beams are installed in non-clinical areas, they should be positioned to ensure that cold draughts are avoided.
- 5.21 In order to avoid condensation on the beam coils and the potential for mould growth, the temperature of the secondary chilled water circuit needs to be kept above dew-point (usually 15°C). With active beams the supply air may, under some outside air conditions, need to be dehumidified. Manufacturers of these devices can provide specific advice on the design limits and siting of their equipment.

- 5.22 Where chilled beams are installed in rooms with opening windows, the window should be fitted with a switch to automatically turn off the beam when the window is open. To avoid condensation, chilled beams should not be installed in entry lobbies that directly connect to the outdoors.
- 5.23 Active and passive chilled beams require regular cleaning if they are to remain efficient. They should be of a design that allows full access to the beam coils for cleaning and be positioned where they will be accessible for maintenance and not installed above fixed items of equipment.
- 5.24 There is no benefit in installing chilled beams if the resources to keep them in efficient working order over their entire life cycle will not be available. The maintenance aspects of using chilled beams should be discussed and the decision to use them agreed in writing with the client.

**Note:** Maintenance access to chilled beams will require the use of pulpit steps or wheel-around access equipment. The use of such equipment in a working hospital is very restricted.

#### Stand-alone air-conditioners

- 5.25 Stand-alone air conditioners include fan coil units, split-comfort air-conditioners, room conditioners and cassette units. All of these devices recirculate air which affects indoor air quality and may increase the risk of healthcare-associated infections (HAIs). Therefore, they should not be installed in clinical areas.

**Note:** Patient bedrooms are classed as clinical areas as treatment is often delivered at the bedside rather than in a designated treatment room.

- 5.26 Stand-alone air conditioners may be installed in suitable non-clinical areas, but they should be positioned to ensure that cold draughts are avoided. The control settings should ensure that the external elements of the units are always above dew-point. Manufacturers of these devices can provide specific advice on the siting and design limits of their equipment.
- 5.27 Stand-alone air-conditioners recirculate air, therefore, a primary fresh air supply of at least 20% of the room air-change rate, or that required by the Building Regulations, or 10 L/s/person – whichever is the greatest – should be provided.
- 5.28 Whether single or multiple systems are used, it is essential that the designer give due consideration to the source of electrical supply, location of the heat rejection unit, environmental effects and flammability of the refrigerant used, and drainage provision for the cooling-coil condensate.
- 5.29 Stand-alone air conditioners require regular cleaning if they are to remain efficient and not become a source of airborne bio-hazards. If they incorporate an open water drainage system, they must be risk assessed under L8/HSG274 as part of the Legionella assessment (see the Health & Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems'). They should be easily accessible for maintenance and should not be installed above fixed items of equipment which would make access difficult.

**Notes:** Maintenance access to stand-alone air-conditioners will require the use of pulpit steps or wheel-around access equipment. The use of such equipment in a working hospital is very restricted.

Traditional refrigerants are being phased down because of their effects on the environment and are becoming ever more expensive. Their replacements at the time of writing have a degree of flammability. Both these factors pose serious consideration as to whether stand-alone air-conditioners are suitable devices to choose. In scanning and control equipment rooms, the use of chilled racks, shelves and embedded panels supplied with water above dew-point would be a more suitable option.

Where the refrigerant pipework is located must be checked against the need to restrict risk. This may necessitate the need for refrigerant gas monitoring. The requirement must be checked during the design (refer to BS EN 378, using the relevant current edition for the application).

### System selection

- 5.30 Natural ventilation is always the preferred solution for a space, provided that the quantity and quality of air required, and consistency of control to suit the requirements of the space, are achievable. This should also take account of the guidance from the WHO (Natural Ventilation for Infection Control in Health-Care Settings). If this is not the case, mixed mode or a mechanical ventilation system will be required.
- 5.31 Ventilation costs can be minimised by ensuring that, where practicable, core areas are reserved for those rooms that need to have mechanical ventilation. Examples are:
- sanitary facilities, dirty utilities and those rooms where clinical or
  - functional requirements have specific environmental needs; and
  - those rooms where – for reasons of privacy, absence of solar gain, etc. – windowless accommodation is acceptable.
  - Other spaces appropriate to core areas are those which have only transient occupation and therefore require little or no mechanical ventilation (for example, circulation and storage areas).

### Zoning of the building

- 5.32 The efficiency and effectiveness of any ventilation or air-conditioning installation depends largely on the zoning and control of the installation. The factors to consider when determining the zoning of a ventilation system for a building or department are:
- periods of occupancy;
  - the service delivery resilience;
  - fresh-air/ventilation requirements;
  - the fire and smoke control strategy for the area.

- 5.33 Where the ventilation system is not merely tempering the air, but also providing the heating and/or cooling requirements (air-conditioning) the following additional factors should be considered:
- internal or peripheral location;
  - orientation of windows;
  - variation of internal loads;
  - level of control required.
- 5.34 For single-zone plant in staff areas, local control (with a run-on-timer if required) is recommended, as the system can be turned off when the space is not in use, thus saving both thermal and electrical energy. Most clinical-zone supply and extract systems, conversely, are required to operate continuously while the department is occupied; thus some form of time or use control is necessary.
- 5.35 The control of individual plant items is covered in Chapter 9, with examples of typical control strategies in Chapters 6 and 7. For control parameters of particular critical ventilation and air-conditioning systems, see Chapter 8.
- 5.36 On rare occasions a duplicate standby air-handling plant may be justified. If installed, it should be provided with a gas-tight damper (see BS EN 1751) at its junction with the supply distribution duct so that no back-flow can occur. Standby plant can become sources of contamination if warm, moist air is allowed to dwell within them. Their design and control system should ensure that this cannot happen.

**Note:** The presence of duplicate plant should be reflected in the fire strategy.

### Fire and smoke control

- 5.37 Within a designated departmental fire zone, the total mechanical supply and extract ventilation volumes should be approximately equal so that in the event of a fire, smoke is neither drawn into nor blown out of the zone. Note that individual sub-zones within the departmental zone may be positively or negatively pressured to suit the clinical need (for example, isolation rooms, operating theatres).

**Note:** In atria, stairwells and designated escape routes, dedicated smoke clearance fans may be installed to keep evacuation routes clear in the event of a fire. These together with their associated smoke dampers do not form part of the building's general ventilation system and their operation will be automatically initiated by the building's fire detection system and/or manually controlled by fire service personnel (see Health Technical Memorandum 05 Firecode).

### Air-conditioning

- 5.38 Air-conditioning is the facility to filter, heat, cool, dehumidify and if required humidify the supply air to maintain an internal condition regardless of changes in the external conditions or internal load. It is expensive in plant and energy.
- 5.39 Due to capital and running costs, air-conditioning should only be used in essential areas. These include operating departments, critical care areas, manufacturing pharmacies and areas with particularly sensitive equipment. Information on system performance requirements for individual departments is given in Chapter 8.

### Local exhaust ventilation

- 5.40 There is a statutory requirement under the COSHH regulations to prevent or control the escape of chemicals, toxic fumes, biological materials or quantities of dust into the general environment. For airborne hazards to people, control may be by the provision of an LEV system designed to the standard set out in HSG 258.

### Ventilation for general areas

- 5.41 Chapter 8 and Appendix 2 provide recommended air-change rates, temperatures and pressures for general areas requiring mechanical ventilation in healthcare buildings.

### Mechanical extract ventilation

- 5.42 General extract systems can vary in complexity from a single wall-mounted fan to a central ducted air system with dual extract fans.
- 5.43 Replacement air is provided by either a central supply system or enters the building through gaps in the structure or purpose-made openings. The design should ensure that the latter does not result in an unacceptable level of draughts occurring in winter.
- 5.44 If individual systems are used, the ventilation can be operated intermittently, provided it continues to run for at least 15 minutes after the room is vacated (as with light-switch-operated fans in individual toilets).
- 5.45 If general exhaust systems are used, filtered and tempered replacement air should be provided to adjoining lobbies or corridors, to prevent the risk of discomfort caused by the ingress of cold air. Fire compartmentation requirements should be maintained.
- 5.46 Information on specialised extract systems is given in Chapters 8 and 9.

### Mechanical tempered-air-supply systems

- 5.47 Where mechanical supply systems are required, the fresh air should be tempered and filtered before being delivered to the space in order to avoid discomfort.
- 5.48 The majority of space air temperature heating load will be provided by the energy-recovery device with the balance from a constant or variable temperature battery. In most instances, the low pressure hot water (LPHW) heating system should offset any fabric loss so that set-back room temperatures can be maintained during unoccupied periods without the need for the ventilation system to operate.

### Balanced ventilation

- 5.49 A balanced ventilation system is a combination of both a supply and an extract system of equal volume; either a single space or a whole building may be considered to be balanced.
- 5.50 A balanced system is necessary in instances where it is essential to maintain consistent air movement within an area (for example, recovery rooms).

### Cascade ventilation

- 5.51 In operating departments, it is normal practice to supply air to the operating theatre and allow it to flow through less clean areas – corridors, utility rooms, etc (from where

it is eventually extracted). Pharmacy aseptic preparation facilities, maternity delivery rooms and treatment rooms are similar.

- 5.52 In negative pressure facilities it will be necessary to provide make-up air in order to promote the correct pressure cascade from the clean to the less clean (for example, supply in an outer area – to lobby to patient's room – to toilet extract). Infectious diseases units and bronchoscopy rooms are similar.

### Recirculation systems

- 5.53 Air recirculation systems are normally used in HEPA-filtered cleanrooms where the return air is significantly cleaner than the outside supply and where odour levels are not significant.
- 5.54 Recirculation is also routinely used in the canopy section of ultra-clean operating theatre ventilation systems (UCV). The recirculated air is EPA filtered to ensure that biological contaminants released by the surgical team are not discharged back into the clean zone.
- 5.55 Recirculation may also be used for swimming and hydrotherapy pool ventilation.
- 5.56 Where the designer is considering the installation of an air recirculation system, due account should be taken of:
- a 20% minimum fresh air supply volume or that required by the Building Regulations or 10 L/s/person, whichever is the greatest;
  - prevention of supply air contamination from vitiated return air;
  - prevention of stratification occurring within plenum chambers and mixing boxes, which may result in freezing of downstream coils;
  - ensuring sufficient velocities through automatic control dampers (ideally 5–6 m/s) where fitted, to provide suitable authority and good shut-off;
  - modulating control of mixing to provide optimum on-plant conditions;
  - the use of "free cooling" by cycling the dampers to minimum fresh air when the enthalpy of the outside air is greater than that of the extract air under conditions when cooling is required.

**Note:** Recirculating air can create particular problems when its ductwork breaches fire compartmentation. Designers should ensure that the system complies with the fire strategy in all modes of operation.

### Dilution ventilation and clean airflow paths

- 5.57 In the past dilution ventilation has been used as the sole means of controlling levels of airborne hazardous substances in a space. This approach in itself is no longer considered acceptable. COSHH requires that airborne hazardous substances should be controlled at source by using a closed system (such as an anaesthetic gas scavenging unit) or a protective enclosure (such as a fume cupboard). A good level of background ventilation will assist in diluting any casual release of the substance.
- 5.58 In anaesthetic rooms, the casual exposure of staff to leakage or spillage when administering anaesthetic agents should be dealt with by establishing a clean airflow

path. Air should be supplied at high level above or behind the area where the staff will typically stand and extracted at low level directly behind the anaesthetic equipment position (see Figure A25 and photographs in Appendix 9).

- 5.59 The philosophy of establishing a clean airflow path – from the air-supply point, past the breathing zone of the staff, on to the patient or other source of airborne hazard, and out via a low-level extract – would also apply in recovery rooms, birthing rooms, bronchoscopy rooms, laboratories and post-mortem rooms. A suitable air-change rate (see Chapter 8) will provide background dilution ventilation as an additional safeguard. This approach ensures that regarding the ventilation aspects, “all reasonable steps are taken to prevent or control exposure (of staff) to the hazardous substance” as required by COSHH.

**Note:** In these areas the supply air should be 100% fresh and not recirculated.

- 5.60 In operating theatres, patients will be on a closed breathing circuit in a room with a high air-change rate. Under these circumstances, the dilution effect would be considered sufficient to control any casual exposure of staff to anaesthetic gases.

#### Displacement ventilation

- 5.61 Displacement ventilation introduces air at low level and removes it at high level. It uses the natural thermal buoyancy resulting from heat gain to achieve air movement throughout a space with minimal or no energy input. Displacement ventilation can be natural, mixed mode or mechanical with the supply untreated, tempered or fully conditioned depending on the application.
- 5.62 Displacement ventilation can be very energy-efficient and works well in applications that have significant casual heat gains from solar effects, people or equipment. Typical applications in a healthcare setting would be the ventilation of atria, central dining rooms, main kitchens, hydrotherapy pools, computer server rooms, lecture theatres and open-plan waiting or office areas. It is also applicable to non-interventional imaging and scanning suites where there are significant equipment-generated casual gains but no aerobiological infection risks.
- 5.63 Supply terminals will be located at low level, usually in the form of large perforated plate style diffusers mounted vertically. The supply air terminal face velocity is low so that it does not create draughts. It is essential that they are located in several positions so that they can ventilate the entire space. Care should be taken to ensure that fixed or movable equipment and devices cannot obstruct them. Extract will be at high level through vents or by a ducted extract system. The ventilation rate may be controlled by temperature or CO<sub>2</sub> sensor-initiated motorised dampers with or without fan assistance at the extract points. The supply air volume is then slaved to match.

## 6. Energy Control Strategies

---

- 6.1 The operation of ventilation systems should be monitored through a building management system (BMS). The basic objective should be to provide the necessary service utilising the minimum energy. To this end, switching a system "Off" when not required is the most energy-efficient policy.
- 6.2 If the system is needed to maintain a minimum background condition, reducing its output by "Setting back", to the minimum necessary to achieve and maintain the desired condition, is the next best option.

### **Note** on "Set back":

In previous times when fan motors only had two speeds, turning the system

to "Set back" meant switching to the lower fan speed. With modern fans the speed is widely variable so "Set back" is not a fixed fan speed but rather a

control strategy that reduces the system output in order to maintain a desired minimum condition. This may be related to the air velocity at a fixed point,

air-change rate, pressure differential, temperature, humidity or a combination of these parameters. Providing a dew-point sensor in an internal space that brings the system on to "Set back" is a simple way of maintaining a minimum condition.

- 6.3 The system should only run at full output when needed to achieve and maintain the defined "in-use" operating condition
- 6.4 Care should be taken when specifying plant to discover the true "in-use operating condition". Overstating the condition will lead to oversized plant, unstable control and excessive energy consumption.
- 6.5 The design and selection of set points for an AHU and associated extract system will have a significant impact on the overall energy consumption and efficiency of the system as a whole (see Chapter 9 for detailed information).

### **Timed control**

- 6.6 Switch the AHU "On" and "Off" at fixed times using a time clock or BMS programme. The AHU needs to come on early enough in the morning to bring the space up to temperature by the normal start time.
- 6.7 As above but with an "Optimum start" control that uses the outside temperature to determine the start time. In the winter, the lower the outside temperature, the earlier the AHU starts. In summer, the higher the outside temperature above that desired, the earlier the AHU starts.
- 6.8 As above but link the AHU to a temperature sensor in the space. If out of hours the temperature inside drops to the dew-point, typically 16°C in winter, or rises above 25°C in summer, the AHU will start and run at "Set back" (see definition in the Note after paragraph 6.2).

- 6.9 Any combination of the above or any other appropriate and applicable method that uses the least energy to maintain the specified condition is valid. Various options for the control of single- and multi-zone air-conditioning systems are given in CIBSE Guides F and H.

### Occupancy control – user triggered

- 6.10 The ventilation system output should be linked to occupancy detectors. These may take the form of movement, CO<sub>2</sub>, passive infrared (PIR) or other sensing technologies that can detect that the area served is in use and switch the system “On” or “Off” and/or adjust the ventilation output to suit the actual load.
- 6.11 In intermittently used spaces such as operating suites, movement sensors (for example, PIR or similar) should be installed in the space with a “double knock” program so that if movement is detected twice within 10 minutes the AHU will switch “On” to full speed. If no movement is detected for 30 minutes, the AHU switches “Off”. Double-knock detection prevents the system from switching on in situations where a person has briefly entered a space when it is not in use.
- 6.12 The above may be combined so that if there is no movement for 15 minutes, the AHU switches to “Set back” (see definition in the Note after paragraph 6.2) during the working day and “Off” outside of normal hours.

**Note:** In Ultra Clean Ventilated (UCV) operating theatres the UCV terminal should be linked to the AHU control so that when the AHU goes to “Set back” the UCV also goes to “Set back”, and if the AHU goes “Off”, the UCV terminal fans also switch “Off”. There is no aerobiological benefit in keeping the UCV terminal fans running when the theatre is not in use, it results in wasted energy.

- 6.13 An alternative strategy in operating suites is to link the AHU control to the lighting. If the theatre general lights are switched “On” the AHU switches “On” in “Set back” mode. If the main operating lamp is then switched “On” the AHU goes to “Full speed”. If all the lights are out the AHU goes “Off”.

**Note:** There are occasions when this approach may need to be used with caution; for example, if a type of surgical procedure requires the operating or general lights to be “Off” during a part of the operation, an override timer or plant extension switch will be needed. The operating department manager and VSG should be consulted for approval before adopting this strategy.

### User control

- 6.14 Some applications require intermittent mechanical ventilation, frequently at a high air-change rate (for example, in certain types of treatment room for odour control). Local controls to facilitate this mode of operation if required should be placed in a prominent position to encourage economical use. Specifying timers that shut the system down after a suitable operating period and need to be reset manually will reduce energy waste.
- 6.15 Local controls that enable the user to select more than one mode of operation should be clearly labelled to identify the particular mode selected.

- 6.16 Where the system allows different room pressures to be selected, a direct-reading pressure gauge should be fitted within the eye line of the users, 1.5 m above floor level, adjacent to the selector control unit to provide an independent confirmation of the resultant mode of operation. A permanent notice giving a clear description of the selectable modes of operation should be mounted adjacent to the control unit.

Interim

## 7. Environmental Control

---

- 7.1 The primary objective of a ventilation control system is to keep the space served within the required environmental control limits, at the appropriate times – regardless of external conditions or internal loads – and with the minimum energy consumption.
- 7.2 The building heating load will normally be met by a wet heating system with ventilation provided to suit the activities within it. The control of the heating system will normally be compensated to the outside air temperature. Control of the ventilation will usually be via a building management system (BMS) with “outstations” in individual plantrooms and/ or for individual AHUs.
- 7.3 A BMS incorporating self-adaptive control algorithms that automatically adjust the set-point to suit the usage and load is preferred. This will enable the operating conditions and control tolerances to be set and monitored. It is often not possible to accurately predict building load variation at the design stage. Information provided by monitoring the operation of the plant via a BMS will enable optimum set-points to be established and energy consumption reduced.
- 7.4 The BMS may also be set to log the actual energy consumed by the system together with that recovered by the energy- recovery device. This will provide a useful check on overall operating efficiency and provide evidence that energy targets are being achieved. The provision of movement sensors within the controlled space in order to determine the actual occupancy will facilitate this process.
- 7.5 The failure of ventilation systems serving critical areas can have grave consequences for the delivery of healthcare. Control systems should therefore be simple, robust and reliable.
- 7.6 Computer-software-driven control systems are now the norm in building services. However, healthcare ventilation systems need to be available for operation outside of normal working periods when software support is not available. Should the software fail, it will be left to site staff, who may have little knowledge of the control algorithms, to restart the ventilation system. It is therefore essential to ensure that a simple means of restarting critical systems in the event of a software failure is provided (see also Chapter 9).
- 7.7 Where BMS use “outstations” to control plant, the “outstation” should be independently able to control the plant if the BMS link is lost.

### Location of controls

- 7.8 Whether within the plant, duct or room, sensors should be located to provide accurate measurement of the condition of the air being monitored.
- 7.9 Sensors and control items such as control valves should be located close to the element being sensed or plant item being controlled in order to minimise time lags within the system. These may create over- shoot of conditions beyond the design envelope and result in additional energy consumption.
- 7.10 Where there is a requirement for close control of air-conditioning parameters in a number of zones (for example, an operating department), separate plant should be

provided for each zone in order to avoid the need for expensive over-cooling and reheating of individual zones. The control of most multi-zone systems within healthcare premises is based on off-coil control within the central plant, with trimmer heater-batteries on individual zones.

**Note:** In modern buildings the cooling load is often significantly greater than the heating load and may exist all year round. Whenever possible, the design should take advantage of free cooling when available.

- 7.11 Facilities to start, set back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location (for example at the reception or staff base).
- 7.12 Many ventilation systems may be completely shut down when the area served is not in active use (for example, operating suites). Alternatively, where there is a need to maintain a background condition, the ventilation output may be reduced by "setting back" the system (see paragraph 6.2 and associated Note). This will significantly reduce energy consumption and extend the life of filters and other system components

#### Multi-zone control methods and application

- 7.13 Close control of all air-conditioning parameters may be difficult to achieve with multi-zone systems, since each zone will in theory require a reheater and humidifier to give total control of humidity, if that is what is required. In reality, such close control is rarely required. It is therefore usual with multi-zone systems to provide control of zonal temperature only, with humidity control, where fitted, being based on average conditions within all zones, or a minimum condition within one zone.
- 7.14 Designers should consider whether it is necessary for the supply and extract fans to be interlocked – either so that the supply fan will not operate unless airflow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served (see also Chapter 8).
- 7.15 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratories and pharmacies that contain fume cupboards, safety cabinets and other LEV systems.

#### Fire aspects

- 7.16 The control strategy for ventilation systems in the event of a fire should be set out in an agreed fire and smoke control strategy for the site (see Chapter 1).
- 7.17 All supply AHUs should have a smoke sensor linked to the fire control panel and mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the AHU to shut down and the main supply-air damper and system fire damper(s) to close.
- 7.18 In critical areas a ventilation control panel should be mounted at the main entrance of the area that the ventilation serves (see Health Technical Memorandum 05-02 for more detailed guidance). Access to the panel should be restricted to the fire officer and appointed site AP(V). It should include independent on/off controls and an

indication of the status of the supply and extract systems. A notice should be affixed to the control panel stressing the need to liaise with departmental staff before switching off fan units

**Note:** In certain critical care areas, it is preferable to maintain the supply ventilation in case of a fire within the area. For example, in an operating department, while undergoing surgery, the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department, or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke. This will allow time for the patient to be stabilised so that they can be safely evacuated if necessary.

## User requirements

### Room temperature control

- 7.19 The limits for room temperature set- point are generally between 18°C and 22°C depending on the particular application. In some specialised applications (for example, operating departments), the user may require a wider range of adjustment (see Chapter 8).
- 7.20 The selection of temperature set-point for each room or zone may be by a control facility in the room/zone or be carried out remotely at the control panel or BMS. Where the control device is mounted within the room/zone and is adjustable by the user, it should be marked either "raise" and "lower" or "+" and "-". It should control within a specified temperature range to suit the user requirement with a control tolerance of  $\pm 1$  K. All other control set- points should be selectable either on the control panel or at the BMS interface.
- 7.21 Where local control is provided, an indication of temperature will be required locally or at a staff base (if appropriate) using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example at the operating table in a theatre). This may be mounted in a supervisory control panel, with the signal repeated on the main system control panel or BMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

### Alarms and indication

- 7.22 Supply and extract systems should include indicator lamps on the control panels to confirm the operational status of each system. Where the usage is on a regular daily pattern, time control with a user-operated, timed manual override should be provided.
- 7.23 Where a system is provided for a particular space, the indicator should be in, or immediately adjacent to, that space, and local controls should be provided with permanent labels clearly defining their function (for example isolation suites).
- 7.24 If room differential pressure gauges are required, they should be mounted directly adjacent to the entry door of the room to which they apply at a height of 1.5 m above floor level so that they are in the eye line of staff entering the room. If a mechanical gauge is fitted, it should have a green sector to indicate the acceptable normal

pressure range. If electronic, it should have a permanent label affixed underneath it giving the normal acceptable pressure range.

**Note:** For specific departmental control parameters, see Chapter 8. For plant controls see Chapter 9.

### Maintaining balanced air flow rates

Consideration must be given to the method of maintaining the correct proportional balance throughout a system when in use. This becomes particularly important where duct or terminal mounted filters are to be used. As the filters soil, the pressure and flow balance of the system would change unless control measures are included to enable automatic compensation/adjustment (e.g. constant volume boxes, variable speed drives).

## 8. Specific Healthcare Department Requirements

---

### General considerations

8.1 The foregoing chapters of this document contain general information on healthcare aspects of ventilation system design and specification. This chapter gives information relating to the specific design requirements for a range of healthcare applications.

8.2 The following departments will require a degree of ventilation appropriate to their function.

- the operating department;
- treatment rooms, endoscopy and minimally invasive suites;
- critical care area – levels 2 and 3;
- diagnostic and interventional imaging and cardiology suites;
- obstetrics/maternity;
- infectious diseases unit and isolation facilities;
- bone marrow and other transplant units;
- chemotherapy and oncology units;
- the pharmacy department;
- the pathology department, mortuary and post-mortem suite;
- central decontamination units;
- burns unit;
- cystic fibrosis unit;
- tissue bank, gene therapy and emerging treatment specialties;
- physiotherapy and hydrotherapy;
- estates infrastructure.

Design information for many of these applications is given below, in Appendix 2 or the relevant SHPN/HBN.

8.3 It is not possible to give definitive guidance for every healthcare ventilation application; however, the section on operating theatres contains much information that is common to other applications. Where no specific guidance is given, the principles set out below should be followed:

- the CIBSE guides and technical manuals contain basic information on ventilation design that can be applied to most applications;
- where a British or European standard exists that is specific to the application (for example, a cleanroom), it should be used as the basis of the design requirement;

- air should always move from clean to less clean areas. A hierarchy of room cleanliness is given in Appendix 3;
- differential pressure will prevent contamination between areas when doors are closed. Information on air leakage through gaps around closed doors and hatches for a range of differential pressures is given in Appendix 4;
- the flow of air will prevent contamination between areas of different cleanliness when doors are open. Information on airflow through open doors and hatches is given in Appendix 5;
- a methodology for calculating a design solution for a non-standard operating suite in terms of its room sizes, layout or number of people present is given in Appendix 8. This may be adapted as necessary to suit other less complex applications where air is required to cascade through rooms from clean to less clean areas.

**Note:** In all cases it is essential that the design solution adopted will ensure adequate scouring of the space being ventilated. The selected airflow rates, relative position of supply terminals, extract terminals, air transfer devices and pressure stabilisers will all have a bearing on the effectiveness of the room ventilation.

8.4 There are four routes by which airborne contaminants may appear in a room:

- shed directly by the room occupants;
- arising as a result of the work activities;
- transferred from adjacent spaces;
- through the supply air.

Particles shed directly by the room occupants can be controlled by:

- restricting access to essential persons only;
- the choice of the occupants' clothing;
- the room air-change rate.

Particles arising as a result of the work activity can be controlled by:

- enclosing, semi-enclosing or otherwise controlling the work-based source;
- the room air-change rate.

The transfer of particles from adjacent spaces can be controlled by:

- a differential pressure between spaces when doors are shut;
- airflow paths flowing from clean to less clean spaces when doors are open.

Particles entering with the supply air can be controlled by the selection of a suitable filter.

When designing ventilation for a healthcare application, the sources of airborne contamination, their degree of hazard to patients and/or staff and the ability of ventilation to control them should be taken into account. For any particular healthcare

application, the ventilation safety group (VSG) should be able to give advice on any specific risks to patients and staff.

8.5 The supply of air to a room has the following main functions:

- to dilute airborne contamination;
- to control air movement within such that the ingress or discharge of airborne contaminants from or to adjacent areas is minimised;
- to control the temperature and, if necessary, the humidity of the space;
- to aid the removal of and dilute fumes, odours and waste gases.

8.6 The supply air volume flow rate for any particular application will be that required to:

- achieve the application's recommended air-change rate;
- provide closed and/or open-door protection;
- achieve comfort or application-specific room conditions;
- replace (make up) that removed by an installed extract system;
- meet the fresh air requirement relating to the number of people anticipated to be present;
- achieve the minimum fresh air requirement if air is recirculated.

Whichever is the greatest amount.

**Note:** Air-change rates are given in Appendix 2. These figures have been found to give enough dilution of airborne contaminants, provided the mixing of room air is reasonably uniform. Closed and open door protection volumes are given in Appendices 4 and 5. Fresh air requirement is at least 10 L/s/person. Minimum fresh air volume if recirculated is 20%, whichever is the greater.

8.7 Natural and/or mixed mode ventilation should be used wherever possible. Where mechanical ventilation is chosen, a downward displacement turbulent air distribution is generally preferred, though displacement ventilation may be used if appropriate.

8.8 The supply and extract terminals should be positioned to ensure that all parts of the room are actively ventilated and that where necessary the staff will be in a clean airflow path. Extract and air-out paths via door gaps, transfer grilles, pressure stabilisers and low-level active extract should be evenly distributed to encourage efficient scouring of the room. (See paragraphs 8.37–8.40 and 9.161–9.172 for additional guidance on location and types of terminal.)

8.9 Horizontal flow room air distribution with or without a coanda effect (see paragraph 9.162) can be a source of draughts and difficult to set up correctly. Its use should be confined to non-critical areas or situations where ceiling-mounted diffusers could be obstructed by movable equipment support tracks (for example, in imaging rooms). Alternatively, a displacement ventilation scheme may be considered.

### Temperature and humidity control

- 8.10 Supply flow rates to achieve the required room conditions are calculated conventionally, taking account of all heat and moisture gains and losses, and of maximum permissible temperature differences between the room and supply air. In most applications the base heating load will be provided by a heating system. In critical systems the room or suite being considered will be within the heated building envelope so the ventilation will be sized to suit the casual gains or losses.
- 8.11 Temperature differences between supply and room air of up to 10 K for winter heating and 7 K for summer cooling should not be exceeded.
- 8.12 Room air humidity should be kept below 70% in order to minimise risks associated with condensation and mould growth. There is generally no lower limit in unoccupied spaces; however, see application-specific guidance.

### Ventilation where anaesthetic agents are present

- 8.13 During treatment, anaesthetic gas or anaesthetic agents may be delivered to the respiratory tract of a patient either directly or using a carrier gas. Anaesthetic gases and agents are subject to workplace exposure limits and while beneficial to the patient are harmful to staff. Waste anaesthetic gas should be contained and removed by a suitable anaesthetic gas scavenging system (AGSS). Some leakage from the anaesthetic equipment and the patient's breathing circuit will occur with all systems, particularly during connection and disconnection and from the interface with the patient. In recovery areas the patient will exhale the anaesthetic agent directly into the room air. The room ventilation scheme should ensure that any leakage or exhaled anaesthetic agents are diluted and removed.

**Note:** Staff tend to be standing and patients lying down when anaesthetic agents are delivered; also anaesthetic agents are slightly heavier than air, so locating the supply terminal at high level behind where staff normally stand, with an extract at low level adjacent to the source (for example, the anaesthetic gas terminal units), will ensure that staff are in a clean airflow path.

- 8.14 The design primary air supply to an operating suite anaesthetic room that is equipped with a N<sub>2</sub>O terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas, or an operating department recovery room, should be 15 ac/h.
- 8.15 In delivery rooms the intake of anaesthetic gas is controlled on demand by the patient, who will then exhale directly into the room air. Locating the supply air at high level at the foot end of the bed with extract at low level at the head end will establish a clean airflow path and reduce the casual exposure of staff to the waste gas.
- 8.16 The primary air supply to any other room that is equipped with a N<sub>2</sub>O or N<sub>2</sub>O/O<sub>2</sub> (Entonox) terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas or in which the patient is subsequently recovered, where the anaesthetic is employed for the purpose of pain relief or sedation but not full anaesthesia, should be 15 ac/h. However, subject to risk assessment, consideration may be given to reducing this to no less than 10 ac/h, only where use of the anaesthetic gas release into the space will be both very infrequent and in very small quantities.

**Note:** Staff employed in operating suite anaesthetic rooms and an operating department recovery room will potentially be exposed to anaesthetic agents for the duration of their working day. In other areas (for example, maternity, imaging, treatment rooms), anaesthetic agents are only used for pain control and/or sedation. The strength, quantity and frequency of use may be significantly less, hence the the option to carry out a risk assessment.

### Door protection

- 8.17 Air should flow from the cleaner to the less clean areas as shown in Appendix 3 and Figure A23 in Appendix 8. There are several factors that affect the likelihood of a reverse airflow through doorways:
- when a person passes through a doorway, both the passage of the person and the movement of the door flap cause a transfer of air between the areas separated by the door;
  - when a door is left open, there is a transfer of air between the two areas separated by the doorway. This is caused by air turbulence, but is greatly increased by any temperature differential between the areas (a 1.4 m wide doorway may allow the transfer of 0.19 m<sup>3</sup>/s of air in each direction when there is no temperature difference, but when the temperature differential increases to say 2 K, the volume transferred may increase to 0.24 m<sup>3</sup>/s). This may be a problem if for example the heat gain from a fluid warming cabinet is not allowed for.
- 8.18 In order to reduce the likelihood of contamination of a clean area by a reverse airflow from a less clean area two methods of door protection are used:
- closed door protection – a pressure differential is created across a closed door so that any air leakage is from the clean to the less clean area. Appendix 4 gives details of closed door leakage rates for a range of differential pressures;
  - open door protection – the pressure differential drops when a door is opened (see Appendix 6) and is effectively replaced by a flow of air through the doorway from the clean to the less clean area. The flow of air needs to be sufficiently large to ensure that significant reverse airflow cannot occur and will be related to the relative cleanliness of the areas being considered. Appendix 5 gives airflow rates for open-door protection related to door/opening size and the classification of the adjoining area.
- 8.19 Pressure stabilisers enable the room differential pressure to be set when the doors are shut, thus providing closed-door protection. When a door is opened, the stabilisers will close, forcing air to be directed through the doorway, thus providing open-door protection. Provided that the dilution criteria in Appendix 3 are met, the occasional small back-flows created (when two doors are opened simultaneously; or when there is a high temperature difference across an open door) will have little effect on the overall air cleanliness of the affected room.
- 8.20 In applications where it is critical to maintain a specific airflow and/or pressure regime, for example isolation rooms, all windows in the zone should be locked shut or sealed. Trickle vents, if fitted, should also be sealed.
- 8.21 The design of the ventilation system for an area depends on the overall configuration of the department. Where the department is served by more than one AHU the

control of the units may need to be interlocked so that reverse airflow patterns do not occur.

- 8.22 Extract grilles should be sited and balanced to promote air movement in the desired direction.
- 8.23 Transfer grilles enable air to pass in either direction between rooms of equal class and pressure. Pressure stabilisers operate in one direction only; they allow excess air to be directed to the area desired and assist in maintaining room pressure differentials.
- 8.24 The relative locations of supply and extract terminals and their design air volume rates will determine the basic airflow between adjacent spaces. Transfer grilles and pressure stabilisers will permit and control the flow of air between spaces, ensuring a flow from the clean to less clean areas of the suite. Failure to provide such devices will lead to uncontrolled airflows when personnel move between rooms and doors being held partially open by air pressure.

#### Air handling unit

- 8.25 AHUs should be to the standard set out in Chapter 9. The extent of the system served by an individual AHU should reflect the operational need and required resilience of the application.

#### Fire aspects

- 8.26 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system to limit smoke spread in the event of a fire.

### Operating department

#### General

- 8.27 An operating department will consist of one or more operating suites, a recovery area, sterile pack and equipment stores, entry/exit/service corridors, office, staff changing and support facilities. Each operating suite will typically comprise a preparation room, operating theatre, anaesthetic room, scrub area and a utility room. In order to ensure satisfactory conditions and the correct movement of air, the entire department will usually be mechanically ventilated.
- 8.28 The information given in this section relates to conventional operating suites used for general surgery. It will be applicable to other types of operating suite such as maternity whose layout and dimensions conform to the principles of Health Building Note 26 (see Note below). Additional information for UCV theatres is given in paragraphs 8.75 onwards.

**Note:** Health Building Note 26 – 'Facilities for surgical procedures' (2004) and Health Building Note 10-02 – 'Facilities for day surgery units' (2007) are under revision and will be replaced by a single document: Health Building Note 10-01. It will provide guidance on the planning and design of infrastructure for in-patient and day-patient surgical services in the UK.

- 8.29 For other types of operating suite, the standard values may need to be adjusted to reflect non-standard room sizes, pressure regimes and air-change rates. A method of obtaining a design solution for non-standard theatres from first principles is given in Appendix 8 (see also paragraph 8.3 and accompanying Note).

#### **Standard air movement control schemes**

- 8.30 In all previous versions of this guidance, standard air-movement control schemes were given that provided a range of design solutions for typical operating-suite layouts. Improvements in the technology of ventilation control systems coupled with the ability to accurately sense and control real-time fan output has enabled operating-suite ventilation parameters to be tightened. These now more accurately meet the airborne-infection-control requirement (see the Lidwell Report). The previous standard design solutions have therefore been fully revised to take advantage of the technological advances and benefit from the reduced energy consumption and plant size they allow.
- 8.31 A new set of standard operating suite design solutions extensively amended to conform to the guidance contained in this edition of Scottish Health Technical Memorandum 03-01 are given in Appendix 7. They contain diagrams that show the relationship of rooms and the various doors and transfer devices between them but should not be regarded as architectural layouts. The schemes have been developed using the methodology described in Appendix 8.

These design solutions should be used for new projects and when refurbishing or upgrading existing operating suites.

- 8.32 Any other scheme may be used, and the standard solutions applied, if the following conditions are met:
- room relationships in air network terms are as shown in the plans;
  - room sizes and shapes approximate to those given in Health Building Note 26 (under revision at the time of writing and to become Health Building Note 10-01);
  - door gaps approximate to those given in the designer's notes in Appendix 4;
  - casual heat gains are accounted for;
  - a trimmer battery is installed in the air supply to the anaesthetic room and lay-up prep room;
  - leakage through the structure is kept to a minimum. Note that theatre suites will be subject to an air permeability test at first-fix and final validation (see Chapters 10 and 12).

It is recommended that every effort should be made to adopt one of the schemes described above.

#### **Ventilation design requirement**

- 8.33 The need for ventilation of the individual rooms and areas within the operating department will be as follows:
- Preparation room – to protect sterile packs and instruments from pre-contamination;

- operating theatre – to control the airborne infection risk, remove airborne contaminants and prevent the ingress of airborne contaminants from adjacent areas;
- anaesthetic room – to protect staff from casual exposure to anaesthetic agents and maintain a suitable environment for patients;
- scrub – to remove aerosolised microbiological contamination and moisture released when staff scrub- up;
- utility (also known as sluice or disposal) – to contain any airborne hazards arising from the initial processing of biological material, contaminated instruments and general waste and prevent it entering the operating theatre or adjacent spaces;
- entry/exit/service corridors – to remove vitiated air cascading from the operating suite(s);
- sterile pack/ Layup Prep and equipment stores – to prevent airborne contamination of the packs and equipment;
- staff changing, shower and toilet facilities – odour control and moisture removal;
- staff rest room – moisture and odour control;
- office and general areas – comfort conditions;
- recovery – to protect staff from casual exposure to exhaled anaesthetic agents and maintain a suitable environment for patients.

The ventilation requirement for each space will be met by the desired air-change rate, room pressure differential, relative position of the room supply and extract, comfort requirement or a combination of all elements.

8.34 **Preparation room – sterile pack store (SPS)** - The preparation room is used simply as a store; sterile packs are set out on trolleys but not opened. They are then transferred to the operating theatre and opened as required. The nominal room pressure can therefore be the same as that of the operating theatre and the air allowed flow between the rooms in either direction. Air supplied to the preparation room should be directed into the operating theatre either through a door-mounted transfer grille or if no door is fitted, through the opening. It should not flow via a pressure stabiliser or transfer grille into the corridor.

8.35 **Preparation room “lay up”** – When the preparation room is used as an instrument “lay up” room (that is, sterile packs are opened and their contents exposed ready for transfer to the operating theatre), it should be regarded as being of greater cleanliness than the operating theatre. The preparation room should be at 10 Pa above the operating theatre to minimise the transfer of air and prevent pre-contamination of the instruments. The design air supply volume should relate to the door protection factors (for example, open door to theatre and closed door or hatch to corridor, where provided) and result in not less than 22 ac/h. Air should discharge into the operating theatre through a pressure stabiliser fitted with a stand-off baffle plate on the theatre side (see photograph). It should not flow via a pressure stabiliser or transfer grille into the corridor. The volume of supply air being discharged through the pressure stabiliser may be used to offset the volume of supply air to the operating theatre.

Where the unpacking of the instruments involves not only the removal of the protective packing but also the opening of the sterile barrier, the supply air to the room must be delivered via a terminal HEPA filter (H12 grade). The system must include constant volume and variable speed controls to ensure that the air flow rates remain constant as the HEPA filter soils. In this case it is also necessary to design a specific air flow regime to enhance the cleanliness of the environment. The supply air must be delivered from the ceiling in a manner which directs that air down into the zone where the sterile barriers are to be removed. Air will then be relieved from the room at low level with an air pressure stabiliser into the theatre.

8.36 **Operating theatre** – The supply of air to an operating theatre has four main functions:

- to dilute airborne microbial contamination – this will arise from the surgical activity and microbiological material shed by staff;
- to aid the removal of and dilute fumes, odours and waste anaesthetic agents;
- to control air movement so that the airborne contaminants from other less clean areas do not enter;
- to control the temperature and if necessary, the humidity of the room.

#### Design notes

- an air-change rate of 22 ac/h will control (a) and (b) above. When calculating the air volume required to achieve the air-change rate, the physical volume of the operating theatre will be based on whether the scrub does or does not form part of it. See Note to paragraph 8.46 for further information;
- the room to corridor differential pressure and amount of air required to give door protection will control (c). Door protection is calculated on the basis that during use, only one door or a single leaf of a double door will be open transiently, and all the rest will be closed. The designated "open" door will be the worst case (for example, typically that between the operating theatre and utility). The volume of supply air can be calculated from the flow rates for open and closed door protection given in Appendices 4 and 5. The smaller the number of rooms (and therefore doorways) leading from the operating theatre the better, as traffic is reduced, and a less complicated air movement control scheme is required;
- the supply air volume to control (d) temperature and humidity conditions can be calculated conventionally, taking account of all heat and moisture gains and losses resulting from equipment, lighting and number of occupants. Supply to room air temperature differences of up to 10 K for winter heating and 7 K for summer cooling should not be exceeded. Room humidity should not exceed 70% saturation.

The design supply air volume for an operating theatre will be whichever of the above calculations yields the greater figure.

In the case of an operating suite with a "lay up" preparation room, the actual air volume supplied by the operating theatre terminals will be the design air volume determined above minus that entering via the preparation room pressure stabiliser.

**Note:** In the majority of operating theatres the air-change rate will be the dominant factor; however, for small operating theatres the door protection factor may dominate.

- 8.37 The supply and extract terminals should be positioned to ensure that all parts of the operating theatre are actively ventilated. The ceiling should be divided into four quadrants and a supply terminal positioned at the centre of each quadrant and along the lines that join them as necessary to ensure that all parts of the room are equally supplied. In a large theatre, additional terminals around the centre point may be necessary to promote efficient scouring and achieve satisfactory air movement at the operating table level. This will help create in ventilation terms a well-mixed space and ensure good dilution of any airborne contaminants. Extract and air-out paths via door gaps, transfer grilles, pressure stabilisers and low-level active extract should be evenly distributed to encourage efficient scouring of the room. A minimum of three and preferably four air-out paths, approximately equally spaced, should be provided.

**Note:** In order to ensure correct air distribution, it is essential that the supply terminal locations are not displaced by light fittings or ceiling-mounted pendants and articulated booms. Ideally the supply terminals should alternate with light fittings along the quadrant lines described above.

- 8.38 Supply terminals should be ceiling-mounted circular "air master" style, square "four-way blow" or perforated plate style that produce a downward displacement, turbulent airflow (see paragraph 9.170 onwards). Multi-section plenum-style perforated-flow diffusers with a footprint that encompasses the operating site are acceptable but may be prone to buoyancy effects as a result of temperature difference. Manufacturers' type test data should be consulted to ensure that the terminal will achieve the required performance envelope. Note that these are not true laminar flow systems in the strict sense of the word but produce a downward displacement parallel flow style of air distribution.

**Note:** Where an operating theatre requires a higher than normal air-change rate (for example, cranial surgery, which may specify 35 ac/h), the volume of supply air means that four-way blow diffusers would be noisy and probably cause unacceptable draughts. A UCV terminal would deliver too much air, which could result in exposed tissue drying out during the procedure. A multi-section, plenum-style perforated flow diffuser with a footprint that encompasses the operating site would be the most suitable option.

- 8.39 The diffuser equipment chosen should not cause "dumping" and provide an air velocity 1 m above floor level at the operating position of between 0.2 m/s and 0.3 m/s.
- 8.40 Horizontal flow distribution should not be used in new installations; however, space constraints may force its retention when refurbishing existing installations. Where fitted, the supply grilles will require a means of directional adjustment that is lockable in position to prevent casual alteration in future when being cleaned.
- 8.41 Anaesthetic room – Anaesthetic gas or anaesthetic agents will be delivered to the respiratory tract of a patient either directly or using a carrier gas. Anaesthetic gases and agents are subject to workplace exposure limits and while beneficial to the patient are harmful to staff. Some leakage from the anaesthetic equipment and the

patient's breathing circuit will occur with all systems, particularly during connection and disconnection, and from the interface with the patient. The room ventilation scheme should ensure that any leakage is diluted and removed, and that staff are in a clean airflow path. Locating the supply terminal on the ceiling in a position behind where the anaesthetist will normally stand, and the extract terminal at low level adjacent to the medical gas pipeline terminals, will encourage a clean airflow path past the breathing zone of the anaesthetist, thus reducing their casual exposure to airborne anaesthetic agents (see information in Appendix 9).

- 8.42 An operating theatre suite anaesthetic room that is equipped with a N2O terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas should have a design primary supply and extract flow rate to achieve 15 ac/h.
- 8.43 In order to maintain the core temperature of patients being anaesthetised, a trimmer heater-battery should be provided in the anaesthetic room supply. It is also important that the location of pressure stabilisers and transfer grilles does not cause draughts across the patient.
- 8.44 The anaesthetic room will be at an intermediate pressure between the operating theatre and corridor.
- 8.45 **Scrub** – This may be a separate room or a bay within the operating theatre. If the scrub is a separate room, a door between the scrub and operating theatre is an inconvenience to scrubbed staff and may be replaced by an opening that is larger than a normal single doorway. If a door is fitted between the scrub and operating theatre it should have a transfer grille in its lower half. In either case there should be an active extract at low level under the end of the scrub trough most remote from the operating theatre, or a low-level pressure stabiliser that discharges onto a corridor at the end of the scrub room most remote from the operating theatre (see figure 1). If the scrub has an outside wall and/or is particularly large, additional extract terminals may be required to ensure air movement throughout the entire space and prevent surface condensation and mould growth.

Figure 1 Scrub room with extract under trough

- 8.46 Where the scrub is a trough on the wall or in an open bay within the operating theatre, it should have low-level extract under it.

**Note:** If the Scrub is in effect a separate room that is open (no door) to the operating theatre and it has a low-level pressure stabiliser discharging onto a corridor or an active low-level extract at its far end, so that air has to travel through the scrub to leave the operating theatre, the volume of the scrub will not be counted as being a part of the operating theatre room volume.

If the scrub is a trough on the wall or in an open bay within the operating theatre, the volume of space it occupies will be considered part of the operating theatre room volume for the purpose of calculating the operating theatre air supply.

- 8.47 **Utility (sluice or disposal)** – The room is kept at negative pressure with respect to the operating theatre so that contaminants contained in the surgical waste do not re-enter the operating theatre. A utility opening onto a clean corridor is considered to pose a greater risk than one opening onto a service corridor and so has a greater differential pressure. A utility may be shared between two operating theatres or be centralised to serve a group of operating suites.
- 8.48 **Entry/exit corridor** – Air cascading from the operating suite should be removed in the adjacent corridors. Note that though design flows may be calculated, the actual extract airflows may need to be adjusted at commissioning in order to achieve the design room differential pressures.
- 8.49 **Service corridor** – If materials to be disposed of are placed in impervious material for transportation, it is not necessary to have a separate corridor for this purpose. However, a service corridor has many operational advantages in terms of the flow of materials through the operating suite. It provides a heated envelope around the operating suite, thus obviating the need to run the theatre ventilation out of hours to maintain its temperature above dew-point, so significantly reducing energy consumption. Lastly it permits access for routine service and maintenance, and the eventual refurbishment of an operating suite without compromising the use of adjacent suites.
- 8.50 **Sterile pack store** – The central operating department sterile pack and prosthesis store should be supplied with 6 ac/h and be at a positive pressure to their corridor. It is important to coordinate the position of the supply air terminals with any racking so that the terminals are accessible for annual airflow measurement with a balometer.
- 8.51 **Equipment store(s)** – Supply air ventilation only to keep them at positive pressure to the corridor.
- 8.52 **Staff changing, shower and toilet facilities** – ventilation as per building regulations and for moisture control.
- 8.53 **Staff rest room** – Ventilation for kitchen area and general comfort.
- 8.54 **Office and general areas** – Ventilation as per building regulations and comfort.
- 8.55 **Recovery room** – Anaesthetic agents will be exhaled by patients while recovering; they are subject to workplace exposure limits and are harmful to staff. Anaesthetic gas scavenging systems (AGSS) will be provided but the room ventilation scheme should ensure that any leakage is diluted and removed.

- 8.56 The supply air terminals should be ceiling-mounted above the foot end of the recovery bed positions. Extract should be at low (bed height or below) level behind the bedhead positions or in the corners of the bed bay. This will establish a clean airflow path so that staff do not inhale anaesthetic agents exhaled by recovering patients (see the COSHH Regulations).
- 8.57 In an operating department recovery room, the design primary air supply will be 15 ac/h with a balanced airflow.

#### General notes

- 8.58 Supply flow rates for the main rooms of the operating suite are given in Appendix 7. For the other areas where room sizes and activities vary from site to site, air-change rates are given in Appendix 2 and Tables 2–7 in this chapter. These figures have been found to give enough dilution of airborne microbial contaminants, provided the mixing of room air is reasonably uniform.
- 8.59 For conventionally ventilated operating theatres, the primary air supply would be filtered in the AHU. Terminal filters, EPA or HEPA, are not required.
- 8.60 Air extracted from operating suites should not be recirculated as it may contain malodorous contaminants.

**Note:** Where thermal wheels are used for energy recovery, the small leakage across them from extract to supply should not cause odour problems and is not considered aerobiologically significant. In any event, all the air supplied will pass through the final filter.

#### Operating suite pressure regime

- 8.61 When designing the ventilation scheme the room pressure differentials given in Appendix 7 should be used. However, when the suite is balanced and commissioned these values are not to be taken as immutable but rather as desired orders of magnitude. What is important is the direction of airflow between rooms when doors are closed. Specifying doors of a laboratory standard that close and sit against a seal or have drop seals on their bottom edge is not necessary and will be counterproductive of the aim to allow air to flow from clean to less clean areas.

**Note:** Fire officers often require that doors are fitted with cold smoke seals as standard. These will significantly reduce the door-leakage rate and increase the differential pressure when new and undamaged. It is therefore recommended that provision for the design door leakage be factored into the sizing of the appropriate transfer grille or pressure stabiliser.

#### Temperature and humidity control and indication

- 8.62 In an operating theatre the temperature should be adjustable within the range 18°C to 25°C by the staff at the theatre control panel. The ventilation system should be capable of maintaining an internal temperature of 20°C at summer outside design and 22°C at winter outside design in all but the most extreme outside conditions. There may be instances where these temperatures may not be appropriate (for example, children and patients with a low body mass). The internal design temperatures should then be discussed with the VSG and agreed in writing.

- 8.63 Theatre temperature and humidity control sensors should be actively ventilated. They would typically be located in a sampling extract duct mounted in or adjacent to the theatre control panel, positioned at normal working height (1.5 m above finished floor level). Alternatively, they may be mounted in one of the operating theatre's low-level extract ducts. Whichever location is chosen they should be accessible for cleaning, and removable for periodic calibration and replacement.
- 8.64 Passive wall-mounted temperature and humidity sensors are not recommended.
- 8.65 Controls should be provided to enable operating department ventilation plant to be closed down when the operating suites are unoccupied (see also Chapter 9).
- 8.66 When in the "off" mode, to provide dewpoint protection the control system should switch the ventilation "on" to "Set back" if the space temperature falls below 16°C.
- 8.67 All operating theatres and rooms where surgical interventions are carried out should have a control panel mounted on a wall with its screen centre at 1.5 m high and in the direct line of sight of staff standing at the normal operating position. The theatre control panel should include plant status indication, clearly readable temperature and humidity indicating gauges, and a means of adjusting the set point for temperature. Theatre ventilation plant status indication should also be located at the operating department staff control base (see the Specialised Ventilation for Healthcare Society's (2017) SVHSoc.01 – 'Operating theatres: energy control strategies and the surgeon's panel' for further details).
- 8.68 The following indicators should be incorporated in the theatre control panel and their functions clearly labelled.
- a readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the temperature of the air in the theatre;
  - a readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the relative humidity of the air in the theatre;
  - a red indicator light that will illuminate when either the supply AHU fails or is switched off or is in "Set back" (legend: "Theatre not to be used in this condition");
  - a green indicator light that will illuminate when the supply AHU is operating at full speed (legend: "Conventional theatre mode").

**Note:** In touch-screen panels, the red indicator should be a band across the screen with the statement "Theatre ventilation not operational. Do not use". The green indicator may be moving arrows representing airflow with the legend "Ventilation operational".

- 8.69 The humidity within the operating department when in use should fall within the range 35% to 60%. Where it is considered necessary to fit a humidifier, it should be selected to humidify to 40% saturation at 22°C during the design winter outside conditions. The cooling coil should be able to remove sufficient moisture so that 60% saturation at 20°C is not exceeded during the design summer outside conditions.

**Note:** When not in use the humidity may be allowed to fall below 35% but should not be allowed to rise above 70%.

- 8.70 The automatic control of ventilation in operating suites needs to be simple and robust. Over-reliance on complex room pressure and flow relationships linked to automatic fan speed control are unnecessary and in the long term have been shown to be unreliable. Complex software algorithms that can only be accessed and interpreted by off-site specialists should not be used. Whichever control strategy is chosen, it is important that on-site staff have the facility to override the control system and keep the ventilation operating at least until the surgical procedure is complete (see also Chapter 9).

#### Operating suite air handling unit

- 8.71 Each conventional operating theatre suite should have its own dedicated AHU to the standard set out in Chapter 9. To ensure operational flexibility and permit routine maintenance, an air handling unit should not be shared between suites.
- 8.72 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances, subject to VSG approval, an AHU may be shared between not more than two operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre suite so that the primary air volume to each can be determined. In addition, the branch supply and extract should be capable of being physically isolated and the main airflow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

**Note:** An AHU provided under paragraph 8.72 may be shared between two conventional operating suites, but not between a conventional and a UCV suite

- 8.73 The AHU supply and extract fans should be interlocked so that the supply starts up first and shuts down last, thus preventing reverse airflows. If the extract plant fails when the theatre is in use, it may continue to be used but a warning should show on the BMS and theatre control panel. If the supply fails when the theatre is in use the extract should shut down to prevent reverse airflows and an alarm should sound and show on the theatre control panel.

#### Fire aspects

- 8.74 When considering the overall airflow movement, careful thought needs to be given to the operation of the ventilation system to limit smoke spread in the event of a fire. However, this is a highly staffed department with a low fire risk/load status and these factors need to be recognised when developing the fire strategy. Operating departments typically comprise a series of linked rooms with multiple exits. Over-compartmentation can lead to difficulties in establishing clean airflow paths and room air dilution rates. This will lead to an increased risk of healthcare-acquired infections. Staff areas within the department should be treated as a subcompartment.

### Ultra-clean ventilation system

#### General requirements

- 8.75 The design philosophy of a conventionally ventilated operating suite is based on the need to dilute contaminants and control both the condition and movement of air in an operating suite. Ultra-clean ventilation (UCV) is a means of significantly increasing

the dilution effect by providing a large volume of clean filtered air to the zone in which an operation is performed, and sterile items are exposed. Air is discharged above the operating zone and while not truly laminar, its downward displacement purges the clean zone of contaminants and particles generated by the activities within it. The airflow in and around the clean zone also serves to prevent particles originating outside the zone from entering it. The resulting reduction in contaminants has been shown to significantly reduce post-operative sepsis following certain orthopaedic procedures.

**Note:** The number of microorganisms that are present in the air at the wound site and exposed surgical items is dependent on the operating team, their procedural discipline, choice of clothing and the type of UCV system. Ultra-clean air is defined as that containing not more than 10 colony forming units per cubic metre of air (10 cfu/m<sup>3</sup>) present at the wound site during a surgical procedure. In practice levels of only 1 cfu/m<sup>3</sup> are often attained.

- 8.76 UCV systems are very successful in reducing contaminants at the wound site so it is often considered that there is no need for complex air movement control schemes in the rest of the suite. However, when designing the ventilation scheme, it should be noted that the users may switch the UCV terminal to "low speed" when non-orthopaedic surgery is taking place. This is because the high airflow rates can cause increased moisture evaporation of exposed tissue which may be detrimental to the surgical outcome. In recognition of this, the ventilation scheme should be capable of providing operating conditions to at least a "conventional" theatre standard throughout the suite with the UCV in "low speed" mode. It should also be remembered that suitable levels of ventilation will always be required in the peripheral rooms.
- 8.77 UCV systems can be designed and built from first principles or a range of bespoke modular units of varying shapes and sizes are available, with each manufacturer having a slightly different approach to UCV design. Notwithstanding any variation in their design philosophy, all UCV systems will be required to completely achieve the performance standard set out in Chapter 12.
- 8.78 As with conventional theatres, each UCV operating suite should have its own dedicated AHU to the standard set out in Chapter 9. To ensure operational flexibility and permit routine maintenance, an AHU should not be shared between suites.
- 8.79 In retrofit installations, site conditions may preclude individual AHUs for each suite. In these circumstances, subject to VSG approval, an AHU may be shared between not more than two UCV operating suites providing each suite has its own control of temperature. An accessible airflow measurement test point should be provided in the supply branch duct to each theatre so that the primary air volume to each UCV canopy can be determined. In addition, the branch supply and extract should be capable of being physically isolated and the main airflow rate reduced so that either suite can be taken out of use without detriment to operating conditions in the other.

**Note:** An AHU provided under paragraph 8.79 may be shared between two UCV operating suites, but not between a conventional and a UCV suite.

- 8.80 An inherent feature of a UCV system is its large airflow so it is essential to recirculate the air supplied to the operating theatre and/or to recover its energy in order to optimise operating costs.
- 8.81 The primary fresh air volume supplied to a UCV operating suite will be the same as for a conventional suite and it should be dispersed to the rooms in the suite in the same manner. The UCV canopy will typically incorporate recirculation fans. In order to prevent these fans "robbing" the air supply to the rooms, the primary air supply to the UCV theatre suite should be split into two ducts each with a volume control damper, one duct to feed the UCV canopy and the other for the anaesthetic and preparation rooms (which will be subdivided to accommodate heater batteries before they serve their respective room).
- 8.82 "Laying up" instruments in the clean zone is preferable microbiologically and considered best practice by the Royal College of Orthopaedic Surgeons, so an SPS preparation room should be provided. A transfer grille will be needed in the door between the theatre and preparation room.
- 8.83 If the client requires a "lay up" preparation room, a pressure stabiliser will be required between the preparation room and theatre. It should be fitted with a baffle on the theatre side to prevent air transfer interfering with the airflow distribution under the UCV canopy (see figure 2). Where space planning permits, consideration may be given to a location of the lay up preparation room in which the air pressure stabiliser discharges from it into the theatre at a point beyond the end of the canopy.

Figure 2 Pressure stabiliser fitted in preparation "lay up" room with stand-off baffle in theatre

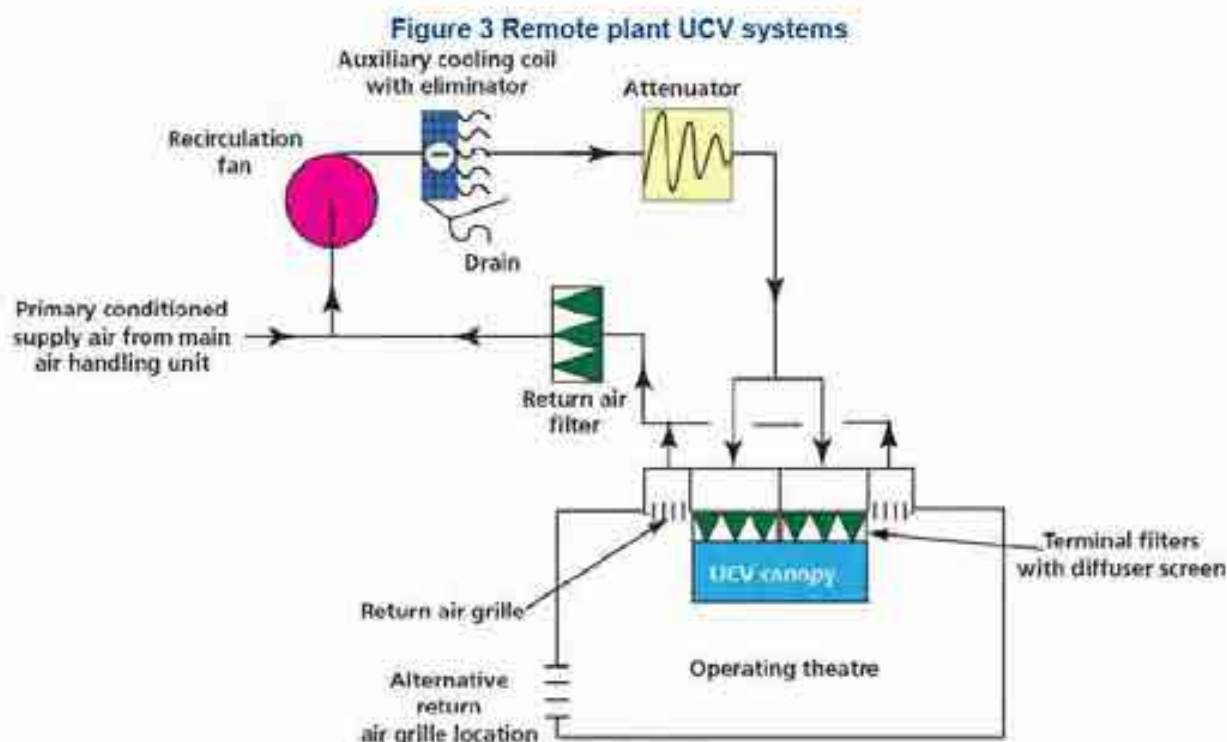

- 8.84 Separate scrub-up or disposal facilities are not necessary for air cleanliness, although operational policy may prefer such a provision. A separate anaesthetic room should however be provided.

### Types of UCV system

#### Remote plant systems

- 8.85 In a remote plant system, all the air- conditioning equipment is located outside of the operating theatre, except for the unidirectional airflow terminal, terminal filter, air diffuser and the return air grilles (see Figure 3).
- 8.86 This arrangement has the following advantages:
- the recirculation fans are out of the theatre, thus reducing noise. Multiple recirculation fans may be replaced by a single fan unit.
  - casual heat gains from recirculation fan(s), canopy lights, equipment and people within the theatre can be removed by a cooling coil in the return air stream. This will prevent heat build-up in the theatre.

- the return air filters can be changed without needing access to the theatre, making routine maintenance more feasible.
- the opportunity exists to locate the EPA filter in the primary supply duct rather than the theatre terminal. This will reduce the number of filters required and allow them to be changed without entering the theatre.

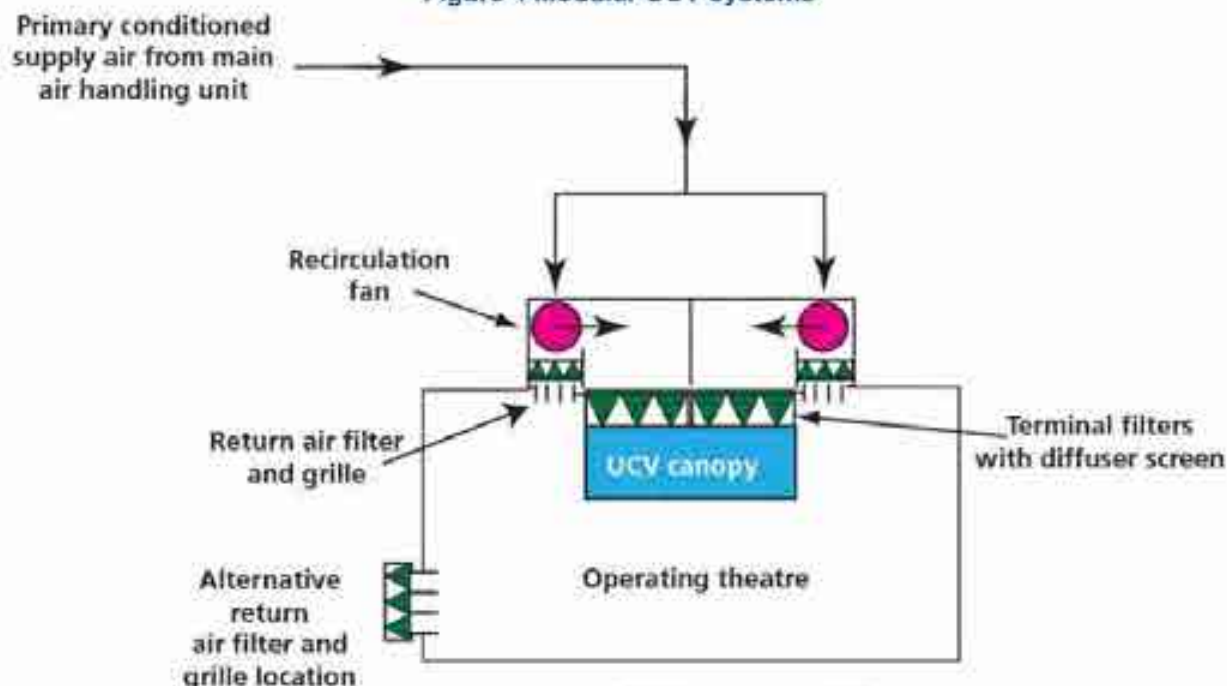

### Modular systems

- 8.87 Vertical-flow modular units comprise a ceiling-mounted canopy containing return air filters, final filter and air diffuser. Primary air is supplied by a remote air-conditioning unit at the volume and to the standard required for a conventional operating suite. The UCV-canopy return-air fans may be within the unit or mounted independently of it in the ceiling void or wall space (see Figure 4).
- 8.88 Modular units have the following advantages:
- as they are produced in a modular form, installation is generally more straightforward;
  - they can be used to upgrade an existing conventional operating suite to a UCV suite without the need to change the AHU;
  - all the UCV elements are in one place, making maintenance simpler.
- 8.89 UCV systems can be designed and built from first principles, or a range of bespoke modular units of varying shapes and sizes are available, with each manufacturer having a slightly different approach to UCV design. Whichever system is used, in order for the UCV terminal to produce the desired airflow within its footprint without entraining non-filtered air, the physical outside edge of the UCV canopy unit should not be less than 1 m from the operating theatre wall.

Notwithstanding any variation in their design philosophy, all UCV systems will be required to completely achieve the performance standard set out in Chapter 12.

Figure 4 Modular UCV systems

### Vertical flow UCV systems

- 8.90 Vertical flow systems are effective at reducing infection risks (Lidwell et al., 1982). Some systems have no walls and use auxiliary fans to create an air curtain around the clean zone. Partial wall systems have side screens that terminate 2 m above floor level and full wall UCV have side screens that terminate 1 m above floor level.
- 8.91 Full wall systems provide a physical barrier between the operating team and other theatre occupants and guide the air down to the operating table level. They can therefore work at a lower air velocity.
- 8.92 Siting the return air grilles around the periphery of the theatre at low level will help control short-circuiting and give an improved airflow path. In any event there should be an "air out" path on each face or in each corner of the theatre. These may be provided by combination of pressure stabilisers and passive or active low-level extract grilles. Failure to provide "air out" paths on all faces of the theatre may result in the surplus air causing entrainment into the clean zone.
- 8.93 Vertical systems should have a clean zone large enough to encompass the operating site and all instrument trays likely to be needed for the procedures to be undertaken. Where the surgical site is small, a 1.4 m circular or rectangular terminal may be provided. For major orthopaedic procedures, a minimum size of 2.8 m × 2.8 m will be required. This is the area projected on the floor under the supply air terminal within the full walls, partial walls or air curtain. Any air outside this zone cannot be guaranteed to be ultra-clean although given the dilution factor, the level of microbiological contamination will be much lower than the general level in a conventional operating theatre. Having a contrasting coloured area on the floor delineating the extent of the "clean zone" will assist staff and is therefore essential.

**Note:** The entire “clean zone” footprint of the UCV canopy will be designated by a contrasting coloured inlay in the floor covering. A line marked on, or cut into, the floor covering is not sufficient and will not be accepted at validation.

- 8.94 When upgrading an existing conventional theatre to an ultra-clean standard the only solution may be the installation of a modular system. In these units, the heat gains from the return air fans may warrant the inclusion of supplementary cooling within the module. However, issues of cooling-coil drainage, condensate removal and maintenance access within the space constraints of the module may make this option impracticable. The additional cooling load should then be catered for by conditioning the primary air to compensate.
- 8.95 If an existing AHU is to be retained, it may require modification to ensure that it achieves the standards set out in Chapter 9 of this document (see also paragraph 4.73). The fan may need re-rating to accommodate the change in system resistance. The cooling coil may also need to be upgraded to cater for the increased load resulting from the return air fans and terminal lights. Failure to make adequate provision for this may make the theatre unusable during prolonged warm spells.
- 8.96 A factor affecting the airflow pattern is the supply/room air temperature difference. When the supply air temperature is significantly above room temperature, buoyancy effects will reduce the volume of air reaching the operating zone. This can occur at start-up in a large theatre where the temperature when not in use has dropped below 18°C. If it is anticipated at design stage that this will be a regular occurrence, a system incorporating full walls should be used. Demountable extensions that convert a partial wall to a full wall unit are available.
- 8.97 Convection up-currents from the surgical team and operating lamp tend to counter the movement of clean air towards the operating site, hence the air velocity reaching the operating level is critical. The minimum velocity given below has been selected to take account of these factors and is greater than the theoretical minimum value. For all vertical UCV systems the design discharge velocities will be as follows:
- air velocity 2 m above floor level:
    - no side wall system = 0.38 m/s average;
    - partial wall system = 0.38 m/s average;
    - full wall system = 0.30 m/s average.
  - air velocity 1 m above floor level:
    - all systems = 0.2 m/s minimum within the inner operating zone.

Chapter 12 gives details of the method of measurement.

- 8.98 Variable speed recirculation fans with differential pressure control may be the most suitable solution for maintaining consistent performance and energy saving. The recirculation fans should be accessible for replacement without the need to disturb the fabric of the operating suite.

### UCV filters

- 8.99 The AHU primary and secondary filters should be to the standards and in the location set out in Chapter 9.
- 8.100 Terminal filters should be provided within the UCV canopy or in the air supply to it. Efficiency particulate air (EPA) filters grade E10 as specified in BS EN 1822 will be required as a minimum. There is no aerobiological benefit in fitting filters of a higher grade than this.
- 8.101 In some modular UCV units their manufacturers state that the terminal filter is used as a pressure equaliser to balance airflow so a grade higher than E10 is fitted. The increased resistance may affect the velocity of air reaching the operating level and there will be penalties in terms of installed fan power, energy consumption and higher noise levels.
- 8.102 The final filters should be installed in a leak-proof housing in a manner which allows the terminal unit, filters and their seals to be validated. The UCV canopy and its terminal filters will be scanned with a light scattering airborne particle counter (LSAPC) during validation to prove the effectiveness of the complete installation.
- 8.103 Where UCV units are constructed in sections, a means of measuring the pressure drop across the terminal filters in each section should be provided. The pressure test points should be located outside of the partial wall, capped to prevent air leakage and accessible within the theatre without the need to open the unit inspection panels. Alternatively, direct-reading non-electronic pressure gauges (of the minihelic type) may be fitted.
- 8.104 The UCV system will require a return air filter to capture the relatively coarse particles which would otherwise significantly reduce the life of the final filter. This should be at least an ISO 16890 Coarse 60%. In remote recirculation systems there may be advantages in fitting a higher-grade return air filter as it will reduce the load on the terminal EPA filters and extend their life.

### Noise level

- 8.105 If sound-attenuating material is used to line any portion of the inside of the UCV unit it should be non-particle shedding and non-combustible.
- 8.106 The maximum noise level in an operating theatre fitted with a UCV terminal of any type should not exceed 53 dB(A). Chapter 12 gives details of the method of measurement.

### Lighting and operating lights

- 8.107 The position of the UCV light fittings and style of partial walls, where fitted, should neither adversely disturb the airflow nor result in significant spatial variations in illuminance levels.
- 8.108 In vertical units, specialised task lighting should be provided by toroidal, cruciform or small multiple dome-shaped luminaires as they have good aerodynamic properties. The ideal luminaire will have a minimal effect on the airflow regardless of where it is positioned. Large diameter saucer-shaped luminaires should not be used in vertical

flow systems as they will occlude the airflow in the critical central zone. It is important to consider the suitability of existing luminaires when retrofitting UCV systems.

- 8.109 In vertical UCV installations the distance between the UCV canopy diffuser screen and the floor should be between 2.75 m and 3 m. This will allow space for the operating lamps and their articulation arms, and ensure that air at the correct velocity arrives at the operating level. When parked the lowest point of the central light stem, luminaire, monitor, camera, their associated articulation arms and any other ceiling-hung equipment should never be less than 2 m above floor level.

**Note:** The traditional means of light support is a central column that passes through the UCV canopy and is rigidly fixed to the building structure. The position of the support therefore prevents air being supplied at the centre of the canopy. Separate supports displaced from the centre of the clean zone would lead to improved airflow. This approach was advocated in the 1994 version of this guidance but at the time of writing no UK manufacturer has chosen to adopt this solution. Alternatively, equipping the operating team with battery-powered headset lamps may remove the need for traditional operating lamps and their supports.

#### Controls and Instrumentation

- 8.110 The functions of the supply AHU and extract ventilation should be continuously monitored by a BMS control unit and interlocked with the UCV terminal control and monitoring functions. The room temperature sensor should be located in the re-circulated air return path. The controls and instrumentation for the main plant are set out in Chapter 9.
- 8.111 UCV systems will additionally require a low speed facility that can reduce the air supplied through the UCV canopy to a volume that equates to not less than 22 ac/h of the operating theatre gross volume or that required for door protection, whichever is greater, whilst still leaving the supply AHU operating at full speed. In this operational mode the theatre may be used as a conventional operating suite. A means of switching between conventional and UCV mode will be provided on the theatre control panel and its function clearly labelled (see the Specialised Ventilation for Healthcare Society's (2017) SVHSoc.01 – 'Operating theatres: energy control strategies and the surgeon's panel' for further details).

**Note:** UCV theatre ventilation may be completely switched off when the theatre is not in use, but the room temperature should not be allowed to drop below 18°C (see paragraph 8.96). The AHU and UCV control should be interlocked so that when the AHU goes to "Set back" the UCV also goes to "Set back", and if the AHU goes "Off", the UCV terminal fans also switch "Off".

There is no aerobiological benefit in keeping the UCV terminal fans running when the theatre is not in use, it results in wasted energy.

- 8.112 The following indicators should be incorporated in the theatre control panel and their functions clearly labelled. In retrofit installations, an auxiliary panel for the UCV may be the most practical option. If fitted it should be mounted adjacent to the theatre panel and their control functions interlocked.

- A readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the temperature of the air at the UCV canopy.
- A readout sufficiently large (25 mm) to be clearly visible from the operating table that shows the relative humidity of the air at the UCV canopy.
- A red indicator light that will illuminate when either the supply AHU or the UCV canopy fails, or either or both are switched off or the AHU is in "Set back" (legend: "Theatre not to be used in this condition").
- An amber indicator light that will illuminate when the UCV canopy is at low speed and the supply AHU is running at full speed (legend: "Conventional theatre mode").
- A green indicator light that will illuminate when both the supply AHU and UCV canopy are operating at full speed (legend: "UCV theatre mode").
- A blue indicator light that will illuminate when the UCV canopy airflow, as detected by a differential pressure sensor, falls below 80% of the design flow rate (legend: "UCV requires service").

**Note:** In touch screen panels the red indicator should be a band across the screen with the statement "Theatre ventilation not operational. Do not use" The amber indicator may be moving arrows representing airflow with the legend "Conventional Theatre mode". The green indicator may be moving arrows representing airflow with the legend "UCV Theatre mode". The blue indicator may be a band across the UCV terminal mimic stating "UCV requires servicing".

- 8.113 When a system is designed to have partial walls with full wall extensions, a volume control facility may be incorporated to allow the system to be run with reduced velocity when the demountable full walls are in place. It would be the responsibility of the user to ensure correct operation of the system. To assist the user, an explanatory notice should be included on the theatre control panel.
- 8.114 The UCV unit manufacturer's control box should be located in an accessible position preferably in the operating department adjacent to the operating theatre that it serves. A service corridor, if provided, is an ideal location. The control box should be clearly labelled with the identity of the operating theatre that it serves.

### Barn and semi-barn theatres

- 8.115 There is no aerobiological reason why two or more UCV systems should not be installed in a common area if adequate spacing is provided. These are known as barn theatres and require special design considerations and operational discipline. The relative positions of the UCV units, temperature control range and location of doors and openings to other areas will all significantly affect the airflow at the operating positions.
- 8.116 A barn theatre has two or more operating positions each ventilated by a UCV canopy all in one open operating theatre. There may be a common scrub trough, SPS preparation room and shared utility, all of which reduce the facility's footprint. For reasons of privacy and dignity, there is usually a separate anaesthetic room for each operating position. The operating positions may be separated by glass screens to

prevent bone fragments being propelled from one position to another when high-pressure air-driven surgical tools are being used.

- 8.117 A semi-barn theatre is very similar but would have a full-height dividing wall between the operating positions. The wall will not extend across the full width of the room, only its middle section. This creates a degree of physical separation between the operating positions but allows staff to walk from one to another around the ends of the dividing wall.
- 8.118 It is important that the physical layout and ventilation strategy of the barn or semi-barn are in harmony if the installation is to work successfully. The following points should be resolved with the architect and VSG when considering the design:
- in order to reduce the risk of pre- contamination, surgical instruments should not have to pass one operating position in order to get to the one that they are destined for;
  - staff having scrubbed should not have to pass one operating position in order to get to the one that they are destined for;
  - waste material being cleared from an operating position should not pass another when being removed from the operating theatre;
  - the operating positions and their UCV canopies should be placed in line and not staggered or offset, otherwise their airflow patterns will interfere with each other;
  - while barns and semi-barns have, from the staffing and space utilisation point of view, many advantages, they can create problems with temperature control and energy efficiency. It is not advisable to shut their ventilation off at night or weekends as if the operating theatre temperature drops it can take a considerable time for the ventilation to achieve the required air velocity at the operating position (paragraph 8.96). Because the barn is a large open space, when it becomes cold the warm air supplied by the UCV canopies tends to rise and stratification occurs. As a result, although from the user's point of view the ventilation appears to be running, the air being delivered does not actually have enough velocity to reach the operating table;
  - access for service, maintenance and future upgrades or refurbishment will be restricted as this can only be carried out when none of the operating positions is in use.
- 8.119 Ventilation of each UCV canopy and associated anaesthetic room will be by a dedicated AHU; ventilation of the shared spaces and perhaps recovery area would either be shared between the operating position AHUs or provided by a separate AHU.

### Hybrid theatres

- 8.120 A designation given to operating theatres that contain scanning equipment on a robotic arm. Major surgical procedures are carried out and the patient is scanned as necessary during the procedure. The scanning equipment may be floor-mounted or ceiling-hung and there will be one or more large monitors, a variety of screens and the medical gas terminal units all ceiling-hung on articulated pendants. The number of pendants and their supporting steelwork can reduce the space available to install

ventilation ductwork and compromise the location of the supply air terminals. Liaison with the architects at an early stage in the project design is essential to ensure a satisfactory ventilation solution.

- 8.121 Hybrid theatres tend to be significantly larger than conventional theatres and may have a radiation protected control room and an equipment room to house the servers for the scanning equipment and its robotic arm in addition to the standard operating suite of rooms. The ventilation load will therefore be larger and standard solutions should be adapted to suit or the designer will need to return to first principles (see Appendix 8).
- 8.122 Because of the increased airflow requirement, the AHU will be larger than for a standard conventional operating suite.
- 8.123 In all other respects the ventilation design and theatre control panel will be as for a conventional operating suite as above.

### Neutral pressure theatres for infectious patients

- 8.124 The client may have a requirement for an operating suite for surgery on infectious patients. This may be a dedicated neutral-pressure operating suite or a standard operating suite that is designed to be easily convertible to a neutral-pressure suite. If airborne microorganisms liberated from a patient during a surgical procedure are allowed to cascade out into the adjacent corridors, they could infect other patients or the staff in the operating department.
- 8.125 The room provision and layout will be as for a conventional operating suite with the following variation to the ventilation scheme:
- the operating theatre will have a balanced supply and extract so that it is at the same pressure as the corridor;
  - air should not cascade from the theatre to the surrounding rooms, so pressure stabilisers and/or transfer grilles should not be fitted. In the case of a convertible operating suite, permanently fitted hinge-down blanking plates with clamps should;
  - be provided to close the pressure stabiliser/transfer grille openings when required;
  - the preparation room may be dispensed with to avoid having stock that could become pre-contaminated. Sterile packs, instruments and consumables would be delivered to the theatre on a case by case basis. If a preparation room is required, it should be maintained at 10 Pa to both the theatre and corridor;
  - the anaesthetic room should have a supply in excess of extract so that is maintained at 10 Pa above both the corridor and the theatre. There should be a pressure stabiliser between the anaesthetic room and the corridor but no transfer device between the anaesthetic room and the theatre;
  - the scrub should have an active extract as for a conventional operating suite but no pressure stabiliser between it and the corridor;
  - the utility should be at negative pressure of not less than  $-5$  Pa to the theatre and its corridor;

- the corridor extract will be sized to cater for the air leakage from the preparation and anaesthetic rooms.

Overall, the ventilation scheme should ensure that all air supplied to the operating theatre is removed in the theatre. The theatre should be neutral (at the same pressure) to the corridor so that when the theatre exit door is open there is effectively no interchange of air between them. When the preparation or anaesthetic doors are opened, air flows from them into the theatre and not the other way.

- 8.126 The theatre control panel, automatic control strategy and air handling unit will be as for a conventional operating suite.

### Interventional imaging suites

- 8.127 Interventional imaging refers to rooms in which surgical interventions are carried out guided by imaging equipment. The risk of infection by the airborne route is low as the surgical site is small, and sterile instruments tend to be unwrapped immediately before use. Anaesthetic gas or agents are used for pain relief or sedation. Patients requiring full anaesthesia will normally be treated in a hybrid or conventional operating suite. The VSG should advise on the likely scope of use.
- 8.128 An interventional image suite may simply be a room containing the imaging equipment, an adjoining radiation protected control room or bay for staff and an equipment room for the imaging server. Support rooms for patient changing, sit recovery, toilets and a utility may also be needed.
- 8.129 Ventilation of the imaging room would be 10 ac/h with the room at a positive pressure to the corridor. Ceiling-mounted steelwork to support the imaging equipment may reduce the space available to install ventilation ductwork and compromise the supply terminal locations. This may mean that sidewall linear terminals are the only viable option. If fitted, their discharge velocity should not cause draughts and the direction vanes should be fixed or capable of being locked to prevent alteration during routine cleaning. Alternatively, a displacement ventilation scheme may be considered.
- 8.130 A full "theatre style" control panel is not required, but a green light to show the ventilation is operational and a red one to show it is not should be provided.
- 8.131 Radiation shielding and warning notices may be required to ductwork where it penetrates ceilings, walls or floors to plantrooms or adjacent spaces to which staff may need access.

## Other application-specific design guidance

### Application: Bronchoscopy, Endoscopy, Dental and General treatment facilities

Table 2: Treatment and procedure facilities

Area/zone	Reason for ventilation	Typical design factors
Bronchoscopy procedure room	Control of exposure of staff to airborne pathogenic material discharged by the patient e.g. multi-drug-resistant tuberculosis (MDR-TB) during the procedure being undertaken. (COSHH Regs) Control of exposure of staff to waste anaesthetic agents when used. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level at foot end of patient's chair/couch and extract terminal at patient's head level behind the chair/couch. Design parameters Air change: 15 per hour Pressure regime: Where patient membranes are breached and the procedure would present an infection risk to the patient, the pressure should be +10 Pa to the corridor. In Bronchoscopy and all other Endoscopy procedure rooms –5 Pa to corridor shall be established. (NOTE The decision as to the preferred pressure regime for each room must be made at design stage. They must not be designed and set up as switchable pressure rooms) Noise level: 40 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via BMS Humidity: Floating; max 70%RH Air quality: BS EN 16798 - SUP2 Extract discharge – Discharge in safe position away from people or open windows. If no suitable position available treat the discharge in the same way as a LEV with a discharge stack at a minimum of 3 m above the roof line.
Endoscopic procedure room	As above and odour control	
Dental treatment room	Control of exposure of staff to airborne pathogenic material discharged by the patient during the procedure being undertaken. (COSHH Regs) Control of exposure of staff to waste anaesthetic agents when used. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level and extract terminal at low level near patient's chair/couch. Design parameters Air change: 10 per hour Pressure regime: Neutral to corridor Noise level: 40 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via BMS
Emergency department resuscitation room	As above	Humidity: Floating; max 70%RH Air quality: BS EN 16798 - SUP2
General treatment room	Comfort conditions only	

All of the above rooms are suitable for aerosol-generating procedures (AGPs)

### Applications: Level 2 and 3 critical care areas, bone marrow transplant (BMT), oncology, organ and tissue transplant units

Table 3: Airborne protective facilities

Area/zone	Reason for ventilation	Typical design factors
Note: Level 2 & 3 Critical care areas should be treated identically in terms of service provision as their only difference is the staff- to-patient ratio.		
Level 2 or 3 critical care individual room	Protection of patients from airborne organisms and fungal spores	Supply only in patient's room and cascade air out via door undercut, transfer grille or pressure stabiliser through rooms of a lower classification. Design parameters Air change: $\geq 10$ per hour Pressure regime: +10 Pa to general area Noise level: 35 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via BMS Humidity: Floating; max 60%RH Final filter: BS EN 1822 – EPA10
Level 2 or 3 critical care open bays	As above	
Bone Marrow Transplant (BMT) unit	Protection of patients from airborne organisms and fungal spores Note: Patient(s) will have a very poor immune system (neutropenia) so will be particularly vulnerable to infection by the airborne route.	Supply only in room and cascade air out via door undercut, transfer grilles or pressure stabilisers through rooms of a lower classification. Design parameters Air change: $\geq 10$ per hour Pressure regime: +15 Pa to corridor Noise level: 35 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via BMS Humidity: Floating; max 60%RH Final filter: BS EN 1822 – EPA12
Haematology/Oncology ward	As for BMT	
Organ and Tissue Transplant unit	As for BMT	

### Applications: Isolation rooms category 2 & 3, Infectious disease units, Containment level 3 rooms

Table 4: Airborne isolation facilities

Area/zone	Reason for ventilation	Typical design factors
Category 2 isolation room	Protection of staff and all other building occupants from airborne organisms dispersed by a patient with an infectious disease. See Scottish Health Planning Note 4 Supplement 1	Extract only in patient's room and ensuite. Supply air from corridor passing into room via door undercut, transfer grille or pressure stabiliser. Alternatively the patient's room may have a supply and extract provided they are interlocked to ensure that the room is always at -ve pressure with regard to the corridor. Design parameters: Air change: $\geq 10$ per hour Pressure regime: -5 Pa to general area Noise level: 35 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via BMS Humidity: Floating; max 60%RH Air quality: BS EN 16798 – SUP2
Category 3 isolation room		

Area/zone	Reason for ventilation	Typical design factors
Positive pressure ventilated lobby (PPVL) isolation room Universal isolation facility	Protection of building occupants from patients who may be infected and protection of patients who may be immunocompromised and protection for patients with both conditions. See Scottish Health Planning Note 4 Supplement 1	Supply in lobby flowing through a pressure stabiliser to patient's room and on via a door undercut or transfer grille to an extract in the en-suite. Design parameters: Bedroom air change: $\geq 10$ per hour Lobby pressure: +10 Pa to corridor Bedroom pressure: Neutral En-suite pressure: -ve Comfort parameters as above Air quality: BS EN 16798 – SUP2 With facility to fit BS EN 1822 – EPA12
Containment level 3 laboratory	Protection of occupants in adjoining spaces from airborne bio-hazards	For design details see the Medical Research Council's "Standards for containment level 3 facilities"
Category 4 facility	Design advice will be provided by the client	

**Application: Obstetrics theatre, delivery rooms, nursery, neonatal intensive care and special care baby units**

Table 5: Maternity facilities

Area/zone	Reason for ventilation	Typical design factors
Obstetrics theatre	Protection of patients from airborne organisms and fungal spores. Control of exposure of staff to waste anaesthetic agents (COSHH Regs)	Ventilation design parameters as for a conventional operating suite. System should normally be at "set back" with a minimum temperature of 18°C and be able to attain full operating conditions within 5 minutes of triggering the system
Delivery room	Control of exposure of staff to waste anaesthetic agents. (COSHH Regs)	Establish a clean airflow path – Supply terminal at high level at foot end of bed and extract terminal at low level at head end of bed. Design parameters: Air change: 15 per hour Pressure regime: Neutral to corridor Noise level: 35 d(B)A Temp range: 20 to 25°C must maintain any selected set point in the range via local control Humidity: Floating – max 70%RH Air quality: BS EN 16798 – SUP2
Delivery room with birthing pool	As for standard delivery room above	
Specials delivery room	As for standard delivery room above	
Nursery	Comfort conditions only	
Neonatal intensive care unit or special baby care unit (SCBU)	Protection of neonates from airborne organisms and fungal spores. Neonates are kept in incubators but may be removed for feeding, changing etc. so local temperature control and ensuring a draught-free environment is essential.	Standard supply and extract Design parameters: Air change: 10 per hour Pressure regime: +5 Pa to corridor Noise level: 45 d(B)A Temp range: 20 to 28°C must maintain any selected set point in the range via local control Humidity: Floating – max 70%RH Air quality: BS EN 16798 – SUP1 (Filter grade depends on ODA category – see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02)
N.B. This is a critical healthcare facility and consideration should be given to system resilience and/or how suitable alternative accommodation may be provided in the event of a ventilation system failure.		

### Applications: pharmacy aseptic suite, gene therapy, radiopharmacy, support rooms

Table 6: Pharmacy facilities

Area/zone	Reason for ventilation	Typical design factors
Aseptic suite Cleanroom	<p>Protection of product during and after processing.</p> <p>Protection of the wider environment from cytotoxic agents and antibiotics.</p> <p>EUGGMP standards (European Commission, 2011) apply and the Medicine Act if the facility is licensed.</p> <p>Control of exposure by the airborne route to staff of substances during and after processing products. (COSHH Regs).</p> <p>Note: While this application is a critical facility, it is usual to have a plan in place to decant to another site in the event of a ventilation system failure</p>	<p>Supply only in cleanroom and cascade air out via pressure stabilisers through rooms of a lower classification or where there are multiple cleanrooms, a balanced supply and stable cascade out. Thimble extract may be provided for class 3 safety cabinets depending on the location of room within the building.</p> <p>Note: Advice from the client's lead pharmacist should be sought prior to engaging in detailed design.</p> <p>Design parameters:</p> <p>Air change: <math>\geq 20</math> per hour</p> <p>Pressure regime: +15 Pa between unclassified rooms and +10 Pa between classified rooms</p> <p>Noise level: 45 d(B)A</p> <p>Temp range: 20–24°C must maintain any selected set point in the range via BMS</p> <p>Humidity: Floating – max 60%RH</p> <p>Final filter: BS EN 1822 – HEPA14</p>
Gene therapy cleanroom	As above, plus protection of the wider environment from product	As per cleanroom above plus negative-pressure access lobby and controlled exhaust
Radiopharmacy cleanroom	As for standard cleanroom with additional requirements of the Ionising Radiation (Medical Exposure) Regulations	As per cleanroom above
Non-sterile stores and support rooms	Comfort conditions only	

### Application: decontamination facilities

Table 7: Decontamination unit

Facility	Applicable Standards
Central Decontamination Unit	<p>These are highly regulated production facilities dictated by:-</p> <p>Planning note - Scottish Health Planning Note 13 Part 1: 2010</p> <p>Decontamination Facilities: Central Decontamination Unit. HFS, 2011</p> <p>Mandated by compliance document - Requirements for Compliant Central Decontamination Units Version 2 – GUID 5014, HFS 2019</p> <p>Equipment manufacturer's design and installation instructions</p>
Local Decontamination Unit	<p>These are highly regulated production facilities dictated by:-</p> <p>Planning note - Scottish Health Planning Note 13 Part 2</p> <p>Decontamination Facilities:</p> <p>Local Decontamination Units, HFS 2008</p> <p>Mandated by two compliance documents - Compliant Dental Local Decontamination Units in Scotland Version 2 – GUID 5005, HFS 2019</p> <p>and Provision of Compliant Podiatry Instruments – GUID 5007 Version 3.0, HFS 2020.</p> <p>Equipment manufacturer's design and installation instructions</p>

Facility	Applicable Standards
Endoscope Decontamination Unit	<p>These are highly regulated production facilities dictated by:-</p> <p>Planning note - Scottish Health Planning Note 13. Part 3 – Decontamination Facilities: Endoscope Decontamination Units, HFS 2010</p> <p>Mandated by compliance document - Requirements for Compliant Endoscope Decontamination Units, v2 – GUID 5013 HFS 2014</p> <p>Equipment manufacturer's design and installation instructions</p>

### Hydrotherapy: general requirements

- 8.132 In a hydrotherapy suite, heat recovery should be via a heat pump.
- 8.133 In general, the quantity of supply air should be calculated as 25 L/s/m<sup>2</sup> wetted surface, with the wetted surface taken as 110% of the pool water surface area. (See the Swimming Pool and Allied Trades Association (SPATA) for detailed guidance.)
- 8.134 A recirculation plant is recommended, with fresh air make-up to the standard required by the Building Regulations Part F – Non-domestic Buildings. In practice this may need to be increased to control condensation.
- 8.135 As far as practicable, recirculated pool air should be provided to the ancillary changing and recovery accommodation, with the only extract from the toilets, laundry/utility room and pool hall.
- 8.136 Supply air to the pool hall should be introduced at high level and directed towards the perimeter to mitigate condensation, with extract air taken from directly over the pool.
- 8.137 The ceiling void above the pool may need to be ventilated to prevent condensation.

### Control of hydrotherapy pool installations

- 8.138 The supply and extract fans should be interlocked so that the supply fan does not operate until flow is established within the extract system.
- 8.139 Time-clock control should be provided, with a local override switch to extend the normal operating period as required.
- 8.140 Night set-back temperature (in the range of 21–25°C) and high humidity control (in the range of 60–75% sat) should be provided to override the time clock in order to prevent condensation. The exact set points should be ascertained post- installation.
- 8.141 A remote indication panel should be provided in the pool hall, giving a visual display of the pool water and pool air temperature.

### Extract systems

#### LEV systems

- 8.142 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as local exhaust ventilation (LEV) systems under the COSHH

Regulations. Note that the supply or make-up air to a room containing an LEV system may itself be considered to be a part of the LEV system.

- 8.143 An LEV system may comprise a self-contained unit incorporating its own carbon filter such as a simple bench-top fume cupboard. Alternatively, it may be a complete "ventilation system" comprising a make-up air supply, multiple exhaust protected workstations, branch and central extract ductwork, duplex extract fans and a high-level discharge terminal. It may also incorporate a special filtration system appropriate to the hazardous substance being controlled. Such systems could be required for workshops containing woodworking machinery or large centralised pathology laboratories housing multiple safety cabinets, cut-up benches, fume cupboards and specimen stores.
- 8.144 It is important to recognise at the design stage whether an extract is being provided for comfort, to remove odours or as an LEV system. Typical LEV systems in healthcare include:
- microbiological safety cabinets and containment level 3 rooms;
  - fume cupboards;
  - welding fume extracts;
  - woodworking-machinery duct collectors;
  - lead-acid battery charging-bay extracts;
  - powered plaster and bone saws;
  - pharmaceutical preparation cabinets and tablet machines;
  - dissection benches, cut-up tables and some specimen stores;
  - medium- and high-risk infectious diseases isolation facilities;
  - dental furnaces, grinders and polishers.

**Note:** Post-mortem tables may incorporate downflow peripheral ventilation but unless otherwise specified by the equipment supplier, their ventilation is only provided to control odours.

- 8.145 Information on the design of ductwork, fan and discharge stack arrangements will be applicable to all types of LEV system and is given in Chapter 9.
- 8.146 LEV systems are statutory items that will be subject to an independent examination and test at least every 14 months by a competent person holding an in-date P601 certificate.

**Note:** For AGSS, see Scottish Health Technical Memorandum 02-01.

### Bench extract systems

- 8.147 Bench extract ventilation is required in departments such as pathology and mortuary, where activities involve the release of malodorous or toxic fumes which should not be inhaled. They may also be required in central decontamination units and wash-rooms within endoscope reprocessing units to remove airborne biological material liberated when the used items are given a preliminary clean.

- 8.148 In all cases bench extract systems that create an airflow from the front to the rear are preferred over those that rely on a downflow of air through a perforated surface, as the airflow is easily obstructed when in use.

#### **Typical arrangements**

- 8.149 Each ventilated position will usually be accommodated in a continuous run of benching, which should not be more than 650 mm from front to rear and which should be provided with a continuous upstand at the rear. Each position should have a 1200 mm × 150 mm linear extract grille mounted on a purpose-designed plenum box (incorporating guide vanes as necessary), with its face flush with the upstand. The bottom of the grille should be as close as practicable to the level of the working surface (usually 75 mm above, to allow for cleaning). The minimum velocity across any part of the grille should be 1 m/s. The grille should be readily demountable to allow for cleaning.

#### **Control of bench extract systems**

- 8.150 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the bench extract and any associated supply may be shut down. However, a run-on timer with a minimum setting of 30 minutes should be provided. To this end, local control should be provided.
- 8.151 Processes that produce hazardous vapours, fumes, dusts or noxious vapours should be enclosed or semi-enclosed in a suitable cabinet or exhaust-protected workstation (LEV).

#### **Microbiological safety cabinets and fume cupboards**

- 8.152 Safety cabinets and fume cupboards are devices that have an inflow of air to control exposure of staff to hazardous substances. The units and their exhaust systems, filters, fans and discharge terminals are all classified as LEV systems under the COSHH Regulations. The make-up air system to a room that contains an LEV system may also be considered as an essential part of the system and be included in the LEV classification.

#### **Special requirements**

- 8.153 The supply air system should not distort the unidirectional and stable air pattern required for fume cupboards and microbiological safety cabinets. In general, supply air ceiling diffusers should not discharge directly towards fume cupboards or safety cabinets, unless the terminal velocity is such that the airflow pattern at the front of the cabinet is unaffected. The design should ensure that high air-change rates, and/or the opening and closing of doors, do not have any adverse effect on the performance of safety cabinets or fume cupboards. A damped door closure mechanism may help.

#### **Arrangements for safety cabinet installations**

- 8.154 The manufacture and installation of microbiological safety cabinets will be in accordance with the relevant national standards and guidance issued by the Advisory Committee on Dangerous Pathogens (ACDP).
- 8.155 A Class 1 microbiological safety cabinet will be specified for routine work involving Group 3 pathogens. It should be housed in a containment level 3 room. Specific

design information on containment rooms is issued by ACDP in conjunction with the Health and Safety Commission.

8.156 Siting and installation of microbiological safety cabinets are of particular importance because:

- the protection afforded to the operator by the cabinet depends on a specific and stable unidirectional airflow through the open front;
- the protection to the environment by the cabinet depends on the high-efficiency particulate air (HEPA) filters. The exhaust air should never be considered as totally free from microbiological hazard.

8.157 Microbiological safety cabinet extract is HEPA filtered prior to being discharged to outside. Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2 m); such an installation, however, is likely to be noisy and is not recommended for use in new buildings.

8.158 Ductwork and discharge arrangements should be as set out in Chapter 9.

8.159 Discharge should be to outside but where this is impracticable, discharge into the room via a double HEPA filter will be accepted if approved in writing by the VSG.

#### **Arrangements for fume cupboard installations**

8.160 The manufacture and installation of fume cupboards will be in accordance with the relevant national standards and associated guidance.

8.161 The primary factors which contribute to the effective performance of fume cupboards include:

- an adequate volume of supply air and its means of introduction;
- an effective exhaust system to promote the safe dispersal of waste products to atmosphere.

8.162 The air velocities through sash openings should be enough to prevent hazardous materials from entering the laboratory while avoiding excess flow rates that interfere with the investigation process. Average face velocities should be between 0.5 and 1 m/s, with a minimum at any point within 20% of the average, the upper end of the range being applicable to the containment of materials of high toxicity. The design velocity should be maintained irrespective of whether the sash opening is varied, or whether doors or windows are open or closed (see BS EN 14175).

8.163 The possibility of a fire or explosion which may not be contained by a fume cupboard should always be considered. A fume cupboard should not, therefore, be sited in a position where exit to an escape route will necessitate passing directly in front of it.

#### **Control of extract systems**

8.164 It is desirable to provide local control of safety cabinets in order to maximise the life of the HEPA filter, and to permit the sealing of the cabinet and room for fumigation if spillage occurs.

- 8.165 To cope with the risk of an accident or spillage outside safety cabinets, a panic button should be provided to switch off the supply to that area and to discharge all extracted air to atmosphere.
- 8.166 In pathology departments, it will always be necessary to have one or more microbiological safety cabinets and one or more fume cupboards available for use, including weekends; therefore, local overriding controls for all these items and any associated ventilation plant will be necessary.

### **Hood extract systems**

#### **Special requirements**

- 8.167 Extract canopies will be required over steam-and-heat-emitting appliances, for example sterilisers, catering and washing equipment and for the extraction and removal of unpleasant odours. These installations are for the control of non-hazardous airborne contaminants, they are not LEV systems.
- 8.168 Perimeter drain gulleys and corrosion-proof grease eliminators should be provided on kitchen hoods (see BESA DW 172 – ‘Specification for kitchen ventilation’).

#### **Typical arrangements**

- 8.169 The airflow rate should be enough to ensure an adequate capture velocity in the vicinity of the process. Advice from equipment suppliers should be sought, as excessive velocities will be wasteful of power and generate noise.
- 8.170 The lowest edge of the canopy should be 2 m above finished floor level, with a minimum of 300 mm overhang beyond the edge of the equipment on all sides.
- 8.171 A compact arrangement of equipment (but with access for maintenance) will minimise the canopy area, and hence reduce the air volume necessary to achieve the optimum capture velocity.
- 8.172 Hoods required for the control of heat gain and vapours may be connected to the general extract system when it is convenient to do so, but where non-corrosive ductwork materials are necessary, a separate extract system is preferred.
- 8.173 Lighting and internal divider plates are often required to be built into the perimeter of large canopies; however, built-in shelving systems are not recommended, as they interfere with the airflow, and constitute a maintenance problem.

#### **Control of hood extracts**

- 8.174 Provided that it does not interfere with the operation of the department when not in use, the ventilation system for the hood extract and any associated supply may be shut down. To this end, local control should be provided.

### **Plantroom ventilation**

#### **General requirements**

- 8.175 Plantrooms are required to be ventilated in order to maintain acceptable temperatures for satisfactory operation of the plant and controls, and for maintenance activities. Natural ventilation through louvred openings protected from infestation by a

mesh with openings of no less than 6 mm and no more than 12 mm are required. Powered plantroom ventilation should only be needed if natural ventilation is not adequate.

- 8.176 Ventilation requirements should consider all heat sources within a plantroom, and where there are large glazing areas, solar gains. The ventilation rate should limit the maximum temperature within the plantroom to 32°C.
- 8.177 Air handling equipment cannot be located in a fire compartment that houses combustion equipment.
- 8.178 AHUs and other ventilation equipment that serve occupied areas cannot draw their intake air from a plantroom. Neither should extract ventilation plant or medical vacuum pumps discharge air into a plantroom.
- 8.179 Statutory regulations for plantroom ventilation are contained in the Building Regulations, and further guidance in the CIBSE Guide B2. Note the need to assess the risk of services to AHUs freezing in unheated plantrooms.

## 9. Equipment Selection Factors

---

### General requirements

- 9.1 The following gives detailed guidance on the design and selection of ventilation equipment, the distribution system, terminals and control aspects. Designers should take note of the supporting information given in Chapters 10 and 12. Failure at the design stage to make due allowance for the standards to be achieved may mean that the installed ventilation system will not be acceptable to the client's validator at handover.

### Location and access

- 9.2 The plant should be located so that it is remote from possible sources of contamination, heat gains and adverse weather conditions. The design should ensure that wind speed and direction have a minimal effect on plant throughput.
- 9.3 Safe access to and around plant is essential to facilitate inspection, routine maintenance, repair and plant replacement.
- 9.4 Air-handling units (AHUs) should be located in an accessible area secured from unauthorised entry. They may be grouped together in dedicated plantrooms or distributed around the building with AHUs located adjacent to or within the area that they serve. In the healthcare setting, because of the difficulty in gaining access for routine service and maintenance, mounting ventilation units of any type in ceiling voids above clinical spaces is not permitted.

**Note:** If it is proposed to install ventilation units of any type in a ceiling void above a non-clinical area, it should be subject to a formal risk assessment and its use being agreed by the ventilation safety group (VSG) prior to design approval. Their assessment will consider how the unit may be safely accessed and maintained.

- 9.5 AHUs should be located in purpose-built plantrooms or designated service spaces within a building. This will allow for routine service and maintenance (which is a statutory requirement) to be carried out at any time of day and regardless of weather conditions. It will also protect the plant from contamination by bird droppings, so reducing the risk of fungal spore contamination of the air supplied by the AHU. Control of pests and vermin will be simpler and while not in themselves a source of airborne contamination, their corpses can become a reservoir of biological material that may lead to insect infestations within the AHU.

**Note:** In a new building it is not envisaged that there will be any need to locate AHUs outside. The design of the building should incorporate central or distributed plant spaces of sufficient size to accommodate the plant required to service the building.

- 9.6 When refurbishing or changing the use of an existing building, plant space should be created to house the ventilation plant and other services. If located on a roof they should be enclosed in a plantroom with a safe means of access. If located at ground level they should be secured within a plantroom to prevent unauthorised access. Measures should be taken to exclude vehicles from the vicinity to ensure that exhaust fumes will not be drawn into intakes. Intakes for ground level AHUs should

be extended to a height and distance from contamination sources that allows them to draw in unvitiated air.

- 9.7 In the unlikely event that an internal or external plant room cannot be provided, and ventilation units have to be located outside, they should be fully weatherproof to IP65 and secured from unauthorised access. Protection against the elements should also be provided for personnel carrying out routine inspection and maintenance activities. As an example, when two units are outside, and they are installed with their access doors facing each other, if the gap between them is roofed over and the open ends capped, the AHUs themselves create what is in effect a plant room (see photographs).
- 9.8 Water will be used during routine cleaning or spilt when maintenance is being undertaken. The area around plant should be tanked to prevent water penetration to adjacent areas and adequately drained

Figure 5 AHU formed plant room (external)

Figure 6 AHU plant room (internal)

**Note:** Plant rooms should be provided with a sink so that glass drainage traps may be cleaned out and staff can wash their hands after handling contaminated/dirty filters. A source of domestic hot water (DHW) with a valved hose connection point will also be required so that AHUs can be washed out internally as part of their routine maintenance. Plant rooms at roof level should be served by a lift.

- 9.9 Fire precautions should be incorporated in accordance with the Health Technical Memorandum 05 Firecode series. Guidance is available in Chapter 1 of this document.

- 9.10 Combustion equipment cannot be located in a fire compartment that houses air handling equipment

### Standard requirements

#### Identification and labelling

- 9.11 All ventilation systems should be clearly identified with a permanent (traffolyte type preferred) label in accordance with the requirements of Chapter 13. The label should identify both the AHU and the area that it serves. The lettering should be at least 100 mm high and be screwed or riveted onto the AHU in an easily visible place near the fan of the unit, adjacent to the local electrical isolator. Any subsystems and the principal branch ducts should be similarly labelled.

**Note:** The AHU identification code should conform to the plant identification system in use at the premises (see Chapter 13).

- 9.12 The nature of air and direction of flow should be clearly marked on all ducts using the symbols given in BS 1710.
- 9.13 All airflow test-points should be clearly identified with a permanent label and the design information given (for example, TPS 1 – Anaesthetic supply; 400 × 300; Design 185 L/s).

#### Plant minimum standards

- 9.14 Plant should comply with the minimum standards set out in Table 8.
- 9.15 External finish to be corrosion resistant and may be available in a variety of colours at no additional cost. This can aid identification by colour-coding of units in a plantroom (for example, green for general ventilation; blue for theatres; red for laboratories and isolation facilities; grey for extract).
- 9.16 Organic materials or substances that can support the growth of microorganisms cannot be used in the construction of the plant or its distribution system. The water fittings and materials directory list suitable materials for sealants and gaskets (see also BS 6920).
- 9.17 AHU internal wiring should comply with BS 7671 and be installed in a cable containment system providing suitable mechanical protection. The wiring and its containment system should not allow air bypass at the filters. The wiring, its containment system, connection boxes and fixings should permit the effective internal cleaning and inspection of the AHU.
- 9.18 Plastic-bladed dampers and plastic plate heat exchangers should not be fitted. This accords with the national policy to reduce the use of plastics.
- 9.19 Motorised spring-return low-leakage (BS EN 1751 class 3) isolation dampers should be located at the intake, supply, return air and discharge duct connections of an AHU and associated extract unit. They should be of the opposed-blade type and be fitted with end switches. They should close automatically in the event of power failure or plant shutdown to prevent any reversal of the system airflow. They will also function to isolate the plant from the distribution system when undertaking cleaning or maintenance.

**Note:** Internal plant dampers or provision for the fitting of shut-off plates, also known as dagger plates, between elements within an AHU are not required.

- 9.20 Access to elements that require routine service such as filters, fans and all types of heat-transfer device should be via hinged doors. In horizontal units the doors should be wide enough: 500 mm minimum at a unit height >1 m. For smaller units the doors need to be at least 600 mm wide, to allow easy access. Items requiring infrequent access such as attenuators may be via removable panels fitted with lifting handles, or access hatches. All doors and panels should be secured from casual access, close-fitting and without leaks.

**Table 8: Plant minimum standards**

AHU Element	Minimum Standard	Notes
Construction	Double metal or composite skin with sandwiched insulation to "Euroclass A" fire rating Smooth internal surface without channels or ridges No projecting spire or tech screws inside the unit.	Note: Capping projecting spire screws is not acceptable.
Internal surface finish	Non-corrodible, washable and smooth and of a colour that allows accumulations of dirt to be easily seen	Stainless steel or white powder coated mild steel or with an equivalent protective treatment; but NOT surface galvanised
Thermal transmittance	BS EN 1886 Class T2	Manufacturer's declaration
Thermal bridge	BS EN 1886 Class TB2	Manufacturer's declaration
Deflection	BS EN 1886 Class D2	Manufacturer's factory test
Factory airtightness test – pre-delivery	BS EN 1886 Class L2	Test at +700 Pa and –400 Pa
Site airtightness test	BS EN 1886 Class L2	+700/–400 Pa
Filter frame bypass leakage	BS EN 1886 Section 7	
Supply and extract intake and discharge isolation dampers	BS EN 1751 C3 (low loss)	Motorised opening and fitted with an end switch and spring return
Access doors	Secured from casual access. Fan chamber doors to be fitted with a two-stage latch	Key or similar device required to open access doors Door hinges should be adjustable to so that leakage can be eliminated on site
Specific fan power -Internal (SFPint)	Current Eco design requirement for energy-related products (ErP)	EU 1253 – 2014
Specific fan power - System (SFPsyst)	UK Building Regs	Part L2
Energy recovery	Current ErP EU 1253	Run-around coil – 68% Heat pipes – 73% Plate heat exchanger – 73% Thermal wheel – 73% Heat pump – EU 2281/201 Any other device – see standard

- 9.21 All access doors should be fitted with seals and have adjustable hinges so that leakage can be eliminated once the unit is installed on site. Access doors to fan chambers should have a two-stage opening sequence to prevent the door blowing violently open if it is unlatched while there is still residual pressure in the unit.

**Note:** Providing the AHU is located in a plantroom or area secured from unauthorised entry, its access doors can only be opened with a key or similar device, the fan door is fitted with a viewing port and a two-stage opening latch and there is a fan electrical isolation switch adjacent to the fan-chamber access door, there is no requirement to fit an internal fan chamber mesh guard.

- 9.22 In the healthcare setting it can be difficult to turn off AHUs in order to inspect filters and drainage trays. Viewing ports and internal illumination will therefore facilitate routine inspection of such items. Viewing ports should be at a convenient height so that temporary ladders are not required. In double-stacked units the viewing ports in the upper section will be located in the lower portion of their access doors. Internal illumination should be provided by fittings to at least IP55 rating. Light fittings should be positioned inside the unit (not on the access doors) so that they provide illumination for both inspection and task lighting. All lights in a unit should be operated by a single switch and be powered independently of the AHU main switch. LED lights are preferred.
- 9.23 Access to air intakes and discharges, AHUs and items in the distribution system such as filters or auxiliary trimmer batteries located in a plantroom or plant area above 1.5m should be via platforms, fixed ladders, hook ladders, pulpit style movable steps or access platforms. The method of access chosen should reflect the frequency and nature of the maintenance requirement. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow access equipment to be moved into position.

#### **Chiller units: heat rejection devices**

- 9.24 The design conditions given in Chapter 8 make no allowance for the elevated temperatures that can occur on the roof of buildings. Refrigeration condensers and chiller units should, if practicable, be shaded from direct solar radiation, or the design adjusted to take account of the gain. Care should be taken to ensure that there is sufficient clearance around the plant to allow effective air movement. Allowance may also be needed for the effect of walls, obstruction or other equipment in the area and for the prevailing wind direction.
- 9.25 Air-cooled condensers and/or dry coolers will always be the first choice for heat rejection from any refrigeration plant. The use of heat pump systems is also an option. Wet evaporative cooling systems cannot be used in healthcare premises unless limitations of space mean that they are the only way that the cooling load can be met. If they are used, national guidance on preventing and controlling Legionella should be closely followed (see the Health and Safety Executive's (HSE) Approved Code of Practice and guidance document HSG274 'Legionnaires' disease: the control of Legionella bacteria in water systems').
- 9.26 Traditional refrigerants are being phased down and some of their replacements at the time of writing have a degree of flammability. The level of risk this poses should be formally addressed at the design stage and agreed with the client or their fire safety representative. The selection of a refrigerant should be made with reference to the F-Gas Regulations and should take account of the life expectancy of the plant versus the future availability and increasing cost of the refrigerant. Ultimately, choosing refrigerants with the lowest global warming potential is the ideal and will ensure that

greenhouse gas emissions are minimised. Refrigerant gas monitoring must be included where required under BS EN 378.

#### Chiller selection: size and resilience

- 9.27 There is a tendency to meet the calculated maximum chiller load by specifying multiples of a standard size of chiller (for example, the calculated load to be met by three chillers each capable of 33% and an extra chiller of the same size to achieve the N+1 resilience requirement). This approach does not lend itself to efficient operation. It is preferable to split the load with, for example, two chillers capable of 40% each and two capable of 25% each. This will give an overall minimum capacity of 90% resilience at maximum summer design conditions and allow for the actual part load demand to be met in the most energy-efficient way.

### Supply AHUs and associated extract units

#### Typical sequence of components

- 9.28 The AHU should be arranged so that most of the items are under positive pressure. Cooling coils and humidifiers will require a drain and should be on the positive pressure side of the fan. The following arrangement of components is typical, although in many instances not all elements will be required:

- fresh air intake;
- motorised isolation damper;
- fog coil if energy recovery fitted or frost coil if no energy recovery fitted;
- pre-filter;
- energy-recovery device (possible location);
- attenuator1;
- supply fan;
- attenuator1;
- energy-recovery device (possible location);
- cooling coil;
- eliminator (for face velocities above 2 m/s);
- heater-battery;
- humidifier (if required);
- final filter;
- motorised isolation damper.

- 9.29 AHUs may be configured as horizontal, linear single or double-stacked; or as cabinet type units. For double-stacked supply/extract units, the fans should be located on the bottom deck where possible as it will make them simpler and safer to change (see Figures A1–A3 in Appendix 1 for possible arrangement.).

### Intakes and discharges

- 9.30 Air intakes and discharge points should preferably be located at high level, to minimise the risks of noise nuisance to surrounding buildings, contamination and vandalism.
- 9.31 Intakes and discharges should be designed and located so that wind speed and direction have a minimal effect on the plant throughput.
- 9.32 Helicopter landing pads in the vicinity of ventilation intakes and discharges can result in large short-term pressure changes. This can cause pressure surges in supply systems and reverse airflows in extracts. Exhaust fumes from the helicopter may also be drawn into intakes.

**Note:** It is not appropriate to "plan to turn the ventilation off when a helicopter lands" as a means of permitting the location of a helipad adjacent to ventilation intakes and discharges.

- 9.33 Intake points should be situated away from cooling towers, heat sources, boiler flues, vents from oil storage tanks, fume cupboards and other sources of contaminated air, vapours and gases and places where vehicle exhaust gases may be drawn in.

**Note:** Attenuators may be located in the intake and discharge duct if they are of a suitable type and provided with cleaning access both sides (see paragraph 9.116).

**Note:** Steps should be taken to prevent birds landing or roosting in the vicinity by removing ledges or fitting anti-pigeon spikes.

- 9.34 On the rare occasions where intakes have necessarily to be sited at or near ground level, the surrounding area should be paved or concreted to prevent soil or vegetation being drawn in. In addition, intakes should not be situated near established gardens/trees so as to avoid intake of environmental microorganisms. They should be caged or located within a compound to restrict unauthorised access and prevent rubbish being left in the vicinity. The likely proximity of vehicle exhausts should also be taken into account when determining the protected area around the intake and additional filtration may be required. The VSG should be consulted about the standard of air quality required. There should be a minimum 4 m clear zone around the intake (see paragraph 9.50 and paragraphs 9.63–9.64).
- 9.35 The discharge from an extract system will be located so that vitiated air cannot be drawn back into the supply air intake or any other fresh air inlet. Ideally, the extract discharge will be located on a different face of the building from the supply intake(s). At all times, there has to be a minimum separation of 4 m between them, with the discharge mounted at a higher level than the intake.

**Note:** Ventilation intakes and discharges cannot face each other across a passageway or courtyard even if they are 4 m or more apart.

- 9.36 Each intake and discharge point should be fitted with a corrosion-resistant weatherproof (BS EN 13030 class B) louvre or cowl to protect the system from

driving rain. Louvres should be sized based on a maximum face velocity of 1.5 m/s in order to prevent excessive noise generation and pressure loss.

**Note:** If there is a bend in the ductwork directly behind a louvre, it will affect the air velocity through the louvre. This may result in moisture carry-over or increased noise.

- 9.37 The inside of the louvres should be fitted with a mesh of not less than 6 mm and not more than 12 mm to prevent infestation by vermin.
- 9.38 The duct behind a louvre should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system.
- 9.39 Cleaning access should be provided either from the outside via hinged louvres or by access doors in the plenum behind the louvre. Where a floor-level common plenum is provided, cleaning access should be via a walk-in door. High-level plenums should be able to be safely accessed by temporary or permanent means

**Note:** Builders' work plenums or intake ducts will need to have a smooth finish and be surface-sealed to prevent dust shedding (see paragraph 10.5).

### Fans

- 9.40 Direct-drive electronically commutated (EC) fans are the preferred choice for ventilation systems. If necessary, resilience and an increased capacity can be achieved by installing two or more EC fans with gravity or motorised dampers to prevent backflow.

**Note:** At the time of writing the concept of a "fan wall" made up of multiple small variable speed fans all controlled as a single unit was under development. This concept has several advantages as the failure of one fan can be accommodated by speeding up the rest. Because the fans cover the full area of the duct, it will result in a more uniform air velocity downstream at the battery face. This will increase the heat transfer efficiency and may allow a reduction in battery size. Nothing in this document will preclude the use of such innovation that improves resilience and reduces energy usage.

- 9.41 For an application outside of the capacity range of EC fans, direct-drive plug fans controlled by an inverter mounted externally to the air stream may be selected.
- 9.42 In either case, the fan motor will be protected with a high-temperature safety cut-out.
- 9.43 Whichever type of fan is selected, if it serves a critical area it will be fitted in a way that allows it to be changed within 20 minutes. Mounting the fan unit on slide rails with plug and socket connections for power and control cables will facilitate this. Whenever possible, both supply and extract fans should be located on the bottom deck of a double-stacked AHU.
- 9.44 Selecting fans from a preferred size range will reduce the number of spares held.
- 9.45 Belt- and pulley-driven fans should not be installed in healthcare ventilation systems.
- 9.46 Supply fans should be positioned to blow through the central plant so that the cooling coil and humidifier drains (when fitted) will be under positive pressure. The energy-

recovery device may be either side of the fan and should have a drainage system on the extracted air discharge side.

- 9.47 In extract systems where the air is potentially contaminated, explosive, aggressive or has a high moisture content, the extract fan motor will be located outside the air stream and be capable of being changed without the need to access or change the fan impeller.

#### Control

- 9.48 Where two or more fans are fitted in a fan wall, the preferred normal operation is all fans running in parallel. In case of a single fan failure the remaining fan(s) should provide at least 80% of the design output.
- 9.49 For most healthcare applications, the fan output should be set to give a constant volume of air. This should be controlled by measuring the pressure drop across the fan suction nozzle using a sensing ring and associated volume controller that will automatically integrate the fan K factor to determine and control the preset output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.

**Note:** Measuring the air pressure in the main supply duct and using that to set the supply fan speed as a percentage of its rated output and using that to set the extract fan speed as a percentage of the supply fan speed is not a satisfactory, accurate or an acceptable way of controlling the desired supply and extract air volumes.

#### Filters

- 9.50 The purpose of filtration is to reduce the level of airborne contamination in an air stream. It is generally carried out in stages
- 9.51 Filters should be securely mounted in well-fitting frames designed so that the airflow pushes the filter into its housing to minimise air bypass. Vertical supports with seals should be provided to master the joints between filters and eliminate bypass. Mounting frames that withdraw so that the filter can be changed without having to reach into the unit are preferred.
- 9.52 Filters need to be readily accessible, so a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.
- 9.53 For AHUs, provided that each filter's pressure drop is monitored by a sensor linked to the BMS, direct reading gauges or manometers will not be required. Capped pressure tappings should be provided so that a portable manometer can be connected for diagnostic purposes when necessary.
- 9.54 General air filters (see Table 9) are divided into four categories, related to the size of particle (in microns ( $\mu\text{m}$ )) that they can remove as a percentage of the load.
- coarse filters – remove less than 50% of 10  $\mu\text{m}$  particles;
  - PM10 medium filters – remove 50 to 95% of 10  $\mu\text{m}$  particles;

**Table 9: General filters: typical healthcare selections**

ISO 16890 Class	Notes and typical healthcare
ISO Coarse 60%	May be used as temporary addition filtration at an air intake when building or demolition works are being undertaken in the vicinity
ISO ePM10 ≥50%	Panel pre-filter or return air filter to protect the energy-recovery device
ISO ePM2.5 ≥50%	Supply air filter for areas with temporary occupancy
ISO ePM1 ≥50%	Supply air filter for areas with permanent occupancy

- PM2.5 medium filters – remove 50 to 95% of 2.5 µm particles;
- PM1 fine filters – remove 50 to 95% of 1 µm particles.

**Note:** Ventilation filters can only remove particles from the incoming air. Most particles that could cause an infection originate from the occupants and activities within the building. In AHUs the pre-filter and return air filter will keep the energy-recovery device, cooling coil and heater-batteries clean and working efficiently. The secondary filter will keep the distribution ductwork and supply air terminals clean.

**Note:** For additional information on filter selection and indoor air quality, see the Specialised Ventilation for Healthcare Society's (2018) SVHSoc.02 – 'Change in air filter test and classification standards'.

9.55 In areas of high atmospheric pollution, a higher standard of filtration may be required in order to meet the indoor air quality standard (IAQ).

9.56 Compact filters are preferred, because bag filters are often incorrectly oriented and prone to damage when changed.

#### **Efficiency and high efficiency particulate air (EPA and HEPA) filters**

9.57 These filters are designed to provide filtration of particles in the sub-micron size range. EPA and HEPA filters self-select the particle that they are least able to trap and are graded against that "most penetrating particle size" (MPPS) (see Table 10):

- efficiency particulate filters (EPA): three grades E10 to E12;
- high efficiency particulate filters (HEPA): two grades H13 to H14;
- ultra-low particulate air filters (ULPA): three grades U15 to U17.

**Table 10: EPA and HEPA filters: typical healthcare selections**

Typical healthcare application	Minimum filter grade to BS EN 1822 - 2019	% Efficiency @ MPPS
UCV theatre terminal	EPA – E10 – (EU10)	85
No standard healthcare application	EPA – E11 – (EU11)	95
Immunosuppressed and neutropenic patient rooms or wards	EPA – E12 – (EU12)	99.5

Typical healthcare application	Minimum filter grade to BS EN 1822 - 2019	% Efficiency @ MPPS
No standard healthcare application	HEPA – H13 – (EU13)	99.95
Pharmacy aseptic preparation facility supply Containment level 3 room extract	HEPA – H14 – (EU14)	99.995
*Incorporates ISO 29463 tests methods.		

**Note:** ULPA filters are designed to remove particles below a size that is either surgically or aerobiologically significant. There would have to be exceptional circumstances in order to justify their use in a healthcare ventilation system.

9.58 EPA and HEPA filters are expensive, so their use should be kept to a minimum. When used they should be of the replaceable panel type with leakproof seals and installed in a manner that permits the validation of the filter and its housing (see Chapter 12).

9.59 In supply systems an EPA or HEPA filter will have a non-shedding metal case.

#### Return air and extract air filters

9.60 Return air filtration will always be required where heat recovery devices are installed. Return air filters are also used to reduce the load on EPA filters in recirculating applications such as ultra clean operating suite ventilation canopies and pharmacy aseptic preparation facilities. They should be the same grade as their AHU pre-filter.

9.61 EPA or HEPA filters are sometimes fitted in extract systems to capture hazardous substances or organisms. Design provision should be made for the subsequent safe handling of contaminated filters by maintenance staff. This may be achieved by:

- sealing the hazardous substance into the filter before it is removed;
- providing a system to fumigate the filter to kill any organisms;
- housing it in a "safe change" unit that permits the filter to be ejected into a bag and sealed without personnel having to come into direct contact with it.

#### Notes:

1 In view of the costs and problems associated with placing EPA or HEPA filters in extracts, it is essential that a full risk assessment be carried out at the design stage. This should include defining the true need for a filtered extract, the validation of its performance at installation, the method of safely changing a contaminated filter, and its subsequent disposal.

2 General extracts from mortuaries and post-mortem rooms may contain odours, but these are not in themselves hazardous to health and do not require filtration prior to discharge. In high-risk post-mortems (for example, known or suspected tuberculosis cases), the infected organs will be removed and then dissected in a class 1 microbiological safety cabinet provided under the COSHH Regulations.

Extracts from infectious disease isolation rooms or wards do not normally require filtration prior to discharge. However, if the discharge cannot be made in a safe location and it is likely that the vitiated air could be drawn back into the building or there are people in its vicinity (for example, a discharge into a courtyard), filtration would be required

- 9.62 Extract EPA or HEPA filters should have a particleboard or plywood case so that they can be incinerated.

#### Activated carbon filters

- 9.63 Activated carbon filters can remove gases and vapours from an air stream and are graded according to the range of substances they can remove. They are not normally fitted in air-conditioning supply systems. They are occasionally fitted retrospectively because an air intake has been poorly sited and is drawing in noxious fumes or the outdoor air quality is exceeding WHO levels for NO<sub>x</sub>/O<sub>3</sub> or SO<sub>x</sub>. Where used they should be protected by or incorporated into a particulate air filter.
- 9.64 Activated carbon filters are more commonly used in specialised fume extraction systems when the location of the discharge means that dilution cannot be relied upon to disperse noxious fumes.

#### Energy-recovery devices

##### General requirements

- 9.65 Energy recovery will be fitted to all supply and extract healthcare ventilation systems. It may be omitted only where permitted by the current ErP Directive EU 1253/2014.
- 9.66 For most systems in healthcare premises, a plate heat exchanger, "run-around coil" system or thermal wheel would be appropriate. Selection should be based on the relative locations of the supply and extract units, ease of maintenance and practicality. Cleaning access will be required to both sides of any energy-recovery device.

**Note:** Plate heat exchangers are the preferred option as they require the least maintenance to retain their energy transfer efficiency. Thermal wheels may be used, as the degree of air transfer from extract to supply is not sufficient to cause aerobiological problems and in any event the air will be filtered before being supplied to the user. Run-around coils are used when the supply and extract units are separate or in case of space problems.

- 9.67 At the time of writing, the following are the minimum energy transfer efficiencies required under EU 1253 for devices handling equal air volumes:
- run-around coil – 68%;
  - plate heat exchanger – 73%;
  - thermal wheel – 73%;
  - heat pipe – 73%;
  - heat pump or any other device – see specific regulations.

**Note:** These efficiencies are regularly reviewed and are likely to be increased periodically.

- 9.68 If a plate heat exchanger is chosen, the plates should be constructed of metal; in coastal areas stainless steel is preferred. Plastic should not be used for the plates, internal bypass dampers or gears. (This is in keeping with the reduction in the use of single use plastics.)
- 9.69 If a thermal wheel is selected, only a sensible heat wheel should be used that incorporates a purge sector. In order to reduce bypass leakage, brush seals should not be used; enhanced airtightness seals should be fitted.
- 9.70 Whichever energy-recovery device is chosen, the extract side should be protected by at least an ISO ePM10  $\geq 50\%$  filter and provided with a drainage system as described in paragraphs 9.105–9.112, to remove condensate. Note that most condensate will occur at intermediate rather than at extreme outside air conditions.
- 9.71 The energy-recovery device should be located downstream of the fog coil and pre-filter, before the cooling coil and main heater-battery. It may be on either side of the supply fan.
- 9.72 It is essential to consider the set points and control of the fog coil, energy-recovery device, cooling coil and heater-battery in order to achieve the most efficient operation for the maximum time. The primary energy provided by the fog coil will directly reduce the heat exchange of the energy-recovery device. To this end, the off-coil setting of the fog coil should be the minimum possible to keep the pre-filter dry (2 to 3 K above intake air temperature) (see paragraph 9.75 onwards for further guidance).
- 9.73 The energy-recovery device should be controlled in sequence with the main heater-battery and should incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the required plant set-point.
- 9.74 In instances where the plant is cooling the air, it may be possible to remove heat from the supply air at high ambient conditions, under the dictates of enthalpy sensors in the intake and extract ducts.

### Heater-batteries

#### General requirements

- 9.75 Fog coils are installed to protect the downstream filters from low temperature, high humidity intake air conditions. They should raise the incoming air temperature by 2 K so that it is above its dew-point when it arrives at the filter. As they handle unfiltered air they should be constructed of plain tubing without fins and be as near to the outside as possible to minimise condensation during cold weather. Access for cleaning should be provided to both sides of the coil. In order to prevent them freezing they should be controlled as constant flow variable temperature devices.
- 9.76 Traditionally frost coils were set to raise the incoming air temperature to between +2°C and +5°C to protect the batteries downstream. All new AHUs should be equipped with an energy-recovery device (see paragraph 9.65); the greater the temperature difference across this device, the more heat will be recovered. Also, the

device will now provide the frost protection. Where an energy-recovery device is fitted, the frost coil will be replaced by a fog coil.

- 9.77 Where steam coils are used for a fog or frost coil, they may be constructed using spiral finned copper tube. As they will be prone to fouling, the tube layout and spacing should permit easy access for regular cleaning.
- 9.78 Main and branch heater-batteries should be constructed of solid drawn copper tube coils with copper fins, generally connected in parallel. In coastal and particularly exposed areas the client may require an anti-corrosion treatment.
- 9.79 Where there is a wet heating system in the areas served, the main heater-battery should be sized, in conjunction with the energy-recovery device, for the ventilation requirements only and not for the building fabric loss. Ventilation should only be used for heating the building fabric if the room specification precludes the use of heat emitters and it is not within the heated volume of the building (for example, a cleanroom or operating theatre with external walls).
- 9.80 Access for cleaning will be provided to both sides of all fog coils and heater-batteries.
- 9.81 Main heater-batteries may be water or steam. Electric heaters are expensive to operate, and their efficiency is particularly dependent on the air velocity through them. Their use should be restricted to branch trimming control.
- 9.82 Where steam supplied heater- batteries are used, their control, venting and trapping systems should be designed so that a vacuum cannot occur within the coil. The condensate drainage arrangements should not allow pressure to build in the condensate main as this will result in a back-up of condensate in the battery.
- 9.83 Where possible, wet trimmer heater- batteries should be located in plant areas.
- 9.84 Where it is necessary to locate heater- batteries in false ceilings etc, consideration should be given to the use of electric heaters (note that additional fire detection may be required). If this is not practicable and a LPHW system is used, a drip-tray should be installed under the control valve assembly to protect the ceiling. A moisture sensor and alarm should be fitted in the tray. In any event, to facilitate maintenance access, they should be located above corridors or other non-clinical areas and never above patient-occupied spaces
- 9.85 Auxiliary fan coil units are not to be installed in the ceiling above a patient- occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the area that they serve.

#### Cooling coils and drift eliminators

- 9.86 Cooling coils supplied with chilled water are the preferred option. For small loads, or where chilled water cannot be made available, direct expansion (DX) coils may be used.

**Note:** For DX coils, it may be necessary to divide the chiller circuits unevenly in order to achieve efficient operation under part-load conditions. The turn- down ratio should allow stable control down to 10% of the peak load.

- 9.87 Cooling coils should be periodically decontaminated so the fin spacing needs to be  $\geq 2.5$  mm and the fins rigid enough to withstand cleaning (for example,  $\geq 0.25$  mm thick). Hinged access doors with viewing ports and illumination inside the AHU or duct should be provided both sides of the coil.
- 9.88 In an AHU when the cooling-coil face velocity is greater than 2 m/s a drift eliminator will be required downstream of the coil. The eliminator will be an entirely separate device mounted on slide rails so that it can be easily removed without the need for tools. If the size of the AHUs precludes the use of slide rails, and the eliminator is constructed in sections which maintenance personnel will have to enter the unit to remove, each section should have lifting handles. In order to reduce the use of plastics, alternative materials should be considered for the eliminator elements.
- Note:** For small DX coils and in fan coil units, the eliminator may take the form of a joggled extension of the fins.
- 9.89 All cooling coils are to be fitted with their own independent drainage system as specified in paragraph 9.105 onwards. A baffle or similar device should be provided in the drip-tray to prevent air bypassing the coil. The tray should be large enough to capture the moisture from the coil headers and drift eliminator.
- 9.90 Where coils are greater than 1.8 m high and the air velocity is  $> 2$  m/s, either intermediate drip-trays will be required or the fin spacing should be increased to  $\geq 3$  mm.
- 9.91 In order to minimise electrolytic action resulting from condensation on the air side, cooling coils constructed from copper tubes with copper fins and electro-tinned after manufacture are preferred. Aluminium fins should only be used if vinyl-coated.
- 9.92 All parts of the coil and its associated ductwork in contact with moisture will be manufactured from corrosion-resistant materials. Pressed steel coil headers, even if treated, have been shown to be prone to corrosion over time and should not be used. Steel mounting frames and casings present similar problems so stainless steel is preferred.
- 9.93 Where a cooling coil has to be located above a ceiling, a drip-tray should be installed under the battery and control valve assembly to protect the ceiling from leaks and condensation drips. A moisture sensor and alarm should be fitted in the tray. To facilitate maintenance access, they should be located above corridors or other non-clinical areas and never above patient-occupied spaces. The air velocity should be below 2 m/s to avoid the need for a drift eliminator. All drainage piping should be rigid type not flexible hose.
- 9.94 Auxiliary fan coil units should not be installed in the ceiling above an occupied space. They should be accessible for routine maintenance and cleaning without the need to cause significant disruption to the operation of the department that they serve. The drainage of such items is often problematic. If a suitable fall in the drain line cannot be achieved, a pump out system should be provided. Drainage piping should be rigid type (not flexible hose).

## Humidifiers

- 9.95 Humidification was originally required for some healthcare applications in order to control the risk associated with the use of flammable anaesthetic gases. The use of such gases has now ceased. Humidification is therefore no longer required unless there is a very specific application requirement (see Chapter 8 and associated SHPNs/HBNs).

**Note:** In an operating theatre, if high humidity is required to help prevent tissue drying during surgery, it should be provided when required using sterile water in a disposable nebuliser driven by medical air, and not from a humidifier installed in the ventilation system. In that way the quality of the moisture delivered will be assured.

- 9.96 If it is unclear at design stage whether humidification is required, provision for retrofitting in terms of space provision and a capped drainage system may be provided either in the AHU or in a zone branch duct. The need for such provision and the amount of space allowed for it should be agreed in writing with the client.
- 9.97 If a humidifier is required, the manufacturer's instructions regarding selection, capacity, installation and control need to be followed. Incorrectly sized, installed or operated humidifiers can become a source of fungal and microbiological contamination within a ventilation system. This may result in a significant airborne infection risk to patients and staff.
- 9.98 Only steam injection manifold-type humidifiers are considered suitable for use in health building air-conditioning systems. The injected steam will be generated locally either by mains steam or electricity, within or adjacent to the humidifier. Water-curtain, water mist or spray humidifiers of any type cannot be used.

**Note:** Jacketed lance mains steam humidifiers will always be a source of heat within the system during the cooling season unless completely isolated when not required.

- 9.99 All parts of the humidifier and its associated ductwork in contact with moisture should be manufactured from corrosion-resistant materials. Stainless steel is preferred.
- 9.100 For self- and locally-generated steam humidifiers, the cleanliness of the water supply is essential for their safe operation. The water supply should be derived from a wholesome source or demineralised supply. Chemical treatments cannot be added to the water supply to humidifier units. The electrodes of self-generating electrode boiler-type humidifiers should be stainless steel.
- 9.101 If the quality of the water supply to a self-generating humidifier unit cannot be assured, an ultraviolet (UV) system to control microbiological growth may be installed. However, given the limitations of UV systems, this will require high-quality water filtration to ensure the effectiveness of exposure of organisms to the UV irradiation. As with all water treatment systems the unit should be of proven efficacy and incorporate UV monitors so that any loss of transmission can be detected.
- 9.102 Provision should be made for draining down supply pipework and break tanks for periodic disinfection and cleaning during the seasons when they are not required in service. The humidifier branch water supply isolation valve will be located at the junction with the "running" main to prevent the creation of a dead leg. All parts of the system should be capable of being cleaned or disinfected as necessary. Hinged

access doors with viewing ports and internal illumination should be provided. A label warning that the device emits live steam and should be isolated prior to opening should be affixed to the access door.

- 9.103 A zone humidifier, if required, may be installed in a supply branch. The ductwork in which the humidifier is mounted and for at least 1 m downstream should be stainless steel.
- 9.104 All humidifiers wherever installed will be fitted with their own independent drainage systems as detailed in paragraph 9.105 onwards and be completely accessible for cleaning.

### Drainage

- 9.105 All items of plant wherever located that could produce moisture should be provided with a drainage system. The system will comprise a drip-tray, glass trap, air break and associated drainage pipework.
- 9.106 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent "pooling", it is essential that the drain connection should not have an up-stand; and that a slope of approximately 1 in 20 in all directions should be incorporated into the drain outlet position.
- 9.107 In AHUs that have access doors large enough for a person to enter, the drip-tray should be easily accessible for inspection and cleaning.
- 9.108 In AHUs with access doors too small for a person to enter, the complete drip- tray should be capable of being withdrawn. It should be clamped into the AHU with thumb screws so that it can be removed without the need for tools (see photograph).

Figure 7 Removable AHU drainage tray

- 9.109 Each drip-tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed, thus giving an early indication of corrosion, biological activity or contamination within the duct. The trap should have a means for filling and incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting the drainage tray to the trap should have a continuous fall of not less than 1 in 20.

- 9.110 Traps fitted to plant located outside or in unheated plant rooms need to be trace heated in winter. The trace heating should not raise the temperature of water in the trap above 5°C.
- 9.111 Water from each trap will discharge directly via a clear air gap of at least 15 mm above the unrestricted spill-over level of either an open tundish connected to a foul drainage stack via a second trap, or a floor gully (or channel). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish providing each has its own air-break.
- 9.112 Drainage pipework from the tundish may be thermoplastic, copper or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22 mm and have a fall of at least 1 in 60 in the direction of flow. It should be well-supported and located so as not to inhibit access to the AHU.

**Note:** In the case of fan coil units, the glass trap and air-break may be omitted and a pump out system fitted. The unit drainage should connect to the main drainage system via a waterless trap that does not allow discharged water to return. The drainage tray itself will be easily removable for routine inspection and cleaning.

### Attenuators

- 9.113 Provided care is taken in the design and construction of low pressure systems to avoid significant noise generation in the ductwork, attenuation should only be needed to absorb fan noise
- 9.114 Fans radiate noise through both the inlet and outlet connections, and it may be necessary to provide attenuation to limit the noise from both of these connections. It is always preferable and more economic to control noise and vibration at source, or as close to source as possible. It should be noted that attenuators offer a resistance to airflow and by causing turbulence can be the cause of regenerated noise in a system.
- 9.115 A thorough assessment of the design should be made to assess the potential noise problems. It should consider the following factors:
- fan and plant noise generation;
  - airflow-generated noise in ductwork fittings and dampers;
  - noise generated at grilles, diffusers and other terminals;
  - noise break-in and break-out of ductwork;
  - cross-talk and similar interference;
  - the noise limitations for the building and surrounding areas;
  - external noise generation.

A method of assessment of these factors and the sound attenuation requirements of ductwork systems is given in CIBSE Guide B

**Note:** Attenuators fitted in distribution ducts can themselves become a source of regenerative noise if the air velocity through them exceeds their tested performance value.

- 9.116 Attenuator units with a sound- absorbing in-fill suitable for the quality of air being handled and protected by a perforated sheet metal casing are the preferred option. Absorption of moisture, dirt and corrosive substances into the "in- fill" and the release of fibrous particles into the airstream should be prevented using a membrane with a declared service life of at least 25 years. If these conditions can be met, the attenuator may be located in the supply ductwork downstream of the final filter. Cleaning access should be provided at both ends of the unit.
- 9.117 Sound-absorbing material should not be applied to the inside surface of a duct.
- 9.118 End of line mixing and VAV boxes may be supplied lined internally with sound-absorbing material. The material will be non-particle-shedding, protected from casual damage during maintenance and be fire-resistant.
- 9.119 See paragraph 9.149 onwards for guidance on distribution and point of use noise control.

**Note:** Developments in "dynamic attenuation" may replace the more traditional physical attenuators and overcome noise "break in" and point of use noise regeneration issues.

#### **Recirculation – minimum fresh air requirement**

- 9.120 Where return air is recirculated, fresh air should be introduced equivalent to at least 20% of the supply air volume, or that required by the Building Regulations, or at least 10L/s/person, whichever is greater.

#### **Distribution system**

- 9.121 The CIBSE guide B2 provides the standard design Information for ventilation systems, their ductwork and terminal devices. The guidance in this SHTM highlights the specific factors that are required for or excluded from healthcare ventilation installations.
- 9.122 For normal applications in healthcare buildings, low velocity systems are recommended; velocities below 2 m/s are unlikely to be justified.
- 9.123 The site will often dictate the main routing of ductwork systems, as will the location of the AHU relative to the load. Grouping AHUs in centralised plantrooms results in large vertical service shafts and long main duct runs. Decentralising AHUs into service spaces adjacent to the load results in a more compact duct layout.
- 9.124 Whichever option is chosen, the design should seek to make the layout as symmetrical as possible; that is, the pressure loss in each branch should be as nearly equal as possible. This will aid balancing and may reduce the number and variety of duct fittings that are needed.
- 9.125 Main distribution ductwork should not be routed above sleeping areas. Where there is no alternative route, additional external acoustic insulation may be required.
- 9.126 Where auxiliary air-conditioning units, fans, filters or trimming devices are installed in the distribution system, they will be independently supported and fitted with a suitable drainage system where appropriate. If they are a source of vibration, they should be linked to the distribution ductwork via flexible connections.

**Ductwork materials and construction**

- 9.127 The choice of duct material should take account of the nature of the air or gas being conveyed and the environment in which the duct will be placed.
- 9.128 Galvanised sheet steel is suitable for normal ventilating and air-conditioning applications. Its inherent mechanical strength renders it resistant to casual damage both during the construction phase and throughout its service life when mechanical and electrical services around it are accessed. It may also readily withstand the impacts sustained when rotary equipment is used to clean it internally.
- 9.129 In instances where moisture levels and/or corrosive elements in the air being conveyed are very high, aluminium, stainless steel, PVC or GRP ducts should be used. Stainless or black steel are the only suitable materials for high temperature ductwork.
- 9.130 Where other ductwork materials are considered, care should be taken to ensure that the material is satisfactory for the application having regard to the likely service life, possibility of mechanical damage and performance in the event of a fire. Where used it will be installed strictly in accordance with its manufacturer's instructions.
- 9.131 Rectangular ducting with an aspect ratio of 1:1 is preferred but ratios of up to 3:1 are acceptable where there are space constraints. Circular spiral-wound or flat-oval are also acceptable providing they meet the leakage standard when tested (see Note after paragraph 9.136). Flexible ductwork is not suitable for air distribution in healthcare applications. In situations where solid ductwork cannot be used, flexible ductwork may be used to make the final connection to a terminal providing it does not exceed 0.5 m in length, is extended as far as possible and is never used in lieu of a bend (see paragraph 9.160).
- 9.132 The inside of the ductwork should be free from structural projections and as smooth as possible. Flanged gasketed joints between sections are preferred for rectangular ductwork, blind-riveted mastic-sealed slip-joints for circular and flat-oval.
- 9.133 In inherently wet areas, such as the base of fresh air inlet ducts and some extract systems, the ductwork may require draining to prevent a build-up of standing water. The layout of the drains should be as specified in paragraph 9.105 onwards.
- 9.134 Where builders' work plenum chambers or ducts are employed, all internal surfaces should have a smooth finish and be sealed to prevent dust shedding.
- 9.135 All types of ductwork should be manufactured and installed to the appropriate current BESA specification.
- 9.136 Ductwork should be supported with threaded rod and channel. Note that sheet metal ductwork cannot use bolt-through supports. Gripple wire may only be used for circular galvanised spiral-wound or flat-oval ductwork.

**Note:** All installed ductwork whether new or reused should be subject to a leakage test on site prior to the application of any insulation. The leakage test will be to BESA DW144 but with a permissible leakage rate of not greater than 3%.

### Fire aspects: damper types and locations

- 9.137 It is essential that all relevant fire aspects of ducting systems are agreed with the fire officer before the design is finalised (see paragraph 1.15 onwards).
- 9.138 Ductwork will be fire-stopped where it penetrates fire compartment walls, floors and enclosures, cavity barriers and subcompartment walls or enclosures, and provided with weatherproof collars where roofs or external walls are penetrated.
- 9.139 Fire and smoke dampers should be provided at the locations required by the Health Technical Memorandum 05 series of documents. The damper mounting frame should be securely attached to the building fabric strictly in accordance with the manufacturer's tested details. Where a fire and smoke damper is not mounted directly in a fire compartment wall, it must be correctly supported and the ductwork between it and the fire wall must possess the same fire rating as the fire wall that it penetrates. The fire-rated portion of ductwork must not be penetrated by test holes or inspection hatches (see also BESA DW145).
- 9.140 Any non-standard fire duct or damper arrangement should be agreed in writing by the client's fire advisor and subsequently tested and signed off by the installer.
- 9.141 An access hatch should be provided adjacent to each fire and smoke damper so that its correct operation can be directly observed. The hatch will be as large as necessary to permit inspection, testing and maintenance. The damper test switch should be mounted adjacent to the inspection hatch so that the routine test and visual confirmation of the damper operation can be carried out by a single person. For circular ductwork, rectangular saddle mounted hatches should be fitted (see BESA DW144).
- 9.142 Smoke-diverting dampers will be provided on recirculation air systems to automatically divert any smoke-contaminated return air to the outside of the building in the event of a fire. It should be arranged so that the normally open diverting damper in the return air branch to the input unit closes and all the return air is exhausted to outside (see paragraph 5.53 onwards).

### Duct sections

- 9.143 When sizing ductwork, the designer should consult the CIBSE B2 guide.
- 9.144 All fittings should conform to the current BESA specification. Wherever possible, long radius bends, large radius main branches, not more than 45° angle sub-branches and long taper transformations should be used.
- 9.145 Bad design in relation to airflow can lead to vibration of flat duct surfaces, an increase in duct-generated noise, pressure loss in ductwork, unpredictable behaviour in branch fittings and terminals, and adverse effects on the performance of installed plant items, such as trimmer batteries.

### Thermal insulation

- 9.146 In order to reduce energy consumption, achieve efficient energy recovery and prevent condensation in service voids, all supply and return air ductwork should be thermally insulated. Insulated ductwork runs outdoors should be weatherproofed.

- 9.147 The thermal insulation of intake and discharge ductwork will be dependent on its location in heated or unheated plant spaces and risk of surface condensation.
- 9.148 In normal circumstances, the insulation thickness for heat resistance is sufficient to prevent surface condensation, but in extreme conditions the insulation thickness for vapour resistance may be greater than that for heat resistance. When cold ducts pass through areas of high dew-point, carefully selected vapour barriers should be applied externally to the insulation.

#### **Noise generation within the ductwork**

- 9.149 Noise is generated in ductwork at sharp edges, by tie rods, damper blades, duct obstructions, sharp bends, etc. This airflow-generated noise becomes an important factor if it is about the same or greater level than the upstream noise level. Airflow-generated noise is often referred to as regenerated noise.
- 9.150 The noise level generated by airflow in ductwork is very sensitive to the velocity. The sound power of this noise is approximately proportional to the sixth power of the velocity; that is, a doubling of the duct velocity will increase the sound power by a factor of 64 (or about 18 dB). The duct velocities should therefore be kept as low as possible. In general, duct fittings which have lower pressure loss factors in similar flow conditions will generate less noise.
- 9.151 Ductwork serving quiet areas should not be routed through noisy areas, where noise break-in can occur and increase the noise level in the ductwork.
- 9.152 Grille register and louvre noise should be kept to the minimum by selecting types having low noise-producing characteristics, without high tonal noise; and should be fitted with acoustically treated external inlet and outlet louvres.
- 9.153 Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required. They will normally be of the "through-the-ceiling, up-and-over" type and may include a fire and smoke damper.

#### **Volume control damper locations**

- 9.154 In order to be able to carry out a full proportional balance, manually operated dampers are typically needed:
- in branches of zone ducts;
  - in sub-branch ducts serving four or more terminals;
  - in dedicated sub-branch ducts serving a room;
  - at terminals not covered by any of the above.
- 9.155 Dampers integral with terminals are to be avoided for final trimming of air volumes, as they often create noise and air distribution problems.
- 9.156 Dampers in rectangular ducts should be opposed-blade multi-leaf type. In circular ducts, iris-type dampers are recommended. Dampers should be accessible, incorporate a position indicator and means of locking in the commissioned position. They should be installed with the adjusting handle or knob at the lower vertical edge

so that they are accessible for the commissioning team once the ceilings are in place. Dampers should be located as far away as possible from adjacent branches or plant items.

#### **Duct cleaning and access door locations**

- 9.157 Cleaning and access doors are required to facilitate access to plant items and ductwork components for inspection, maintenance, cleaning and replacement, and should be of sufficient size to permit safe access for the required functions.
- 9.158 Recommended locations for access doors are given in the current BESA TR/19 specification and are generally provided to give access to:
- every regulating damper;
  - every fire-and-smoke, and motorised damper;
  - filters (to facilitate filter withdrawal);
  - both sides of trimmer cooling/heating coils;
  - zone humidifiers;
  - auxiliary fans;
  - ducts, where required for cleaning.
- 9.159 Care should be taken when siting access doors to ensure that no other services to be installed will prevent reasonable access.

#### **Flexible ducting**

- 9.160 Flexible ductwork can only be used to make the final connection between rigid ductwork and a terminal in exceptional circumstances where a solid connection is not possible. Where used it will cause a significant frictional loss and may be difficult to clean, so it should take the most direct route and be as short as possible, never exceeding 0.5 m in length. It can never be used in lieu of a bend and will possess the same fire rating as the ductwork it is connected to.

#### **Terminal fittings selection and sizing**

- 9.161 The effectiveness of all ventilation and air-conditioning systems depends on the methods by which air is introduced to, and vitiated air is removed from, the space. The usual results of poor air-terminal selection and/or positioning are:
- draughts;
  - stagnation;
  - poor air quality;
  - large temperature gradients;
  - excessive noise.
- 9.162 Air can be supplied to a space in a number of ways, although any device can be broadly placed into one of two categories:
- that producing a diffused supply;

- that producing a perpendicular jet.

Diffusers may be radial or linear, and normally utilise the coanda effect (that is, adhesion of the air stream to an adjacent surface) to reduce the risk of excessive room air movement. A perpendicular jet is formed by discharging air through grilles, louvres or nozzles, which are generally adjustable.

- 9.163 Supply air terminals can be incorporated into any room surface, for example, floors, walls (high or low level), desktop.
- 9.164 As they operate on the jet principle, the use of sidewall and linear grilles is restricted to areas where air-change rates are low, that is, less than 10 per hour.
- Perforated rectangular diffusers can provide acceptable conditions within the occupied zone at up to 15 ac/h. In areas where a higher air-change rate is required, square or circular ceiling-mounted diffusers should be used.
- 9.165 The performance of supply air terminal devices is based on three criteria – throw, spread and drop:
- throw is defined as perpendicular or parallel distance from the terminal to the point at which the air velocity is;
  - 0.5 m/s isovel;
  - Spread is defined as the width of the;
  - 0.5 m/s isovel;
  - Drop is defined as the vertical distance from the centre line of the terminal to the bottom edge of the 0.25 m/s isovel.
- 9.166 It is necessary to consider each of these parameters in both summer and winter conditions to ensure satisfactory operation of the air terminal device, as warm jets behave very differently from cold jets.
- 9.167 A warm jet tends to rise until it attaches itself to a horizontal surface, while a cold jet falls. Care should be taken to ensure that this does not lead to unacceptable temperature gradients in winter, or excessive air velocities in the occupied zone in summer.
- 9.168 In order to ensure satisfactory air movement within a space, it is necessary to consider interaction between air movement from adjacent terminals, and ceiling-mounted fixtures (light fittings, etc), as well as interaction between air movement and room surfaces.
- 9.169 If the supply and extract terminals are too close, short-circuiting may occur, while if they are too far apart, stagnant zones may be formed. Where two opposing air streams meet, the individual velocities should not be greater than 0.25 m/s. Further guidance on the selection of grilles and diffusers is given in the CIBSE Guide B
- 9.170 In operating theatres, the supply terminals should be able to produce a movement of air in the operating zone 1 m above floor level of between 0.2 and 0.3m/s:

- ceiling-mounted diffusers with fixed directional vanes that provide a downward turbulent airflow are the preferred option: 600 × 600 four-way blow or circular “air-master” style;
- plenum boxes fitted with perforated screens to produce a laminar downflow are also acceptable;
- linear ceiling-mounted diffusers that provide a downward-flowing air curtain around the operating theatre may also be used (additional supply terminals may be located within the area bounded by the linear diffusers to provide ventilation within the;
- air-curtained zone).

9.171 The following terminal types are not suitable for use in operating theatres because they do not produce an appropriate pattern of air distribution:

- swirl diffusers;
- single- or multi-outlet adjustable directional nozzles or jets of any type;
- sidewall-mounted linear diffusers that utilise the coanda effect to send air across the ceiling and “droop” it into the operating zone.

9.172 Extract terminals should be of an easy-to-clean design and, in order to assist identification when commissioning and subsequently measuring, be of a different design style to the supply terminals. Extract terminals mounted at low level should be of the spring clip retained, pull off face type to enable ease of cleaning. The terminal should be mounted on an angled face to prevent it becoming occluded by movable equipment or stores (see Appendix 9 for examples). Perforated plates are not to be fitted in extract terminals or extract plenums as they quickly become blocked with lint. Extract terminals do not need any directional adjustment so fixed-vane or “egg-crate” styles are preferred.

#### UCV terminal canopy

9.173 UCV canopies should be fitted with one or more non-electronic, mechanical, direct reading pressure gauge(s) to indicate the pressure drop across either a representative terminal EPA filter or the pressure in each zone of the canopy.

9.174 If a UCV canopy incorporates a method of adjusting the air discharge direction so that the canopy can be “tuned” to the room in which it is installed, the directional adjustment device(s) are to be capable of being locked in position once commissioning is complete to prevent future casual alteration.

9.175 Ceiling-mounted canopy diffusion screen(s) can become contaminated with blood spatter when in use. If the UCV canopy is fitted with perforated diffusion screens the blood spatter can penetrate, so the screens should be capable of being hinged down for cleaning between theatre cases. The screen retaining mechanism will have a double action to release the screen. Mono-filament diffusion screens should be retained by clip-in profiles or an alternative system that allows them to be easily removed when necessary.

9.176 For the validation of UCV terminal canopies, see Chapter 12.

**Transfer grille: size and location**

- 9.177 Air transfer grilles in walls, partitions or doors form an integral part of the building's air distribution system. Modern door sets have very low leakage rates so cannot be relied upon to permit even quite small airflows. Failure to make adequate provision for air to move from room to room will result in excessive pressure differentials and "door whistle".
- 9.178 Transfer grilles are required in locations where there is a significant imbalance between the supply and extract rates in a room. They will relieve any pressure differentials which may affect the operation of the spaces and/or the ventilation system and permit airflow in a known direction.
- 9.179 Care needs to be taken to ensure that the positioning of transfer grilles does not interfere with the fire or smoke integrity of the building. In general, the air transfer grilles should not be installed within fire- resisting boundaries, although if this is unavoidable, they should be fitted with fire or smoke dampers.
- 9.180 Where installed, transfer grilles should be of the non-vision type, sized for a maximum face velocity of 1.5 m/s.

**Note:** Cross-talk attenuators may be necessary where noise intrusion between adjacent spaces can arise and where individual room confidentiality is required.

**Pressure stabilisers: size and location**

- 9.181 Pressure stabilisers are required in areas where it is necessary to maintain a pressure differential between adjacent rooms and to prevent reversal of airflows for example, in operating suites, isolation facilities and cleanrooms (see paragraph 8.24).
- 9.182 Fire precautions for pressure stabilisers are the same as for transfer grilles. If the pressure stabiliser is fitted with a fire and smoke damper, the damper test switch should be easily accessible from, in airflow terms, the least clean side of the damper.
- 9.183 Pressure stabilisers should be of the balanced blade type, with the facility to make fine adjustment of the pressure setting. They should be silent in operation and give a seal as tight as practicable when closed. The materials of construction and method of assembly should allow for cleaning and disinfection.
- 9.184 Pressure stabilisers should be wall- mounted in a visible location so that their operation can be readily observed. For sizing criteria, refer to the manufacturer's information. When fitted at low level, they may require a stand-off cage to prevent occlusion (see photograph).

Figure 8 Pressure stabiliser with stand-off cage

- 9.185 Pressure stabilisers may need to be fitted with a stand-off baffle on their discharge side to prevent a sight line in situations where a laser will be used, and may be lead-lined for radiological protection if required (see photograph after paragraph 9.184). Baffles may also be needed to preserve privacy or prevent discharge air causing draughts within an anaesthetic room or bedroom. A stand-off baffle will always be needed on the theatre side of the pressure stabiliser between a "Lay-up" preparation room and a UCV theatre to prevent perturbation of the UCV canopy air pattern

**Note:** Baffles should be easy to clean and where radiological or laser protection is not required can be made of a rigid transparent material so that the action of the pressure stabiliser can be easily observed.

## Distributed air-conditioning elements

### Active and passive chilled beams

- 9.186 See paragraph 5.18 onwards for information on the use of these devices in healthcare premises and CIBSE Guide B for technical guidance.

### Constant volume boxes

- 9.187 These are units fitted in or at the termination of ductwork that contain a mechanism to maintain a constant output air volume regardless of variation in the air pressure to the supply side of the unit. Where fitted they should be accessible for maintenance as the internal mechanism that controls the constant output will need periodic cleaning.

### Variable Air Volume (VAV) boxes

- 9.188 Variable air volume systems are all-air systems which achieve local control by varying (throttling) the amount of air being supplied to each space, room or zone.

Standard type VAV systems deliver air that has been cooled to a set temperature (usually 13°C) and then control the temperature in a space by varying the quantity of air supplied rather than the supply air temperature – which is kept constant.

VAV boxes are used as terminal devices at the supply end of ductwork to modulate the quantity of supply air to the space.

There are variations to standard VAV systems which allow air supply temperatures to modulate upwards with the aim of:

- reducing energy usage by allowing higher air supply temperatures at part-load conditions;
- improving ventilation effectiveness at part-load by having higher airflows
- – VAV can be as low as 10% of peak at low-load conditions depending on the equipment used;
- allowing the system to operate using warm air in winter for pre-heating warm-up in well-insulated buildings where heating is only used in very cold weather and for building pre-heat.

9.189 In most critical areas of a hospital a fixed air-change rate is required when they are in use. VAV is therefore generally limited to non-clinical applications.

#### **Stand-alone air-conditioners**

9.190 See paragraph 5.25 onwards for information on these units. The ceiling void should never be used as a plenum either for the primary air supply or fan coil supply or return air paths. (See CIBSE Guide B for installation notes.)

#### **Powered air terminal filter units**

9.191 This is an air-distribution-supply terminal box fitted with a fan and EPA or HEPA filter. Their use in the healthcare setting would be confined to spaces where a high air quality is required for a single room in an area supplied by a general AHU (for example, a local cleanroom).

9.192 They are not suitable for use in patient bedrooms due to the fan noise and maintenance access issues.

#### **AHUs: automatic control**

9.193 Chapter 6 of this document gives guidance on energy control strategies and Chapter 7 gives guidance on the point of use factors. Chapter 8 contains guidance to specific healthcare departments and their environmental and functional requirements. This section gives guidance on the control of the AHU and its subsystems. When developing a "controls specification", the designer should consider the guidance given in all of these chapters.

9.194 Various options for control of single- and multi-zone air-conditioning systems are given in CIBSE Guide B.

#### **General requirements**

9.195 The basic requirements for an automatic control system are as follows:

- plant start, run, set-back and stop sequence;
- control of the volumetric airflow;

- control of the system or room pressure;
- temperature control and indication;
- humidity control and indication;
- devices to monitor and indicate the plant's operating state;
- alarms to indicate plant failure, low airflow, and filter state;
- the facility to collect data of actual usage and energy consumption.

The control functions actually provided will depend on the purpose of the ventilation system.

- 9.196 The designer should consider whether it is necessary for the supply and extract fans to be interlocked, either so that the supply fan will not operate unless airflow is established within the extract system, or vice-versa depending on the required pressures within the rooms being served.
- 9.197 The sequence switching of units in order to prevent transient reverse airflows will be particularly important in laboratory and pharmacy areas that also contain fume cupboards, safety cabinets and other LEV systems.
- 9.198 There will also be a need to determine the control strategy in the event of a fire either within the zone being served or within an adjoining zone and as detailed in the fire alarm cause and effect statement (see paragraph 7.16 onwards).
- 9.199 All supply AHUs should have a smoke sensor linked to the fire control panel and mounted in the main supply duct immediately downstream of the AHU. In the event of a fire in the AHU or smoke being drawn into the system from an outside source, it should cause the supply air fire damper to close and shut down the AHU.

**Note:** In certain critical departments, it is preferable to maintain the ventilation in the case of a fire within the area. For example, in an operating department while undergoing surgery the patient cannot always be easily moved without significant risk. In the event of a fire in a staff or support area of the department or adjoining zone, the continued supply of air to a theatre will maintain it at a positive pressure and protect the patient and staff from the effects of smoke.

This will allow time for the patient to be stabilised so that they can be safely.

#### Location of controls

- 9.200 Facilities to start, set-back and stop the plant should be provided in the plantroom. Remote start and set-back control and indication, if required, should be provided at a manned staff location, for example, at the reception or staff base.
- 9.201 Many ventilation systems may be completely shut down when the area served is not in active use. Alternatively, where there is a need to maintain a background condition, the ventilation output may be reduced by "setting back" the system. This will significantly reduce energy consumption and extend the life of filters and other system components. Controls to facilitate this should be triggered by the actual occupancy of the area rather than by a fixed time program (see paragraph 6.2 and associated Note).

### Start up and shut down control sequence

- 9.202 The AHU should start and shut down in a pre-determined sequence. It should ensure that the fan does not start until the main dampers are open and the energy-recovery device is operational. On shut down there may be a need for a "run on" time to purge the area served before stopping the fan and closing the main dampers. Whether the supply or extract fan should start first and stop last will be determined by the pressure regime for the area served.

### Set-back control

- 9.203 In previous times when fan motors only had two speeds, turning the system to "Set back" meant switching to the lower fan speed. With modern fans the speed is widely variable so "Set back" is not a fixed fan speed but rather a control strategy that reduces the system output in order to maintain a desired minimum condition. This may be related to the air velocity at a fixed point, air-change rate, pressure differential, temperature, humidity or a combination of these parameters. Providing a dew-point sensor in an internal space that brings the system onto "Set back" is a simple way of maintaining a minimum condition.

### AHU running controls

#### Fog/frost coil control

- 9.204 Fog coils supplied by low pressure hot water (LPHW) should be controlled using the Proportional mode. Their sensor should be located downstream of the coil to give "closed loop" control. The coil should raise the incoming air temperature by 2 K in order to ensure that air entering the pre-filter is above its dew-point, thus keeping it dry. The greater the energy put into the incoming air by the fog coil, the lower will be the efficiency of the energy-recovery device.
- 9.205 If the temperature downstream of the fog coil, as sensed by a serpentine thermostat, falls below the required set point over any part of the coil, the plant should automatically shut down in order to prevent damage to the other batteries. The serpentine thermostat cannot be in direct contact with the coil and should cover the entire coil face.
- 9.206 Steam-supplied fog or frost coils should be operated as an on/off device to ensure that there is no standing condensate at the base of the coil. They should be fitted with a serpentine sensor mounted upstream of the coil but not in contact with it. This will give "open loop" control; a set point of +1°C is recommended.

#### Energy-recovery device

- 9.207 The energy-recovery device is normally controlled by sensors in the air intake downstream of the supply fan, before the cooling coil and the extract duct from the ventilated space.

### Supply & extract fans

- 9.208 The ErP Directive 1253/2014 requires a means of adjusting the fan speed. For plug fans this is provided by a separate inverter unit; for EC fans the control is integral to the fan motor. It should be remembered that most healthcare applications require known amounts of air to be delivered while the system is in use. Constant volume systems that deliver specified air-change rates are therefore the norm. Duct- or room-

pressure-controlled variable-volume systems have a limited application in healthcare. However, fan-speed control is beneficial when “setting back” the system.

- 9.209 Inverters should not be mounted inside the air stream within the AHU. Ideally, they will be mounted on a frame with the control valves. Where inverters are mounted inside a control box with a safety master switch to cut the power supply when the box is opened, the inverter control and indicator pad will be located on the outside of the box. This will allow on-site staff to view the operating parameters and switch the system to manual control if a fault occurs with the automatic control system.
- 9.210 It is necessary to ensure that should the computer control system or its software develop a fault, the fan can be switched to manual operation. This is particularly important for critical systems serving operating suites, high dependency care units of any type, patient isolation facilities, laboratories and pharmaceutical production suites.

**Note:** In the healthcare setting it is important to recognise that “off-site” software support is no substitute for the ability of “on-site” staff to override the automatic control and keep the system operating in an emergency. Under these circumstances actions that may shorten the life of the plant are considered of secondary importance to that of preserving the health and safety of patients and staff.

#### Heater-batteries

- 9.211 The main heater-battery should be controlled in the same manner under the dictates of an off-coil temperature sensor, or a room temperature sensor, or the return air temperature depending on the plant configuration and method of control. Trimmer heater-batteries are generally controlled by a temperature sensor within the room, or by averaging temperature sensors within a zone.
- 9.212 Heater-battery control valves should drive closed on system shutdown or fan failure. The control system should then automatically set to provide frost protection.

#### Cooling coils

- 9.213 There are two basic methods of control for cooling coils:
- off-coil control – used in multi-zone systems or single-zone systems where close humidity control is required, to provide a constant maximum off-plant condition which satisfies the temperature and humidity requirements of the zone with the highest load;
  - sequential control – used in single-zone systems, or multi-zone systems with averaging sensors where close control is not required. A room or duct temperature sensor controls the cooling coil and heater-battery in sequence to maintain constant room conditions.
- 9.214 The advantage of off-coil control is that accurate humidity control can be provided without relying on humidity sensors, which are prone to inaccuracy and drift. Off-coil control is expensive to operate in terms of energy consumption because of the lack of feedback of room loads. As a result, at low loads and in systems where there are large zonal variations, significant over-cooling and reheating will occur.

- 9.215 The control logic should prevent the cooling coil and heat recovery and/or heater-battery being on at the same time.

#### Humidifier control

- 9.216 Accurate humidity control can only be provided on single-zone systems, or multi-zone systems with zonal humidifiers. In the above systems, humidity sensors control the humidifier for low-level humidity control, and override the temperature controls to open the cooling-coil valve for high-level humidity control.
- 9.217 Multi-zone systems are more usually controlled by a minimum humidity sensor located in the supply duct(s) following the last heater-battery.
- 9.218 Overriding controls separate from the normal plant humidistat should be installed. Their purpose is to prevent excessive condensation in the conditioned space when starting up. A time delay should be incorporated into the humidifier control system such that the humidifier does not start until 30 minutes after the ventilation/ plant start-up. In addition, a high limit humidistat should be installed to limit the output of the humidifier so that the saturation in the duct does not exceed 70%. This humidistat is to control the added moisture; it is not necessary to install a dehumidifier to reduce the humidity of the incoming air if it already exceeds 70% (part load control).
- 9.219 The humidifier control valve should close when the ventilation system is in "set back". In addition, on system shutdown, low airflow or fan failure, the humidifier should be isolated.
- 9.220 In a self-generating humidifier, if the humidifier is unused for a period exceeding 48 hours, it should automatically drain its water content, including that contained in the supply pipework, right back to the running main and leave itself empty.
- 9.221 With certain types of steam humidifier, it may be necessary to install a thermostat in the condensate line from the humidifier's steam supply, to ensure that the steam at the control valve is as dry as possible before it is injected into the air supply.
- 9.222 The humidifier control system should ensure that it is switched off with the fan. It is preferable to design the control system so that the humidifier is isolated for an adequate time before the fan is turned off to purge humid air from the system.

#### Control valves: general

- 9.223 The fog/frost battery control valve should fail-safe, that is open in the event of power or airflow failure. All other valves will stop in their current position in the event of power failure and should drive closed in the event of airflow failure.
- 9.224 Control valves should be located in an accessible position. Isolation valves should be provided to enable the control valve to be removed for service or replacement without the need to drain down the system
- 9.225 Care should be taken to ensure that the installation of control valves and their associated pipework do not obstruct access to the AHU inspection doors, removable drainage trays, eliminator units and access hatches.

**Note:** There are practical advantages in locating all control valves for an AHU in a bank (at a convenient height) at one end of the unit. (This should not result in an

additional control lag.) The bank will hold the control valves and actuators, and fan inverters/controllers as necessary, and can be constructed "off site" (see also paragraph 9.209).

### Monitoring and alarms

- 9.226 Monitoring of the plant performance should be via a BMS to the estates and maintenance department.
- 9.227 The "plant failure" and "low airflow" alarm should be initiated by a sensor located in the main air supply duct. This should operate when the air quantity fails to reach or falls to around 80% of the design value and will give indication of fan failure, damper closed, access door left open, or any other eventuality that could cause a reduction of air quantity. Monitoring the current drawn by the fan motor is not a substitute for a sensing device that is directly affected by the airflow. The sensing ring fitted to plug and EC fans will fulfil this function.
- 9.228 The "filter fault alarm" should be initiated by a predetermined increase of pressure differential across the filters, thereby indicating a dirty filter. The filter fault indication and alarm is information for the maintenance department; it should not appear on any point of use indicator or control panel.
- 9.229 Visual indication that the AHU is operating within its prescribed parameters should be provided in critical areas at a manned staff location, for example, the reception or staff base. These need only take the form of a green light to show the system is operational and a red light to show that it is not.

### Room temperature control

- 9.230 The limits for room temperature set point are generally between 18°C and 25°C depending on the particular application, and in some specialised instances (for example, operating departments) are adjustable within a predetermined range by the user.
- 9.231 The selection of temperature set point for each room or zone may be by a control facility in the room/zone, or remotely at the control panel or BMS. Where the control device is mounted within the room/zone and adjustable by the user, it should be marked either "raise" and "lower" or "+" and "-". It should control within a specified temperature range to suit the user requirement with a control tolerance of +1 K. All other control set points should be selectable either on the control panel or at the BMS interface.
- 9.232 Where local control is provided, an indication of temperature will be required locally, or at a staff base (if appropriate), using an analogue or digital indicator. The indicator should be large enough to be read from the normal working position (for example, at the operating table in a theatre). This may be mounted in a supervisory control panel, with the signal repeated on the main system control panel or BMS. It is important that this indicator displays the actual measured temperature and not the selected temperature.

## Local exhaust ventilation (LEV)

- 9.233 Devices that use an inflow of air to control exposure of staff to hazardous substances are classified as LEV systems under the COSHH Regulations.
- 9.234 An LEV system will typically comprise a unit where the airborne hazard is captured, ductwork to convey the extract air to the fan and a discharge stack. The extract air may be filtered or centrifugally separated to remove any particulate material prior to discharge. HSG 258 produced by the Health & Safety Executive gives detailed guidance.
- 9.235 It is important to recognise at the design stage whether an extract is being provided for comfort, to remove odours or to remove hazards, in which case it will be an LEV system. Chapter 8 lists typical devices used in healthcare applications.
- 9.236 The quantity and location of the terminals supplying the make-up air is an important factor in the design of LEV systems.
- 9.237 LEV systems are statutory items that will be subject to an independent examination and test at least every 14 months by a competent person.

### Extract ductwork and fan

- 9.238 Extract ductwork for an LEV system should, where possible, be installed outside of a building. Where it has to be inside, it should take the most direct route through, with as few bends or changes of direction as possible.
- 9.239 All ductwork joints should be sealed and ideally there should be no access hatches. Where access hatches have to be provided, they should be of a type that has a hermetic seal.
- 9.240 Some substances are particularly corrosive, so the choice of material for the ductwork, and type of extract fan fitted, should reflect the nature of the substance being conveyed.
- 9.241 The ductwork should either be fire rated or fitted with intumescent collars where it passes through fire compartments within the building. This will ensure that the extract system is unobstructed and always open to atmosphere up to the discharge point.
- 9.242 Some LEV systems (for example, microbiological safety cabinets) HEPA-filter the extract air within the cabinet unit, but it should not be assumed that the exhaust air will be totally free from microbiological or other hazardous material.
- 9.243 The extract ductwork should as far as practicable be kept under negative pressure while inside the building. The extract fan should be located outside of the building or if this is not practicable, as close as possible to the outside so that any ductwork on the discharge side inside the building is kept to an absolute minimum.
- 9.244 The extract fan drive motor should be out of the airstream and it should be possible to change the motor without disturbing the fan or its casing.
- 9.245 Duplex fans are only required when several LEV systems share a common extract system (for example, multiple fume cupboards in a large pathology department where it can be anticipated that at least one cupboard will always be in use or need to be

available for use). In such a situation each cupboard should be fitted with a non-return damper at the point that it joins the common system and be capable of being isolated from the common extract system. The common extract duct should be large enough to handle the combined extract volume from all the systems that feed into it.

- 9.246 If extract filters are fitted in the ductwork the system design should allow them to be changed safely.
- 9.247 Current standards permit the installation of microbiological safety cabinets with integral fans, provided that the extract ductwork can be kept short (that is, less than 2 m); such an installation, however, is likely to be noisy and is not recommended for use in new buildings.

#### **LEV discharge stack arrangements**

- 9.248 Roof-level discharge, wherever practicable, is preferred since it removes much of the uncertainty over air re- entering the building through ventilation inlets or windows. In such an installation, the extract fan should be situated separate from the LEV captor unit and close to the discharge stack to maintain the duct within the building under negative pressure.
- 9.249 The discharge point on a flat roof should be through a terminal at least 3 m above roof level but as high as necessary to limit re-entry into supply air inlets or other plant openings. This will protect those who may need to access the roof. Terminals at other roof types need to be high enough to prevent the wind blowing across the roof from causing downdrafts.
- 9.250 Where there are adjacent buildings with opening windows, or where downdrafts are likely to occur, it may be necessary to increase the height of the discharge stack in order to achieve adequate dispersal. In complex locations, airflow modelling or wind tunnel tests may be required to determine the optimum height.
- 9.251 The discharge stack should have an open end. It may be fitted with a collar to reduce its area and so increase the air efflux velocity at the point of discharge (known as the venturi effect). To ensure that air leaving the terminal is not deflected down but allowed to disperse freely, the terminal cannot be fitted with any sort of cover or hat. A drain may be required at the base of the discharge stack to remove any rain that enters (see photograph).

**Figure 9 Typical LEV discharge stacks**

**LEV system information and identification**

- 9.252 Once installed, all elements of each LEV system should be uniquely identified with a permanent label as described in Chapter 13. There is a statutory requirement to have information on the design and required operational performance of an LEV system available to those who are responsible for its operation and
- 9.256 maintenance. The designer should ensure that this information is available at handover.

Interim

## 10. Installation Standards

---

### General

- 10.1 AHUs, ductwork sections and associated elements of the ventilation system will be delivered to site suitably packaged to protect them from damage and casual contamination. They should remain protected when stored on site awaiting installation.
- 10.2 Ductwork should be installed to the "Advanced Level" as defined in BESA's (2019) 'TR/19: Guide to good practice – internal cleanliness of ventilation systems'. Should any doubt exist as to whether the guidance has been observed, the ducts should be cleaned internally to restore them to this standard and be visibly clean before being taken into use.
- 10.3 When the ventilation elements are installed, all open ends have to be sealed to prevent the ingress of construction dust as installation progresses. The access doors and panels of AHUs should be kept closed. All AHU dampers and fire dampers should be covered to prevent casual contamination during the construction phase. This is particularly important for fire dampers mounted in the plantroom floor. The damper blades should be wiped clean before final connection to the distribution ductwork.
- 10.4 The area around the supply air intake should be kept free of vegetation, waste, rubbish, builders' debris or any other possible source of contamination.
- 10.5 "Builders' work" ducts of brick or concrete should have a smooth internal finish and be surface sealed to prevent the release of dust before being taken into use. They should be fitted with a drainage system if not self-draining.
- 10.6 Every effort should be made to prevent the internal contamination of the ventilation system during the construction phase as once contaminated, it is extremely difficult to completely remove dust and debris. In particular, extract and recirculation fans should not be run up until the area is at least "builders clean" – that is, the floors swept and wet-mopped – otherwise the energy-recovery device in the AHU could become contaminated and its efficiency significantly reduced.

### AHUs

- 10.7 Units should have a working life of up to 20 years; it can be anticipated that over this period there will be a need to access every element within the unit for deep cleaning. It is also quite possible that during the life of the unit, the main fan and all control valves will need replacement. Heater and cooling coils may also need to be repaired or replaced. Suitably positioned service connection joints and adequate spacing should permit these items to be isolated and withdrawn without the need to drain down entire systems or dismantle other installed plant.
- 10.8 Care should be taken during installation to ensure that electrical and mechanical services are not installed in positions that will reduce or impede access. Mounting all control valves and fan controllers on a frame positioned adjacent to the unit is the

preferred option. This approach has the advantage that the frame and its components can be built and tested "off-site".

- 10.9 In order to reduce the effects of galvanic corrosion, black iron fittings should not be used in the pipework installation. Rolled jointed stainless-steel pipework is preferred.
- 10.10 Vibration from a remote plantroom can be transmitted by the structure of the building, and may be regenerated and sometimes magnified many times. Pipe and ductwork should incorporate anti-vibration couplings, pipe hangers and supports, preferably in two planes at right angles, as close to the vibration source as possible.
- 10.11 The service connection points for pipework and electrical conduits will have been made during construction of the unit. The unit will then have been leak-tested in the factory prior to delivery to site. If there is a need to drill through the AHU casing or panels (for example, to mount a sensor), the hole should be as small as practicable and sealed to prevent air leakage.
- 10.12 It is essential that the AHU/ductwork is mounted far enough from the floor to permit the correct installation of drainage systems for cooling coils, humidifiers and heat recovery systems. If the AHU is located on a roof, it will require a clearance of 600 mm to provide access to maintain the building structure below. Sufficient height for the installation of drainage pipework and traps should always be allowed. Easy access for maintenance of drainage systems and their associated pipework should be provided. It should be possible to fully withdraw the drainage tray if it is of the removable type.
- 10.13 AHUs should be positioned so that all parts are easily and safely accessible for routine inspection and service. If a unit is located against a wall or backs onto another unit, access to all parts should be available from the front. Units greater than 1 m wide should preferably have access from both sides or access doors large enough to permit the full and safe entry of maintenance personnel.
- 10.14 Air filters, cooling-coil drainage trays and drift eliminators are all items that should be changed, inspected or withdrawn on a regular basis. The installation of the AHU should permit this without the need for tools or to dismantle other plant or systems.
- 10.15 Access to air intakes and discharges, AHUs and items in the distribution system such as filters or auxiliary trimmer batteries located in a plantroom or plant area should be via fixed ladders, hook ladders, pulpit style steps or other moveable access platforms. The installation of distribution ductwork and other electrical or mechanical services should provide sufficient clearance to allow access equipment to be moved into position.

### Distribution systems

- 10.16 Where ductwork penetrates a roof, it should be protected by an upstand to prevent water penetration. Where it penetrates an outside wall, the method of installation should prevent water tracking along the ductwork into the building or its wall cavity.
- 10.17 The installation of all services in service ducts and above ceilings should be coordinated so that cable trays, medical gas and other pipework do not obstruct or

prevent access to the ductwork cleaning doors, dampers and any auxiliary plant elements. The use of BIM should highlight clashes at the design stage.

- 10.18 Plant elements such as VAV boxes, trimmer heaters or cooling coils, humidifier lances or branch filters that are located outside of plant spaces should be accessible for routine inspection and have a cleaning access door on both sides. They cannot be installed above any of the following areas:
- operating theatres;
  - preparation rooms or sterile pack stores;
  - anaesthetic rooms or recovery areas;
  - rooms containing imaging equipment;
  - pharmacy cleanrooms;
  - containment laboratories;
  - patient bedrooms and isolation rooms.
- 10.19 Rectangular ductwork sections should be joined by bolted or clipped gasketed flanges. Circular and flat-oval slip-joints should be mastic-sealed and held with blind rivets, not screws. The mastic used should not support biological growth. The ductwork installation will be leak-tested prior to acceptance.
- 10.20 Volume control dampers (VCD) should be oriented so that their adjusting handles or knobs are located at the lower vertical edge or bottom of the damper when mounted above ceilings. The means of adjusting the damper will be within sight and reach from a designated ceiling void access hatch once the ceiling is complete. Volume control dampers mounted in any location should have the control adjuster mounted to allow easy access for the commissioning team and for future access when a post-cleaning rebalance is undertaken.
- 10.21 Access to VCDs or local auxiliary fans mounted above ceilings should be via low-leakage access hatches mounted in the ceiling or hatches integral to a light fitting.
- Note:** Obtaining access by removing a light fitting is not acceptable.
- 10.22 Where ducts are drilled to provide test holes or to mount sensors, the swarf should be removed, and the hole deburred before the fan is started.
- Note:** Care should be taken to prevent the inadvertent drilling of attenuators.
- 10.23 Flexible ductwork may only be used if there is no other way of connecting an air terminal to a duct. The flexible duct should be not more than 0.5 m in length, be as fully extended as possible and never used in lieu of a bend. The fire rating of the flexible duct should be no less than that of the fixed duct that it is connected to (see also paragraphs 9.131 and 9.160).
- 10.24 Fire and smoke dampers must be installed strictly in accordance with their manufacturer's instructions. There will be a rectangular access hatch (saddle mounted for circular ducts) and test switch adjacent to the damper so that a single person can trigger the damper and directly observe its operation during the annual

test (see photograph). When pressure stabilisers incorporate a fire damper, the test switch is to be located in an easily accessible position on the less clean side of the pressure stabiliser.

Figure 10 Fire damper with test switch and inspection hatch

### Point of use

- 10.25 Items of equipment that require access for inspection and cleaning should not be accepted if they are installed in locations that prevent easy access.
- 10.26 Items of equipment that require access for inspection and cleaning such as fan coil units will not be accepted if they are installed directly above medical or diagnostic equipment.

**Note:** A common problem occurs because installation layout drawings show fan coil or similar units on the room plan. These are often only "indicative" of the fact that there will be a unit in the room but are taken as the desired position by those carrying out the installation. As an example, the installation drawing for an interventional imaging room shows a fan coil unit in the centre of the ceiling. If it is installed in this position it will be directly above the scanner once that is installed. The fan coil unit will then not be accessible for routine inspection and maintenance, and should it leak water, it will put the scanner out of action.

- 10.27 The installed position of ceiling terminals in storerooms (for example, a theatre's bulk sterile pack store) should coordinate with the siting of the storage racking. The airflow at the terminals should be routinely measured, so the racking and its contents should not obstruct access to the terminal when using a calibrated hood. The same problem can occur in recovery rooms and ward areas where bed curtain rails and bed hoist tracks can prevent the measurement of airflow from ceiling terminals.
- 10.28 Low-level extract grilles should be of the pull off face type for ease of cleaning.
- 10.29 See pictures of low level extract installations in Appendix 9.

### Service penetrations

- 10.30 Where services penetrate the fabric of the building, they should be sealed to prevent any uncontrolled air leakage between rooms and service spaces or voids. Situations where this occurs will be:
- service spaces behind IPS panels at wash basins and scrub troughs;
  - cased in wall-mounted medical gas pipeline units and ceiling-mounted pendants;
  - electrical trunking and bedhead rail systems;
  - boxed-in main and local drainage pipework;
  - ceiling-mounted operating lights, examination lights and other pendant-supported items.
- 10.31 The sealing should be at the point that the service penetrates the wall, ceiling or floor and not at the access panels or covering shrouds as these will need to be removed from time to time. Sealing of the penetrations should be done at first-fix stage as access will become progressively more difficult once final covers and finishes are applied. In certain applications, permeability testing will be carried out at first-fix stage to ensure that this has been done.

**Note:** The "clean zone" is not the same as the overall size of the canopy, and it is vital to consult the UCV canopy supplier in order to get the position and size of the zone correct, as mistakes are expensive to rectify.

# 11. Commissioning Systems

---

## General

- 11.1 Commissioning is the process of advancing a system from physical completion to an operating condition. It will normally be carried out by specialist commissioning contractors working in conjunction with equipment installers. Commissioning of the ventilation system will normally be the responsibility of the main or mechanical contractor who should coordinate the process.
- 11.2 Commissioning is often subdivided into sections (for example, air handling unit, automatic controls, air side balance, building fabric and fittings). Each section may be commissioned by its specialist installer, and they are often accepted in isolation.
- 11.3 Commissioning is an essential process for ventilation systems. It is therefore important that adequate provision for the process be made at the design stage of the project. Procedures for commissioning air-handling systems are given in CIBSE Commissioning Codes and BSRIA BG 49 – Commissioning Air Systems.
- 11.4 The duct design process should take into account the requirements of system balancing. The position and number of regulating dampers included in the design should be sufficient for this purpose.

## Location of dampers and test holes

- 11.5 Balancing/commissioning dampers will be required in each branch of the distribution ductwork. In a critical system such as an operating suite, the branch to each room and each location where it is required to carry out a proportional balance should have a balancing damper.
- 11.6 Test holes for the measurement of airflow will be required at carefully selected points in main and all branch ducts. The number and spacing of holes are given in the BSRIA BG 49/2015 Commissioning Air Systems. Their positions should be identified at the design stage.
- 11.7 The test positions need to be accessible for commissioning to take place. They may also be required for subsequent annual verification of the system performance, so they should not be covered by permanent lagging.
- 11.8 The measurement point should be in a straight length of duct as far away as possible from any upstream bends, dampers or other elements that could cause disturbance to the airflow. The actual location should be:
- at least 1.5 duct diameters upstream of sources of turbulence such as dampers and bends;
  - if this is not possible, ten diameters downstream of dampers, bends or tees, and five diameters downstream of eccentric reducers;
  - where there is enough space round the duct to insert the pitot tube and take readings;
  - where the duct has a constant cross-sectional area.

Test holes for measuring total airflow from a fan should be located either four diameters upstream or ten diameters downstream of the fan. Provision should also be made for measuring the fan's speed of rotation.

**Note:** Plug and EC fans are supplied with a measuring ring so their output can be read directly. This needs to be connected to an external pressure tapping or electronic fan control unit.

### Information to be provided

11.9 It is essential that the designer should pass on the system-design intent fully to the commissioning engineer by providing:

- relevant parts of the specification;
- schematic drawings indicating data listed in Table 11;
- equipment schedules;
- controller and regulator schedule;
- fan performance curves;
- wiring diagrams for electrical equipment, including interlock details

**Table 11: Information to be provided on schematic drawings**

Items in system	Information to be provided
Fans	Fan total pressure Volume flow rate at normal and set back speed Maximum motor current
Plant items	Type and identification numbers from equipment schedules Fluid and air volume flow rates Fluid and air side pressure losses Dry bulb temperatures Wet bulb temperatures Humidity
Dampers, including motorised and fire dampers	Identification numbers from equipment schedules Location Identification number Volume flow rate
Main and branch ducts	Dimensions Volume flow rates and velocities Identification numbers from equipment schedules
Test holes and access panels	Location and size of duct Identification number Design airflow rate
Room supply and extract terminals	Location Identification number Grille or diffuser factor Volume flow rate and neck velocity Operating static pressure
Pressure cascade	Room differential pressures Airflow direction between rooms Pressure stabiliser and transfer grille locations
Internal environment conditions	Design room conditions and adjustable range Specific room air velocity if specified Noise level
Controllers	Set points

**Notes:** Fan total pressure is the difference between the total pressure (static pressure + velocity pressure) at the fan outlet and the total pressure at the fan inlet. Where volume flow rates are variable, maximum and minimum values should be provided.

### Commissioning personnel

- 11.10 It is unlikely that all the required commissioning skills will be possessed by one individual; a commissioning team is therefore usually needed. The objective of commissioning is to ensure that the necessary performance and safety requirements are met.
- 11.11 During the commissioning process a great deal of information will be generated which will form an invaluable future source of reference about the plant. It is essential to ensure that it is collected together in the form of a commissioning manual and handed over to the client on completion of the contract together with the "as fitted" drawings.
- 11.12 In order to be successful the commissioning process will need to start before practical completion, as many parts of the system will become progressively less accessible. The correct installation of those parts should be witnessed and leak rate tests carried out as construction proceeds. Failure to establish responsibility for commissioning early enough will delay the completion of the project or lead to unsatisfactory plant performance (see CIBSE Commissioning Code M).

### Commissioning brief

- 11.13 The commissioning team will require a detailed brief from the system designer. This should include:
- a "user" brief comprising a description of the installation and its intended mode of operation;
  - the precise design requirements with regard to the scheme of air movement, room static pressures, supply and extract airflow rates and acceptable tolerances;
  - full details of the design conditions both inside and out, for winter and summer, together with the control strategy;
  - equipment manufacturers' type test data, commissioning, operation and maintenance recommendations;
  - drawings showing the layout of the system, positions of airflow measurement test points, dampers, regulating devices and filters within the duct runs, together with sizes of ducts and terminal fittings. It will save time if these drawings are annotated with the design volumes and static pressures required at each branch and outlet point;
  - wiring diagrams for all electrical equipment associated with the air-handling systems, including motor control circuit details and any interlocking and safety devices.
- 11.14 CIBSE Commissioning Code A – 'Air distribution' or BSRIA BG 49 – 'Commissioning air systems' provide full guidance on the information that will be required by the commissioning team.

- 11.15 Designers should specify the type of measuring instruments and test procedures. They should include in the contract documents instructions on verifying the accuracy of test instruments, which should be supported by reference to relevant calibration certificates.
- 11.16 The system, on completion, should be operated by the contractor as a whole and subject to performance tests in accordance with the contract requirements. These will include independent validation of the system performance on behalf of the client.
- 11.17 The commissioning process should be carried out in the order in which it appears in this guidance document. That is to say, the static checks and visual inspections itemised in paragraphs 11.20–11.26 should be followed by the dynamic tests described in paragraphs 11.27–11.46, the performance tests listed in paragraphs 11.47–11.64 and finally the handover procedures set out in paragraphs 11.63–11.65.
- 11.18 Once the system is shown to meet the design intent, the handover documentation should be completed. In the event of performance not being acceptable, the matter should be dealt with in accordance with the contract arrangements.

### Pre-commissioning checks

- 11.19 The pre-commissioning checks consist of visual inspection, manual operation of equipment, static measurements and functional tests of individual components. They should be carried out prior to setting the system to work and undertaking the dynamic commissioning process set out in paragraph 11.27 onwards.

**Note:** Before commencing commissioning, it is essential that builders' work in the area served by the system is complete. The doors and windows should be fitted, floor finishes applied, walls and ceilings completed and their final finish applied. Fans should not be run until the area is clean (see paragraph 10.6).

### Standard of installation

- 11.20 During the installation of the system the following will be witnessed:
- that the plant and installations have been provided and installed in accordance with the design specification and drawings;
  - that only approved sealants have been used in the installation;
  - that all components function correctly;
  - that the satisfactory sealing of access doors and viewing ports has been carried out;
  - that the AHU airtightness test as per BS EN 1886 has been carried out;
  - that air-pressure tests and air-leakage tests on ventilation ducting have been carried out in accordance with the methods set out in the BESA DW143 – 'Ductwork leakage testing' but the leakage rate to be not greater than 3% (it is usual to carry out these tests a section at a time as the ductwork is installed and before its insulation is applied. The results will be recorded in the commissioning manual);
  - that gaps around doors and hatches are as specified in the design;

- that the permeability tests are carried out as per paragraph 12.17;
- that the correct operation of pressure stabilisers, control dampers, isolating and non-return dampers have been checked;
- that test holes have been provided in their specified locations and are sealed with suitable grommets;
- that control dampers are secured and their quadrants fitted correctly;
- that any interlocks are operative and in accordance with specification;
- that the electric circuits are completed, tested and energised;
- that electric motors have been checked for correct direction of rotation both at full speed and set back;
- that cooling and heating media are available at correct temperatures and pressures and in specified quantities
- that the air-conditioning plant components and controls function correctly;
- that the air-conditioning plant interlocks and safety controls function correctly;
- that the plant is physically complete, insulation is applied and all ducts and pipework are identified as specified;
- that all service penetrations of the fabric of the area are sealed at the point of penetration (see also paragraph 10.30);
- that the building housing the ventilation plant is generally in a fit condition for commissioning and performance tests to commence, that is, windows, doors, partitions, ceilings, etc. are completed, surfaces sealed and their final finish applied;
- that the areas containing the ventilation plant and those being served by it are clean;
- that access to all parts of the system is safe and satisfactory.

#### **Certification of equipment**

11.21 The following test certificates should be assembled by the commissioning team and be available for inspection at any time during the contract period. They will form part of the handover information and should be placed in the commissioning manual:

- type test performance certificates for fans;
- pressure test certificates for:
  - heater-batteries;
  - cooling coils;
  - humidifier (if appropriate);
- type-test certificates for attenuators;
- type-test certificates for primary and secondary filters;
- individual test certificates for EPA or HEPA air filters.

### Equipment tests

- 11.22 Prior to setting the system to work the following will be witnessed and proving tests should be carried out as detailed:

#### Filters

- 11.23 The quality of filter housing and in particular, the seals, is a critical factor in maintaining the efficacy of the filtration system by ensuring that air does not bypass the filter elements. Therefore, the following checks should be made:

- filter seals should be fitted and in good condition;
- filters should be installed correctly with respect to airflow;
- bag filters should be installed so that the bags are vertical and their pockets free;
- all filters should be checked to ensure they are free of visible damage;
- EPA or HEPA filters should be scanned with an LSAPC to prove that they and their housings achieve the specified filter efficiency;
- the differential pressure indicators should be checked for accuracy and that they are marked with the initial and final filter resistance.

#### Drainage arrangements

- 11.24 The drain should conform in all respects to the standard set out in paragraph 9.105 onwards. In addition, the following should be proved:

- that the drain tray is easily removable or completely accessible;
- that the drift eliminator (if fitted) is removable without the use of tools;
- that a borosilicate glass trap is fitted and is easily removable;
- that the trap discharge point to drain has a clear air-gap of at least 15 mm;
- that the pipework is supported so that the air-break cannot be reduced;
- that the drain system from each drain tray is independent up to the air- break.

- 11.25 The operation of the drainage system is then proved by introducing water into the duct at the drain tray and observing that it completely drains out. This check is to be repeated both at normal speed and set back once the fans have been commissioned. At this time the clear trap can be marked to indicate the normal water level with the fan running.

#### Fire dampers

- 11.26 The following will be witnessed and proving tests should be carried out as detailed:

- the operation of all fire and smoke dampers (fire dampers fitted with a thermally actuated "memory metal" mechanism should be proved using a hot air heat source);
- the access provided to enable the dampers to be visually inspected and/ or reset should be sufficient for the purpose;
- indication should be provided of the dampers' position (open/tripped);

- indication of the fire dampers' location should be provided both on the ductwork and at a visible point on the building fabric if the ductwork is concealed.

## Dynamic commissioning

### Air-handling and distribution system

- 11.27 Before commencing the dynamic commissioning all rubbish should have been removed and the floors swept and wet- mopped (see paragraph 10.6). Any IPS panels should be in position, access hatches closed, light fittings in place and ceiling tiles clipped down as necessary.
- 11.28 The fan drive, direction of rotation, speed and current drawn should be set in accordance with their manufacturer's instructions. In the vast majority of healthcare applications, the fan output should be set to give a constant volume of air. This to be controlled by measuring the pressure drop across the fan using a sensing ring and associated volume controller that will automatically integrate the fan 'K' factor to determine and control the pre-set output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.
- 11.29 After the installation has been checked to ensure that it is in a satisfactory and safe condition for start-up, it should be set to work and regulated to enable the plant to meet its design specification. The proportional balancing method described in the CIBSE Commissioning Code A should be followed. The airflow rates will be set within the tolerances laid down in the design brief. This will normally be the design airflow rate +10%; -0%.

**Note:** Plug fans are fitted with a measuring ring so that the design volume flow can be set when first started. It can then be reset as the airflow balance progresses. This method will result in the correct airflow with the least total system resistance once balancing is completed.

### Air commissioning measuring equipment standards

- 11.30 All test and measuring equipment used will have a certificate to prove that its calibration has been checked within the previous 12 months at a facility using traceable national standards.
- 11.31 System performance should be measured at the main and branch duct supply and extract test points using a pitot and manometer or a thermal anemometer.
- 11.32 Supply and extract air volumes at the room terminals should be measured using a calibrated hood with back pressure compensation. If a hood correction factor is applied, it should be determined by a direct comparison with a duct measurement immediately adjacent to a terminal and not a general comparison between air at the main supply duct and the total as measured at the terminals. For multi-directional terminals a correction cross will be fitted in the measuring hood.

**Note:** Measurements taken with a "home- made" hood or cone will not be accepted.

- 11.33 Measurements at extract grille faces should, where possible, be taken using a calibrated hood. Alternatively, they may be measured with a rotating vane anemometer fitted with a hood, or as a last resort, scanned using a rotating vane anemometer and a free area factor applied. The grille face free area and factor used should be stated in the commissioning report.

#### Order of commissioning

- 11.34 When combined supply and extract systems are to be balanced and the area that they serve is to be at or above atmospheric pressure, the supply should be balanced first with the extract fan switched off, and then the extract balanced with the supply fan(s) on. The supply balance should then be rechecked.
- 11.35 For combined systems where the area that they serve is to be below atmospheric pressure, the extract should be balanced first with the supply fan switched off and then the supply balanced with the extract fan on. The extract should then be rechecked.
- 11.36 On completion of the balance, all volume airflows in supply and extract ducts and from grilles and diffusers will be measured and recorded. The true air- change rate can then be calculated from the data obtained.

**Note:** For accuracy the room dimensions should be actually measured on site rather than deriving them from design drawings.

- 11.37 All supply and extract duct volume control dampers should be locked and their position marked and the fan motor settings noted and recorded.
- 11.38 All grille and diffuser volume control registers should be locked to prevent alteration and their final position marked.

#### Room air distribution

- 11.39 The pressure relief dampers and pressure stabilisers will be set to achieve the specified room differential pressures and locked. The grille direction control vanes and diffuser cones will be set to give the specified air movement pattern. Visualisation techniques may need to be employed to prove the required airflow pattern is being achieved and detect any adverse coanda effects (see paragraph 9.162).

**Note:** When balancing combined supply/ extract cascade ventilation systems (for example, operating suites, cleanroom suites), the airflow through the extract terminals in the adjacent corridors may need to be adjusted outside of their original design values in order to achieve the desired room pressure differentials.

#### Air-conditioning plant

- 11.40 The specified flow rate and/or pressure drops will be set for all heater- batteries, cooling coils and humidifiers. The methods described in the CIBSE Commissioning Codes W and R should be followed. On completion their regulating devices will be locked to prevent alteration.

#### Control system

- 11.41 The control system should not be commissioned until both the air distribution system and air-conditioning equipment have been commissioned.
- 11.42 Because of the specialised nature of control systems and the fact that each manufacturer's system will contain its own algorithms and settings, commissioning should be completed by the supplier, and witnessed and documented by a representative of the client (for example, the healthcare organisation's appointed validator).
- 11.43 In the vast majority of healthcare applications, the fan output should be set to give a constant volume of air. This to be controlled by measuring the pressure drop across the fan using a sensing ring and associated volume controller that will automatically integrate the fan factor to determine and control the pre-set output air volume. The fan output will then in air volume terms remain constant regardless of changes of system resistance. The actual volume delivered will be related to the air-change rate for the application.

**Note:** Measuring the air pressure in the main supply duct and using that to set the supply fan speed as a percentage of its rated output and using that to set the extract fan speed as a percentage of the supply fan speed is not a satisfactory, accurate or acceptable way of controlling the desired supply and extract air volumes.

- 11.44 The location of all control and monitoring sensors should be checked and their accuracy proved.
- 11.45 The control system's ability to carry out its specified functions will need to be proved. The correct operation of any alarm systems should also be proved.
- 11.46 If the plant is provided with a "users" control panel in addition to the one located in the plantroom, the operation of both should be proved. This will typically apply to operating departments and laboratory systems.

### Specific performance standards

- 11.47 The performance of the system should be measured and compared with information provided by the designer.

### Plant capacity and control

- 11.48 When setting to work and proving the design, both the manufacturer of the air handling plant and the control specialist should attend site together and jointly commission the system.
- 11.49 If any doubt exists as to the capacity of the installed system, its ability to achieve the specified inside design conditions with the plant operating at winter and summer outside design conditions should be proved. Artificial loads will be required in order to simulate the internal gains/losses and the outside design conditions.
- 11.50 On completion of the plant performance test, recording thermo- hygrographs should be placed in each room/ area served by the plant and also the supply air duct upstream of the fog coil. The plant should be run for 24 hours with all doors closed.

During this period the inside conditions should stay within the tolerances specified. Alternatively, the BMS may be used to obtain the information required.

### Noise levels (general)

- 11.51 The commissioning noise level is that measured with a sound level meter in the unoccupied room, taking account of the external noise together with the noise generated by the ventilation system. Chapter 8 and Table 1 in Chapter 4 give information for many applications.
- 11.52 The noise levels apply at the maximum velocity for which the system is designed to operate. Acoustic commissioning tests should be carried out with all plant and machinery running normally and achieving the design conditions of airflow, temperature and humidity.
- 11.53 An industrial-grade Type 2 sound level meter will normally be sufficient to check the noise level. Its accuracy should be checked using a calibrated sound source before use.
- 11.54 The noise level readings are to be taken at typical normal listening position 1.5 m above floor level and at least 1 m from any surface and not on any line of symmetry. In critical rooms the noise should be measured at the centre of the room and at the centre of each quarter. The mean of the five readings should then be calculated.
- 11.55 In the event of a contractual deficiency a Type 1 precision-grade sound level meter should be used and the noise level determined by the procedure given in Scottish Health Technical Memorandum 08-01.

### Filter challenge

#### General ventilation filters

- 11.56 In-situ performance tests will not normally be required for primary and secondary filters and their housings. However, the filters should be visually inspected for grade, tears, orientation and fit within their housing. Filters should be clean and a replacement set available. Bag filters should be installed so that their bags are vertical and spaced so that air can move through them freely.
- 11.57 Air leakage around a filter housing significantly reduces the filter efficiency. The as-fitted filter housing and access door arrangement should not permit air to bypass.
- EPA or HEPA filters (for exhaust protective enclosures and laboratories)
- 11.58 Pathogenic material may be discharged through damaged or badly installed EPA or HEPA terminal filters. The complete installation should be tested using the method set out in BS EN ISO 14644 and ISO 17141.

The challenge tests may be carried out using either of the following techniques:

- a light scanning airborne particle counter (LSAPC) and a natural challenge to detect leaks;
- dispersed oil particle (DOP) to provide the challenge and a photometer to detect leaks.

- 11.59 In both cases the upstream challenge should be measured. A measurement of particle penetration through a representative section of the EPA filter media is then taken and used as the reference background level. These two readings enable the range of the detecting instrument to be set.
- 11.60 With an LSAPC the filter face is sampled at several points to establish the smallest non-penetrating particle size. This will directly relate to the grade of filter under test. The filter face, its seal and housing are then scanned, and if a significant number of particles at or above this size are detected, there is deemed to be a leak at or near the test position.
- 11.61 With DOP a challenge aerosol of inert particles of the type produced by a dispersed oil particle generator is introduced into the air, upstream of the EPA or HEPA filter. The downstream face of the filter, its mounting seal and housing are then scanned for leakage using a photometer. A leak should be deemed to have occurred if a steady and repeatable reading on the photometer at any point exceeds 0.01% of the upstream reading.
- 11.62 Should the EPA or HEPA filter fail this test, it will be replaced. Should the filter mounting seal or housing fail this test, it may be repaired and the test repeated.

### **Ventilation system commissioning records**

- 11.63 Following commissioning, the main contractor will collate the individual commissioning reports together with the plant user manuals ready for handover.
- 11.64 The fire dampers will have been tested by a specialist, and a written statement detailing which fire dampers were tested, when and by whom should be provided. If any fire dampers in the system were not tested, they should be listed and appended to the statement.
- 11.65 The airflow balancing report compiled by the commissioning engineers should be available to the validator. The report should include copies of the equipment calibration certificates.

## 12. Acceptance Testing: Validation

- 12.1 All new and refurbished ventilation systems should be independently validated prior to acceptance by the client.
- 12.2 Validation differs from commissioning in that its purpose is to look at the complete installation from air intake to extract discharge and assess its "fitness for purpose as a whole". This involves examining the fabric of the building being served by the system and inspecting the ventilation equipment fitted as well as measuring the actual ventilation performance. Validation is not a snagging exercise; see the Note after paragraph 12.30.
- 12.3 Validation is a process of proving that the system in its entirety is fit for purpose and achieves the operating performance originally specified. It will normally be a condition of contract that *"The system will be acceptable to the client if at the time of validation, it is considered fit for purpose and will only require routine maintenance in order to remain so for its projected life."*

### Appointment of validator

- 12.4 In order to ensure that the complete system operates correctly it will be necessary to validate it as a whole from the air intake through to the extract discharge. It is unlikely that the client's in-house staff will possess the knowledge or equipment necessary to undertake this process. Validation should therefore be carried out by a suitably qualified competent engineer appointed by the client. The validator would be the client's AE(V) (see Chapter 2 in Part B of Scottish Health Technical Memorandum 03-01) or someone of similar standing who is familiar with the ventilation requirements for healthcare facilities. They will be completely independent of the system designers, contractors, suppliers, installers, commissioners and those who will subsequently operate and maintain the system.
- 12.5 To retain independence, the validator should be appointed and paid directly by the client. The validator will act as the client's representative to inspect the system, check its performance and recommend acceptance, or not, to the client.

**Note:** "Client" means the healthcare provider, not a contractor or service provider.

### Design proposal review

- 12.6 It is essential that whoever has been appointed to carry out the final validation acceptance of the system should be involved in the initial client's brief and design specification, preferably prior to the project being put out to tender. They will then be fully aware of the client's requirements and any limiting factors.

**Note:** While it is beneficial to involve the client's validator in the design process, it should be remembered that the appointed designer carries the "design risk" and advice from the validator will not obviate this.

- 12.7 It is important that the validator understands the complete project and not just the obvious ventilation aspects. Decisions about the type of ceilings, doors, access

hatches, fire compartmentation, floor markings, room functions, their adjacency and the proposed workflow patterns all have a direct effect on the likelihood of being able to achieve the desired ventilation performance. It is not sufficient to consider the ventilation in isolation.

- 12.8 During this process any derogations proposed by the contractor/supplier should be clearly defined, agreed and documented with the client (for example, through the VSG). All parties will then be clear as to what will be the acceptable standard of installation and performance when finally validated.
- 12.9 The ventilation designer(s) should provide the validator with system information listed in Table 11. The information should be in the form of an annotated drawing for each ventilation system to be validated. They should also provide any other design or specification information that will assist the validation process.
- 12.10 The contract arrangement should give the validator the right to visit the site as often as they deem necessary during the contract period.

### First fix inspection

- 12.11 The validator should carry out a physical walk-around inspection of the installation at a point in the project when the AHU is "on site" and the main and branch ductwork is for the main part installed, but prior to the ductwork being concealed behind wall panelling or ceilings.
- 12.12 If possible, the following airtightness tests should be witnessed during the inspection:
- AHU installation leakage (BS EN 1886);
  - supply and extract duct leakage (BESA DW/143);
  - initial permeability test (see paragraph 12.17).
- 12.13 The quality of the installation, compliance of the AHU, suitability of the basic installation, location and future accessibility of commissioning dampers, location and compliance for testing of fire dampers, etc., can all be assessed during the visit.
- 12.14 When validating large projects that have many AHUs, it is worthwhile to visit the AHU manufacturer to inspect a specimen unit and agree its compliance before all remaining units are built and transported to site. At that time the leakage and deflection tests can be demonstrated by the AHU supplier in their factory.
- 12.15 Once units are delivered to site, it is useful to get all mechanical and electrical services connected to a specimen AHU. The location of pipework joints, drain points, anti-vibration couplings, isolating and control valves can all be agreed, as can the route of cable ways and control wiring. The object will be to create an agreed "exemplar unit". If all other AHUs are installed in an identical fashion, they will normally be considered compliant at the time of final validation.
- 12.16 On completion of the first fix visit the validator should provide the client with a short report identifying items that are not compliant with the specification.

## Permeability testing

12.17 The following areas will require permeability testing:

- isolation suites of any type;
- operating suites of any type;
- pharmacy aseptic preparation facilities;
- IAP cleanrooms in central decontamination units (containment leak test in accordance with BS EN ISO 14644-3:2019);
- category 3 and 4 containment facilities;
- any other area specified within the contract.

The methodology for permeability testing is set out in BSRIA document BTS 3 – 'Air permeability testing of isolation facilities'.

12.18 An initial permeability test should be witnessed at first-fix stage when the envelope of the suite is physically complete but before wall, ceiling and floor finishes are applied. The objective will be to find and eliminate any construction leaks (for example, between a floor slab and curtain wall) before they become covered up during the fit-out stage (see paragraph 10.30).

12.19 A full permeability test in accordance with the methodology given in BSRIA BTS 3 will be carried out at practical completion to ensure that all service penetrations have been adequately sealed.

**Note:** Any leaks discovered during the test are to be sealed at the point of penetration of the building fabric envelope and NOT at the gaps around IPS panels, ceiling hatches or bedhead trunking covers, etc. (see also paragraph 10.30).

## Follow-on inspections

12.20 Dependent on the size and complexity of the installation, a second and further inspection visits may be required. The validator should attend site as frequently as necessary in order to try to eliminate any installation issues as the project develops and while trades are still in attendance, rather than having to resolve them at the time of final acceptance.

## Final acceptance inspection: validation

12.21 The commissioning of a ventilation system will normally be carried out by the suppliers of the various elements. The final acceptance validation will check that all of the elements work as a whole to achieve the project aim.

12.22 The following regime of inspection and testing should be applied to the validation of all new and refurbished ventilation systems. It may also be applied to systems that have undergone significant changes such as the replacement of a fan or other major component.

### Basic requirements

- 12.23 The area served by the ventilation system to be validated should be physically complete with final finishes applied. The doors should fully close against the design pressure differential with IPS panels fitted and any access hatches closed. All ventilation plant serving it should be operating correctly and have been commissioned in accordance with the project contract.

**Note:** In projects on existing sites, the area of the building being built/refurbished is often sealed off from the "in use" part to prevent dust penetration. At final validation the seals need to be at least temporarily breached in order to be able to determine the ventilation performance in "normal" conditions.

If this is not possible, validation will be conditional on a final "actual" performance check when the seal is removed at the time of handover.

- 12.24 The area served should be free of any rubbish, debris, obvious dust and have been wet-mopped before the validation is undertaken.

**Note:** There is no need to clean the area to the point that the validator needs to gown up in order to enter it. A certain amount of disturbance to hatch seals, ceilings, panels, etc. will be inevitable during

the validation process, so the area will require a final "clinical" clean prior to being taken into use.

- 12.25 The validation process should be a continuation of the earlier site inspections and will in many cases be carried out in parallel with the commissioning process.

- 12.26 Unless stated elsewhere in the design specification, the conditions in the principal space served by the ventilation system being validated should be stable and within the given ranges.

Temperature: 18–22°C dry bulb.

Humidity: 30–70% Relative humidity.

- 12.27 Any test or measuring equipment used should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards.

- 12.28 In the case of a noise meter, its "matched sound source" should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

- 12.29 The validator has the right to either witness readings taken by the commissioning team or to independently take such readings and measurements as they deem fit in order to satisfy themselves as to the actual performance of the system.

### Validation process

12.30 The validation process should follow the sequence given below. Any failures discovered during the process should be rectified before continuing. The validator should check the following:

- the location of the air intake and discharge and their position relative to each other and other intakes and discharges;
- inspection and cleaning access to the vermin mesh and as necessary throughout the installation;
- the security, suitability of and access to the AHU location;
- sufficient space and access arrangements for service and maintenance;
- that the AHU is uniquely identified (see paragraph 13.17) and complies with the minimum standards set out in Chapter 9;
- that the AHU and distribution system have been leak-tested and comply with the design;
- that the AHU and supply ductwork system are clean and free of visible dust;
- that all fire and smoke dampers have been inspected and tested for correct installation and operation. A certificate to that effect, signed and dated by the inspector and tester, will be available for inspection;
- that the area served by the ventilation system is complete and free from significant defects that could invalidate the validation process;
- that the supply and extract airflow rates are in accordance with the design +10%; -0% and the system terminals are in balance. Note that the total supply and extract air volumes measured at the AHU should equate to those measured at the terminals. A discrepancy in the totals would indicate a leak in the system which should be resolved before proceeding further;
- that the air-change rate calculated from the measured airflow and room dimensions accords with the design specification;
- that the room differential pressure regime is in accordance with the design and that if pressure stabilisers are fitted, they operate correctly and silently;
- the air velocity at a specific location(s) if required in the application specification;
- that the noise level does not exceed the design value;
- that the system indicators correctly and clearly show whether or not the ventilation system is in an operational state;
- that any user controls fitted operate correctly (for examples of "cause and effect testing", see Appendix 10);
- that the temperature and humidity in the space being ventilated are accurately indicated on the user panel and that they can be adjusted within the specified limits, if applicable;
- that the estates control functions operate correctly and the plant condition is clearly shown both on the plant control panel and at the BMS/ BEMS interface;
- that the fire cause and effect strategy has been demonstrated and operates correctly. This may be carried out by others, in which case a statement signed

and dated by the person carrying out the test will form part of the handover information;

- that any additional tests called for in the project specification have been carried out and witnessed by the validator or the client's appointed expert.

**Note:** Validation is not a "snagging" inspection. The main contractor has presented the installation as being complete, fully commissioned, achieving the specified level of performance and ready for handover. The validator's role is to check on behalf of the client that the contractor is correct in that assertion.

If the validator discovers that there are a significant number of snags and non-compliances, the validation should be terminated. It is the contractor's responsibility to snag the project, carry out remedial works and re-present the installation for acceptance. The validator will then need to repeat the validation process. The client is entitled to deduct any resulting additional validation fees incurred from the contractor.

- 12.31 It is vitally important to complete the validation process before the system is accepted by the client. Due to the nature of the ventilation installation and the intensity of use in the healthcare setting, it will not be possible to correct any faults or non-compliances once the system has been accepted and taken into use. There are also medico-legal aspects around taking a non-compliant system into use. Pre-announced handover or occupancy dates are not a reason for the validator or client to accept a non-compliant installation.

#### **Validation report**

- 12.32 Following validation, a full report detailing the findings will be produced and sent to the client's lead project manager. The report should conclude with a clear statement on whether the system achieved or did not achieve the standard set out in the agreed design specification.

- 12.33 The client's lead project manager should lodge a copy of the validation report with:
- head of the user department;
  - infection prevention and control;
  - estates and facilities.

#### **Additional specialist tests**

- 12.34 Certain critical areas will require additional testing and validation in addition to the process given above.

#### **UCV theatres**

- 12.35 The following regime of inspection and testing should be applied to the validation of new installations designed to provide ultra-clean conditions in an operating suite. The test regime has been devised to ensure that the system as installed fully achieves the operational requirement for these systems as set out in Chapter 8.

#### **UCV canopy validation procedure**

- 12.36 The validation procedure set out in paragraph 12.30 onwards should have been satisfactorily completed prior to attempting to validate the UCV canopy. The

operating suite to be validated should be physically complete with final finishes applied. All ventilation systems serving it should be operating correctly and delivering their design airflow rates.

- 12.37 Tests to validate the suitability and performance of a UCV canopy should be undertaken in the order that they appear below. If an item fails to meet the required standard it should be rectified and successfully retested before passing on to the next test.

#### Summary of test regime

- 12.38 Leakage tests should ensure that:

- the UCV canopy is correctly assembled and sealed so that no air will bypass the filters;
- the canopy terminal filters are correctly sealed in their housings;
- the canopy terminal filters are of a uniform quality and undamaged.

- 12.39 Air velocity measurements should ensure that:

- a sufficient quantity of air is being delivered by the canopy;
- the airflow has sufficient velocity to reach the operating site plane.

- 12.40 An entrainment test should ensure that contaminants arising outside of the UCV canopy footprint are not drawn into it.

- 12.41 Visualisation techniques should gain an understanding of the overall system performance.

- 12.42 Noise measurement should ensure that working conditions are satisfactory.

- 12.43 Control system "cause and effect" checks should ensure that the system operates and indicates as specified (for example, see Appendix 10).

- 12.44 The successful completion of the test regime will ensure that the system will be effective if used correctly.

#### Test and measuring background conditions

- 12.45 The entire theatre suite should be clean and free from debris and visible dust. It should be in a condition that if the validation is successful the suite will only require a final clinical clean before being taken into use (see paragraph 12.24).

- 12.46 All doors should remain closed when readings and scans are being taken.

- 12.47 The conditions in the operating theatre should be stable and within the given ranges.

Temperature: 18–22°C dry bulb.

Humidity: 30–70% Relative humidity.

### Test and measuring equipment

- 12.48 Any test or measuring equipment used should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards.
- 12.49 In the case of a noise meter, its “matched sound source” should have a certificate to prove that it has been calibrated within the previous 12 months at a facility using traceable national standards. The noise meter should be calibrated to the sound source on each occasion that it is used.

### Test grid – vertical flow canopies

- 12.50 A test grid should be constructed on the floor within the UCV canopy footprint as projected by the inside dimensions of the side walls or boundary air curtain. A suitably marked test sheet will provide a consistent standard of test grid.

**Note:** The entire clean zone footprint of the UCV canopy will be designated by a contrasting coloured inlay in the floor covering. A line marked on or cut into the floor covering is not sufficient and will not be accepted.

- 12.51 The test grid should comprise test squares of 280 mm × 280 mm dimension.
- 12.52 The test grid should be aligned along the centre lines of the canopy footprint with its centre under the centre point of the canopy.
- 12.53 Any test square with 80% of its area within the UCV footprint should be used as a test position.
- 12.54 An inner zone will be designated that is not less than 36% of the total footprint. It will be made up of a number of test squares distributed symmetrically about the canopy footprint centre line. Regardless of the size or shape of the canopy footprint, the inner zone will comprise a minimum grid of 6 × 6 test squares.
- 12.55 Unless specified otherwise, a test position should be in the geometric centre of a test square.
- 12.56 Test position 1 will be the left-most test square in the row nearest to the operating theatre wall that houses the theatre control panel. (For an example of a grid for a 2.8 m × 2.8 m canopy, see Figure 11.)

### UCV canopy leakage tests

- 12.57 The diffuser screen fitted below the face of the canopy terminal filters should be lowered or removed while the leakage tests are being carried out.
- 12.58 The installed terminal EPA filters are to be checked to ensure that their grade accords with the design specification and that their performance has been certified by their manufacturer.

### Test equipment

- 12.59 An LSAPC connected to an isokinetic fishtail scanning probe will be used to detect the size and number of particles present.

- 12.60 Spot readings are taken at several filter faces to establish the smallest non-penetrating particle size. If particles at or above this size are detected when subsequent scans are made, there is deemed to be a significant leak at, or near, the test position.

### UCV canopy clean zone leak test

- 12.61 The test will confirm that there is no unfiltered air leakage in the canopy.
- 12.62 The construction joints and service penetration points under the UCV canopy within its side walls or boundary air curtain should be scanned to prove that there are no leaks.

Figure 11: Example of a test grid for a 2.8 m × 2.8 m UCV terminal

**Note:** For larger UCV terminals, add extra (280 mm x 280 mm) test squares symmetrically around the periphery of the grid and increase the inner zone in accordance with the guidance in paragraphs 12.50–12.56 of Scottish Health Technical Memorandum 03-01 Part A.

- 12.63 A leak is defined as a significant and repeatable rise above the background level.

### Terminal EPA filter seal leak test

- 12.64 The test will confirm that there is no unfiltered air bypassing the EPA filter seal.

- 12.65 Each EPA filter seal should be scanned to prove that there are no leaks.

- 12.66 A leak is defined as a significant and repeatable rise above the background level.

### EPA filter media leak test

- 12.67 The test will confirm that the EPA filters have not sustained damage while being installed.

- 12.68 The face of each EPA filter should be scanned to prove that there are no leaks.

- 12.69 A leak is defined as a significant and repeatable rise above the background level.

## Vertical flow UCV canopy air velocity tests

### Test setup

- 12.70 The canopy face diffuser screen should be in place for these tests.
- 12.71 Take spot readings to establish that the room is within the specified temperature and humidity test conditions.
- 12.72 Set out the test grid as described previously.
- 12.73 Swing the operating lamp arms and any other stem arms so that they align to present the least resistance to airflow, are perpendicular to the front edge of the test sheet and face the back edge. Any lamp and equipment heads should as far as practicable be outside of the UCV canopy footprint (see photographs).

### Test instrument

- 12.74 The measuring instrument should be a thermal anemometer with a digital readout. The instrument resolution should be at least 0.01 m/s, have a tolerance of  $\pm 0.015$  m/s or 3% and be calibrated down to 0.15 m/s or lower. An alternative instrument may be used providing it is of no lesser specification.

### Test method

- 12.75 The instrument should be mounted on a test stand and set to take a mean reading over a 10-second sample interval.
- 12.76 The test instrument should record readings automatically for later download or be connected to a printer.
- 12.77 The test stand should be positioned on each test point in turn and the reading taken when the instrument has stabilised.
- 12.78 When taking a reading, the test person should not stand within the same quadrant as the test instrument.
- 12.79 Readings are to be taken at the test positions with the instrument probe facing the wall housing the theatre control panel commencing at the first test position. Readings are taken either working along the rows from left to right or for all test positions in one quadrant at a time.
- 12.80 When all test positions under one half of the canopy have been covered, readings of temperature and humidity are taken at the specified height in the centre of the canopy. The readouts from the theatre control panel should be recorded at this time.
- 12.81 Having completed one half of the test grid, the operating lamp arms and any other stem arms should be swung round through 180° and the test stand reversed so that the wall housing the theatre control panel is behind the test person. Readings are recommenced starting at the right of the test row and working from right to left or a quadrant at a time, as above.

### UCV canopy high level discharge velocity test

- 12.82 Measurements of air velocity are to be taken at every test position 2 m above floor level and the results averaged. The average of the total readings taken is to be not less than:
- 0.38 m/s for a canopy with no side walls or side walls that terminate at 2 m above floor level.
  - 0.30 m/s for a canopy with side walls that terminate 1 m above floor level.
- 12.83 For UCV canopies that are an assembly of two or four units, each fed by a recirculation fan, the average air velocity for each unit should not exceed  $\pm 6\%$  of the measured average velocity for the canopy.

Figure 12: UCV 2m air velocity test set-up

### UCV canopy low level air velocity test

- 12.84 Measurements of air velocity are to be taken at each of the inner zone test positions 1 m above floor level.
- 12.85 The measured velocity at every test position in the inner clean zone should be not less than 0.20 m/s.

Figure 13: UCV 1m air velocity test set-up

### UCV canopy entrainment test

#### Rationale for the entrainment test

- 12.86 The performance of a UCV canopy may be compromised by room air being drawn into the ultra clean airflow, a phenomenon known as entrainment. Significant levels of entrainment could lead to microbial contamination of items left exposed on instrument trolleys laid out beneath the canopy.

- 12.87 UCV canopies having permanently fitted side walls that terminate 1 m above floor level do not need to be tested, as the walls physically prevent entrainment.

#### **Principle of the test**

- 12.88 A source of particles is produced outside of the UCV canopy footprint and is used to challenge the system. A sample probe and detector are placed within the ultra clean airflow and used to determine the percentage penetration of the test particles at predefined locations under the UCV canopy footprint. The source and sample probe are moved in tandem around the UCV canopy and pairs of readings taken at the detector, from which the percentage penetration at specified locations is calculated. The degree of penetration should be below specified maximum limits if entrainment is to be declared not significant.

#### **Test setup**

- 12.89 The challenge will be provided by using non-EPA-filtered air emerging from the preparation room via the pressure stabiliser or transfer grille and ducted to the specified release position.
- 12.90 The canopy face diffuser screen should be in place for these tests.
- 12.91 The test is performed without any theatre equipment in place beneath or closely adjacent to the UCV canopy. All doors in the theatre suite should be closed and remain so for the duration of the test.
- 12.92 The operating lights and support booms should be moved to a central position beneath the canopy and raised to 2 m above floor level, so as not to interfere with the peripheral airflows (see photograph).
- 12.93 Spot readings are taken at the centre of the canopy, 1 m from floor level, to establish that the room is within the specified temperature and humidity limits (see paragraph 12.47).
- 12.94 The test grid is set out as described previously (see paragraph 12.50).

#### **Test equipment**

- 12.95 The source unit will be a fan/blower or other method that ducts non-EPA- filtered air (see paragraph 12.89) and expels it via a delivery head mounted on a test stand or clamped to the UCV canopy sidewall at the specified release position to provide the particle challenge. The challenge air will be delivered vertically downwards from a position 2 m above floor level alongside the outside edge of the side wall or in line with the downward air curtain if the canopy does not have side walls. The challenge airflow velocity should be the same as the measured average velocity at the 2 m level for the canopy under test.

Figure 14 UCV entrainment test setup

12.96 The detector will be an LSAPC capable of sampling a minimum of 28.3 L of air (1 ft<sup>3</sup>) per minute and providing readings for particle sizes from 5  $\mu\text{m}$  to 0.3  $\mu\text{m}$ . Measuring instruments should be compliant with the requirements of BS EN ISO 14644 or ISO 17141 to reflect the type of test. An alternative instrument may be used providing it is of no lesser specification

12.97 The sampling head will be an isokinetic fishtail scanning probe mounted horizontally on a test stand 1 m above floor level and connected to the LSAPC by a hose no longer than 2 m

#### **Test positions and orientation of source and detector sampling probe**

12.98 The test positions will be at the centre of each test square, as defined for the velocity test (see paragraph 12.50).

12.99 For rectangular UCV canopies, measurements of penetration are to be taken at the four corner test squares of the test grid and at intermediate positions along the line of test squares between the corners. The number of intermediate test positions will be

as equally spaced as possible around the periphery, with not fewer than three and not more than five complete test squares between test positions.

- 12.100 A further series of measurements are to be obtained around the periphery of the inner zone (defined in paragraph 12.54). Measurements of penetration are to be taken at the four corner test squares of the inner zone of the test grid and if necessary at intermediate positions along the line of test squares between the corners as equally spaced as possible, with not fewer than three and not more than five complete test squares between test positions.
- 12.101 The centre of the challenge particle source delivery head is aligned with the centre of the designated test square, with its longer edge against the outer edge of the side wall or air curtain and delivering the challenge 2 m above floor level. The air containing challenge particles is directed vertically downward. Where there is physical interference due to obstructions such as gas pendants, the source will be moved to the next available non-obstructed test square location nearest to the stipulated test position. The sampling probe will then also be moved to remain opposite the source.
- 12.102 In the case of non-rectangular canopies, an interpretation of the above strategy should be adopted that will yield a no less searching examination of the unit's ability to control entrainment.

#### Test method

- 12.103 A measurement of particle penetration through a representative section of the EPA filter media is to be taken. The smallest non-penetrating particle size will be used as the reference background level and set in the detector instrument. The detector instrument should be set to take a reading over a 15-second sample interval and record the number of particles at the non-penetrating particle size determined above.
- 12.104 An initial sample of air at the source delivery head should be taken to check that there are sufficient particles of the considered size present. The challenge will be considered suitable if:
- the particles are within the size range 5 to 0.3  $\mu\text{m}$  and thus capable of remaining airborne for a substantial time;
  - the particles should not be able to penetrate the canopy EPA filters in sufficient numbers to cause a background count that is more than 0.1% of the challenge count;
  - the number of particles present will enable a minimum of three logarithm (1000-fold) range of counts to be recorded between the source and background readings. A concentration of approximately 105 particles per cubic metre of source air has been shown to be adequate.

**Note:** The same equipment should be used to measure both the challenge source and penetration so as not to bias results through particle losses within the test equipment.

- 12.105 The sampling probe of the detector instrument is mounted on a test stand with its orifice facing outwards horizontally from the centre of the UCV canopy, 1 m above floor level. The sampling probe will be orientated at right angles to the partial wall

when sampling along the sides of the test grid but will be set to bisect the angle when measuring at the corner test positions. (See Figure 15 for test locations and see photograph of entrainment test equipment in Figure 13.)

- 12.106 The test will commence at the first test position; this being designated the left-most corner of the test grid when facing the wall housing the theatre control panel. The penetration will also be measured at the corresponding test point on the inner zone commencing at the corner nearest to the first test position.

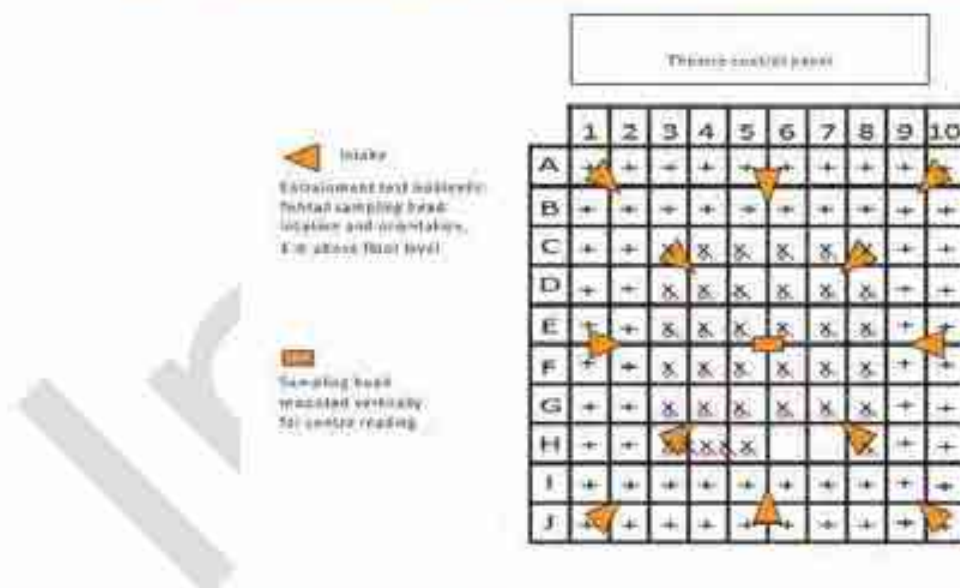

When these tests have been completed, the source distribution head and sampling probe will be moved to the next test positions, working around the test grid in a clockwise direction.

- 12.107 The test stands will be positioned on each test point in turn and a pair of readings (challenge, then penetration) taken when the instrument has stabilised.

- 12.108 When taking a reading, the test person should stay within the UCV canopy footprint but on the side opposite the sampling probe.

- 12.109 A single measurement will be taken at the geometrical centre of the UCV canopy footprint. The centre measurement will be taken with the sampling probe mounted vertically 1 m above floor level

Figure 15: Entrainment test locations for a 2.8 m x2.8 m UCV terminal

**Note:** Test grid layout is as for Figure 11. Entrainment test set-up and guidance is given in paragraphs 12.86 onwards.

For this test the challenge source distribution head will be placed at the test position that yielded the greatest penetration at the periphery of the canopy footprint.

### Analysis and Interpretation

- 12.110 The following standard is to be achieved:

- penetration to be no greater than 10% of the challenge at each test position in the outer zone;

- penetration to be no greater than 1% of the challenge at each test position in the inner zone;
- penetration to be no greater than 0.1% of the challenge at the centre of the test grid.

12.111 If a result is close to or above the given limits, a further reading should be obtained using a longer time base (1 minute) and the penetration should not exceed the given limit.

#### **UCV canopy flow visualisation**

12.112 The use of smoke to gain an understanding of the overall performance of the canopy may prove useful at this stage in the validation process but cannot be relied on to produce a contractually definitive measure of performance.

#### **UCV canopy noise level**

12.113 An industrial-grade sound level meter to BS EN 61672 Type 2 fitted with a muff will be used to check the noise level. The instrument should be calibrated using a matched sound source prior to each set of readings.

12.114 The noise level readings are to be taken at a typical normal listening position 1.5 m above floor level and at least 1 m from any surface and not on any line of symmetry. Measurements should be taken under the centre of each quadrant and in the centre of the canopy, and the five readings averaged.

12.115 The readings should be taken with the UCV canopy at operational speed and repeated with it at set back.

12.116 For UCV operating suites, the noise level should not exceed:

- operating theatre and spaces without doors that are open to it (for example, the scrub): 53 dB(A);
- all other peripheral rooms of the suite: 48 dB(A).

#### **UCV terminal control system checks**

##### **Temperature**

12.117 The readings of temperature taken under the UCV canopy should be within  $\pm 1^{\circ}\text{C}$  of the readout on the theatre control panel.

##### **Humidity**

12.118 The readings of humidity taken under the UCV canopy should be within  $\pm 5\%$  RH of the readout on the theatre control panel.

##### **Direct reading differential pressure gauges**

12.119 The differential pressure across the terminal filter should be measured to confirm the accuracy of the indicated reading of any gauge.

### Control functions

- 12.120 The operation of all control functions provided on the theatre control panel should be checked for conformity with the design specification (see Appendix 10).
- 12.121 If an auxiliary panel has been fitted, its interlocking with the main theatre control panel control functions will be checked for conformity with the design specification.

### Panel indicator lights

- 12.122 The panel indicators should illuminate as appropriate when the control functions are selected, or warning levels are reached (see Appendix 10 for an example "cause and effect" test regime).

### BMS interface

- 12.123 The operation, monitoring and alarm functions should be checked for conformity with those set out in the design specification.

### UCV theatre microbiological tests

- 12.124 There is little value in performing microbiological sampling in an empty operating theatre supplied with ultra clean ventilation. The foregoing filter challenge tests, air velocity measurements and entrainment test will have proved that the system operates satisfactorily and achieves the contracted level of performance. The EPA filters will remove bacteria-sized particles from the air supplied through the UCV canopy. Therefore, there will be an insignificant number of bacterial and/or fungal cfus present until the theatre is actually used.
- 12.125 Following full validation, in-use microbiological sampling during a surgical procedure will not be required unless specified by the client's VSG.

### UCV operating suite validation report

- 12.126 Following validation, a full report detailing the findings will be produced and sent to the client's lead project manager. The report should conclude with a clear statement on whether the UCV operating suite as a whole achieved or did not achieve the standard set out in the agreed design specification.
- 12.127 The client's lead project manager should lodge a copy of the report with:
- theatre manager;
  - infection prevention and control;
  - estates and facilities.

### Pharmacy aseptic preparation facilities

- 12.128 The following regime of inspection and testing should be applied to the validation of new installations. The test regime has been devised to ensure that the system as installed fully achieves the operational requirement for these systems as set out in EUGGMP and the design specification.

**Basic requirement**

- 12.129 The validation procedure set out in paragraphs 12.1–12.33 should have been satisfactorily completed prior to attempting to validate the aseptic preparation facility. The suite to be validated should be physically complete with final finishes applied and have been completely cleaned. All ventilation systems serving it should be operating correctly and delivering their design airflow rates.

**Aseptic preparation facility validation procedure**

- 12.130 Tests to validate the suitability and performance of the aseptic preparation facility should be undertaken in the order that they appear below. Should an item fail to meet the required standard it should be rectified and successfully retested before passing on to the next test.

**Summary of test regime**

- 12.131 Challenge tests should ensure that:

- the supply terminal HEPA filters are sealed in their housings so that no air will bypass them;
- the terminal filters are of a uniform quality and undamaged.

- 12.132 Differential pressure measurements should ensure the correct pressure cascade.

- 12.133 Particle counting should be carried out at a specified number of test positions in order to determine the individual cleanroom classification in accordance with ISO EN 14644 and ISO 17141.

- 12.134 Control system checks should ensure that the system operates as specified.

- 12.135 Microbiological sampling should check the air quality.

**Test and measuring conditions**

- 12.136 While validating the aseptic preparation facility, the conditions in the cleanrooms should be stable and within the given ranges.

Temperature: 19–23°C dry bulb.

Humidity: 30–70% relative humidity.

**Test and measuring equipment**

- 12.137 Any test or measuring equipment used should have a certificate to prove that its calibration has been checked within the previous 12 months at a facility using traceable national standards.

**Supply terminal EPA or HEPA filter seal leak test**

- 12.138 The test will confirm that there is no unfiltered air bypassing the EPA or HEPA filter seal.

- 12.139 Each EPA or HEPA filter seal should be scanned using a light scattering airborne particle counter (LSAPC) to prove that there are no leaks.

- 12.140 A spot reading will be taken at the face of the filter to determine the background particle level. A leak is defined as a significant and repeatable rise above the background level.

#### **Terminal (EPA or HEPA) filter media leak test**

- 12.141 The test will confirm that the terminal filters have not sustained damage while being installed.
- 12.142 The face of each terminal filter should be scanned using an LSAPC to prove that there are no leaks.
- 12.143 A leak is defined as a significant and repeatable rise above the background level.

#### **Cleanroom particle count**

- 12.144 The test will confirm the number and size of particles present and therefore the classification of the cleanroom in terms of ISO 14644 or EUGGMP as specified in the project brief.
- 12.145 The number of test positions is determined by reference to Table A.1 in ISO 14644-1.
- 12.146 The complete test methodology will be as set out in ISO 14644.

#### **Cleanroom biocontamination control**

- 12.147 BS EN 17141 gives details on cleanroom biocontamination control.

#### **Radiopharmacy aseptic preparation facilities**

- 12.148 Validation will be as for a pharmacy aseptic preparation facility.
- 12.149 Additional radiological tests as specified in the project brief will be required. These will be carried out and/or witnessed by the client's appointed specialist.

#### **Inspection, assembly and packing (IAP) rooms in central decontamination units**

- 12.150 Validation will be as for the standard practice described in paragraphs 12.1–12.33.
- 12.151 The pressure cascade and associated automatic monitoring sensors and alarms should be tested for correct operation in accordance with the design specification.

**Note:** The detail of the sealing between the instrument washers, transfer hatches and sterilizers that penetrate the walls of the IAP room will be critical in attaining the specified room pressure.

- 12.152 Following the satisfactory validation, the IAP room should be physically cleaned using specialist contractors. Particle counts at locations related to the floor area as set out in table A.1 of ISO 14644 Part 1, along with instructions from ISO 17141 will then be used to establish whether the room achieves a Class 8 cleanroom standard.

### Containment level 3 laboratories

- 12.153 Validation will be as for the standard practice described in paragraphs 12.1–12.33.
- 12.154 The room will be subject to a permeability test as set out in paragraph 12.17.
- 12.155 The pressure cascade and associated automatic monitoring sensors and alarms should be tested for correct operation in accordance with the design specification.

### Isolation rooms

- 12.156 Validation will be as for the standard practice described in paragraphs 12.1–12.33.
- 12.157 See Scottish Health Planning Note 4 Supplement 1 for details of the test regime.

### Microbiological sampling

- 12.158 It is essential that all parts of the validation test specified above have been successfully completed and the areas thoroughly cleaned prior to any microbiological sampling.
- 12.159 Microbiological sampling will not normally be required for either general or local exhaust ventilation (LEV) systems unless otherwise specified within the contract.
- 12.160 The procedure for carrying out microbiological sampling in cleanrooms is set out in ISO 17141.

### Microbiological sampling conventional theatres

- 12.161 The level of airborne bacteria introduced by the supply air can be checked by closing all doors and leaving the operating room empty with the ventilation system running for 15 minutes. An active air sampler set to 1 cubic metre and mounted on the operating table should then be activated remotely. Aerobic cultures on non-selective media should not exceed 10 bacterial and/or fungal colony forming units per cubic metre (CFU/m<sup>3</sup>).
- 12.162 The results should be examined to establish the broad category of organisms present. A high preponderance of fungal organisms may be an indication of inadequate filtration for the particular installation. Precise guidance is inappropriate and will depend on local circumstances.
- 12.163 It may be appropriate to carry out a check of airborne bacteria during a surgical operation. If required, this should be carried out as soon as possible after handover. Unless there are unusually high numbers of personnel or extensive activity in the room, the number of airborne bacterial and/or fungal CFU averaged over any five-minute period, would be unlikely to exceed 180 per cubic metre.
- 12.164 Information on the microbiological testing of UCV Operating suites is given in clauses 12.124 and 12.125.

## 13. Information

---

### Records required

- 13.1 There is a requirement under the Building Regulations to provide documentary evidence of the design, commissioning and subsequent performance of ventilation systems as well as recommended maintenance routines (Building Regulations, 2010, Part 8, Paragraph 39).
- 13.2 Electronic records should be in a format that is compatible with the client's archive and retrieval system.

### Handover

- 13.3 The following general information is required at plant handover:
- "as fitted" drawings of the plant showing the location of all items and listing the size of ducts, grilles and diffusers together with their factors;
  - "schematic" drawing of the air distribution system showing design and actual airflows from all outlets together with the design and actual airflows in each duct. The duct centre correction factors should be given and the grille factors;
  - the location of all volume control dampers should be marked on the "as fitted" and "schematic" drawings;
  - a floor plan of the area served by the plant showing all doorways, hatches, transfer grilles, pressure relief dampers, pressure stabilisers, supply and extract terminals. The total supply and extract volumes should be shown for each room served by the plant. The volume flow and direction of flow through transfer grilles, pressure relief dampers and pressure stabilisers should also be shown, together with the room pressures in pascals measured with regard to atmospheric pressure. For operating suites the "key" door should be identified;
  - a fire plan of the area served showing the fire zone and location of all fire and smoke dampers and detectors. An explanation of the ventilation strategy in the event of an in-zone fire, adjacent zone fire or smoke being drawn into the airhandling unit from an outside source should be provided.
  - wiring diagrams for all electrical equipment associated with the air handling systems including motor control circuit details and any interlocking and safety devices such as emergency stop buttons adjacent to the item of plant;
  - manufacturer's operating instructions and "setting to work" guidance for all specialist components incorporated in the systems;
    - a schematic of the control system showing the location of all plant sensors;
    - control algorithm(s) of the actual plant operation and the set points entered during commissioning together with the control panel access codes and keys.

### Plant design information

- 13.4 The following plant design information is required at plant handover:

- a simple statement of the design intent;
- a description of the plant's intended mode of operation;
- winter outside design temperature in °Cdb;
- winter outside design humidity in % saturation;
- winter room supply air design temperature in °Cdb;
- winter room supply air design humidity in % saturation;
- winter inside design temperature for each room in °C;
- winter inside design humidity for each room in % saturation;
- summer outside design temperature in °Cdb;
- summer outside design humidity in % saturation;
- summer room supply air design temperature in °Cdb;
- summer room supply air design humidity in % saturation;
- summer inside design temperature for each room in °C;
- summer inside design humidity for each room in % saturation;
- winter psychrometric chart showing the condition of the air between all items of plant and the design outside, supply and room air conditions;
- summer psychrometric chart showing the condition of the air between all items of plant and the design outside, supply and room air conditions;
- the design mass airflow rate used to size the plant in kg/s;
- the design volumetric flow rate in m<sup>3</sup>/s.

### Individual equipment information

#### Heater-batteries including energy recovery

13.5 The following information concerning heater-batteries is required at plant handover:

- the size of the battery, number of passes and fin spacing;
- the design flow and return temperatures and flow rate in L/s;
- the pressure drop across the water side of the battery in Pa;
- the number of phases, supply voltage, current drawn and number of steps if electric;
- the maximum rated capacity of the battery and actual design rating in kW;
- the design and actual face velocity in m/s;
- the pressure drop across the air side of the battery in Pa;
- the design on and off coil air temperature and humidity at winter and summer design conditions

#### Cooling coils

13.6 The following information concerning cooling coils is required at plant handover:

- the size of coil, number of passes and fin spacing;
- the design flow and return temperatures and flow rate in L/s if chilled water;
- the pressure drop across the water side of the coil in Pa;
- the supply pressure and mass flow rate if direct expansion;
- the maximum rated capacity of the coil and actual design rating in kW;
- the contact factor;
- the design sensible and latent cooling loads in kW;
- the design and actual face velocity in m/s;
- the pressure drop across the air side of the coil in Pa;
- the design on and off coil air temperature and humidity at summer design conditions.

### Humidifiers

13.7 The following information concerning humidifiers is required at plant handover:

- the size of the humidifier and number of lances;
- the supply pressure and mass flow rate of the steam;
- the number of phases, supply voltage, current drawn and number of steps if electric;
- the maximum rated capacity of the humidifier and actual design rating in L/hour;
- the design and actual face velocity in m/s;
- the design upstream and downstream air temperature and humidity at winter design conditions

### Filters

13.8 The following information concerning filters is required at plant handover:

- the size of the filter and number in bank;
- its grade;
- the design and actual face velocity in m/s;
- the initial pressure drop across the filter when clean in Pa;
- the final pressure drop across the filter when dirty in Pa;
- the manufacturer's name and filter identification code.

### Fans

13.9 The following information concerning fans is required at plant handover:

- the size of the fan and its type;
- the fan curve;
- speed and direction of rotation;

- the drive motor frame size;
- the number of phases, voltage and maximum design and actual current drawn;
- the design and actual delivered air volume in m<sup>3</sup>/s;
- the fan suction pressure at high and low speed in Pa;
- the fan delivery pressure at high and low speed in Pa;

### Attenuators

13.10 The following information concerning attenuators is required at plant handover:

- the size of the attenuator and number in bank;
- the design and actual face velocity in m/s;
- the initial pressure drop across the attenuator in Pa;
- the upstream sound level in dB(A); the downstream sound level in dB(A).

### System information

13.11 The preservation of information and records of ventilation systems and their performance is a legal requirement. It is therefore essential that when new systems are completed, full information as to their purpose, design, layout and actual commissioned performance are handed on to the client. If any derogations were agreed from this standard, they should be noted and the reason for them explained. The system information if electronic (for example, BIM model) should be in a form that is compatible with the client's IT standard and can be accessed and searched by it.

13.12 In new "green field" developments an inventory of the installed ventilation systems should be compiled. In existing developments the client will normally have an inventory of their installed systems, and all new systems should be added to it.

13.13 The inventory will be subdivided into the following categories:

- local exhaust ventilation systems (LEV) – note these are statutory items;
- critical healthcare ventilation systems (CHV).

(These are systems the loss of which would seriously limit the delivery of healthcare – for example, operating suite, SCBU, critical care areas, interventional imaging suite, aseptic preparation facility.)

- general ventilation system [supply and extract] (GVS);
- general extract systems (GES);
- systems installed for smoke clearance in the event of a fire, classed as smoke and heat exhaust ventilation systems;
- – (SHEVS) (for example, smoke extract fans in stairwells, automatic smoke clearance dampers in atria).

**Note:** During the design and contract process, ventilation systems are often given "construction" codes for drawing reference and site identification purposes. It is

imperative that prior to handover the actual identification codes and labels affixed to the systems conform to the inventory in use at the site or desired by the client. Each system code should be unique and conform to the categorisation format for the client's inventory given above.

For ease of future reference, a list of design and construction references for drawings and plant, cross-referenced to the client's building designations and plant inventory codes, should be produced.

- 13.14 For each ventilation system the inventory should contain the following details:
- a unique system identification code (for example, LEV 001; CHV 001) as appropriate;
  - the location of the ventilation fan unit or supply and extract AHU(s);
  - the location of the fresh air inlet;
  - the location of the extracted air discharge;
  - the specific area(s) served by the system;
  - the date the system was installed;
  - the date the system was validated and accepted by the client.
- 13.15 Each ventilation system should have a logbook (physical or electronic) that contains the following information:
- the unique system identification reference;
  - purpose of the system;
  - date of installation;
  - details of the installed equipment and ductwork layout;
  - detail of the fire plan and location of fire and smoke dampers;
  - design performance parameters (for example, airflow rates, air-change rates, pressures);
  - commissioned date and performance;
  - record of the system validation and acceptance;
  - records of the annual inspection and verification;
  - maintenance records and plant information (for example, fan specifications and filter sizes).
- 13.16 The records should be linked to the inventory and stored in such a way as to be readily available in the event of plant breakdown or other incident.
- 13.17 Every ventilation system should be clearly identified with a permanent label. The label should show in lettering 100 mm high the inventory reference code of the AHU and clearly identify the area that it serves. The label should be mounted with screws or rivets in an easily visible place near the fan of the unit adjacent to the local electrical isolator. The system control panel should have a duplicate label. Any subsystems and the principal branch ducts should be similarly labelled.

- 13.18 The nature of air and direction of flow should be clearly marked on all ducts using the symbols given in BS 1710.
- 13.19 All airflow test-points should be clearly identified with a permanent label and the design information given (for example, TPS 1 – Anaesthetic supply; 400 × 300; Design 185 L/s).
- 13.20 If two ventilation systems supply a common room or an outlier from another zone, the room identification label should state the relevant ventilation identification codes, for example: Theatres 5&6 Utility; [CHV 012 and CHV 015], as should the labels on their individual AHUs.
- 13.21 Any ventilation system that conveys a hazardous substance or is affected by a hazardous radiation must be clearly marked with the appropriate symbol.

### **Fire and smoke dampers**

- 13.22 A complete schedule of dampers fitted, their location and unique identification code should be provided.
- 13.23 A statement of when they were tested and by whom should be included.

### **Spares**

- 13.24 Unless otherwise agreed with the site maintenance department, spares should be stored on a rack in the entrance of the relevant plantroom and preserved from casual damage or contamination.
- 13.25 The scale of spare fans to be provided should relate to the number of AHUs using fans of the same size. The spare fans should be pre-wired with power and control connectors so that when used they are plug and play.
- 13.26 A complete set of new filters should be handed over.
- 13.27 A complete set of any other consumable item installed in the installation should be handed over.

### **BIM status**

- 13.28 If the installation was modelled using BIM during construction, the BIM model should be brought up to date and all asset tags incorporated prior to handover.
- 13.29 Training for estates staff who will be tasked with keeping the BIM model in date should be given, ideally while the original BIM team is available.

### **Maintenance routines**

- 13.30 Any product or installation-specific maintenance routines should form part of the handover documentation and, if necessary, training.
- 13.31 Information on routine inspection and maintenance is given in Part B of Scottish Health Technical Memorandum 03-01.

### Expected service life

- 13.32 Air handling units (AHUs) have an expected service life of 20 years. Part B of this SHTM states that ventilation systems should be taken out of service, deep cleaned, their controls renewed and recommissioned after 10 years. The handover information will both assist this process and help inform the selection of replacement plant.

### Additional end user information

- 13.33 The information itemised above is intended to fulfil the contract requirement and provide a record for the client and their appointed operational management and maintenance teams. There is also a need in some circumstances to provide the end-user with information as to the role that them and their patients from airborne contaminants.
- 13.34 In operating suites and interventional imaging suites of any type, a simplified plan of the suite showing the principal direction of air movement should be displayed at the entrance to the suite. The following bullet points should be appended to the plan:
- the air supplied to each room is intended to dilute any airborne contaminants;
  - the airflow between rooms will ensure that contaminants do not enter;
  - people are the main source of airborne contaminants; they disperse such contaminants as they move around: the more people, the more movements, the more airborne contaminants;
  - optimum conditions exist when all doors are closed;
  - in order to ensure that the system operates correctly and efficiently:
    - routine checks should be carried out of the system performance;
    - the system should be taken out of use periodically to carry out essential maintenance.
- 13.35 The VSG should advise if other applications require similar explanatory information.

### Staff training

- 13.36 On completion of the project, training in the correct use, operation and routine maintenance of the installed systems should be given as appropriate to the following staff groups:
- the end-users;
  - those who will operate and maintain the installed systems.

Note: Other configurations are possible

**Figure A3: Schematic of typical double-stacked Cabinet AHU with energy recovery by plate heat exchanger**

Note: Other configurations of the fan positions are possible

### Cabinet AHU

**Figure A4: Schematic of typical cabinet-style AHU with energy recovery by run-around coil**

Note: Other types of compact vertical AHUs are possible

## Appendix 2: Summary of design conditions

Table A1 Design conditions for miscellaneous rooms

Application	Ventilation	Air-change rate (ac/h)	Pressure (Pascal Pa)	Supply filter grade (BS EN 16798 or BS EN 1822-1)	Noise (dB(A))	Temp (°C)	Comments (for further information see Chapter 8)
General ward (level 0 and 1 care)	S/N	6	–	SUP2	35	18–28	
Communal ward toilet	E	6	–ve	–	45	–	
Single room	S/E/N	6	0 or –ve	SUP2	35	18–28	
Single room WC	E	>10	–ve	–	45	–	
Clean utility	S	6	+ve	SUP3	45	18–22	
Dirty utility	E	6	–ve	–	45	–	
Ward isolation room (PPVL)	S	10	Lobby +10 Room 0	SUP2	35	–	See Scottish Health Planning Note 4 (Supplement 1)
Infectious diseases isolation room	E	10	–5	SUP2	35	–	See Table 4
Neutropaenic patient ward	S	10	+10	E12	35	–	See Table 3
Critical care areas (Level 2 and 3 care)	S	10	+10	SUP1	35	–	Isolation room may be –ve pressure or PPVL. See Table 3
Birthing room	S & E	10	0	SUP2	45	20–25	See Table 5
NICU/SCBU	S & E	10	+ve	SUP1	35	20–28	Isolation room may be –ve pressure
Operating department recovery room	S & E	15	0	SUP2	45	18–25	Provide clean airflow path
Catheterisation room	S & E	10	+ve	SUP2	45	18–22	
Interventional or non-interventional Imaging room of any type	S & E	10	+ve	SUP2	48	–	Stable conditions as specified for the imaging equipment
Sedation recovery room as in paragraph 8.16	S & E	15	S/E	SUP2	45	18–28	
Endoscopic procedure room	S & E	15	–5	SUP2	40	20–25	See Table 2
Endoscope reprocessing wash room	E	10	–ve	–	45	–	
General treatment room	S & E	10	Neutral	SUP2	45	20–25	See Table 2
Emergency department waiting area	S & E	6	–	SUP2	–	18–25	See Table 2

Application	Ventilation	Air-change rate (ac/h)	Pressure (Pascal Pa)	Supply filter grade (BS EN 16798 or BS EN 1822-1)	Noise (dB(A))	Temp (°C)	Comments (for further information see Chapter 8)
Containment level 3 laboratory	#	>20	#	H14*	–	18–22	# See ACDP guide: *Filter in extract See Table 4
Post-mortem room	S & E	S = 10 E = 12	–ve	SUP2	45	18–22	Provide clean airflow path
Specimen store	E	–	–ve	–	–	–	Fan accessible from outside of store

## Notes:

For general and UCV operating suites and associated rooms, see specific guidance in Chapter 8 and typical design solutions in Appendix 7

Waiting and circulation areas should be directly or indirectly ventilated to provide a comfortable environment and control airborne contamination and odours.

**18–22°C** indicates the range over which the temperature may float.

18–22°C indicates the range over which the temperature should be capable of being controlled at any point within that range.

S = Supply

E = Extract

N = Natural ventilation where possible where natural ventilation is used the design must reflect clauses 5.2 to 5.9

SUP refers to the supply air quality as defined in BS EN 16798

## Appendix 3: Hierarchy of cleanliness

Table A2 Hierarchy of cleanliness

Class	Room	Nominal pressure (Pa) <sup>a</sup>	Airflow rate for bacterial contaminant dilution Flow in or supply (m <sup>3</sup> /s)	Flow out or extract(m <sup>3</sup> /s)
Sterile	Preparation room	35	See standard schemes in Appendix 7 and detailed calculation process in Appendix 8 for recommended design values	
	lay-up	25		
	sterile pack store	25		
	Operating theatre Scrub bay	25		
Clean	Sterile pack store Anaesthetic room	+ve 15c	6 ac/h	–
	Scrub room	15	The greater of 15 ac/h or 0.15 –	The greater of 15 ac/h or 0.15 0.10 mind
Transitional	Recovery room	0	15 ac/he (See note f) (See note f) 7 ac/h	15 ac/he
	Clean corridor	0		7 ac/h
	General access corridor	0		7 ac/h
	Changing rooms	3		7 ac/h
Dirty	Service corridor	0	–	(See note g)
	Utility room	–5 or 0	–	0.40 or 0.10

### Notes:

Nominal room pressures are given to facilitate setting up of pressure-relief dampers, the calculation process, and the sizing of transfer devices. In practice, the resultant pressures are not immutable provided the desired airflow rates and movement directions are achieved.

An open or semi-open bay is considered to be part of the operating theatre; a low-level extract under the scrub trough is required. (See Chapter 8 paragraph 8.45 onwards and "Note" for more information.)

For design purposes, anaesthetic should be assumed to be at 15 Pa. When commissioning, equal to or greater than 10 Pa is considered suitable.

May need to be increased if scrub is large to promote scouring.

15 ac/h is considered necessary for the control of anaesthetic gas (see Appendix 9).

Supply airflow rate necessary to make up 7 ac/h after taking into account secondary air from cleaner areas.

No dilution requirement. Temperature control requirements only.

## Appendix 4: Leakage flows in m<sup>3</sup>/s through closed door gaps

### Pressure difference (Pa)

Table A3 Leakage flows through closed door gaps

Type	5	10	15	20	25	30	35	40
Single door	0.03	0.05	0.06	0.06	0.07	0.08	0.09	0.10
Single door + half	0.04	0.06	0.07	0.08	0.09	0.10	0.11	0.12
Double door	0.05	0.08	0.10	0.11	0.12	0.13	0.14	0.15

#### Designers' notes:

The door gaps assumed are 4 mm along the bottom, 3 mm at the top and sides, and 2 mm between double leaves.

If doors are fitted with cold smoke seals, these will significantly reduce the door leakage rate when new and undamaged. It is therefore recommended that provision for the design leakage be factored into the size of the appropriate transfer grille or pressure stabiliser. Failure to do this will result in air-gap whistles and doors being held partially open by air pressure.

Factory-assembled door-sets with a steel frame and pre-hung leaves are becoming common. There is effectively no leakage across these doors when closed. Therefore, when this type of door assembly is fitted, the door leakage can be ignored and the design airflow into the room reduced accordingly. The design airflow would then become that required either (i) for open door protection (Appendix 5), or (ii) to achieve the specified air-change rate – whichever is the greater.

## Appendix 5: Recommended airflow rates in m<sup>3</sup>/s through a doorway between rooms of different cleanliness to control cross-contamination

Table A4 Flows through doorways

Room class		Dirty	Transitional	Clean	Sterile
Sterile	Hatch	0.3	0.24	0.18	
	Single door	0.47	0.39	0.28	0 or 0.28a
	Double door	0.95	0.75	0.57	0 or 0.57a
Clean	Single door	0.39	0.28	0 or 0.28a	
	Double door	0.75	0.57	0 or 0.57a	
Transitional	Single door	0.28	0 or 0.28a		
	Double door	0.57	0 or 0.57a		
Dirty	Single door	0	Open single door = 0.80 m x 2.01 m high	Open single door = 0.80 m x 2.01 m high	Open single door = 0.80 m x 2.01 m high
	Double door	0	Open double door = 1.80 m x 2.01 m high	Open double door = 1.80 m x 2.01 m high	Open double door = 1.80 m x 2.01 m high

### Designers' notes:

The degree of protection required at an open doorway between rooms is dependent on the degree of difference in cleanliness between them.

Flow-rate required between rooms within the same class tends to zero as class reduces.

If two rooms are of equal cleanliness, no flow is required (in practice there will be an interchange in either direction) and the design of the air movement will assume zero airflow. In certain cases, however, interchange is not permitted, and a protection airflow of 0.28 is assumed in the design – for example, in the case of a preparation room used as a "lay up".

## Appendix 6: Typical approximate pressures in an operating suite when a given door is open

### Typical approximate effect on other rooms

Table A5 Pressure in room with open door

Door open between	Typical approximate resultant	Room	Pressure (Pa) pressure in these rooms (Pa)
Operating theatre and corridor or Scrub bay and corridor	0	Anaesthetic Preparation – lay-up Utility Preparation – sterile pack store	0 12 -6 5
Operating theatre and anaesthetic room (or other series room with double doors)	17	Preparation – lay-up Utility Preparation – sterile pack store	26 -9 22
Operating theatre and Utility room or Operating theatre and preparation room	25	No change	
Anaesthetic room and corridor (or other series room with double doors)	0	Preparation – lay-up Utility Operating theatre Preparation – sterile pack store	30 -6 20 25
Preparation room and corridor or Utility room and corridor	0	No change	
Utility room and outer corridor	0	No change	

#### Notes:

The room differential pressure protects against reverse flows when the door is closed.

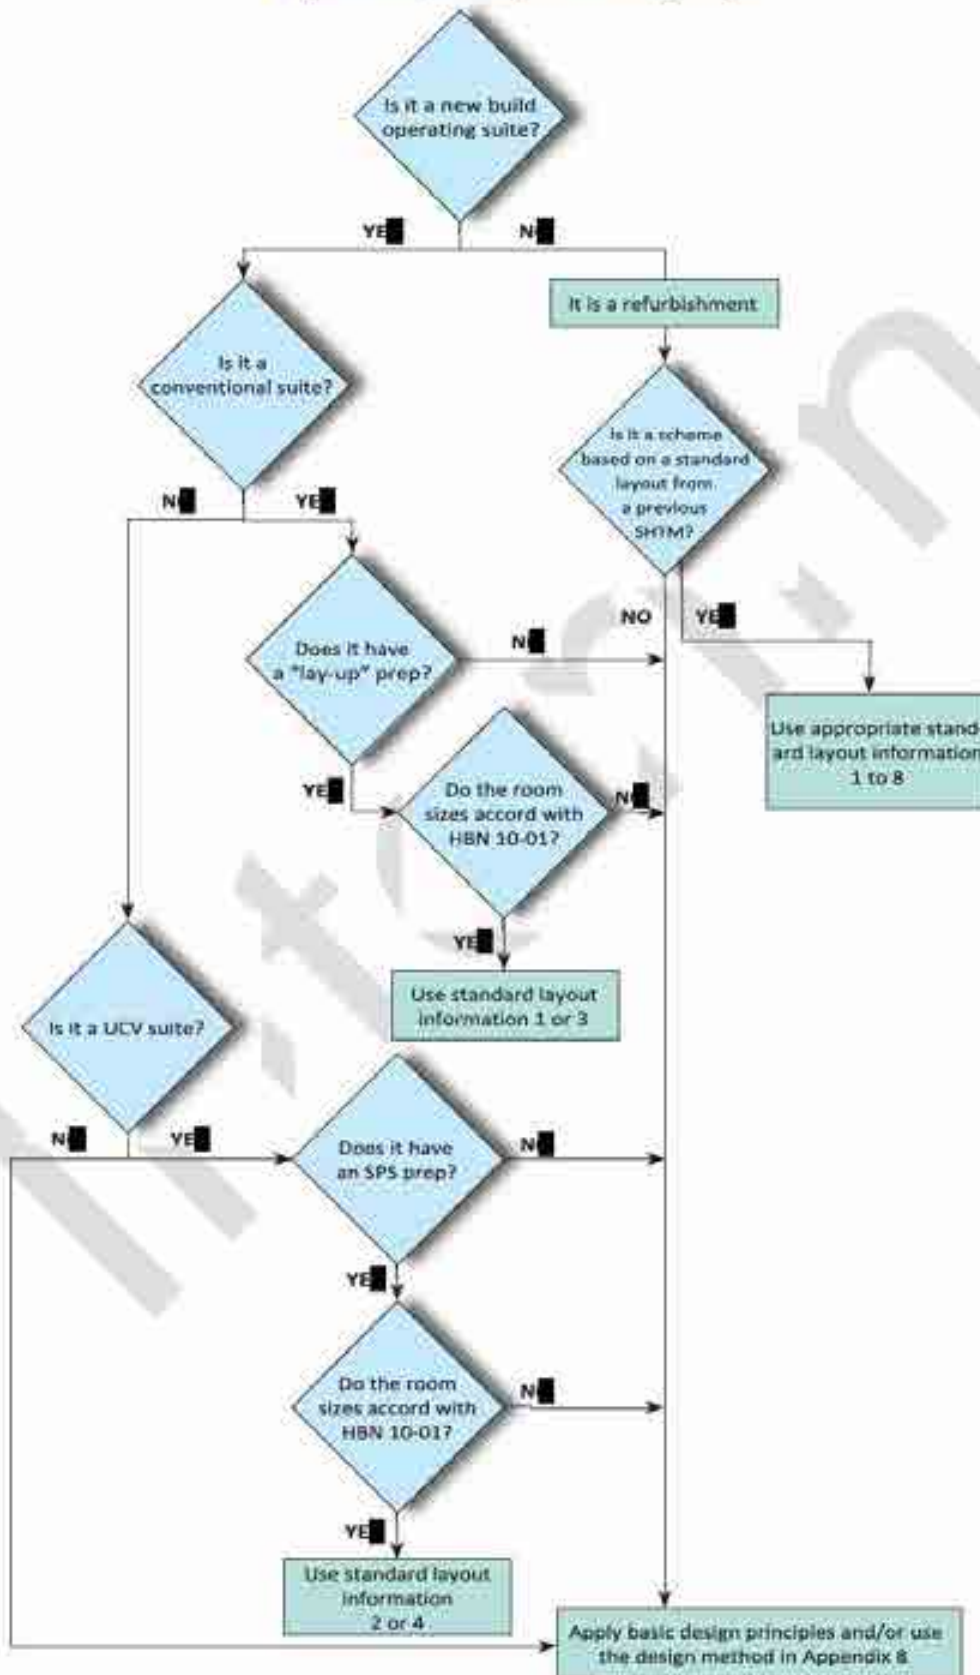

The flow of air through a doorway protects against reverse airflow when the door is open.

Pressure stabilisers control flow and ensure a known airflow path between rooms when doors are closed and also reduce backflow between rooms when doors to other rooms are open.

# Appendix 7: Operating suite design logic

Figure A5 Operating suite design logic

## Standard layout 1 – Two-corridor conventional operating suite with “lay-up” prep

Table A6 Two corridor conventional operating suite with “lay up” prep design criteria

Room	Size (m3)‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m3/s)
Theatre	165	≥22	25	Primary = 0.73 From Prep = 0.28 Total = 1.010
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Lay-up prep	36	≥22	35	0.28**
Scrub	*	–	25	–

Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

\*This is a separate scrub and is not considered as being part of the theatre volume.

\*\*Interchange is not permitted between the theatre and lay-up prep; therefore, as in Appendix 5, an airflow protection of

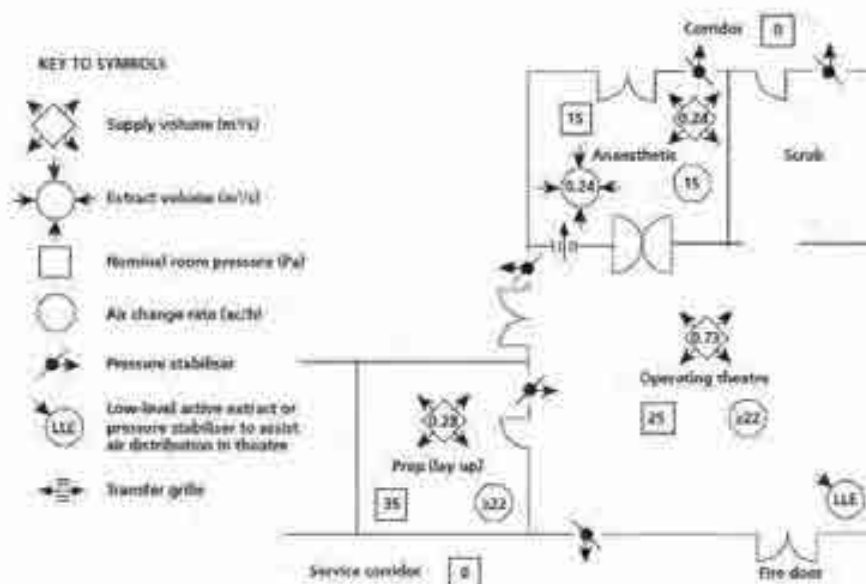

0.28 m3/s is required as a minimum (but see also the “designers’ notes” in Appendix 4).

N.B.If the lay-up prep also has a door or hatch to the corridor, its supply airflow volume would increase to 0.35 m3/s

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the key door from the total air entering the space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A6 Two corridor conventional operating suite with "lay up" prep, schematic layout

## Standard layout 2 – two-corridor UCV operating suite with SPS prep

Table A7 Two corridor UCV operating suite with SPS design criteria

Room	Size (m <sup>3</sup> )‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	165	≥22	25	# 1.01
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Sterile pack store prep	36	10	25	0.10
Scrub	*	–	25	–

### Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

\* This is a separate scrub and is not considered as being part of theatre volume.

# Primary fresh-air volume to UCV canopy only or ≥22 or door protection

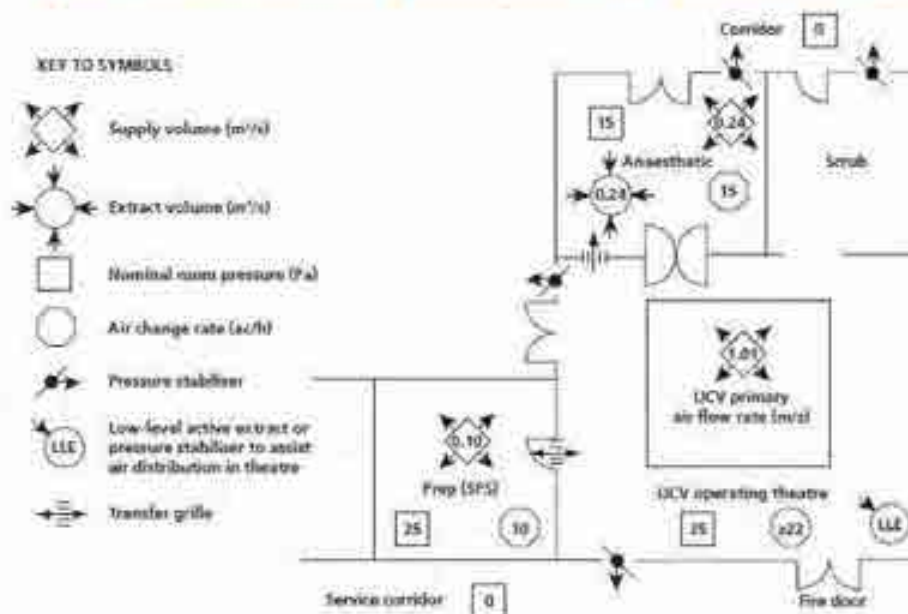

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for door protection at the key door from the total air entering the space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see

paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A7 Two corridor UCV operating suite with SPS schematic layout

### Standard layout 3 – single-corridor conventional operating suite with “lay-up” prep

Table A8 Single corridor conventional operating suite with “lay up” prep design criteria

Room	Size (m <sup>3</sup> )‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	165	≥22	25	Primary = 0.73 From Prep = 0.28 Total = 1.01
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Lay-up prep	36	≥22	35	0.35**
Scrub	*	–	25	–
Utility	36	–	–5	0.40

Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

\* This is a separate scrub and is not considered as being part of the theatre volume.

\*\* Interchange is not permitted between the theatre and lay-up prep; therefore, as in Appendix 5, an airflow protection of 0.28

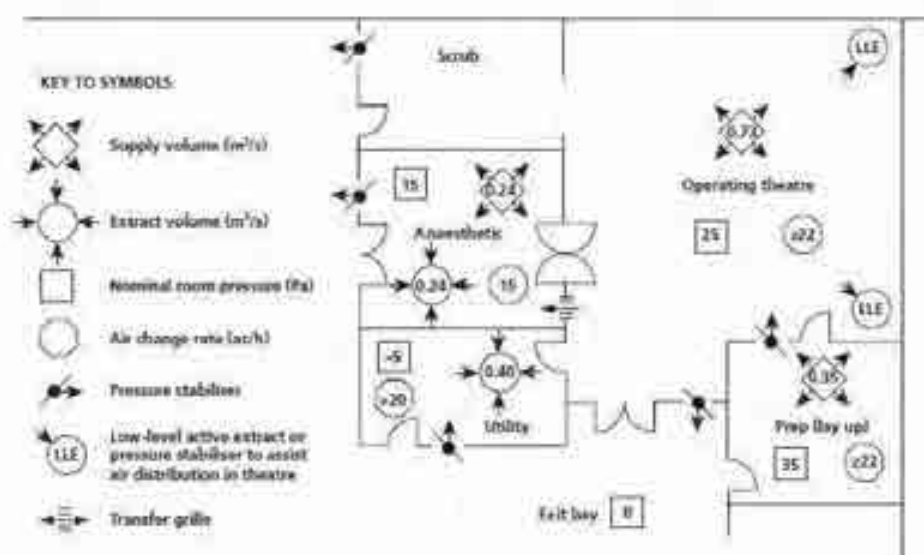

+ 0.07 closed-door airflow is required as a minimum (but see also the "designers' notes" in Appendix 4).

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for protection at the key door from the total air entering the space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A8 Single corridor conventional operating suite with "lay up" prep schematic layout

## Standard layout 4 – single-corridor UCV operating suite with Lay-up prep

Table A9 single-corridor UCV operating suite with Lay-up prep design criteria

Room	Size (m <sup>3</sup> )‡	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	165	≥22	25	#1.01
Anaesthetic	57	15	Design 15 Commissioned ≥10	0.24
Sterile pack store prep	36	≥22	35	0.35**
Scrub	*	–	25	–
Utility	36	–	-5	0.4

Notes:

‡ Derived from Health Building Note 10-01 (2021). If room sizes differ from those given, recalculate the design air flows to achieve the air change rate or door protection.

\* This is a separate scrub and is not considered as being part of the theatre volume.

\*\* Interchange is not permitted between the theatre and lay-up prep; therefore, as in Appendix 5, an airflow protection of 0.28

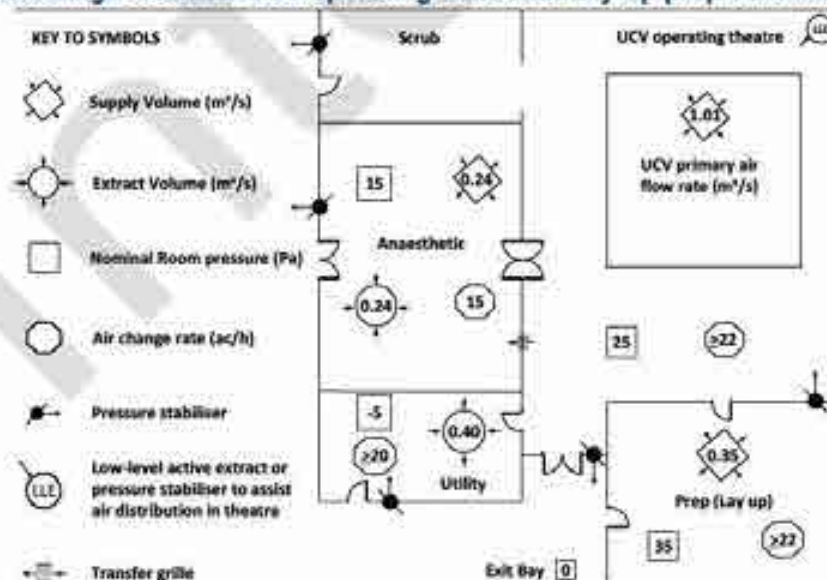

+ 0.07 closed-door airflow is required as a minimum (but see also the "designers' notes" in Appendix 4).

# Primary fresh-air volume for the UCV canopy or  $\geq 22$  ac/h or door protection

The volume of air to be extracted from the theatre should be determined by subtracting the airflow required for protection at the key door from the total air entering the theatre space. The balance should be equally divided between the passive or active extract locations.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A9 single-corridor UCV operating suite with Lay-up prep schematic layout

### Standard layout 5 – (ex SHTM 2025 Plan 1b): single-corridor conventional operating suite with “lay-up” prep

**Note:** This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning.

Table A10 (ex SHTM 2025 Plan 1b): single-corridor conventional operating suite with “lay-up” prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Lay-up prep	* See Notes below	≥22	35	0.35**

Utility	* See Notes below	>20	–5	0.40

Notes:

\* Existing theatre suite rooms to be measured on site

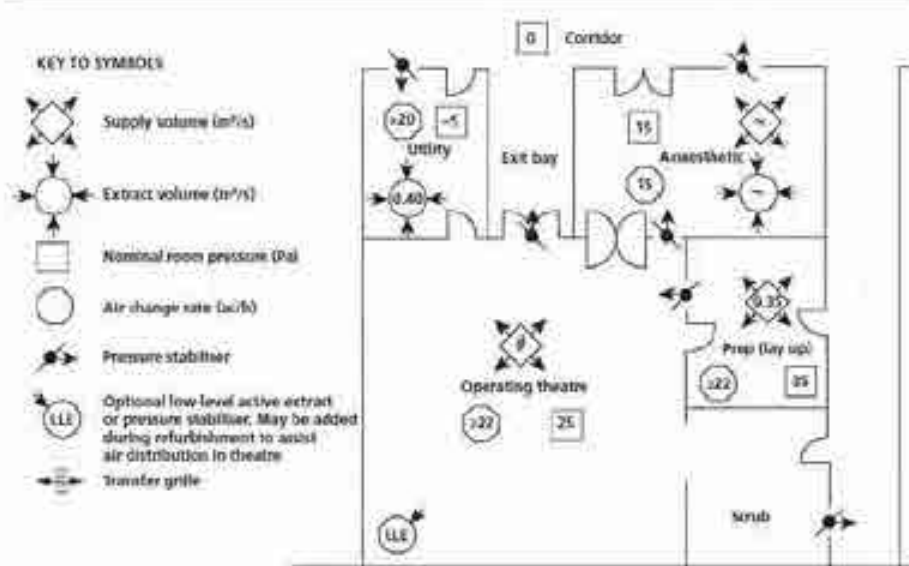

# Total airflow related to volume of theatre to give ≥22 ac/h or door protection value = primary theatre supply + 0.28 m<sup>3</sup>/s from the Lay-up Prep pressure stabiliser

\*\* See the “designers’ notes” in Appendices 4 and 5.

The utility layout design figures will remain the same if a hatch is fitted instead of a door onto the service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A10 (ex SHTM 2025 Plan 1b): single-corridor conventional operating suite with "lay-up" prep schematic layout

### Standard layout 6 – (ex SHTM 2025 Plan 1a): single-corridor UCV operating suite with SPS prep

**Note:** This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning. If difficulties are experienced with entrainment around the periphery of the UCV, adding a low-level active or passive extract in the location indicated will usually resolve the problem.

Table A11 (ex SHTM 2025 Plan 1a): single-corridor UCV operating suite with SPS prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Sterile pack store prep	* See Notes below	10	25	0.1
Scrub	* See Notes below	–	25	–
Utility	* See Notes below	–	–5	0.4

Notes:

\* Existing theatre suite to be measured on site

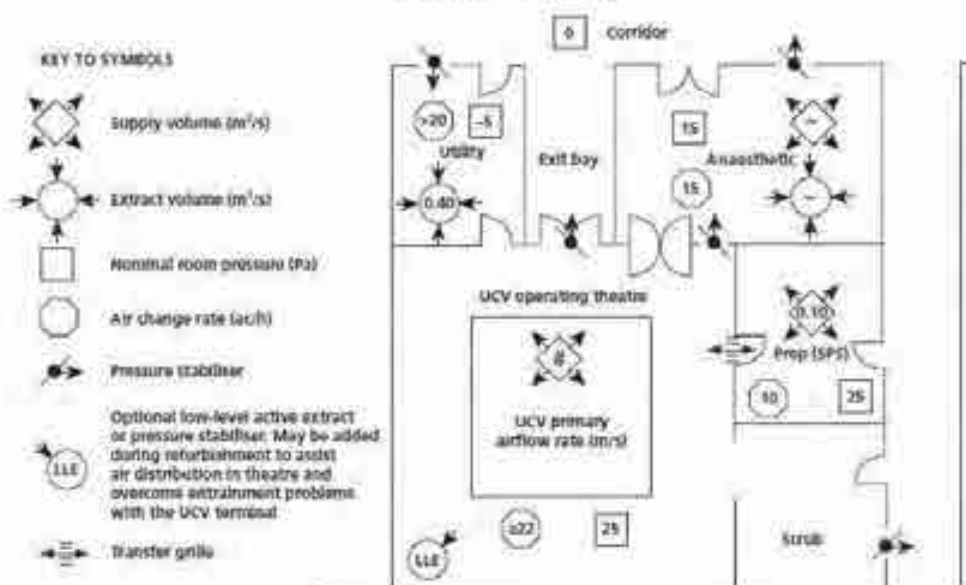

# Theatre total airflow related to volume of theatre to give ≥22 ac/h or door protection value

The utility layout design figures will remain the same if a hatch is fitted instead of a door onto the service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A11 (ex SHTM 2025 Plan 1a): single-corridor UCV operating suite with SPS prep schematic layout

### Standard layout 7 – (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with “lay-up” prep

**Note:** This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning.

Table A12 (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with “lay-up” prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Lay-up prep	* See Notes below	≥22	35	0.35**
Scrub	* See Notes below	–	25	–
Utility	* See Notes below	–	0	0.1

Notes:

\* Existing theatre suite to be measured on site

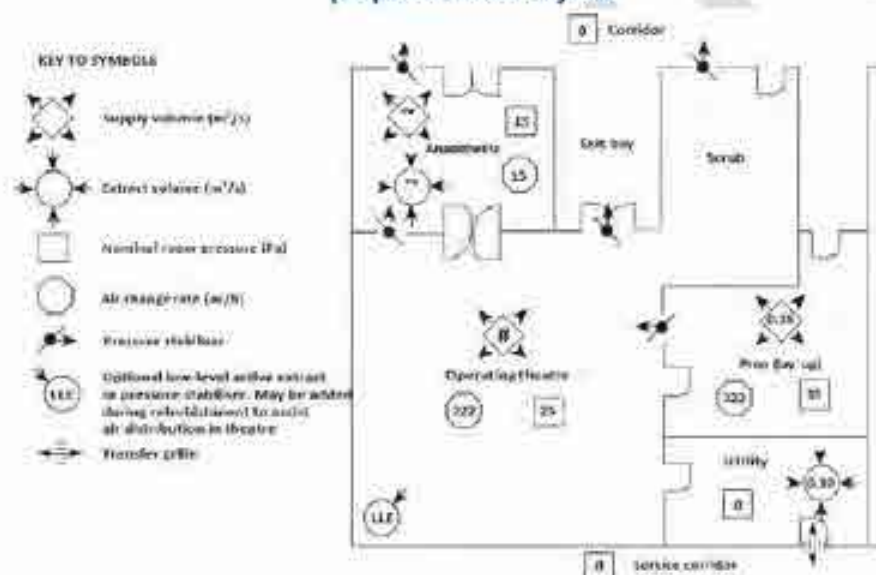

# Theatre total airflow related to volume of theatre to give  $\geq 22$  ac/h or door protection  
 = primary theatre supply + 0.28 m<sup>3</sup>/s from Lay-up Prep pressure stabiliser

\*\* See the "designers' notes" in Appendices 4 and 5

The utility design figures will remain the same if a hatch is fitted instead of a door onto the service corridor. Alternatively, if the operating department has a central waste processing station, the utility room may be omitted and replaced with a hatch between the theatre and service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A12 (ex SHTM 2025 Plan 5b): two-corridor conventional operating suite with "lay-up" prep schematic layout

### Standard layout 8 – (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep

**Note:** This layout and data is for historical purposes only. The information is to be used for the evaluation of existing systems, the fitting out of existing shell schemes or rebalancing of such systems following cleaning. If difficulties are experienced with entrainment around the periphery of the UCV, adding a low-level active or passive extract in the location indicated will usually resolve the problem.

Table A13 (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep design criteria

Room	Size	Air-change rate (ac/h)	Nominal pressure (Pa)	Flow rate (m <sup>3</sup> /s)
Theatre	* See Notes below	≥22	25	# See Notes below
Anaesthetic	* See Notes below	15	Design 15 Commissioned ≥10	~ Supply and extract to achieve the air change rate
Sterile pack store prep	* See Notes below	10	25	0.1
Scrub	* See Notes below	–	25	–
Utility	* See Notes below	–	0	0.1

## Notes:

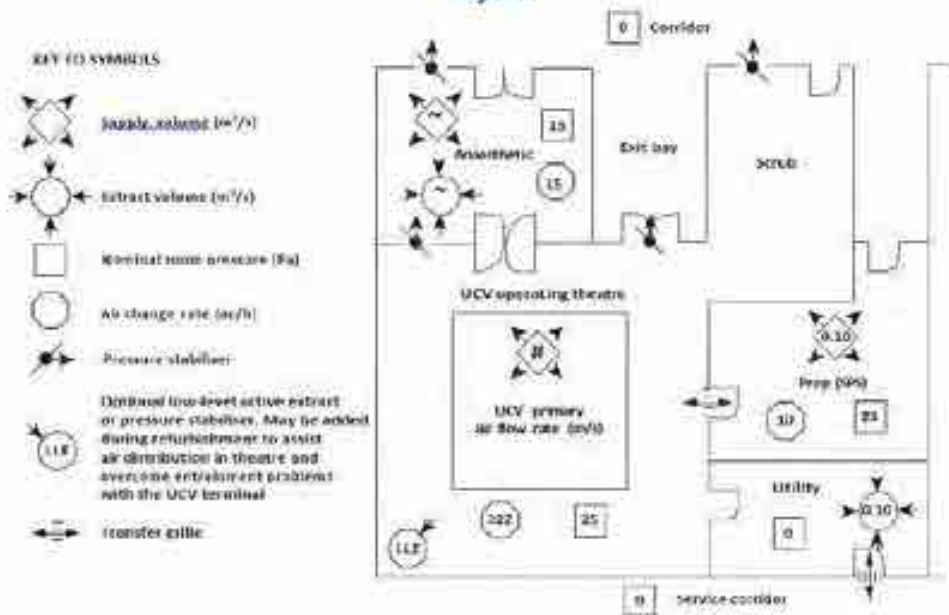

\* Existing theatre suite to be measured on site

# Primary fresh supply air for the UCV canopy is related to volume of theatre to give ≥22 ac/h or door protection

The utility design figures will remain the same if a hatch is fitted instead of a door onto the service corridor. Alternatively, if the operating department has a central waste processing station, the utility room may be omitted and replaced with a hatch between the theatre and service corridor.

The extracts within the theatre and scrub may be either passive and fitted with pressure stabilisers or active and connected to the extract system. They should where possible be located at low level and positioned to promote the active ventilation and scouring of all areas of the space (see paragraph 8.92). Air transfer from theatre to anaesthetic room may be by pressure stabiliser or transfer grilles (see paragraphs A8.51 and A8.52 in Appendix 8). The anaesthetic room extract will be at low level (see Appendix 9).

Figure A13 (ex SHTM 2025 Plan 5a): two-corridor UCV operating suite with SPS prep schematic layout

## Appendix 8: Design of air- movement control schemes for operating theatres

---

### General

- A8.1 Standard operating suite design solutions are given in paragraphs 8.27–8.74 and Appendix 7. If these standard solutions cannot be used, the following procedure should be adopted, which will result in an acceptable design. Note that the method employed may equally be used to provide a design solution to a ventilated suite of rooms for any application.
- A8.2 The method is concerned with the calculation of air-flow rates to ensure that correct air movement occurs between rooms when any one door is open. Under most circumstances, the air quantities required for air-movement control will approximate to those for either temperature control or bacterial contaminant dilution. This flow rate is sufficient to control the effects of any slight reverse flows occurring when a door is opened.
- A8.3 The progression through the design procedure is shown in the air-flow design procedure chart (Figure A24) and is supported by worksheets WS1 to WS7 described in paragraph A8.4. It is recommended that a plan of the suite and an air-flow network be made (Figure A23) to collate all information. Flow rates, air- transfer devices etc should be entered as required. The remainder of this Appendix may be treated as reference data to assist in the various steps. The following symbols are used:
- SS – supply air-flow rate for summer temperature control;
  - SW – supply air-flow rate for winter temperature control;
  - SD – supply air-flow rate for dilution of bacterial contaminants;
  - SL – supply air-flow rate for heat loss;
  - SG – supply air-flow rate for heat gain;
  - ED – extract air-flow rate for dilution of bacterial contaminants;
  - SF – final supply air-flow rates
  - EF – final extract flow rates;
  - SAMC – air-supply flow rate for air- movement control;
  - EAMC – air-extract flow for air- movement control;
  - LOUT – leakage air-flow rate outward;
  - LIN – leakage air-flow rate inward;
  - $\Sigma$ OUT - total air-flow rate outward;

$\Sigma$ IN total air-flow rate inward.

- A8.4 To simplify the procedure, standard worksheets (WS1 to WS7) have been devised. For each operating suite, a set is required comprising one each of WS1, WS3, WS5, WS6a, WS6b and WS7, one WS4 for each corridor and one WS2 to cover each peripheral room. WS2 has five versions:

WS2a single flow,

WS2b parallel/series multi-flow,

WS2c parallel multi-flow or series multi-flow (unbalanced);

WS2d series multi-flow (balanced); and

WS2e bay (semi-open).

### Peripheral room type

- A8.5 The rooms in the operating suite other than the operating theatre and corridor are referred to as peripheral rooms. Peripheral rooms have been classified according to the flows in and out. These room classifications are defined in paragraphs A8.6–A8.11.

#### Single flow

- A8.6 This is a room with only one door and a net surplus of supply or extract air.

#### Parallel multi-flow

- A8.7 This is a room with two or more doors through each of which the air flows either outwards (high pressure) or inwards (low pressure) (for example the Prep (lay-up) in standard layout 5 in Appendix 7).

#### Parallel/series multi-flow

- A8.8 This is a room having a net surplus of supply or extract and with two or more doors. One or more doors will be to an area of equal cleanliness and need not be protected; hence, the flow may vary between inwards and outwards, the remaining door being to an area of greater or lesser cleanliness (for example the Prep (SPS) in standard layout 6 in Appendix 7).

#### Series multi-flow (unbalanced)

- A8.9 This is a room having a net surplus of supply or extract and with two or more doors. Air flows inwards through one or more doors and outwards through one or more doors.

#### Series multi-flow (balanced)

- A8.10 This is a room as in paragraph A8.9 above, but having either no mechanical ventilation or no net surplus of supply or extract (for example an anaesthetic room).

#### Bay

- A8.11 A room which has a permanent opening to the operating theatre may be considered as a bay off the latter (for example a scrub). Two categories exist:

open bay – the opening is larger than a normal single door opening. The bay may be considered as part of the main room;

semi-open bay – the opening is no larger than a normal single door opening. In this case it is possible to protect the bay from the main room by provision of air supply or extract in the bay, or by passing air to or from another area.

### Air-movement control in peripheral rooms

- A8.12 For the design of air-movement control, two types of air-transfer device are considered. These are transfer grilles and pressure stabilisers. Each has a particular field of application within the design, as described in paragraphs A8.34– A8.43. Air movement is controlled in each of the different room types described in paragraphs A8.13–A8.31.

Figure A14 Key to symbols

### Single flow rooms

- A8.13 An appropriately-sized transfer grille should be located in or adjacent to the door of each single flow room to relieve the pressure differences across the door when closed.

Figure A15 Single flow room solution high-pressure room

### Parallel multi-flow rooms

- A8.14 The pressure difference across the closed doors should be relieved, but transfer grilles are not appropriate where two doors lead to areas of different pressures, because reverse flow could occur when the other door is open. For this reason, pressure stabilisers are used.

Figure A16 Parallel, multi-flow room solution high-pressure

Figure A17 Parallel, multi-flow room solution low-pressure

- A8.15 These rooms will be either high- pressure or low-pressure with respect to the adjacent areas (see preparation lay-up room and disposal room, respectively, in standard layout 5 of Appendix 7). The pressure-relief damper is always situated between the room and area, which results in the smaller differential pressure to ensure best use of air.
- A8.16 Just as reverse flow can occur if transfer grilles are used, it can similarly occur via door gaps when the other door is opened. It is not possible to avoid this, except by using air locks, but due to the low flow rates and short durations involved, this is not considered to be of importance.

#### Parallel-series multi-flow rooms

- A8.17 These rooms are similar to those in paragraph A8.14 above, but because the room is of equal cleanliness to one of the adjacent rooms, the nominal pressures will be equal and air may flow through the adjoining doorway in either direction (for example the Prep (SPS) in standard layout 6 of Appendix 7).

Figure A18 Parallel, series multi-flow room solution high-pressure

- A8.18 Where the nominal room pressure equals that of the higher-pressure adjacent room, the best use of air is by supplying air required for bacterial dilution only and allowing this to exhaust via a transfer grille to the area of equal cleanliness. The doorway to the lower pressure area is protected by the combination of the supply air and the air that will flow inwards through the transfer grille from the area of equal cleanliness.

Figure A19 Parallel, multi-flow room solution low-pressure

- A8.19 Conversely, where the nominal pressure equals that of the lower-pressure adjacent room, extract ventilation and a transfer grille to the lower pressure adjacent room should be provided (for example the disposal room in standard layout 8 of Appendix 7).

#### Series multi-flow (unbalanced)

- A8.20 These rooms are somewhat similar to those in paragraph A8.15 above, but because the pressure lies between that of the rooms on either side, the back-flow problem does not exist.

Figure A20 Series, multi-flow room solution medium-pressure

- A8.21 Where the room has a net surplus of mechanical supply air, a transfer grille should be located in or adjacent to the door through which air flows outwards, and the mechanical supply flow rate to the room should be chosen to give protection when this door is open.
- A8.22 Where the room has a net surplus of mechanical extract air, a transfer grille should be located adjacent to the door through which the air flows inwards, and the mechanical extract flow rate to the room should be chosen to give protection when this door is open.
- A8.23 The grille should be sized for the protection requirement of the opposing door when open. When the room on the high-pressure side depressurises, there is a possibility of back-flow through gaps around the door, but this problem may be ignored.

#### Series multi-flow (balanced)

- A8.24 In these rooms, a transfer device adjacent to each doorway is required in order to provide a flow path for the air required to protect the opposing door when opened.

Figure A21 Series, multi-flow room solution medium-pressure

- A8.25 These transfer devices will normally be pressure stabilisers, although transfer grilles may be used where a large amount of excess air is to be exhausted from the operating theatre when all doors are closed (for example anaesthetic rooms).
- A8.26 The calculation procedure is to assume that pressure stabilisers are being used; then – if there is sufficient excess air – change to transfer grilles as described in paragraph A8.50.

### Bay

#### Open bay

- A8.27 A bay of the open type (for example scrub-up) is considered to be part of the operating theatre. There should be an active or passive extract/pressure stabiliser under, or directly adjacent to, the scrub trough.

#### Semi-open bay

- A8.28 In a bay of the semi-open type, protection of one area from the other is possible (for example scrub-up).
- A8.29 As stated previously, the need for protection between operating theatre and scrub-room is not very great. Better use of air can therefore be achieved in this case by installing a pressure stabiliser between the scrub-room and clean corridor. This will allow a flow of air through the scrub-room at all times, except when a door is opened elsewhere in the suite. The pressure stabiliser will then close and the air will be diverted to the other door. When it is considered necessary to protect the scrub-room at all times, either a transfer grille to the corridor or mechanical extract in the scrub-room should be provided.

#### Operating theatre

- A8.30 Once the peripheral rooms have been considered, the operating theatre requirements may then be decided and the supply flow rate required for air-movement control calculated. This flow rate should be such that, with any one door open, the correct air movement directions are maintained. There will be one door in the suite that will require the largest supply flow rate to the operating theatre for protection when open. This is called the “key door” and is discussed separately in paragraph A8.33. Use of this concept avoids repetitive calculations for each door in turn. Having established the required supply flow rate, a relief route should be provided to the clean corridor for any excess air when the doors are closed. This would be via transfer grilles or pressure stabilisers through a series-flow room or via pressure stabilisers to the clean corridor directly.

### Corridors

- A8.31 All surplus air from the suite, except that lost through structure leakage and any passing to the outer corridor, will arrive in the patient/staff corridor. Should this air be insufficient to achieve the required air- change rate (see Appendix 3), some additional air supply should be provided. (The air balance should take account of structural leakage.)
- A8.32 Whereas the resulting pressures are dependent on ductwork layout, room relationships and characteristics of the fan, the generalisations shown in Appendix 6 may be used to estimate the change in room pressure when a door is opened.
- A8.33 The "key door" will be the open double door which leaves the operating theatre at the highest pressure, and/or requires the largest air flow. This should be determined using the procedure in worksheet WS3.

### Transfer grilles

- A8.34 These may be used to limit the pressure differences across the closed door of a single-flow room or, in some instances, for protection of a series-flow or parallel-series-flow room. They allow air flow in both directions and may not be suitable for all applications.
- A8.35 The free area of a grille is calculated from the following equation:

$$A = \frac{Q}{0.84\sqrt{\Delta P}}$$

where:

A is free area (m<sup>2</sup>)

Q is flow rate (m<sup>3</sup>/s)

P is pressure difference (Pa)

0.84 is the grille's resistance- correction factor.

- A8.36 The flow through a grille at a different pressure may be found from the following equation:

$$Q_2 = Q_1 \sqrt{\frac{\Delta P_1}{\Delta P_2}}$$

where:

Q<sub>1</sub> and P<sub>1</sub> are original flow and differential pressure

Q<sub>2</sub> and P<sub>2</sub> are new flow and differential pressure.

- A8.37 The transfer grille may be replaced by carefully proportioned door undercuts of the equivalent free area.

- A8.38 The function of the transfer grille is to provide a means of air-flow control by which the volume and pressure loss can be established. If a grille is used, it should have an easily removable core to facilitate cleaning.

### Pressure-relief dampers

- A8.39 The functions of a pressure-relief damper are now carried out by pressure stabilisers. Accordingly, all mention of them has been removed from this document.

### Pressure stabilisers

- A8.40 Pressure stabilisers can be adjusted to hold the pressure constant over a wide range of flow rates. They are used where requirements exist for accurate room- pressure control or rapid shut-off on pressure fall.
- A8.41 The installation of a grille or baffle in association with a stabiliser will alter the operating characteristics. It is recommended that a location be chosen to avoid the need for visual screening, for example, at high level. The location should be chosen to minimise the likelihood of damage.
- A8.42 The stabilisers used should be virtually silent in operation, adjustable on site, maintenance-free and of a type which cannot be wrongly inserted. They should not be used in external walls or where the pressure difference is less than 5 Pa. The required size of a pressure stabiliser is dependent on the design pressure difference across it and flow rate through it. The manufacturer should provide data relating pressure difference to mean velocity (or flow rate per unit area). From this, the required area can be calculated and then rounded-up to the nearest size manufactured or nearest combination of smaller sizes.
- A8.43 It is sometimes possible to arrange for a pressure stabiliser to perform two tasks. In an anaesthetic room, for example, the two pressure stabilisers may be made to pass the open door protection air, and also control the operating and anaesthetic room pressures with the door closed. To achieve this, the stabilisers are sized for the flow rate required with one of the doors open, but the pressure setting is adjusted to be the value required with the doors closed.

This is shown in Figure A22.

### Door leakage flows

- A8.44 For an air-movement control scheme to work satisfactorily, it is essential that the estimates of door-gap leakage made at the design stage are closely related to those which are achieved in practice. The calculation of gap-flows is complicated by the fact that such flows generally fall into the transition region between laminar and turbulent flow and hence do not follow the normal flow equations. The gaps assumed are 4 mm along the bottom, 3 mm at the top and sides, and 2 mm between double leaves. Doors should not have wider gaps than these. Tighter gaps would result in lower flow-rate requirements and hence lower fan power, but care should be taken to ensure that all doors in the suite have similar gap dimensions. It may be possible to

ignore the door leakage and so reduce the air-flow requirement (see the “designers’ notes” in Appendix 4).

### Room temperature estimation

A8.45 The air-flow rate required to prevent back-flow through an open door is dependent on the temperature difference across the door. The design figures shown in Appendix 6 are based on the temperature differences that will normally occur in practice, assuming heat gains and losses in accordance with Appendix 4.

A8.46 At step 11 of the air-flow design process, the temperature differences across the doors of all rooms classed as “sterile” are calculated. Worksheet WS6 is recommended for the calculations, using the following criteria:

- a. assume that the operating theatre is being controlled at 20°C and calculate the incoming air-supply temperature as shown on worksheet WS6;
- b. the calculation should be repeated for both summer and winter conditions, with an operation in progress;
- c. assume all doors are closed;
- d. use the room supply flow rates from WS1;
- e. use the inward air flows through air-transfer devices and closed door leakages from WS2a to WS2E;
- f. the formula used in worksheet WS6 is as follows:

$$T = \frac{(t_1 Q_1 + t_2 Q_2 + \dots + t_n Q_n) + 0.828H}{(Q_1 + Q_2 + \dots + Q_n)}$$

where:

Q = flow rate from source (m<sup>3</sup>/s)

t = the temperature of source (°C)

H = the room heat gain (kW).

A8.47 If the evaluated temperature differences between rooms do not exceed 2°C, the solution is satisfactory; otherwise proceed as follows:

- (i) check the assumption on which the heat gains are based;
- (ii) take steps to reduce the heat gains;
- (iii) if the door is to a corridor, the flow through the open door will be larger than the value given in Appendix 6. Calculate on WS3, assuming it is the “key door” with door-flow unknown, and the supply as known;
- (iv) if the door leads to a room with mechanical supply, install a trimmer heater in the supply to the room controlled by either a differential thermostat or a

thermostat slaved to the operating theatre thermostat to ensure that T is minimised;

- (v) if the door leads to a room with no mechanical supply, increase the door protection flow as follows:

$$Q_{\text{new}} = Q_{\text{old}} \frac{2}{[\Delta T + 1]}$$

- A8.48 These options should be considered in this order, and (i), (ii) and (iii) should be investigated thoroughly before proceeding to (iv) or (v). The mechanical supply may need to be increased in order to achieve the desired air-change rates.

### Relief of excess air from operating theatre when all doors are closed

- A8.49 As the mechanical supply to the operating theatre is sized to provide an appropriate flow outwards through any door which is opened, it follows that when all doors are closed, there will be more air supplied to the operating theatre than can exit from it via leaks etc. This "excess" air can be relieved by either of the two methods described in paragraphs A8.50– 8.54.

#### By transfer devices via the anaesthetic room

- A8.50 The transfer device (pressure stabiliser or transfer grille) between the theatre and anaesthetic room needs to accommodate an air volume of 0.46 m<sup>3</sup>/s at 20 Pa (see Appendix 6) when the door between the anaesthetic room and corridor is open. An additional 0.11 m<sup>3</sup>/s will pass through the door gaps of the theatre to anaesthetic door to give a total door flow protection figure of 0.57 m<sup>3</sup>/s through the open door between the anaesthetic room and corridor. The optimum duty for this device with all the doors closed would be 0.33 m<sup>3</sup>/s at the room differential of 10 Pa. The following equation shows how this figure is arrived at:

$$\begin{aligned} Q &= \frac{Q_1}{\frac{(\sqrt{\Delta P_2})}{\Delta P_1}} \\ &= \frac{0.46}{\frac{(\sqrt{\Delta 20})}{\Delta 10}} \\ &= 0.33\text{m}^3/\text{s} \end{aligned}$$

where:

Q = excess air to be vented with doors closed

Q1= airflow required for door protection through the transfer device

$\Delta P_1$ = nominal differential pressure with door to operating theatre closed and door to corridor closed

$\Delta P_2$  = nominal differential pressure between the operating theatre and anaesthetic room when the corridor door is open.

- A8.51 If the excess air is less than 0.33 m<sup>3</sup>/s, a pressure stabiliser is required to ensure that the correct pressure and protection airflow is available to pass through the door.
- A8.52 If the excess air is greater than 0.33 m<sup>3</sup>/s, a transfer grille is acceptable because at all times the airflow will exceed the flow required for pressure and door protection.

#### By pressure stabilisers to the corridor

- A8.53 If it is undesirable to pass all the extra remaining air volume through the anaesthetic room after the door flow- protection volumes have been achieved, it may be passed from the theatre directly to the corridor via a separate pressure stabiliser.
- A8.54 If there is sufficient excess air, the transfer grille solution at paragraph A8.52 should be adopted, as it provides the simplest solution and, once set up, will require no further maintenance. With less excess air, it is recommended that the air be passed through the anaesthetic room via the pressure stabilisers as at paragraph A8.51, thus keeping the number of pressure stabilisers to a minimum. Both these solutions increase the air-change rate in the anaesthetic room, but care should be taken to avoid passing excessive amounts through that would cause discomfort to the occupants.

## Appendix 9: Design of air- movement control scheme for anaesthetic room

### General

Figure A25 Schematic of suitable supply and extract solution

The above shows the typical zones for the positioning of ceiling-mounted supply and low-level extracts in an anaesthetic room. The objective is to comply with the COSHH Regulations and SHTM 03-01 Part A by providing a clean airflow path for staff working in anaesthetic rooms and so reduce their risk of casual exposure to waste/leaking anaesthetic agents.

**Note 1:** Supply terminals should not be positioned above wall-mounted cupboards as this will prevent their output being measured directly with a balometer. It will also negatively impact on the air distribution within the room.

**Note 2:** See photographs below for details of the recommended low-level extract installation.

**Note 3:** Low-level extracts should have a spring-clip-retained pull-off grille face for ease of cleaning.

### Low-level extract installation

#### Traditional installation (not recommended)

- Low-level extract easily obstructed by equipment
- Extra corners to clean around

**Figure A26 Low level extract traditional installation (not recommended)**

### Recommended installation

- low-level extract cut back at 80° and stops short of the floor;
- no added detail to floor covering or coving;
- no additional corners to clean around;
- not easily obstructed by equipment;
- pull-off grille face for ease of cleaning;
- grille still accessible for airflow measurement.

**Figure A27 Low level extract recommended installation**

The photograph is for illustrative purposes only and shows a cutback of approximately 65°. This was found to make airflow measurement quite difficult, hence the change to an 80° cutback so that measurement can be easily taken with a balometer.

### Operating theatre to anaesthetic room air-transfer device

The air-transfer device between an operating theatre and anaesthetic room may be either by a transfer grille or pressure stabiliser. The choice will be determined by the volume of air to be transferred.

Paragraphs A8.51 and A8.52 in Appendix 8 give details.

## Appendix 12: Abbreviations used in this document

Table A15: Abbreviations and their meanings

Abbreviation	Meaning
ac/h	Air changes per hour
ACDP*	Advisory Committee on Dangerous Pathogens*
ACOP	Approved Code of Practice
AE(V)	Authorising Engineer (ventilation)
AGP	Aerosol-generating procedure
AHU	Air handling unit
AP(V)	Authorised Person (ventilation)
BESA	Building Engineering Services Association
BIM	Building Information Model
BMS	Building Management System
BEMS	Building Energy Management System
BS EN	British Standard European Number
BSRIA	Building Services Research and Information Association
CCA	Critical care area (Level 2 & 3 care)
cfu	Colony forming unit
CIBSE	Chartered Institution of Building Services Engineers
COSHH	Control of Substances Hazardous To Health
CP(V)	Competent Person (ventilation)
CT	Computed tomography (imaging)
DIPC	Director of Infection Prevention and Control
DOP	Dispersed oil particles
DX	Direct expansion (refrigeration cycle)
EC	Electronically commutated (fan)
EPA	Efficiency particulate air filter (E10 to E12)
ErP	Energy related products
EU GGMP	European Guide to Good Manufacturing Process (pharmacy)
GRP	Glass reinforced polymer
HBN	Health Building Note
HEPA	High efficiency particulate air filter (H13 to H14)
HIS	Healthcare Infection Society
SHTM	Health Technical Memoranda
IAP	Inspection, assembly and packing (room)
ISO	International Standards Organisation
Level 0 care	Patients whose needs can be met through normal ward care in an acute hospital
Level 1 care	Patients at risk of their condition deteriorating, or recently relocated from higher levels of care, whose needs can be met through normal ward care with additional advice and support from the critical care team.

Abbreviation	Meaning
Level 2 care	Patients requiring more detailed observation or intervention, including support for a single failing organ system or post-operative care and those 'stepping down' from higher levels of care.
Level 3 care	Patients requiring advanced respiratory support alone or monitoring and support for two or more organ systems. This level includes all complex patients requiring support for multi-organ failure.
LEV	Local exhaust ventilation
LSAPC	Light scattering airborne particle counter
MDR-TB	Multi-drug-resistant tuberculosis
MRI	Magnetic resonance imaging
NICU	Neonate intensive care unit
PFI	Private Finance Initiative
PPVL	Positive pressure ventilated lobby (isolation room)
PVC	Polyvinyl chloride
RH	Relative humidity
SCBU	Special care baby unit
SPATA	The Swimming Pool and Allied Trades Association
SUP	Supply air quality
SVHSoc	Specialised Ventilation for Healthcare Society
TB	Tuberculosis
TCP	Theatre control panel
UCV	Ultra clean ventilation
ULPA	Ultra low particulate air filter (U15 to U17)
UV	Ultraviolet
VAV	Variable air volume
VCD	Volume control damper
VSG	Ventilation Safety Group
WEL	Workplace exposure limit

Table A16: Symbols

Symbol	Meaning
°C(db)	Degrees centigrade (Dry bulb) temperature
K	Kelvin (temperature difference)
% RH	Percentage relative humidity
L/s	Litres per second
µm	Micrometres, microns
ePM1, 2.5, 10	Particle size in micrometres
≥	Equal to or greater than

\* ACDP Containment levels

Category 1 biohazard: a biological agent unlikely to cause human disease

Category 2 biohazard: a biological agent that can cause human disease and may be a hazard to employees; it is unlikely to spread to the community and there is usually effective prophylaxis or effective treatment available.

Category 3 biohazard: a biological agent that can cause severe human disease and presents a serious hazard to employees; it may present a risk of spread to the community, but there is usually effective treatment or prophylaxis available.

Category 4 biohazard: a biological agent that causes severe human disease and is a serious hazard to employees; it is likely to spread to the community and there is usually no effective prophylaxis or treatment available.

Interim

## Preface

**Note:** This SHTM was prepared prior to the COVID-19 pandemic caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). It has been reviewed against the known transmission evidence available at the time of publication. Ventilation is one of many mitigations against the virus and should be part of a package of infection prevention and control measures. The ventilation rates recommended in this document are likely to provide a lower risk environment for COVID-19 airborne transmission.

Emerging evidence will continue to be reviewed as and when available.

### About Health Technical Memoranda

Health Technical Memoranda (SHTMs) give comprehensive advice and guidance on the design, installation and operation of specialised building and engineering technology used in the delivery of healthcare.

The focus of Scottish Health Technical Memorandum guidance remains on healthcare-specific elements of standards, policies and up-to-date established best practice. They are applicable to new and existing sites, and are for use at various stages during the whole building lifecycle.

### Language usage in technical guidance

In SHTMs, SHPNs and HBNs, modal verbs such as “must”, “should” and “may” are used to convey notions of obligation, recommendation or permission. The choice of modal verb will reflect the level of obligation needed to be compliant.

The following describes the implications and use of these modal verbs in SHTMs/SHPNs/HBNs (readers should note that these meanings may differ from those of industry standards and legal documents):

- “Must” is used when indicating compliance with the law;
- “Should” is used to indicate a recommendation (not mandatory/ obligatory), i.e. among several possibilities or methods, one is recommended as being particularly suitable – without excluding other possibilities or methods;
- “May” is used for permission, i.e. to indicate a course of action permissible within the limits of the HBN, SHPN or SHTM.

### Typical usage examples

- “All publicly-funded organisations must ensure that all contracts established to collect and treat waste conform to the Public Contracts Regulations.” [obligation]

**Note:** This guidance is not mandatory (unless specifically stated). However, any departures/ derogations from this SHTM – including the measures implemented – should provide a degree of safety not less than that achieved by following the guidance set out in this SHTM.

- "All low voltage (LV) distributions should be configured as TN systems." [recommendation]
- "Alcohol hand gels that do not contain siloxanes may be rinsed out and the packaging recycled or placed into the municipal waste stream." [permission]

"Shall", in the obligatory sense of the word, is never used in current SHTMs/SHPNs/HBNs.

## Project derogations from the Technical Guidance

Healthcare facilities built for the NHS are expected to support the provision of high-quality healthcare and ensure the NHS Constitution right to a clean, safe and secure environment. It is therefore critical that they are designed and constructed to the highest and most appropriate technical standards and guidance. This applies when organisations, providers or commissioners invest in healthcare accommodation (irrespective of status, for example Foundation and non-Foundation trusts).

**Note:** Statutory standards plus technical standards and guidance specific to NHS facilities:

Health Building Notes/Scottish Health Planning Notes

Scottish Health Technical Memoranda/ Health Technical Memorandum (where no SHTM equivalent exists)

Complete list of NHS estates-related guidance

The need to demonstrate a robust process for agreeing any derogation from Technical Guidance is a core component of the business case assurance process.

The starting point for all NHS healthcare projects at Project Initiation Document (PID) and/or Strategic Outline Case (SOC) stage is one of full compliance.

Derogations to standards will potentially jeopardise business case approval and will only be considered in exceptional circumstances. A schedule of derogations will be required for any project requiring external business case approval and may be requested for those that have gone through an internal approvals process.

While it is recognised that derogation is required in some cases, this must be risk-assessed and documented in order that it may be considered within the appraisal and approval process.

Derogations must be properly authorised by the project's senior responsible owner and informed and supported by appropriate technical advice (irrespective of a project's internal or external approval processes).

## Sustainability and 'Net Zero Carbon' targets

Healthcare provision is a significant contributor to the UK's carbon footprint. (In 2019, this was estimated to be around 5.4% of our greenhouse gases.) Accordingly, all

NHS organisations have their part to play in meeting Net Zero Carbon targets alongside other [sustainability measures](#).

In January 2020, Health chief Sir Simon Stevens announced three steps the NHS will take during 2020 to tackle this problem:

- NHS England has established an expert panel to chart a practical route map to enable the NHS to get to 'net zero'. The panel will submit an interim report to NHS England in summer 2020 and a final report ahead of the November 2020 [UN Climate Change Conference \(COP26\)](#) in Glasgow. The panel will consider changes the NHS can make in its own activities; in its supply chain; and through wider partnerships;
- the [NHS Long Term Plan](#) commits to [better use of technologies](#) to make up to 30 million out-patient appointments redundant, sparing patients thousands of unnecessary trips to and from hospital. It is estimated that 6.7 billion road miles each year are from patients and their visitors travelling to the NHS;
- the panel will consider changes that can be made in the NHS's medical devices, consumables and pharmaceutical supply, and areas the NHS can influence such as the energy sector as the health service moves to using more renewable energy.

For specific ventilation-related measures, see the "Net Zero Carbon" section on page 10.

# Executive Summary

---

## Preamble

Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' is published in two parts:

Part A: The concept, design, specification, installation and acceptance testing of healthcare ventilation systems.

Part B: The management, operation, maintenance and routine testing of existing healthcare ventilation systems.

The documents give comprehensive advice and guidance on the legal requirements, design implications, maintenance and operation of specialised ventilation in healthcare premises providing acute care. The use of these premises is very intense, the occupancy level high and the patients may be particularly susceptible to airborne infection risks. Their condition may also require close control of the environment.

The ventilation of non-healthcare facilities within the hospital curtilage should be designed to suit the application and specific guidance relating to the activity should be followed, for example pharmacy, decontamination unit, etc. However, as they are on the hospital site, the means of providing ventilation should not adversely impact upon the hospital (for example, evaporative cooling towers should not be installed, sound levels should be appropriate and if the facility is within or attached to an area accessed by patients, their needs and the risk of airborne contamination should be considered).

In other types of healthcare facility that are outside of the hospital curtilage, for example GP practices, health centres, minor injuries units, dental, ophthalmic and podiatry clinics, mental health facilities, respite and long stay care homes and hospices, etc, a risk assessment of the nature of the treatment being delivered, condition of the patients and intensity of use needs to be undertaken by those responsible for the facility in order to determine the extent to which this guidance will be applicable.

The guidance contained in Part A of this Scottish Health Technical Memorandum applies to new installations and major refurbishments of existing installations and should be considered as the standard to be achieved.

The guidance contained in Part B of this Scottish Health Technical Memorandum applies to all ventilation systems installed in healthcare premises irrespective of the age of the installation and should be considered as the standard to be achieved.

Scottish Health Technical Memorandum 03-01 (2022) supersedes all previous versions of Scottish Health Technical Memorandum 03-01 – 'Specialised ventilation in healthcare premises' (2011). It also supersedes SHTM 2025 (1994) and DV4 (1983).

## Who should use this guidance?

This document is aimed at specifiers, designers, suppliers, installers, estates and facilities managers and operations. Elements of the document will also be relevant to managers concerned with the day-to-day management of healthcare facilities and senior healthcare management.

## Main changes since the 2011 edition

- design information for specific healthcare applications has been revised and information on the reason for ventilation given. For example, endoscopy rooms may now be either negative (to contain and remove odours and manage airborne risks to staff) or positive pressure (to maintain a higher level of cleanliness where it is intended to puncture body membranes with the endoscope). These endoscopy-specific risks (i.e. waste anaesthetic gases and pathogenic material (for example, multi-drug-resistant tuberculosis) discharged by the patient during the procedure being undertaken) were identified prior to the SARS-CoV-2 pandemic. As with other elements in Part A, the application of this change is not retrospective but applies to new installations and major refurbishments (see Preamble above);
- the client's needs and legal requirements are more clearly explained;
- this edition of Scottish Health Technical Memorandum 03-01 introduces the concept of the Ventilation Safety Group in healthcare organisations (similar to the Water Safety Group in Scottish Health Technical Memorandum 04-01 and the Electrical Safety Group in Scottish Health Technical Memorandum 06-01). This is a multidisciplinary group whose remit will be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises;
- the SHTM introduces a standard method of identifying and labelling ventilation systems and the creation of an inventory of installed systems;
- the issues of resilience and diversity are addressed;
- guidance is provided on refurbishments or when changing the use of an existing installation;
- guidance is given on lifecycle and the updating of mid-life plant;
- design information for specific healthcare application has been extensively revised;
- issues around rooms where anaesthetic agents are used are addressed;
- airflow rates are more tailored to the applications to take advantage of new fan and control technology and so reduce energy consumption;
- revised air quality and filter standards are given;
- new and emerging technologies are catered for;
- advice is given on installation standards and the appointment of an Independent validator;
- more detailed information is given on the commissioning process;
- validation acceptance standards and methodology has been completely revised;

- routine inspection and maintenance guidance has been revised and updated.

## Net zero carbon

Scottish Health Technical Memorandum 03-01 supports UK legislation to bring all greenhouse gas emissions to net zero by 2050, and promotes sustainable methods of ventilation in healthcare facilities.

The SHTM's core principle is that the default method of ventilation should as far as possible be natural ventilation followed by mixed mode (natural with mechanical ventilation), with mechanical ventilation being the last option.

The energy consumption of ventilation systems should be further minimised by specifying solutions with the lowest lifecycle environmental cost. The basic objective of energy-saving strategies in this SHTM is to provide the required ventilation service using the minimum energy. To this end, Scottish Health Technical Memorandum 03-01 recommends switching a system "off" when not required to be the most energy-efficient policy. If the system is needed to maintain a minimum background condition, reducing its output by "setting back" to the minimum necessary to achieve and maintain the desired condition is the next best option.

Fans represent an enormous potential for energy savings to reduce carbon emissions, as they are among the largest single users of energy (they use approximately 40% of all electricity in ventilation systems). The European Regulation 1253/2014, implementing the Energy-related Products (ErP) Directive, has significantly reduced the power to drive fans. Accordingly, Scottish Health Technical Memorandum 03-01 recommends using electronically commutated fans, as these have been proven to be the most energy-efficient, while also advising that belt-driven fans should no longer be installed.

There have been many legislative changes aimed at reducing energy consumption and technical advances that have increased operational efficiency. This revised SHTM incorporates those changes and has amended many of the design parameters for healthcare ventilation. Designs that are simply repeated from previous installations designed to superseded standards and guidance will not meet the revised energy or operational standards and will not produce a compliant result.

**David Wilson**, Safety Strategy Unit, Department of Health, Northern Ireland

**Dylan Evans**, Senior Performance Standards Engineer, NHS Wales Shared Services Partnership - Specialist Estates Services

**Frank Mills**, Chair, CIBSE Healthcare Group

**Gareth Twynam**, General Manager, AirisQ Ltd

**Graham Taylor**, Authorised Engineer (Ventilation), Specialised Ventilation for Healthcare Society

**Hilary Humphreys**, Professor of Clinical Microbiology, Royal College of Surgeons in Ireland

**Ian Bryden**, Head of Estates and Property, NHS Dumfries and Galloway

**Ian Ferguson**, Capital Projects, University Hospitals of Morecambe Bay NHS Foundation Trust

**Ian Storrar**, Head of Engineering, Health Facilities Scotland

**Jez Beales**, Consulting Engineer, DSSR

**John McEwan**, Senior Project Manager, Hulley & Kirkwood **John Prendergast**, Publishing and Editorial, Archus Ltd **John Rayner**, Authorising Engineer (Ventilation), IHEEM

**Jon Fletcher**, Operations Director, Interfurn Medical Systems

**Karren Staniforth**, Clinical Scientist, Healthcare Infection Society

**Kevin Reynolds**, Head of Estates, Sandwell and West Birmingham Hospitals NHS Trust

**Kevin Ridge**, Head of Engineering, NHS Wales Shared Services Partnership - Specialist Estates Services

**Lester Stuart**

**Linda Dempster**, Head of Infection Prevention and Control, NHS England & NHS Improvement

**Malcolm Thomas**, Main author

**Martin Sarungi**, Orthopaedic Surgeon, Golden Jubilee National Hospital, Clydebank

**Michael Ralph**, Principal Engineering & Senior Policy/Strategy Lead (Hard FM), NHS England & NHS Improvement

**Michael Rope**, Estates & Facilities Management Guidance Lead, NHS England & NHS Improvement

**Mike Arrowsmith**, Consulting Engineer, IHEEM

**Mike Dunne**, Technical Manager, Howorth Air Technology Limited

**Mike Hodges**, Managing Director, Apreco Limited

**Nigel Keery**, Head of Estates, Belfast Health & Social Care Trust

**Peter Broadbent**, Director, Couch Perry & Wilkes LLP

**Peter Hickey**, Assistant Director of Estates, Lancashire Teaching Hospitals NHS Foundation Trust

**Peter Hoffman**, Consultant Clinical Scientist, Public Health England

**Richard Barry**, Director, AirisQ Ltd

**Richard Harris**, Authorised Engineer (Ventilation), Specialised Ventilation for Healthcare Society

**Rob Townsend**, Consultant Medical Microbiologist, Sheffield Teaching Hospitals NHS Foundation Trust

**Robert Porter**, Consultant in Clinical Microbiology & Infection, Royal Devon and Exeter NHS Foundation Trust

**Rosemary Jenssen**, ProCure 22 Framework Representative

**Sigrid Volkmann**

**Simon Allen**, Torbay and South Devon NHS Foundation Trust

**Simon Dale**, Association of Anaesthetists, Chesterfield Royal Hospital NHS Foundation Trust

**Steve Clifford**, Consulting Engineer, Hoare Lea

**Tim Boswell**, Consultant Medical Microbiologist, Healthcare Infection Society

**Tim Sizer**, Regional Pharmaceutical Quality Assurance Officer, NHS England (South West)

**Tom Ford**, Director, Howorth Air Technology Limited

NHSScotland would also like to thank all those who took the time to comment and send contributions during the scoping and technical engagement phases of this document.

# 1. Introduction

---

## Preamble

### 1.1 Scottish Health Technical Memorandum 03-01

'Specialised ventilation in healthcare premises' is published in two parts: Part A deals with the concept, design, specification, installation and acceptance testing of ventilation systems; Part B covers the management, operation, maintenance and routine testing of existing healthcare ventilation systems.

### 1.2 The document gives advice and guidance to healthcare management, design engineers, estates managers and operations managers on the legal requirements, design implications, maintenance and operation of specialised ventilation in all types of healthcare premises.

### 1.3 The guidance contained in Part B of this Scottish Health Technical Memorandum applies to all ventilation systems installed in healthcare premises irrespective of the age of the installation.

### 1.4 This revision of Scottish Health Technical Memorandum 03-01 supersedes the 2011 version of Scottish Health Technical Memorandum 03-01.

## Ventilation in healthcare premises

### 1.5 Ventilation is used extensively in all types of healthcare premises to provide a safe and comfortable environment for patients and staff. It is provided to help control airborne infection risks in areas such as operating departments, critical care facilities, isolation rooms and treatment areas.

### 1.6 It may also be installed:

- to maintain a suitable environment by removing odours and controlling temperature;
- to ensure compliance with the quality assurance requirements of items processed in pharmacies and decontamination units;
- to protect staff from harmful organisms or toxic substances, for example in laboratories and anaesthetic rooms;
- to contain the spread, and clear smoke as part of the fire strategy.

## Statutory requirements

### The Health Act 2009

### 1.7 The Health Act places a duty of care on healthcare providers. Increased health risks to patients will occur if ventilation systems do not achieve and maintain the required standards. The link between surgical site infection and theatre air quality has been well established. If the ventilation plant has been installed to dilute or contain harmful

substances, its failure may expose people to unacceptable levels of contamination. Breaches of the statutory requirements can result in prosecution and may also give rise to a civil suit against the operators.

#### **Health and Safety at Work etc. Act 1974**

- 1.8 The Health and Safety at Work etc. Act 1974 is the core legislation that applies to ventilation installations. As these installations are intended to prevent contamination, closely control the environment, dilute contaminants or contain hazards, their very presence indicates that potential risks to health have been identified.

#### **COSHH**

- 1.9 The Control of Substances Hazardous to Health (COSHH) Regulations 2002 (as amended) place upon management an obligation to ensure that suitable measures are in place to protect their staff and others affected by the work activity. These methods may include both safe systems of work and the provision of a specialised ventilation system. In laboratories the requirements are often met by the provision of fume cupboards and microbiological safety cabinets.
- 1.10 Where specialised ventilation plant is provided as part of the protection measures, there is a statutory requirement that it be correctly designed, installed, commissioned, operated and maintained. The local exhaust ventilation (LEV) section of COSHH requires that the system be examined and tested at least every 14 months by a competent person (P601 certified) and that management maintain comprehensive records of its performance, repair and maintenance.
- 1.11 Certain substances have workplace exposure limits (WELs) set out in the Health and Safety Executive's Guidance Note EH40
- 'Workplace exposure limits' contains the list of workplace exposure limits for use with the Control of Substances Hazardous to Health Regulations 2002 (as amended). If specialised ventilation systems are provided in order to achieve these standards, they will be subject to the COSHH Regulations as above.

#### **Workplace (Health, Safety and Welfare) Regulations**

- 1.12 These state that all enclosed workplaces must be ventilated by natural or artificial means.
- 1.13 Any plant provided under this legislation shall include an effective device to give an audible or visual warning of plant failure where necessary for health and safety.
- 1.14 The Regulations require that ventilation systems are "maintained in an efficient state, in efficient working order and in good repair".

#### **Building Regulations**

- 1.15 These apply to domestic and non-domestic buildings.
- 1.16 They clarify satisfactory methods of providing ventilation and give ventilation rates.
- 1.17 They set minimum standards for:
- the protection of the supply position;

- precautions against Legionella;
- the purity of recirculated air;
- access for service and maintenance;
- documentation and proof of performance.

### **Fire regulations**

- 1.18 The fire regulations require that, if ventilation ductwork penetrates the fabric of a building, it should be designed and installed to contain the spread of fire and smoke (see the Health Technical Memorandum 05 series for guidance).
- 1.19 When a ventilation system was originally designed, it will have conformed to an agreed fire strategy. This will have determined the provision of fire-rated ductwork, the siting of fire and smoke dampers and an agreed control action for the ventilation fans in the event of a fire.
- 1.20 It is management's responsibility to ensure that the fire strategy applied during the design and installation of a system is not reduced during the subsequent operation and maintenance of the equipment.
- 1.21 If a ventilation system is upgraded or altered to suit a change of use, it will be necessary to reassess the fire strategy.

### **Plant installed for units manufacturing medicinal products**

- 1.22 Plant installed for units manufacturing medicinal products to the standards set out in the current European guide to good manufacturing practice may also be subject to particular legislation with regard to their operation in addition to that mentioned above.
- 1.23 There are specific requirements under the Medicines Act 1968 to maintain accurate records of plant performance, room conditions and maintenance events. Such records would need to be preserved for at least 25 years as part of a quality assurance audit trail.

### **Plant installed for laboratories**

- 1.24 Specialised ventilation plant installed for laboratories dealing with research, development, testing or other specialist applications (this could concern medicinal products, IVF, tissue, animals or genetically modified organisms) may be subject to particular legislation with regard to their operation in addition to that mentioned above.

### **Codes of practice and guidance**

- 1.25 All ventilation systems should conform to the principles set out in the Health and Safety Executive's (HSE) Approved Code of Practice and guidance on regulations – 'Legionnaires' disease: the control of Legionella bacteria in water systems' (commonly known as L8), and Scottish Health Technical Memorandum 04-01 – 'Safe water in healthcare premises'.

- 1.26 The HSE has published complementary technical guidance in HSG274, which is split into three specific areas:
- Part 1 – evaporative cooling systems
  - Part 2 – hot and cold water systems
  - Part 3 – other risk systems.
- 1.27 The Department of Health publication 'The Health and Social Care Act (2013) Code of Practice on the prevention and control of infections and related guidance' (the HCAI Code of Practice) is a code of practice that helps NHS bodies to plan and implement how they can prevent and control healthcare-associated infections. It sets out criteria by which managers of NHS organisations are to ensure that patients will be cared for in a clean environment and where the risk of healthcare-associated infections is kept as low as possible. Specialised ventilation systems often play a significant role in achieving this objective.

### Management responsibilities – general

- 1.28 It is a management responsibility to ensure that inspection, service and maintenance activities are carried out safely without hazard to staff, patients or members of the public.
- 1.29 Those required to monitor and/or maintain ventilation equipment will need to show that they are competent to do so (see Chapter 2).
- 1.30 Maintenance procedures should be reviewed periodically to ensure that they remain appropriate.
- 1.31 The preservation of information and records of ventilation systems and their performance is a legal requirement. It is therefore essential that records are kept in a form that when archived can be accessed when necessary. Keeping records on a dedicated computer drive unit within the estates department, while satisfactory for day-to-day operation, is not adequate for archival storage.
- 1.32 Estates statutory maintenance records will be retained and managed through the healthcare provider's information governance arrangements. Estates departments should periodically archive their records of statutory and critical systems.

### System information

- 1.33 An inventory of all ventilation systems installed and in use or capable of being used will need to be kept. The inventory should be readily accessible within the operational section of the estates department in hard copy and electronic form.
- 1.34 The inventory should be subdivided into the following categories:
- local exhaust ventilation systems - (LEV) – note these are statutory items;
  - critical healthcare ventilation systems – (CHV). (These are systems the loss of which would seriously limit the delivery of healthcare, for example operating suite, NICU, critical care area, interventional imaging suite, aseptic suite);

- general ventilation system [supply and extract] (GVS);
- general extract systems (GES);
- systems installed for smoke clearance in the event of a fire, classed as smoke and heat exhaust ventilation systems (SHEVS) (for example, smoke extract fans in stairwells, automatic smoke clearance dampers in atria).

1.35 For each ventilation system the inventory should contain the following details:

- a unique system identification code for example LEV 001; CHV 001 etc as appropriate;
- the location of the ventilation fan unit or supply and extract air-handling unit(s) (AHU(s));
- the location of the fresh air inlet;
- the location of the extracted air discharge;
- the specific area(s) served by the system;
- the date the system was installed;
- the date the system was first commissioned;
- the date of its annual inspection;
- the date and details of any significant alterations or replacements made to the system.

1.36 When systems are removed or replaced, their unique identification code should be transferred from the inventory to an archive together with all its records.

These should be retained for a minimum of five years (25 years for a manufacturing pharmacy) (see paragraphs 1.31 and 1.32).

1.37 New or replacement systems should be allocated a new unique identification and added to the inventory.

1.38 Each ventilation system should have a log (physical or electronic) that contains the following information:

- the unique system identification reference;
- purpose of the system;
- date of installation;
- details of the installed equipment and ductwork layout;
- detail of the fire plan, any fire-rated ductwork and location of fire and smoke dampers;
- design performance parameters, for example airflow rates, air-change rates, pressures, etc.;
- commissioned date and performance;
- record of the system validation and original acceptance;

- records of the annual inspection and verification;
- maintenance records and plant information, for example fan specifications and filter sizes.

- 1.39 The records should be linked to the inventory and stored in such a way as to be readily available in the event of plant breakdown or other incident.
- 1.40 When new ventilation systems are accepted for use, full information as to their designed mode of operation together with recommended maintenance procedures should be provided as part of the handover procedure (Building Regulations 2010 Part 8 Para 39). Part A of this Scottish Health Technical Memorandum gives design parameters for new installations and lists the handover information required.
- 1.41 Many new installations are designed and stored electronically within a building information modelling (BIM) program. It is important to update the BIM model if there are any physical changes made or design parameters modified during the life of the system.
- 1.42 In existing systems, original design and commissioning information will often not be available. It will be necessary to determine a suitable level of system performance based on the function, purpose and age of the installation. This information should be entered in the system log file and form the baseline for the annual verification.
- 1.43 Chapter 3 of this document sets out the minimum standards for all air handling units (AHUs) and their air distribution systems irrespective of when they were installed.

**Note:** The minimum standards were first set out in Scottish Health Technical Memorandum 2025, 1994.

- 1.44 All system records must be kept for at least five years (25 years for a manufacturing pharmacy). The Health and Safety Executive and other interested bodies such as the Care Quality Commission (CQC) have a statutory right to inspect them at any time (see paragraph 1.31).

### Action in the event of an incident

- 1.45 In the event of a reportable incident connected with ventilation equipment or the area that it serves, copies of all records and plant logbooks may need to be collected as evidence. The requirements of the Reporting of Injuries, Diseases and Dangerous Occurrences Regulations (RIDDOR) will apply.

**Note:** In the event of an incident, while there may be a legal requirement to hand over information and records to the investigator, it is essential that the healthcare provider retains copies as they will be necessary for the continued safe operation and maintenance of the system, which is a legal requirement.

## Frequency of inspections and verifications

- 1.46 In order to comply with the Workplace (Health, Safety & Welfare) Regulations and Building Regulations, it is essential that all ventilation systems must be subject to at least a simple visual inspection annually.
- 1.47 In order to comply with the provisions of the Health Act, all CHVs should be inspected quarterly and their performance measured and verified annually. The quarterly inspection should be a simple visual check; the annual verification will be a more detailed inspection of the system together with the measurement of its actual performance.
- 1.48 Chapter 4 sets out the annual inspection and verification requirements and a supporting set of specimen checklists is given in the Appendices. Equipment manufacturers and suppliers may also recommend specific maintenance inspections.
- 1.49 The LEV section of the COSHH regulations contains a statutory requirement that systems installed to contain or control hazardous substances be examined and tested at least every 14 months by a competent person (P601 certificated). The statutory inspection and test must be of the complete system from the point of capture to the point of discharge.
- 1.50 Regular tests, at intervals agreed with the local fire prevention officer, will need to be carried out in order to demonstrate the continuing efficiency of the fire detection and containment systems. These may be in addition to the inspections detailed above. Records of these tests must be kept.

## Lifecycle of ventilation systems

- 1.51 Plant should be scheduled for replacement after 20 years. CIBSE Guide M gives advice on plant lifecycle and the risk assessment of plant condition. In order to secure funding and programme downtime for the area served, a site-wide plant replacement programme should be in place. As an example, if a site has 40 AHUs then at least two will need to be replaced every year. The plant replacement should coincide with a refurbishment of the area served.

**Note:** If the site was a new build with all plant of the same age, then assessment of the replacement programme should commence after 10 years as it will not be practical to replace all units simultaneously at the 20-year mark.

- 1.52 The Ventilation Safety Group (VSG) (see Chapter 2) will prioritise the replacement programme. Failure to plan for plant replacement has led to unplanned system failures with a consequent loss of the facility that they serve and cancellation or disruption to patient services.
- 1.53 In order to maintain efficiency, ventilation systems should be refurbished at their mid-life point (typically 10 years after original installation). The complete system should be taken out of use and thoroughly inspected. The AHU and its distribution ductwork should be cleaned as appropriate, any internal corrosion investigated and treated, the complete control system up-graded and the entire installation rebalanced and recommissioned. The performance of the system should be validated (see Chapter

12 in Part A of this Scottish Health Technical Memorandum) before being returned to service.

**Note:** During this process the opportunity should be taken to replace any belt-driven fans with the most energy-efficient fans available, for example electronically commutated (EC) plug fans or direct-drive plug fans. (Chapter 9 in Part A of this Scottish Health Technical Memorandum gives details of fan types and preferred selection and installation strategies.)

- 1.54 Whenever an area of the healthcare estate is being refurbished, the condition and energy performance of its ventilation plant should be reviewed. The plant should be upgraded, refurbished or replaced as appropriate in order to take advantage of the most energy-efficient equipment and control methods available at the time.

### Competency

- 1.55 The Board and their supply chain must ensure that the competence of all parties is considered at the point of their introduction and on an ongoing basis. The philosophies that are included in the HSE leaflet INDG368 (current revision), "Using Contractors" should be adopted. In addition, the outputs from the "Setting the Bar" report should be adopted as they are introduced through legislation. Evidence that the recommendations of "Setting the Bar" are being implemented in advance of the legislation would be considered to be good practice, particularly for high risk buildings. BSI Flex 8670 "Built environment. Core criteria for building safety in competence frameworks. Code of practice" should also form part of the project planning.

## 2. Functional responsibilities

---

### Management responsibilities

- 2.1 Clear lines of managerial responsibility should be in place so that no doubt exists as to who is responsible for the safe operation and maintenance of the equipment.
- 2.2 A periodic review of management systems should take place in order to ensure that the agreed standards are being maintained.
- 2.3 Those required to inspect, verify or maintain ventilation equipment will need to show that they are competent to do so. As a minimum they should have sufficient knowledge of its correct operation to be able to recognise faults.
- 2.4 Training in the validation and verification of specialised healthcare ventilation systems for Authorised Persons (APs) and Competent Persons (CPs) is available from a variety of providers. While there is a duty on post holders to keep their knowledge up to date, as reflected for APs in their CPD record, there is no requirement to routinely attend any specific refresher course.

### Designated staff functions

- 2.5 A person intending to fulfil any of the staff functions specified below should be able to prove that they possess sufficient skills, knowledge and experience to be able to safely perform the designated tasks (see Chapter 3 in Scottish Health Technical Memorandum 00 for more detailed information).

#### Management (Duty Holder)

- 2.6 Management is defined as the owner, occupier, employer, general manager, chief executive or other person who is ultimately accountable for the safe operation of premises.

#### Designated Person

- 2.7 This person provides the essential senior management link between the organisation and professional support. The Designated Person should also provide an informed position at board level and confirm the appointment of the following staff in writing.

#### Authorising Engineer (Ventilation) (AE(V))

- 2.8 The AE(V) is defined as a person designated by Management to provide independent auditing and advice on ventilation systems, to review documentation on verification and validation and witness the process as necessary.

**Note:** Authorising Engineers should be able to show that they are free to provide independent advice and have been subject to an assessment of their competence by a registration body.

### **Authorised Person (Ventilation) (AP(V))**

- 2.9 The AP(V) will be an individual possessing adequate technical knowledge and having received appropriate training, appointed in writing by the Designated Person (in conjunction with the advice provided by the AE(V)), who is responsible for the practical implementation and operation of Management's safety policy and procedures relating to the engineering aspects of ventilation systems.

### **Competent Person (Ventilation) (CP(V))**

- 2.10 The CP(V) is defined as a person designated by Management to carry out maintenance and periodic testing of ventilation systems.

### **Infection Prevention and Control Person**

- 2.11 The Infection Prevention and Control Doctor or consultant microbiologist is the person nominated by management to advise on monitoring the infection control policy and microbiological performance of the systems.

### **User**

- 2.12 The User is the person responsible for the management of the unit in which the ventilation system is installed (for example head of department, operating theatre manager, laboratory manager, production pharmacist, head of research or other responsible person).

### **Contractor**

- 2.13 The Contractor is the person or organisation responsible for the supply of the ventilation equipment, its installation, commissioning, validation, verification or decommissioning. This person may be a representative of a specialist ventilation organisation or a member of the general manager/chief executive's staff.

### **Appointment of post holders**

- 2.14 All post holders should be appointed in writing by the "Designated Person" (see paragraph 2.7). A record should be kept of those appointed to carry out the functions listed above. The record should clearly state the extent of the post holder's duties and responsibilities, and to whom they are to report.
- 2.15 Substitute or replacement staff should be designated in order to cover for sickness, holidays and staff transfers.

### **Ventilation Safety Group (VSG)**

- 2.16 The management of the ventilation systems of a healthcare provider should be overseen by the Ventilation Safety Group (VSG). The VSG should have clearly defined roles and responsibilities, be part of a healthcare organisation's governance structure and report to the designated person at Board level. It will be led and chaired by a person who has appropriate management responsibility, knowledge, competence and experience (for example the Designated Person).
- 2.17 The VSG should be a multidisciplinary group and will typically comprise:

- an AE(V)/independent adviser for ventilation;
- an Infection Prevention and Control Person (as defined above);
- the AP(V);
- estates (operations and projects) staff;
- clinicians and specialist departments (for example theatres, critical care, pharmacy, medical microbiology, nursing);
- personnel from the finance department with accountability for capital and revenue evaluation;
- other stakeholders as appropriate;
- co-opted expertise, for example ventilation designers, consultants and suppliers.

2.18 The VSG remit will be to assess all aspects of ventilation safety and resilience required for the safe development and operation of healthcare premises. It should inform the following areas:

- the design process for new healthcare premises;
- the design process for modifications to existing premises;
- the commissioning and validation process;
- operational management and maintenance;
- annual verification and performance testing;
- prioritising the plant replacement programme;
- decommissioning and removal of redundant equipment.

**Note:** Where estates-and-facilities provider services are part of a contract (including PFI), it is essential that these providers participate fully in all those aspects of estates-and-facilities management that can affect patients. This includes responding to specific requests from the VSG, which may be in addition to relevant guidance and documentation.

2.19 It is important that decisions affecting the resilience, safety and integrity of the ventilation systems and associated equipment are not taken without the agreement of the VSG. The VSG should ensure that appropriate expertise and competence is available when making such decisions. Whenever significant building work is undertaken, the VSG should consider its effects on the existing ventilation system air intakes. These may need to be protected from airborne dust during construction by the fitting of temporary additional filtration. There will also be a need to identify any risks to construction personnel working in the vicinity of extract air discharges.

2.20 When building work is undertaken inside a building, the VSG should be consulted to determine its effects on the occupants. The VSG may need to specify the extent to which the area is to be sealed off from the operational parts of the building and the need for a temporary extract unit in order to maintain the worksite at a negative pressure to prevent the spread of contaminants into the rest of the building.

2.21 The healthcare provider, through its VSG, will be able to demonstrate that they have suitable governance, competence and accountability arrangements in place to

provide safe critical ventilation systems and appropriate clinical environments in their premises.

### Ventilation policy document

- 2.22 The VSG will produce a ventilation policy document for the healthcare provider. In its simplest form this may just be a statement that the healthcare provider will follow the guidance contained in Scottish Health Technical Memorandum 03-01 Parts A and B as appropriate. It may also specify any departures from that guidance in terms of local additional requirements or derogations.
- 2.23 The policy document will be endorsed by the healthcare provider's board.

### Specific health and safety aspects

- 2.26 Staff engaged in the service and maintenance of extract ventilation systems from pathology departments, mortuaries, laboratories, isolation facilities and other areas containing a chemical, biological or radiation hazard may be particularly at risk. In these cases, the risk should be identified and assessed.
- 2.27 The VSG should be consulted as to the means by which the system can be rendered safe to work on and a permit-to-work system implemented. Appendix 3 gives an example of a typical equipment release certificate (ERC) that could be used for routine inspection and maintenance by competent persons.
- 2.28 Training in the exact procedures should be given to all staff involved.
- 2.29 Some healthcare facilities may contain specialised units that are subject to access restrictions (for example pharmacy aseptic suites). Estates or contract staff requiring access may need additional training or be accompanied when entering the unit.
- 2.30 See also the following guidance published by the Health and Safety Executive:
- 'Safe working and the prevention of infection in clinical laboratories and similar facilities'.
  - 'The management and operation of microbiological containment laboratories'.
  - HSG 283 – 'Managing infection risks when handling the deceased: guidance for the mortuary, post-mortem room and funeral premises, and during exhumation'.

## 3. Ventilation systems – minimum standards

---

### General requirements

- 3.1 All ventilation systems irrespective of when they were installed are to be inspected annually to ensure conformity with minimum standards required by the Building Regulations. These are designed to:
- assure the quality of intake air;
  - ensure that extract air is discharged in a suitable location;
  - prevent or control risks associated with Legionella and other potential hazardous organisms;
  - ensure safe access when carrying out routine service and maintenance activities;
  - provide documentary proof of performance.
- 3.2 All AHUs and their associated ventilation systems should achieve the minimum standard set out below.

**Note:** These standards have not changed since Scottish Health Technical Memorandum 2025 was issued in 1994 so all systems currently in use should therefore achieve them.

### Location and access

- 3.3 All ventilation plant should be secured from unauthorised access.
- 3.4 It is a requirement to uniquely identify individual plantrooms on site and fix a list just inside the door detailing the major plant elements within and the areas that they serve.
- 3.5 Plantrooms should, where possible, be provided with a sink so that glass drainage traps may be cleaned out and staff can wash their hands after handling dirty filters. A source of DHW with a hose connection point will also be required so that AHUs can be washed out internally as part of their routine maintenance.
- 3.6 Units located on roofs should have a safe and permanent means of access and adequate illumination as they may need to be accessed at any time. Suitable precautions should be in place to prevent personnel or equipment from falling off during maintenance activities.
- 3.7 Units located outside at ground level should be secured within a compound to prevent unauthorised access or preferably within a plantroom. Vehicles should be excluded from the vicinity to ensure that exhaust fumes will not be drawn into intakes.
- 3.8 All parts of the AHU should be easily and safely accessible for routine inspection, service and maintenance.

- 3.9 The area around an AHU within a building should be tanked to prevent water penetration to adjacent areas, and should be adequately drained.
- 3.10 Fire precautions should be in accordance with the Health Technical Memorandum 05 series.
- 3.11 Combustion equipment must not be located in a fire compartment that houses air-handling equipment.
- 3.12 Plantrooms that house AHUs should not be used for general storage. Care should be taken to ensure that the amount of combustible material in a plantroom is kept to an absolute minimum. Ventilation stock such as filters should be kept in a central store.
- 3.13 If a spare set of filters is kept in the plantroom they should be kept in their original packing to preserve them from contamination and stored off the floor so that they cannot become wet. The number stored should be kept to a minimum to reduce the fire load in the plantroom. Used filters should be placed in an empty box or bag and removed immediately.
- 3.14 Spare fans should be stored on a purpose-built rack near the plantroom entrance. Staff should be instructed to "spin" the fan every time they enter the plantroom to help prevent the bearings settling.

### Identification and labelling

- 3.15 All ventilation systems should be clearly identified with a permanent label in accordance with the requirements of paragraph 1.33 onwards. The label should identify both the AHU and the area that it serves. The lettering should be at least 100 mm high and be mounted in an easily visible place near the fan of the unit adjacent to the local electrical isolator. Any subsystems and the principal branch ducts should be similarly labelled as should any associated control panels.
- 3.16 The nature and direction of airflow should be clearly marked on all main and branch ducts (see BS1710).
- 3.17 All airflow test-points should be clearly identified with a permanent label and the design information given (for example TPS 1 – Anaesthetic supply; 400 × 300; Design 185 L/s).

### Basic requirements

- 3.18 The ventilation system should not contain any material or substance that could support the growth of micro-organisms.
- 3.19 Access to items that require routine service, such as filters, fog coils and cooling coils, should be via hinged doors.
- 3.20 Items requiring infrequent access such as attenuators may be via clipped or bolted-on lift-off panels.
- 3.21 All doors and panels should be close-fitting and without leaks.

- 3.22 Access to plant and equipment above 1.5 m should be via platforms, fixed ladders, hook ladders, pulpit-style movable steps or access platforms.
- 3.23 Electrical and mechanical services should not restrict or impede access to those parts of the plant that require inspection.
- 3.24 Viewing ports and internal illumination should be fitted in order to inspect filters and drainage trays.
- 3.25 Internal illumination should be provided by luminaires to at least IP55 rating. Fittings are to be mounted inside the unit so that they provide illumination for inspection and task lighting when the access doors are open.
- 3.26 A single clearly labelled switch should operate all the lights in a unit.

### AHU intakes and discharges

- 3.27 Intake and discharge points should not be situated where they will cause vitiated air to be drawn into a system (paragraph 9.30 onwards in Part A of this Scottish Health Technical Memorandum gives detailed information). In existing systems, it may be necessary to extend the intake or discharge point to a suitable position.

**Note:** Steps should be taken to prevent birds landing or roosting in the vicinity by removing ledges or fitting anti-pigeon spikes.

- 3.28 Each intake and discharge point should be fitted with corrosion-resistant weatherproof louvres or cowls to protect the system from driving rain. The inside of the louvres should be fitted with a mesh of not less than 6 mm and not more than 12 mm to prevent infestation by vermin and prevent leaves being drawn in.
- 3.29 The duct behind a louvre should be self-draining. If this is not practicable, it should be tanked and provided with a drainage system. Cleaning access should be provided either from the outside via hinged louvres or by an access hatch or door in the plenum behind the louvre. Where a common plenum is provided, cleaning access should be via a walk-in door. If the intake plenum is a builder's work duct, all of its surfaces should be sealed to prevent dust being shed into the airflow.

### Plant drainage system

- 3.30 All items of plant that could produce moisture should be provided with a drainage system. The system will comprise a drip-tray, borosilicate glass trap, air gap and associated drainage pipework.
- 3.31 Some older units may not have been mounted far enough above the floor to permit the correct installation of a drainage system. If the AHU cannot be raised to an adequate height, an alternative arrangement (such as a pump-out system) should be provided.
- 3.32 The drip-tray should be constructed of a corrosion-resistant material (stainless steel is preferred) and be so arranged that it will completely drain. To prevent "pooling", it is essential that the drain connection should not have an upstand and that a slope of

approximately 1 in 20 in all directions should be incorporated to the drain outlet position.

- 3.33 In AHUs that have access doors large enough for a person to enter, the drip-tray should be easily accessible for inspection and cleaning.
- 3.34 In AHUs with access doors too small for a person to enter, the complete drip-tray should be capable of being withdrawn. It should be clamped into the AHU with thumbscrews so that it can be removed without the need for tools.
- 3.35 Each drip-tray should be provided with its own drain trap. The drain trap should be of the clear (borosilicate) glass type. This permits the colour of the water seal to be observed, thus giving an early indication of corrosion, biological activity or contamination within the duct (see Table 3 in Chapter 5).
- 3.36 The trap should have a means for filling and should incorporate couplings to facilitate removal for cleaning. It should be located in an easily visible position where it will not be subject to casual knocks. The pipework connecting the drainage tray to the trap should have a continuous fall of not less than 1 in 20.
- 3.37 Traps fitted to plant located outside or in unheated plantrooms may need to be trace-heated in winter. The trace heating should be checked for operation. It should be ensured that the temperature of water in the trap does not exceed 5°C.
- 3.38 Water from each trap must discharge via a clear air gap of at least 15 mm above the unrestricted spill-over level of either an open tundish connected to a drainage stack via a second trap, or a floor gully (or channel) or directly onto a roof (if in a location that will not cause a slip hazard). A support should be provided to ensure that the air gap cannot be reduced. More than one drain trap may discharge into the tundish, providing each has its own air gap.
- 3.39 Drainage pipework from the tundish may be copper, thermoplastic or stainless steel. Glass should not be used. The pipework should be a minimum diameter of 22 mm and have a fall of at least 1 in 60 in the direction of flow. It should be well supported, and located so as not to inhibit access to the plant.

## Dampers

- 3.40 All AHUs should be fitted with motorised low-leak shut-off dampers at their intake and discharge ends. The damper actuators should be fitted with end switches and be spring-return so that they close automatically on power failure. Note that all new plant will in addition have motorised dampers at the supply and return air ends of an AHU.

## Fans and their drives

- 3.41 Belt-and-pulley fan drive-trains external to the AHU, whether supply or extract, should be easily visible without the need to remove access covers. Protecting the drive-train with a mesh guard is the preferred option. For weatherproof units located outside, the fan drive should be enclosed. It should be easily visible through a viewing port with internal illumination and be accessed via a lockable hinged door.

- 3.42 Plug and EC fan units are mounted inside the AHU. Their access door should have a viewing port and internal illumination. The door should be fitted with a two-stage opening latch so that if the door is inadvertently opened when the fan is running it will not blow outwards.
- 3.43 The motor windings of induction-drive "plug" motor arrangements, EC fans and in-line axial fans having a pod motor within the airstream must be protected from over-temperature by a thermistor and lock-out relay.
- 3.44 It is necessary to ensure that – should the computer control system or its software develop a fault – the fan in an AHU serving a critical healthcare application can be switched to a fixed speed and manual operation.

### Heater-batteries

- 3.45 Access for cleaning will need to be provided to both sides of all fog coils and heater-batteries.

### Cooling coils

- 3.46 All cooling coils, whether within the AHU or a branch duct, should be fitted with their own independent drainage system as specified above. A baffle or similar device in the drip-tray will prevent air bypassing the coil. The tray should be large enough to capture the moisture from the eliminator, bends and headers.
- 3.47 The cooling-coil control valve should close upon selection of low speed, system shut-down, low airflow or fan failure.
- 3.48 Where auxiliary wet cooling coils are located in false ceilings, they should be fitted with a catch tray and leak alarm. The catch tray should be installed under both the battery and the control-valve assembly to protect the ceiling from leaks. A moisture sensor and alarm should be fitted in the tray.

### Eliminators

- 3.49 Where fitted they should be removable so that the face of the cooling coil can be inspected and cleaned as necessary. In new units the eliminator will be mounted on slide rails for ease of removal. In existing systems, if bolted in position it should be secured with thumbscrews (not tech/spire screws) and fitted with lifting handles to enable removal and replacement without the use of tools.

### Humidifiers

- 3.50 Humidifiers are not generally required. Chapters 8 and 9 in Part A of this Scottish Health Technical Memorandum give examples of where humidification may be required.
- 3.51 Where they are fitted, but have been out of use for a significant period of time, they should be removed. All associated supply pipework must also be removed back to its

junction with the running main. Their drainage trap should be removed and the tray capped off.

- 3.52 Where humidifiers are fitted and their use is still required, they should fully conform to the installation standard set out in Chapter 9 of Part A of this Scottish Health Technical Memorandum.
- 3.53 The section of ductwork containing the humidifier may need to be periodically decontaminated. Hinged access doors with viewing ports and internal illumination should be provided.
- 3.54 All humidifiers should be fitted with their own independent drainage system as detailed in paragraph 3.30 onwards.
- 3.55 Only steam-injection humidifiers, whether mains steam fed or locally generated, are suitable for use in ventilation systems within healthcare facilities. Water humidifiers, if fitted, must be removed.
- 3.56 Self-generating steam humidifiers must be supplied with wholesome water. The installation should be capable of being isolated, drained and cleaned.
- 3.57 Some steam generators require regular cleaning and descaling. The installation should enable them to be physically isolated from the air duct in order to prevent contamination of the air supply by cleaning agents.
- 3.58 The humidifier control system should fully conform to the standard set out in Chapter 9 of Part A of this Scottish Health Technical Memorandum.

## Filtration

- 3.59 Filters should be securely housed in well-fitting frames that minimise air bypass. Air bypass significantly reduces filter efficiency; the higher the filter grade, the greater the effect. In horizontal AHUs the mounting frames should be designed so that the airflow pushes the filter into its housing to help eliminate air bypass. Supports with seals will master the joints between filters.
- 3.60 All filters should be of the dry type. Panel filters are generally used as prefilters and should be positioned on the inlet side of the supply fan, downstream of the fog/ frost coil. Where required, secondary filters (these will be bags or pleated paper) should be on the positive-pressure side of the fan.
- 3.61 The filter installation should provide easy access to filter elements for cleaning, removal or replacement; therefore, a hinged access door should be provided. The upstream side of the filter should be visible for inspection through a viewing port with internal illumination.
- 3.62 All filters should be provided with a means of checking the differential pressure across them. Direct-reading dial-type gauges marked with clean and dirty sectors are preferred.

**Note:** Direct-reading gauges may be omitted (if desired) providing the filter differential pressure is continuously monitored by a sensor connected to the BMS and there are capped tappings so that a portable gauge can be attached when required for diagnostic purposes or fault-finding.

### Efficiency (EPA) and high- efficiency (HEPA) filters

- 3.63 Where fitted, EPA or HEPA filters should be of the replaceable-panel type with leak-proof seals. Their installation should permit the validation of the filter and its housing.
- 3.64 EPA or HEPA filters fitted in supply ducts should have a metal case so that they cannot support fungal growth.
- 3.65 EPA or HEPA filters are sometimes used in extract systems to prevent the escape of hazardous substances or organisms. They may be supplied with a particleboard or plywood case so that they can be disposed of by incineration.
- 3.66 When used for the containment of hazardous substances, the installation should incorporate design provision for the subsequent safe removal and handling of contaminated filters by maintenance staff (see paragraph 5.16).

**Note 1:** In view of the costs and problems associated with placing EPA or HEPA filters in extracts, it is essential that a full risk assessment be carried out in conjunction with the VSG. It should include defining the true need for a filtered extract, the validation of its performance at installation, the method of safely changing a contaminated filter, and its subsequent disposal.

**Note 2:** General extracts from mortuaries and post-mortem rooms may contain odours, but these are not in themselves hazardous to health and do not require filtration prior to discharge. In high-risk post-mortems (for example, known or suspected tuberculosis cases), the infected organs will be removed and then dissected in a class 1 microbiological safety cabinet provided under the COSHH Regulations. Extracts from infectious disease Isolation rooms or wards do not normally require filtration prior to discharge. However, if the discharge cannot be made in a safe location and it is likely that the vitiated air could be drawn back into the building or there are people in its vicinity (for example, a discharge into a courtyard), filtration would be required.

### Energy recovery

- 3.67 Energy recovery, where fitted, will require cleaning access to both sides of the device.
- 3.68 Whichever type of energy recovery device is fitted, the extract side should be protected by an ISO ePM10  $\geq$  50% filter and provided with a drainage system to remove condensate.
- 3.69 The energy-recovery device should be controlled in sequence with the main heater-battery, and may need to incorporate a control to prevent the transfer of unwanted heat when the air-on condition rises above the plant's required set-point.

## Attenuation

- 3.70 Cleaning access should be provided at both ends of any attenuator unit.

## Pressure stabilisers

- 3.71 Pressure stabilisers should be unobstructed and silent in operation. (See Chapter 5 for maintenance requirements.)
- 3.72 Pressure stabilisers that direct air into a UCV operating theatre will need to be baffled on the theatre side to prevent the air jet disturbing the UCV canopy air pattern. Pressure stabilisers between the theatre and anaesthetic room may also need to be baffled if the jet of air from them creates uncomfortable conditions for patients or staff.
- 3.73 Where a pressure stabiliser incorporates a fire and smoke damper, the damper test switch or trip mechanism should be accessible from the corridor side without the need to remove the grille face, if fitted.

## Chilled beams – active and passive types

- 3.74 Chilled beams should not be installed above a patient's bed or diagnostic medical equipment without the agreement in writing of the VSG. Where currently fitted they should be easily accessible for cleaning. In a room with openable windows, the window frame must have a switch to automatically turn the cooling off when the windows are opened (see paragraph 5.18 onwards in Part A of this Scottish Health Technical Memorandum).

## Stand-alone air-conditioners

- 3.75 Stand-alone air-conditioners include fan coil units, split-comfort air-conditioners, room conditioners and cassette units. They should not be installed above a patient's bed or diagnostic medical equipment and should be easily accessible for cleaning.
- 3.76 To avoid fungal-spore contamination, the ceiling void should not be used as a plenum either for supply, extract or as a return air path. All air connections will be ducted directly to the fan coil unit and ceiling terminals.

## Portable air-conditioners

- 3.77 Portable air-conditioners are not recommended for use in healthcare premises. The need for them is to be assessed by the VSG for every occasion that they are requested. If used, they will be subject to a strict cleaning and maintenance regime (see Chapter 5). Units no longer required will need to be stripped down, cleaned and decontaminated before being used again.
- 3.78 Stand-alone units that draw in outside air should do so through a bespoke sealable air intake through a wall, roof or window. They should not just be placed in front of an open window.

### Portable recirculating filter units

- 3.79 The need for portable recirculating air-filter units will be risk-assessed by the VSG for every occasion that they are considered. If used, they will be subject to a strict cleaning and maintenance regime (see Chapter 5). Units no longer required will need to be stripped down, cleaned and decontaminated before being used again.

### Low-level extracts

- 3.80 Low-level extracts should not be obstructed by fixed or portable equipment, furniture or fittings. If necessary, stand-off guarding will need to be fitted.
- 3.81 Low-level extract grille faces should be of the pull-off type to facilitate routine cleaning. (See Chapter 9 in Part A of this Scottish Health Technical Memorandum for further information).

### Fire and smoke dampers

- 3.82 All fire and smoke dampers must be fixed directly to the fabric of the building. They should have an access door with a test switch adjacent so that the actual operation of the damper can be directly observed during the annual test and be undertaken by a single operative. (See also the Health Technical Memorandum 05 series for detailed guidance).

### Control panels

- 3.83 Ventilation control panels of any type and purpose must be clearly marked with the unique identifier of the plant that they control and the area/zone that the plant serves.
- 3.84 Inverters are not to be located within the airstream inside an AHU. They should be mounted externally with the readouts of their control pads and plant data screens visible at a convenient height. Their settings may be password-protected but they should be able to be switched to manual, without the need to isolate plant or unlock access panels.

### Theatre, imaging and treatment room panels

- 3.85 Local control panels should have a clear means of indicating that the ventilation is operating to a satisfactory standard for the application. The minimum requirement would be a green light for "On" and a red light for "Set back", "Off" or "Fault". The panel should also display the room temperature and have a means of adjusting it. (See Chapter 9 in Part A of this Scottish Health Technical Memorandum).

**Note:** The Specialised Ventilation for Healthcare Society's (2017) SVHSoc.01 – 'Operating theatres: energy control strategies and the surgeon's panel' provides additional information of minimum standards for a variety of panel types.

## Energy efficiency

- 3.86 The basic objective will be to provide the necessary service utilising the least amount of energy possible. To this end switching a system "Off" when not required is the most energy-efficient policy.
- 3.87 If the system is needed to maintain a minimum background condition then reducing its output to the minimum necessary to achieve and maintain the desired condition is the next best option.

**Note on "Set back":** In many existing systems the fan motor has two speeds so turning the system down means switching to the lower fan speed and hence air volume. With inverter-controlled or EC fans the speed can be adjusted across a wide range so "Set back" need not be a fixed fan speed but rather a control strategy that reduces the system output in order to maintain a desired minimum condition. This may be related to the air velocity at a fixed point, air-change rate, pressure differential, temperature, humidity or a combination of any of these parameters.

- 3.88 The system should only run at full output when needed to achieve and maintain the defined "in use" operational condition.
- 3.89 Care should be taken to discover the true "in use" operational condition. Overstating the condition will lead to oversized plant, unstable control and excessive energy consumption.
- 3.90 A ventilation system should not be run at full output "just in case it will be needed". This is particularly a problem in operating departments where the ventilation is often run out of hours as it is believed that it will "maintain sterility" in the operating suite. This is not true as airborne contamination in operating theatres is caused by the people in them when they are in use. The theatre ventilation is provided to cater for this "in use" biological load. When the theatre is not in use, there is no biological load so the ventilation can be turned off and set to automatically start at "Set back" (see above note) in order to maintain a minimum background condition, for example room temperature, if needed. The time taken to start the ventilation and achieve full operating conditions in an emergency will be less than the time taken to bring a patient to theatre and prepare the staff and instruments ready for emergency surgery to commence. A similar situation applies to obstetrics theatres and "special" delivery rooms.

**Note:** UCV theatre ventilation can be completely switched off when the theatre is not in use but the room temperature should not be allowed to drop below 18°C (see also paragraph 8.96 in Part A of this Scottish Health Technical Memorandum). The AHU and UCV control should be interlocked so that when the AHU goes to "Set back" the UCV also goes to "Set back", and if the AHU goes "Off", the UCV terminal fans also switch "Off". There is no aerobiological benefit in keeping the UCV terminal fans running when the theatre is not in use, it merely wastes.

- 3.91 The selection of set points for an AHU and associated extract system will have a significant impact on the overall energy consumption and efficiency of the system as a whole.

- 3.92 The control strategy for existing systems should be reviewed in line with the above guidance. (See Chapters 6 and 9 in Part A of this Scottish Health Technical Memorandum for further information.)

**Note:** Energy-recovery devices have been mandatory for all new and refurbished AHUs since 2016. Where installed they provide a significant portion of the heating requirement, and the size of the AHU heater-battery will have been reduced as a consequence. It is therefore essential that the energy-recovery device operates as intended and is well maintained.

Interim

## 4. Annual inspection and verification requirements

---

### Ventilation systems inspection

- 4.1 All ventilation systems will be subject to at least a simple visual inspection annually.
- 4.2 The purpose of the inspection is to establish that:
- the system is still required;
  - the plant conforms to the minimum standard (see Chapter 3);
  - the fire containment has not been breached;
  - the general condition of the system is adequate for purpose;
  - the system overall is operating in a satisfactory manner.
- 4.3 It is recommended that a simple check sheet be used to record the result of the inspection. Examples are given in Appendices 1 and 2.

### Critical healthcare ventilation systems

- 4.4 All critical healthcare ventilation systems will be inspected quarterly and verified at least annually. In some circumstances the verification may need to be carried out more frequently.
- 4.5 The quarterly inspection should be as detailed in paragraphs 4.1–4.3.
- 4.6 The purpose of the annual verification will be to additionally ensure that the system:
- achieves minimum standards specific to the application;
  - is operating to an acceptable performance level;
  - remains fit for purpose.

### Definition of a critical system

- 4.7 Ventilation systems serving the following are considered critical:
- operating suites of any type including rooms used for interventional procedures and their recovery areas;
  - airborne isolation facility;
  - critical care units, neonatal and special care baby units;
  - invasive treatment, endoscopy and bronchoscopy rooms;
  - containment level 3 laboratory;
  - pharmacy aseptic suite;

- inspection, assembly and packing (IAP) room in a decontamination unit;
- MRI, CAT and other types of emerging imaging technologies that require particularly stable environmental conditions to remain within calibration;
- any system classified as an LEV system under the COSHH Regulations;
- any other system that clearly meets the definition that “a loss of service from such a system would seriously degrade the ability of the premises to deliver optimal healthcare”.

**Note:** If any doubt exists as to whether a system falls within this definition, the VSG should be consulted regarding the risk to patient safety and business continuity.

### Annual verification

4.8 The annual verification is intended to establish that:

- the system is still required;
- the AHU conforms to the minimum standard (see Chapter 3);
- the fire containment has not been breached;
- the general condition of the ventilation system is adequate;
- the fabric of the area served is suitable for the function;
- the system performance is adequate with respect to the functional requirement – this will require:
  - the measurement of all system supply and extract airflow rates;
  - the calculation of room air-change rates if applicable;
  - the measurement of room differential pressures if applicable;
  - the measurement of room noise levels;
  - temperature, humidity and any application-specific air velocity measurements;
  - a check of the control functions;
  - microbiological air-quality sampling if required;
  - any other application-specific tests or measurements as required.

4.9 An assessment should then be made by the AP(V) as to whether the system overall is fit for purpose and operating in a satisfactory manner. If any doubt exists, the AE(V) and/or VSG should be consulted.

### Fabric of the area served

4.10 The building elements in the room or rooms served by a critical ventilation system should also be suitable for the function. As an example, in a suite of rooms comprising an operating theatre complex, the following elements should be checked:

- the ceiling should be complete and free from holes, gaps, cracks or obvious air leakage paths. All light fittings, access hatches and suspended fittings should be sealed to prevent uncontrolled air leakage. It is important to check for air-leakage

paths behind the cover shrouds where operating-lamp stems and medical- gas and monitor-suspension booms penetrate the ceiling;

- the walls and floors should be free from significant construction and finish defects;
- windows and their trickle vents should be sealed and locked shut;
- the doors should close completely, and the door closers should be correctly adjusted to hold them against the room pressure gradient;
- all service penetrations should be sealed to prevent uncontrolled airflow between rooms and service voids;
- steps should be taken as necessary to prevent portable equipment and stock items from obstructing low-level supply, transfer or extract airflow paths.

- 4.11 Failure to achieve a suitable standard will render even the most sophisticated ventilation system ineffective.
- 4.12 All fire and smoke dampers should be tested as part of the annual verification unless the local policy dictates otherwise.
- 4.13 Table 1 provides a model for the verification of critical ventilation systems.
- 4.14 LEV systems will be subject to an examination and test by a competent person at least every 14 months. An individual who holds an in-date P601 certificate will be considered competent.

### Critical healthcare ventilation systems – verification standards

**Note:** The following standards apply to the performance of all existing in- use ventilation systems. Performance standards for new or refurbished systems are given in Chapter 12 in Part A of this Scottish Health Technical Memorandum.

- 4.15 When measured at the annual verification the following air change rates should be achieved:
- a. the primary air supply to a conventionally ventilated operating theatre, UCV operating theatre or "lay up" preparation room, regardless of when it was built, should not result in fewer than 18 air changes per hour in the room;

**Note:** If the scrub is in effect a separate room that is open (no door) to the operating theatre and it has a low-level pressure stabiliser discharging onto a corridor or an active low-level extract at its far end, so that air has to travel through the scrub to leave the operating theatre, then the volume of the scrub will not be counted as being a part of the operating theatre room volume.

If the scrub is a trough on the wall or in an open bay within the operating theatre, the volume of space it occupies will be considered part of the operating theatre room volume for the purpose of calculating the operating-theatre air supply.

- b. the primary air supply to an operating suite anaesthetic room that is equipped with a N<sub>2</sub>O (nitrous oxide) terminal or in which an anaesthetic agent is delivered

to the respiratory tract of a patient using a carrier gas or an operating department recovery room should not result in fewer than 12 air changes per hour;

- c. the primary air supply to any other room that is fitted with a N<sub>2</sub>O (nitrous oxide) or N<sub>2</sub>O/O<sub>2</sub> (entonox) terminal or in which an anaesthetic agent is delivered to the respiratory tract of a patient using a carrier gas or in which the patient is subsequently recovered should not result in fewer than 8 air changes per hour. (Note that in these rooms the patient is generally only sedated rather than fully anaesthetised.)

- 4.16 Unless otherwise specified in paragraph 4.15 above, for all other applications the ventilation system should achieve not less than 80% of the design air-change rate given in Chapter 8 and Appendix 2 of Part A of this Scottish Health Technical Memorandum, or its original design parameters.

**Note:** It is to be expected that over the lifetime (typically 20 years) of a ventilation system its performance will gradually reduce due to wear in components, increasing friction due to internal surface degradation and ductwork and access door seals breaking down over time. However, any rapid change in performance should be thoroughly investigated as it is likely to be caused by a failure of a component or control software. Trend analysis of the annual verification results will highlight sudden changes in performance.

**Table 1: Operational management and routine verification process model**

Step	Question	Information/standard required	Comment
1	Is the system still required?	Why was it installed?	Is that function still required?
2	Does the AHU achieve the minimum standard?	Health and safety aspects Intake/discharge positions Inspection access Legionella control and drainage Fire and electrical safety Leaks, cleanliness and insulation Filtration	Inspect to ascertain compliance with minimum standards set out in Chapter 3 of Scottish Health Technical Memorandum 03-01 (Part B)
3	Is the air distribution system satisfactory?	Access Fire dampers Cleanliness Insulation Identification Room terminals Pressure stabilisers	Inspect to ascertain continued fitness for purpose
4	Does the measured system performance still accord with the design intent and achieve a minimum acceptable standard?	Design air velocities Design airflow rates Room air-change rates Pressure differentials Noise levels Air quality	Establish the design values Measure the system output to verify its performance
5	Does the control system function correctly?	Desired environmental conditions Control sequence logic Run; set-back; off philosophy	Establish the true "as used" requirement Inspect/test to verify performance
6	Having regard to the foregoing, is the system "fit		Yes or No!

Step	Question	Information/standard required	Comment
	for purpose" and will it only require routine maintenance in order to remain so until the next scheduled verification?		
7	What routine service and maintenance will be required for the system to remain fit for purpose and function correctly until the next scheduled verification?	Filter changes System cleaning Performance indication Performance monitoring Performance measurement	Decide inspection frequency and maintenance schedule

4.17 The pressure regime should achieve not less than 80% of the design value given in Chapter 8 and Appendix 2 of Part A of this Scottish Health Technical Memorandum, or its original design parameters; and the pressure gradient relationships with regard to surrounding areas should be maintained.

4.18 The sound levels given in Table 2 are maximum permissible levels and should not be exceeded. Measurements should be made using at least a Type 2 sound meter fitted with a muff. Its accuracy should be checked using a calibration sound source before use.

#### Vertical flow ultra-clean ventilated (UCV) operating theatres

4.19 The following additional measurements should be taken:

- the average air velocity at the 2 m level under the UCV canopy: it should achieve a minimum average of 0.38 m/s for a partial or no wall system and 0.3 m/s for a full wall system when all four walls are in place;
- the average air velocity at the 2 m level for each quadrant or actively ventilated section of the UCV canopy should not exceed  $\pm 6\%$  of the measured average velocity for the whole canopy at 2 m;
- the air velocity within the inner zone at the 1 m level: every reading should achieve a minimum velocity of 0.20 m/s.

4.20 The air velocity measurements are to be taken using the equipment, test grid and method set out in Chapter 12 in Part A of this Scottish Health Technical Memorandum.

**Note:** There is no requirement to carry out a filter scan or entrainment test at the annual verification unless the EPA filters or recirculating air fans are changed, or the system in some other significant way is disturbed or altered. Changing the filters in the AHU or the recirculating air filters in the UCV canopy does not constitute a significant disturbance to the UCV unit.

**Table 2: Maximum sound levels (service noise only) for existing systems**

Area	Room Overall noise level – dB(A)
Operating suite including prep, operating theatre, anaesthetic, scrub and utility. Interventional and diagnostic imaging suites – all rooms	50
UCV Operating theatre and adjacent open-plan areas only	55
Treatment rooms, Consulting rooms, Sleeping areas, Recovery rooms	35
Pharmacy aseptic suites – all rooms	45

Area	Room Overall noise level – dB(A)
Sanitary facilities	45
Industrial areas	50
Circulation areas	50

- 4.21 Should the UCV canopy fail to achieve a suitable standard, resulting in the need to disturb or replace the canopy EPA filters or its auxiliary fans, the unit should be revalidated using the procedure given in Chapter 12 in Part A of this Scottish Health Technical Memorandum.

#### Horizontal flow ultra-clean operating theatre terminals

- 4.22 The following additional measurements should be taken:

- a line of test positions should be marked on the floor 1 m in front of the face of the UCV terminal;
- a test position will be marked in the centre of the line. Additional test positions will be marked at 280 mm spacing along the line either side of the centre position, up to the full face width of the unit;
- the discharge velocity test at 1 m, 1.5 m and 2 m levels in front of the terminal are taken at each test position;
- the average velocity should be not less than 0.40 m/s.

- 4.23 The measurements are to be taken using the equipment and method set out in Chapter 12 of this Scottish Health Technical Memorandum.

**Note:** There is no requirement to carry out filter scanning at the annual verification unless the EPA filters or recirculating air fans are changed; or the system is in some other significant way disturbed or altered. Changing the filters in the AHU or recirculating air filters does not constitute a significant disturbance to the UCV terminal.

- 4.24 Should the horizontal UCV fail to achieve a suitable standard, resulting in the need to disturb or replace the canopy EPA filters or auxiliary fans, the unit should be revalidated using the procedure given above.

#### Containment level 3 laboratories

- 4.25 These areas should conform to the requirements of current information published by the Advisory Committee on Dangerous Pathogens and the Health and Safety Executive:

- 'The management, design and operation of microbiological containment laboratories'
- 'Biological agents: managing the risks in laboratories and healthcare premises'
- 'Biological agents: the principles, design and operation of Containment Level 4 facilities'

- 4.26 The Head of Department will be able to advise on any mandatory plant inspection and maintenance frequencies and particular control strategy. The performance measurement of a containment laboratory is normally contracted out to a specialist.

### Pharmacy aseptic suites

- 4.27 Pharmacy aseptic suites should conform to the requirements of the European guide to good manufacturing practice ([https://ec.europa.eu/health/documents/eudralex/vol-4\\_en](https://ec.europa.eu/health/documents/eudralex/vol-4_en)) and the requirements of the Medicine Inspectorate if a licensed manufacturing unit.
- 4.28 The Chief Pharmacist will be able to advise on any mandatory plant inspection, maintenance frequencies and particular control strategy. The performance measurement of the aseptic suite is normally contracted out to a specialist.

### Decontamination Unit – IAP

- 4.29 IAP rooms should conform to BS EN ISO 14644 Class 8, and any additional requirements for the processing of medical devices, as applicable (see also Scottish Health Planning Note 13 Parts 1, 2 or 3 [Central Decontamination Unit, Local Decontamination Unit, Endoscopy Decontamination Unit]).
- 4.30 The Head of Department will be able to advise on any mandatory plant inspection, maintenance frequencies and particular control strategy. The performance measurement of the IAP room is normally contracted out to a specialist.

### Local exhaust ventilation (LEV) systems

- 4.31 LEV systems should conform to the latest version of the Health and Safety Executive's guidance document HSG258 'Controlling airborne contaminants at work: a guide to local exhaust ventilation (LEV)'.
- 4.32 LEV systems must be examined and tested at least every 14 months by a competent person. The person must hold an in-date P601 certificate.
- 4.33 Each LEV system must be examined and its performance measured and/or visualised from the point of capture of the hazard to its point of discharge. A full report of findings and a clear statement as to whether the system does or does not achieve an acceptable standard must be provided by the inspector.

**Note:** Having an annual service contract for an item of equipment such as a safety cabinet does not necessarily fulfil the statutory requirement for an annual LEV examination. The annual LEV examination must test and quantify the performance of the complete system including the location of the item, its interaction with any room ventilation, its discharge arrangement and suitability of the discharge location.

### Critical system verification failure

- 4.34 Should a critical system be unable to achieve the standard set out above, it should not be returned to service and the duty manager who signed the system over for the annual verification will need to be informed immediately. Copies of the verification report stating the reason(s) for non-compliance should be sent to the head of the user department, nominated infection prevention and control person and the healthcare provider's AP(V) as soon as practicable.
- 4.35 If a critical system is refurbished in order to bring it to a suitable standard, it will be subject to the full validation procedure set out in Chapter 12 in Part A of this Scottish

Health Technical Memorandum or other application-specific guidance as appropriate before being taken back into use.

Interim

## 5. Routine inspection and maintenance

### General

- 5.1 Inspection and maintenance activities should be risk-assessed to ensure that they do not create a hazard for those who undertake the work or for those who could be affected by it.
- 5.2 The degree and frequency of inspection and maintenance should relate to the function of the system, its location, its general condition and the consequence of failure.
- 5.3 Specimen inspection and maintenance checklists are given in the Appendices.

### Inspection and maintenance of critical systems

- 5.4 The loss of service of these systems would seriously degrade the ability of the premises to deliver optimal healthcare. In order to ensure reliable service provision, critical systems should be subject to a quarterly inspection and maintenance regime.
- 5.5 For many of these systems an equipment release or permit-to-work certificate will need to be completed to ensure that taking the ventilation system out of service does not compromise the activities of the user department. In any event, it will be necessary to liaise with the user department when switching the system off to carry out routine inspection and maintenance.

**Note:** A specimen equipment release certificate is given in Appendix 3.

### AHU routine inspection

- 5.6 All AHUs should be visually inspected at least every three months. The inspection should note the general condition of the unit in terms of:
- its external and internal condition;
  - pipework and electrical connections;
  - sensor and control elements;
  - the unit's continued ability to maintain the desired condition in the spaces that it serves.

**Note:** Where fitted, energy-recovery devices provide a significant portion of the heating requirement, and the size of the AHU heater-battery will have been reduced as a consequence. It is therefore essential to check that the energy-recovery device operates as intended.

## AHU drainage

- 5.7 AHU drainage systems comprise a drainage tray, glass trap, connecting pipework and an air gap. The system should be inspected to ensure that it is clean and operating correctly. The cleanliness of the drainage tray and colour of the water in the trap will give an indication of a fault condition (see Table 3).

## Filter changing

- 5.8 Dirty supply air filters may pose a general dust hazard when being changed.
- 5.9 Dirty extract and return air filters may pose an increased level of hazard. This will relate to the particular contamination within the air that they have filtered. Filters handling extract air from general areas are unlikely to present a significantly greater hazard than that posed by dirty supply air filters.
- 5.10 Care should be taken to protect staff from inhaling the dust. If there is a need to enter the duct when changing filters, a dust mask or respirator to BS EN 149 should be worn. Dirty filters should be carefully removed and placed in a bag or the box that contained the replacement filters. On completion of the work, the dirty filters should be removed from the plantroom and disposed of appropriately.

**Note:** Dirty general supply or extract filters are not classed as hazardous waste.

- 5.11 The duct in the area of the filter housing should be carefully vacuumed using a cleaner with a filtered exhaust before fitting the replacement filters. This will prevent particles (that is, those that are shed when the dirty filters are disturbed) being blown downstream into the system when it is switched on.
- 5.12 It is important to ensure that replacement filters are fitted in the correct orientation. Most panel filters are manufactured with a membrane or wire support mesh on their downstream side. Alternatively, they may be colour-coded. The manufacturer's instructions regarding fitting should be followed.
- 5.13 Bag filters should be fitted with the pockets vertical. Care should be taken to remove any transit tapes and to ensure that the individual pockets are separate and free to inflate.

**Note:** The preferred option is to replace bag filters with rigid assembly filter packs; however, whichever type is fitted, it is vital not to puncture or damage them during installation.

- 5.14 Whichever type of filters are fitted it is essential to ensure that air cannot bypass them.

## Changing extract filters containing hazardous substances

- 5.15 Filters handling extract air from an LEV system will present a hazard and should be subject to a safe system of work.

- 5.16 Filters used in an extract system for the containment of hazardous substances or organisms should incorporate design provision for their safe removal when so contaminated. This may be achieved by:
- coating the filter with a water-based paint to seal the hazardous substance onto the filter prior to removal;
  - a system to fumigate the filter to kill any organisms;
  - housing it in a "safe change" unit that permits the filter to be ejected into a bag and sealed without staff having to come into direct contact with it.

The method chosen should reflect the nature of the hazard.

- 5.17 Filters fitted to remove hazardous substances from extract air are classed as hazardous waste and should be handled and disposed of accordingly.

#### **Air terminals**

- 5.18 Sooty marks around supply terminals should be vacuumed or wiped clean. Excessive soot marks around supply diffusers indicate an inadequate filter or significant filter bypass.
- 5.19 Extract grilles need to be regularly cleaned to remove dust and bits of fluff. Low-level spring-retained extract grilles should be regularly pulled off so that they can be washed and the debris in the duct behind them vacuumed out.

#### **UCV canopies**

- 5.20 UCV canopies fitted with perforated plate-type diffusers should have them removed and both sides wiped clean at the quarterly inspection. Any canopy side screens should be wiped down on both sides to remove surface contamination and bone dust.
- 5.21 UCV canopies fitted with monofilament diffuser screens do not need to be removed as blood splatter does not easily penetrate. Any visible surface contamination should be carefully wiped off in accordance with the manufacturer's instructions. If the monofilament screen is cut, punctured or physically damaged it will need to be replaced, not repaired.
- 5.22 The return air grilles for all types of canopies will need to be regularly cleaned to remove lint and the return air filters replaced as necessary.

#### **Pressure stabilisers**

- 5.23 Plate and bar stabilisers need to have their screws tightened, pivots cleaned and adjusted, and the sorbo rubber stop inspected and replaced as necessary if they are to operate correctly and silently.
- 5.24 All types of pressure stabilisers to be checked for correct and silent operation and cleaned as necessary.

**Note:** Pressure stabilisers may need to be retrofitted with a stand-off baffle on their discharge side to preserve privacy or prevent discharge air causing draughts within an anaesthetic room or bedroom. A stand-off baffle will always be needed on the theatre side of the pressure stabiliser between a "lay-up" preparation room and a UCV theatre to prevent perturbation of the UCV canopy air pattern.

### Transfer grilles

- 5.25 Both sides of a transfer grille should be vacuumed to remove dust and fluff.

### Ventilation system cleaning

- 5.26 The intake section of a ventilation system should be vacuumed-out as necessary to remove visible particles.
- 5.27 AHUs should be vacuumed-out and wiped or washed down internally as necessary to remove obvious dust and dirt.
- 5.28 Drift eliminators (if fitted) should be removed, and cooling coils, humidifier units, energy-recovery devices and their drainage systems should be washed down with hot water annually to remove visible contamination. Using a hose connected to the DHW is the simplest way. Pressure washers should not be used as they will damage the battery fins or energy transfer matrix.
- 5.29 Supply air distribution ductwork conveys air that has been filtered. It will require internal cleaning only when it becomes contaminated with visible dirt. The frequency of cleaning will depend on the age of the system and grade of the AHU final filter but will typically be in excess of ten years. There is no requirement to clean supply ductwork annually. A rapid build-up of visible dirt within a supply duct is an indication of a failure of the filtration or its housing.
- 5.30 On completion of cleaning, the supply ductwork should not be "fogged" with chemicals. This treatment has no lasting biocidal effect and is responsible for initiating the breakdown of the galvanised coating of ductwork. This results in accelerated corrosion of the inside of the duct, with the products of corrosion being shed into the air stream. It will also significantly shorten service life.

**Note:** If after duct cleaning there are persistent problems with fungal spores being discharged from the supply terminals and there is no evidence of final filter bypass, air samples should be taken at the AHU intake, AHU discharge and at least one supply terminal in each branch of the system. This should pinpoint the actual source of the problem. The affected section should then be inspected and cleaned and finally fogged only if that proves to be necessary.

- 5.31 Extract air systems handle unfiltered air. They should be cleaned as frequently as necessary in order to maintain their operating efficiency. Room extract terminals, particularly those sited at low level in critical care areas, will need regular cleaning.

Table 3: Colour of water in glass trap

Colour of water	Probable cause and comment
Normal	Satisfactory
Green	Copper corrosion of pipework Possible leak in battery tubing
White	Aluminium corrosion of battery fins
Black	General dirt Filter faulty allowing air bypass Possible Aspergillus contamination System is overdue for a thorough clean Urgent action required
Brown/Red	Iron corrosion (rust) within the AHU which may indicate a specific Legionella hazard Immediate action required
Bubbly/slimy	Microbiological activity within the AHU which may indicate a specific Legionella or similar hazard Immediate action required
Dead wildlife	Failure of filtration – immediate action required

5.32 Following duct cleaning, all service hatches should be checked to ensure that they have been correctly replaced and do not leak.

5.33 Duct-cleaning equipment that uses rotating brushes or a vacuum unit can easily damage flexible sections of ductwork. On completion of cleaning, all flexible duct sections should be checked for rips and tears. The opportunity should be taken to reduce flexible ducts in length to the absolute minimum and replace any being used in lieu of bends with rigid duct sections. The straps that secure them to rigid duct sections and air terminals should also be checked to ensure that there is no air leakage.

**Note 1:** If the system has mixing or VAV boxes, the cleaning contractor should be alerted and use a method that avoids damaging any internal acoustic lining.

**Note 2:** Duct-mounted sensors and the elements of electric and fins of heating or cooling trimmer batteries can also be easily damaged during duct cleaning. Sensor probes may need to be temporarily removed and the battery elements protected during the process.

5.34 It is always necessary to re-balance the ventilation system following cleaning as balance dampers and registers will have been disturbed. The system will then need to be validated in accordance with Chapter 12 in Part A of this Scottish Health Technical Memorandum.

### Chilled beams – active and passive types

5.35 The efficiency of these units will rapidly decline if they become blocked with fluff/lint. They should be inspected every three months and cleaned as appropriate.

### Split and cassette air- conditioning units

- 5.36 These units incorporate internal recirculation air filters and a drainage system to remove condensate from the cooling coil. The systems should be inspected and cleaned every three months and the drainage system checked.

### Fan coil units

- 5.37 These units incorporate internal recirculation air filters and a drainage system to remove condensate from the cooling coil. The systems should be inspected and cleaned every three months and the drainage system checked.

### Portable room air- conditioning units

- 5.38 Portable units are sometimes kept in-store or hired-in to cope with temporary local situations giving rise to excessive temperatures. They typically incorporate internal recirculation air filters and a drainage system to remove condensate from the cooling coil. The VSG should be consulted before these types of unit are deployed.
- 5.39 The units should be inspected and thoroughly cleaned before being taken into use. Units that are to be used in areas containing immunocompromised patients will, unless new, need to be fully decontaminated before use.
- 5.40 All portable units should be inspected and cleaned every week that they remain in use.
- 5.41 Units that have been used in isolation rooms or areas containing infectious patients will need to be fumigated before being used in other locations, returned to store or to the supplier.
- 5.42 Units employing an internal water reservoir and wick to promote evaporative cooling are not to be used in healthcare premises.

### Self-contained mobile filter and/or ultraviolet (UV) light units

- 5.43 The VSG will be consulted before these types of unit are deployed. The efficacy of these units is directly related to their cleanliness. In this respect, the manufacturer's instructions regarding initial use, service and maintenance, lamp and filter replacement should be closely followed (see also paragraph 3.79).
- 5.44 Units that have been used in isolation rooms or areas containing infectious patients will need to be fumigated before being used in other locations, or returned to store.
- 5.45 Filters fitted to remove hazardous substances from the recirculated room air are classed as hazardous waste and should be handled and disposed of accordingly (see also Health Technical Memorandum 07-01 – 'Safe management of healthcare waste').

**Inspection and maintenance records**

- 5.46 Records of inspection and maintenance activities should be kept for at least five years (see paragraphs 1.31 and 1.44).

Interim

# Appendix 1 – Annual inspection of critical ventilation systems – AHU and plantroom equipment

---

## Definition of terms used on survey form

### General condition

#### End of useful life

This should be clear from the condition of the AHU and its associated services and plant. The main indicators will be:

- extensive internal and/or external corrosion of the AHU casing;
- failure of filter housings to prevent air bypass;
- general corrosion of heater and cooling battery fins, attenuator surfaces etc;
- significant failure to meet minimum standards;
- associated plant services and control elements in a poor condition or not able to fulfil their purpose;
- AHU aged 20 years or more.

Action: Urgent replacement indicated.

#### Poor

Should be fairly apparent but would include an assessment of the degree of corrosion; cleanliness of coils and batteries; quality of filter mountings and their ability to prevent air bypass; fan and drive train condition; the control system elements' ability to fulfil their function; condition of the access doors and inspection covers. The age of the AHU is generally less important.

Action: Extensive refurbishment or programmed replacement indicated.

#### Average

Some faults but generally free of significant corrosion, clean internally and conforming to minimum standards.

Action: Faults capable of correction at next maintenance period.

#### Good

Conforming to the minimum standards, obviously cared for and subject to routine maintenance.

Action: Routine maintenance will preserve standard of the equipment.

**Compliance with minimum standards (questions 2 to 23, 32 and 33)****Poor**

More than three answers are negative.

Action: Management action required by estates/facilities department.

**Average**

No more than three answers are negative.

Action: Maintenance action required.

**Good**

No answers are negative, full compliance.

Action: None.

**Maintenance quality (questions 5, 12, 26 to 31 and 34 to 40)****Poor**

More than three answers are negative.

Action: Management action required by estates/facilities department.

**Average**

No more than three answers are negative.

Action: Maintenance action required.

**Good**

No answers are negative.

Action: None.

## Annual inspection of critical ventilation systems – AHU and plantroom equipment

Template A1 Annual inspection of critical ventilation systems – AHU and plantroom equipment

Hospital

Plantroom

Air handling unit  Age of unit

Area served by unit

Date of Survey  Name

General Condition: End of useful life  Poor  Average  Good

Compliance with minimum standards  
(Questions 2 to 23, 32 and 33) Poor  Average  Good

Maintenance Quality  
(Questions 5, 12 26 to 31, 34 to 40) Poor  Average  Good

No	Survey question	Yes	No	Comments
1	Plant running?			
2	Is the unit and its associated plant secure from unauthorised access?			
3	Is the unit safely accessible for inspection and maintenance?			
4	Is the air intake positioned to avoid short-circuiting with extract or foul air from other sources such as gas scavenging outlets?			
5	Are all inspection lights operating?			
6	Are motorised dampers fitted to the intake and discharge?			
7	For belt driven fans, is the drive visible without the need to remove covers?			
8	For plug and EC fans, is the fan visible through a viewing port?			
9	Is the cooling coil located on the discharge side of the fan?			
10	Is an energy-recovery system fitted? (state type)			
11	Are condensate drainage systems fitted to all energy recovery systems, cooling coils and humidifiers in accordance with Chapter 3 of Scottish Health Technical Memorandum 03-01, Part B?			

No	Survey question	Yes	No	Comments
12	Are drainage traps clean and filled with water? (see Table 3 in Scottish Health Technical Memorandum 03-01, Part B)			
13	Is the drain trap air break at least 15 mm?			
14	If a humidifier is fitted, state the type	-		
15	Is the humidifier capable of operation?			
16	Is there space to safely change the filters?			
17	Are there test holes in the principal ducts?			
18	Are the test holes capped?			
19	What is the general condition of the exterior of the AHU?	-		
20	Are the principal ducts lagged?			
21	What is the general condition of the associated control valves and pipework?	-		
22	Is the pipework adequately lagged?			
23	Is the system clearly labelled?			
24	Record prefilter differential pressure	-		
25	Record main filter differential pressure	-		
	Switch plant off. Fit padlock to isolator			
26	Did all motorised dampers close on plant shut-down?			
27	Is the vermin/insect screen clean?			
28	Is the intake section including the fog coil clean?			
29	Are the prefilters correctly fitted with no air bypass?			
30	Are all drive belts correctly aligned and tensioned?			
31	Is the cooling-coil matrix clean?			
32	Are all drip-trays fully accessible or capable of being removed for cleaning and have a fall to drain?			
33	Are the drainage trays stainless?			
34	Are the drainage trays clean?			
35	Is the internal base of the AHU free from any sign of ponding?			
36	Is the matrix clean for each heater-battery?			
37	Have the main filters been correctly fitted with no air bypass?			

No	Survey question	Yes	No	Comments
38	Is AHU and its associated main ductwork clean internally?			
	Energise plant			
39	Did unit restart satisfactorily?			
	Test automatic fan-motor change-over, if fitted			
40	Did automatic change-over operate satisfactorily?			

#### Additional comments

(For example: air leaks from access doors; control valves leaking or passing; general cleanliness of the area around the unit; or any other items of concern.)

Are there any issues of particular concern that would prevent the plant being taken back into use?

Competent Person/Authorised Person

.....

## Appendix 2 – Operating suite annual verification

---

### Definition of terms used on survey form

#### Assessment of compliance with Health Building Note 10-01 and Scottish Health Technical Memorandum 03-01 (all questions relevant to the type of theatre)

##### **Poor**

Air-change rate is less than 18 per hour; room pressure differentials do not ensure a flow from clean to less clean areas; supply or extract air diffusers are not clean; pressure stabilisers not clean and/or not operating correctly; significant faults or failures of indicators on surgeon's panel; visible faults in the fabric of the suite; doors unable to close completely; general air of neglect.

Action: Urgent management action required.

##### **Average**

Air volumes and room pressure differentials approximate to the original design values; supply air diffusers clean but extracts visibly fouled, most pressure stabilisers clean and operating correctly; some of the indicators on the surgeons' panel not working; minor faults in the fabric and décor of the suite.

Action: Maintenance action required.

##### **Good**

Better than average.

Action: None.

#### Maintenance quality (all questions relevant to the type of theatre)

##### **Poor**

More than three answers are negative.

Action: Management action required by estates/facilities department.

##### **Average**

No more than three answers are negative.

Action: Maintenance action required.

##### **Good**

No answers are negative.

Action: None.

## Annual verification of theatre ventilation systems Theatre suite information

### Template A2 Annual verification of theatre ventilation systems Theatre suite information

Hospital

Theatre name/no  Type of Theatre

Date of survey  AHU

Location and ID Name

### Compliance with HBN/SHPN & SHTM

Poor  Average  Good

### Maintenance quality

Poor  Average  Good

No	Survey question	Yes	No	Comments
1	Has the annual verification of the AHU been carried out?			
2	Are windows hermetically sealed?			
3	Are the ceilings in the theatre and prep room complete and sealed?			
4	Is the fabric of the rooms within the suite free of any significant faults?			
5	Are room light fittings correctly sealed?			
6	Do all doors close completely and hold against the room pressure?			
7	Are the pressure stabilisers operating correctly and silently?			
8	Are all supply and extract air terminals and pressure stabilisers visibly clean?			
9	Measure and record the operating theatre temperature	-		
10	Does this accord with that displayed on the surgeon's panel?			
11	Measure and record the operating theatre relative humidity	-		
12	Does this accord with that displayed on the surgeon's panel?			
13	Measure and record the supply and extract air flow in the principal ducts	-		

No	Survey question	Yes	No	Comments
14	Measure and record the air flow at all supply and extract terminals	-		
15	Does the derived air-change rate achieve at least 18 ac/h in the Theatre, 12 ac/h in the Anaesthetic room and at least 80% of the design flow in all other rooms?			
16	For UCV units, also measure and record the air velocities within the canopy using the method set out in Chapter 12 of Scottish Health Technical Memorandum 03-01 (Part A)	-		
17	Do the air velocities achieve the standard appropriate for the type of canopy?			
18	Measure and record the room differential pressures	-		
19	Do the room differential pressures ensure a flow of air from the clean to the less clean areas?			
20	Measure and record the noise levels in the principal rooms of the suite	-		
21	Do the noise levels fall below the limits set out in Table 2 of Scottish Health Technical Memorandum 03-01, Part B?			
22	Check the operation of all ventilation control functions represented on the surgeon's panel.	-		
23	Do the indicators accurately represent the operational state of the ventilation system(s)?			
24	For UCV systems: Are the UCV and AHU interlocked to ensure that the AHU runs at full speed when the UCV is at full operating speed or at low speed? (See SHTM 03-01; Part B; Chapter 3; paragraph 3.90 Note.)			
25	With the UCV running at low speed, does the system maintain the standard of a conventional operating theatre?			
26	For all theatres: with the system running at set-back, does it maintain a flow of air from the clean to the less clean areas?			

Additional Comments

(For example: the general décor; are the suite and its ventilation systems suitable for their designated functions?)

Are there any issues of particular concern that would prevent the suite being taken back into use?

Competent Person/Authorised Person .....

## Appendix 3 – Equipment Release Certificate

### Template A3 Equipment Release Certificate

<b>Equipment release certificate</b>		
<b>Certificate No:</b>	<b>Job No:</b> .....	
<b>Issuing Dept:</b> .....	<b>Date &amp; time of issue:</b> .....	
<b>Issuing officer (print name):</b> .....		
<b>Issued to (print name and company):</b> .....		
<p>This certificate is issued for the purpose of carrying out the following task. The MAINTENANCE / SERVICE / REPAIR (delete as appropriate and attach job card to certificate) of the equipment specified below. It is valid for 48 hours.</p>		
<b>Location:</b> .....	<b>Equipment:</b> .....	<b>Serial No:</b> .....
	<b>Yes</b>	<b>No</b>
1	Is the task routine for this equipment?	
2	Are you a fully trained service engineer or have you carried out this task at least 3 times previously?	
3	Has one of the following authorised personnel (circle the name) given permission for the service to take place?  Authorised Person(s):	
<p>Note: If the answer to all of the above questions is YES, proceed to Step 4. If the answer to any of the above questions is NO, <b>do not proceed</b>. Return this Certificate to the Issuing officer and obtain a Permit to Work.</p>		
4	Obtain the signature of the person identified at Step 3 above. Name:..... Signature:..... Date:.....	
5	Isolate the equipment and carry out the task.	
6	Reinstate all services and test-run the equipment.	
7	On completion, the person doing the work to print name, and sign. Name:..... Signature:..... Date:.....	
8	Is the equipment serviceable? If YES, go to Step 9. If NO, isolate equipment and go to Step 10.	
9	Hand equipment back to the person identified in Step 4. Obtain signature. Name:..... Signature:..... Date:.....	
10	Return this certificate to the issuing authority. Receiving officer to sign. Name:..... Signature:..... Date:.....	
Note: The issuing authority to retain this certificate for 12 months

**By Email and Post**

Dear James & Susan,

**Re-Provision of RHSC & DCN at Little France, Edinburgh.**

**Settlement Proposal**

**WITHOUT PREJUDICE**

In our letter dated Tuesday 21 March 2018, we requested that NHS Lothian (the "Board") did not begin any Court proceedings prior to IHS Lothian Ltd ("IHSL") and Multiplex providing an update to a commercial settlement. We remain convinced that this is still the most appropriate approach to successfully deliver the facility and an updated proposal is enclosed within this letter. In addition, we believe it is important to re-emphasise that in order for a settlement approach to progress successfully in practise and for the contract to be successfully delivered over the next 25 years, all parties need to work together as a partnership, from site level up. The need for change in this regard was clearly evident during the mediation sessions and given the mixed progress in this regard since the mediation process, we remain convinced that the successful delivery of the facility is not simply down to a commercial or contractual agreement being reached.

It remains our view that any Court proceedings will be vigorously defended by Multiplex, resulting in a long drawn out and expensive process, which depending upon the determination may not provide the Board with the facilities they require. IHSL consider that a settlement agreement can deliver a facility to the Board's technical requirements, at the earliest opportunity and at the most efficient cost to the project. Opposite a legal dispute, a settlement agreement presents the opportunity to focus the parties' efforts on clarifying technical requirements and agreeing a pragmatic solution, programming and facilitating our respective completion activities to achieve the earliest 'patient go live date'; and ensuring we retain as much money within the project to support the required works. You will also be very aware that in addition to these aspects, proceeding to court at this stage will

also lay out the challenges being faced into a public forum that could cause reputational damage to all parties, as well as the project itself.

In order to progress the items outlined in this letter, IHSL request an urgent meeting – given the deadlines set-out in the Multiplex’s proposal- with members of the NHSL Board to review and consider the attached settlement agreement draft proposal from Multiplex, as an alternative to the current Board position. We recognise that a commercial agreement that underpins these proposals will also need to be agreed as part of these discussions and IHSL recognise that they, along with Multiplex and the Board need to contribute.

With regards to how a settlement agreement might look, it needs to be understood that in order for this to deliver the intended outcome all parties need to work together. Multiplex have already agreed to complete the Without Prejudice Works at their own considerable expense, however we also believe that further works that are currently disputed works, or post Practical Completion Works can benefit from starting as soon as possible to achieve the earliest patient ‘go-live’ date. Included in these works are the post completion NHS Works, the four bedded room ventilation and the MRI quench pipes. The attached proposal from Multiplex explains how the Without Prejudice Works and post completion NHS Works can be completed simultaneously, in tandem with resolving the four bedded ventilation. Please note that there are items where final agreement as to what is required has not been reached, and these will need to be agreed before a final programme can be produced.

One of the key items that needs to be addressed is the technical requirements of the four bedded ventilation to the satisfaction of the Board. The attached paper outlines three ventilation options, each with a capital cost and a timeline to completion. We ask that the Board considers these options. The attached timeline is based on Option 1. It is recognised that were a different solution to be agreed (either in relation to Option 2 and 3) then the overall programme and costs will change to reflect the work required for each of those options.

At the mediation sessions in Edinburgh a number of items were agreed and actions have continued to be progressed. We note that some of these items appear to have stalled. The attached ‘Mediation Progress Report’ dated 21<sup>st</sup> March 2018 provides the current position. At our meeting with lenders on the 16<sup>th</sup> March 2018, the Board advised their frustration with respect to progress achieved on the Without Prejudice Works, highlighting the Single Bedroom Ventilation Change and Cable Calculations as examples. The Multiplex Proposal provides a narrative and timeline with respect to these two items, and refutes the Board’s allegation Multiplex are not delivering upon their commitments. The actual events surrounding the agreement of the ‘Single Bed Ventilation Change’ unfortunately does not convey the joint endeavour, ‘speedy RDD’ process or collaborative working we had collectively hoped for.

The quench pipe is an item that was not included in the mediation sessions, but now appears on the list as it is an item on the Board’s critical path, where a more optimal solution involving Multiplex facilitation is considered beneficial to the project. The quench pipes are an NHSL responsibility, to be delivered under a separate turnkey contract. We understand that early in the construction programme Multiplex made an offer to “help” install the quench pipe alongside the installation of other mechanical services, but this offer was not adopted by NHSL possibly because the MRI equipment had not been selected/procured (and hence technical parameters were unknown). At this stage of the construction programme installation of such equipment infrastructure is not possible without causing significant disruption, abortive work and delay to completion, which would be for the account of the Board. An alternative to the Board’s turnkey contractor undertaking all of the associated works related to the quench pipe installation would be for Multiplex to facilitate and

coordinate these works, to ensure the works are delivered effectively, and minimise costs and programme delays to the Board.

The overall advantage of a settlement agreement should not just be quantified in terms of price and time, but also the overall product. The opportunity to have Multiplex facilitate and coordinate MRI Quench pipe works would have the benefit of removing the risk of Multiplex's warranties being voided. It would also clear the path for Multiplex to carry out Board changes that are currently scheduled to be undertaken post completion. Without agreement, Multiplex could not be contractually compelled to carry out changes post completion, meaning other contractors would need to be engaged. If other NHSL Sub-contractors are brought into to do certain works, warranties could be invalidated and responsibility for defects to affected areas of the building may become an unnecessary area of dispute between the Board and IHSL.

We understand that in order to make a settlement work, there will have to be compromises on both parties, but we believe that it is the most sensible option for all parties involved.

IHSL directors are available for a meeting week commencing the 26 March 2018, and we look forward to your response.

As you will appreciate this letter is 'without prejudice' and privileged, and may not be referred to in Court or other formal forum.

Yours faithfully

Wallace Weir  
Project Co Representative  
For and behalf of IHS Lothian Limited
